ENVIRONMENTAL ASSESSMENT

FOR

NDA 20-687

MIFEPRISTONE

TABLETS

DIVISION OF REPRODUCTIVE AND UROLOGIC
DRUG PRODUCTS (HFD-580)

CENTER FOR DRUG EVALUATION AND RESEARCH

DATE COMPLETED: July 9, 1996

SUMMARY

A FONSI is recommended.

Precautions taken at the sites of manufacture and the disposal methods are expected to minimize occupational exposures and environmental release.

A Tier 0 EA was submitted in accordance with the Industry Guidance. The production estimate is [redacted] kg which is equivalent to an EIC of [redacted] ppb. There is no information that indicates extraordinary circumstances exist that would warrant the submission of additional environmental information.

APPEARS THIS WAY
ON ORIGINAL

ENVIRONMENTAL ASSESSMENT

1. Date:

EA dated: 03/01/1996
Consult #1: 03/20/1996

[redacted]

2. Name of applicant/petitioner:

The Population Council

ADEQUATE

3. Address:

1230 York Avenue
New York, NY 10021

ADEQUATE

4. Description of the proposed action:

a. Requested Approval:

The applicant is requesting approval of the product--200 mg mifepristone tablets. A brief description of the product packaging is provided. The product will be in packaging that is commonly used.

ADEQUATE

b. Need for Action:

Used in the termination of early pregnancy.

ADEQUATE

c. Production Locations:

i. Proprietary Intermediate(s):

The chemist confirmed that there are no proprietary intermediates manufactured elsewhere.

ADEQUATE

ii. **Drug Substance:**

ROUSSEL UCLAF
Vertolaye Plant
63480 Vertolaye
France

ADEQUATE

iii. **Finished Dosage Form:**

ROUSSEL UCLAF
USIPHAR Plant
Route de Choisy-au-Bac
60205 Compiegne
France

ADEQUATE

Facility Description & Adjacent Environment:
A brief description has been provided for each of the facilities. **ADEQUATE**

Note: The information for both of these production facilities is classified as confidential. [redacted] the review chemist, was consulted as to what companies were identified on the labeling. The labeling only identifies The Population Council as the distributor, therefore these facilities can be confidential.

d. **Expected Locations of Use (Drug Product):**

The drug will be used by women in the United States. It will be administered in hospitals, health clinics and physicians' offices. **ADEQUATE**

e. **Disposal Locations:**

Disposition of rejected, expired, returned or waste drug products are expected to disposed of:

1. "In accordance with the Center for Disease Control [sic] Guidelines for handling of hazardous waste in the clinic or healthcare provider's office";

2. The applicant will use a licensed incineration or grinding and landfill facility to dispose of this type of material.

The applicant is in the process of identifying a licensed disposal site to dispose of this product. In the past FONSI's have been written for EAs with identification of the disposal facility as long as it was indicated that a licensed facility would be used. Lack of this information is not considered sufficient to delay issuance of a FONSI. **ADEQUATE**

5. **Identification of chemical substances that are the subject of the proposed action:**

Drug Substance: Mifepristone

Chemical Name: Chemical Abstracts
(11beta, 17beta)-11-[(4-dimethylamino) phenyl]-17-hydroxy-17-(1-propynyl)estra-4,9-diene-3-one

IUPAC
11-beta-4-dimethylaminophenyl-17beta-17α-(1-propynyl-estra-4,9-diene-3-one

CAS #: 84371-65-3

Molecular Weight: 429.58

Molecular Formula: $C_{29}H_{35}NO_2$

Structural Formula: Provided on page 3.

Physical Descrip.: Light yellow to yellow crystalline powder

Additives: The excipients used in the drug product are provided.

Impurities: They state that there are no impurities greater than [redacted]. The Industry Guidance indicates that identification is not necessary in this case.

ADEQUATE

6. **Introduction of substances into the environment: For the site(s) of production:**

a. **Substances Expected to be emitted:**

The chemicals expected to be emitted from drug substance manufacture are include on pages 75-78. The composition of the drug product is included in the non-confidential EA. **ADEQUATE**

b. Controls (Air, Liquid Effluent, Solid):

Drug substance:
In the table listing the emitted substances there is a discussion of the depollution treatment for each waste stream. In general, air emissions are filtered, pre-treated aqueous waste streams are subjected to biological treatment, some solvents are incinerated or recovered and solid waste is sent to off-site disposal facilities in accordance with French regulations.

Drug product:
In general, air emissions are filtered, pre-treated aqueous waste streams are subjected to biological treatment, solvents are incinerated and solid waste is either incinerated or in the case of packaging material recycled.

ADEQUATE

c. Compliance with Federal, State and Local Emission Requirements:

Although there is no specific statement regarding compliance, the manufacturer states that their facilities "operate with all technical means required to protect, preserve and enhance the quality of the environment as specified by French Law in the fields of environmental protection and occupational hygiene." Various French laws and requirements are cited throughout the document. English translations of French government reports are also included as supporting information (originals not provided).
ADEQUATE

d. Effect of Approval on Compliance with Current Emissions Requirements:

It is stated that approval will have no adverse effect upon compliance with current emission requirements.
ADEQUATE

e. Estimated Expected Emitted Concentration/Quantities:

The production estimate is [redacted] kg which is equivalent to an EIC of [redacted] ppm ([redacted] ppb, [redacted] pptr). These calculations do not consider metabolism.
ADEQUATE

7. **Fate of emitted substances in the environment:**
8. **Environmental effects of released substances:**
9. **Use of resources and energy:**
10. **Mitigation measures:**
11. **Alternatives to the proposed action:**

Format items 7-11 are not normally necessary if the EIC is < ppb (See "Tier 0" Industry Guidance). The EIC is much less than ppb even without consideration of metabolism. There are no extraordinary circumstances that indicate additional environmental information is warranted. **ADEQUATE**

12. **List of preparers, & their qualifications (expertise, experience, professional disciplines) and consultants:**

The preparers are identified along with their titles/experience. **ADEQUATE**

13. **Certification:**

The certification is acceptable except Appendix E is listed as non-confidential which contradicts the listing in format item 15. I spoke to Ann Robbins of The Population Council on 7/9/96 and she confirmed that Appendix D is the non-confidential appendix. This will be corrected by hand. **ADEQUATE**

14. **References:**

References are provided. **ADEQUATE**

15. **Appendices:**

Five appendices are attached, four are designated as confidential. **ADEQUATE.**

The EA is formatted appropriately for public release.

MEDICAL REVIEW(S)

JAN 27 2000

MEDICAL OFFICER'S REVIEW OF AMENDMENTS 024 AND 033
FINAL REPORTS FOR THE U.S. CLINICAL TRIALS INDUCING ABORTION UP TO 63 DAYS GESTATIONAL AGE AND COMPLETE RESPONSES REGARDING DISTRIBUTION SYSTEM AND PHASE 4 COMMITMENTS

NDA Number: 20-687

Applicant: Population Council
One Dag Hammarskjold Plaza
New York, New York 10017

Dates of Submission: June 3, 1999 and August 18, 1999

Dates Submissions Received: June 4, 1999 and August 19,1999

Date Review Completed: October 28, 1999

Date Review Revised: November 19, 1999

Date Review Finalized: November 22,1999

I. General Information:

A. Name of Drug:
1. Established Name: Mifepristone
2. Trade Name: None designated as yet.

3. Laboratory Code Name: RU 38486 (RU-486).

B. Pharmacologic Category: Antiprogestational and antiglucocorticoid agent.

C. Proposed Indication: Medical termination of intrauterine pregnancy through 49 days' pregnancy.

D. Dosage Form and Route of Administration: Tablet for oral administration.

E. Strength: Each tablet contains 200 mg of mifepristone.

F. Dosage: Three 200 mg tablets (600 mg) of mifepristone are taken as a single oral dose. Unless abortion has occurred, the patient takes two 200 μg tablets (400 μg) of misoprostol orally two days after ingesting mifepristone.

G. Related Drugs: None marketed.

II. Manufacturing Controls: Please refer to chemist's review for details.

III. Pharmacology and Pharmacodynamics: Please refer to pharmacologist's review for details.

IV. Clinical Background:

Mifepristone is a synthetic steroid that was approved for the termination of pregnancy in France in December 1988 (launched September 1989), in Sweden in 1992, in the United Kingdom in 1991, and in China in 1988. (It should be noted that mifepristone used in China is not manufactured by Roussel Uclaf but by domestic companies). When administered alone in total doses of 1400-1600 mg over 1-10 days, the success rate was 64-85%. Subsequent studies demonstrated that the administration of mifepristone followed by a synthetic prostaglandin analog increases the success rate to over 95%. In a preliminary study of 100 women, the success rate of 600 mg mifepristone and 0.2 mg misoprostol was 95% for pregnancies of no more than 49 days of amenorrhea. Misoprostol is a synthetic prostaglandin E_1 analog [redacted] In the [redacted] misoprostol [redacted]

Nine phase 2 clinical studies to determine the most effective dose and dosage regimen for mifepristone used alone for the interruption of pregnancy were conducted in France between 1983 and 1986. Patients in these studies were entered with a target gestational age of less than or equal to 41 days of amenorrhea. One thousand patients were exposed to doses ranging from 100 mg for one to four days to 800 mg for one day.

Following completion of the phase 2 studies, nine phase 3 clinical trials employing a single 600 mg dose of mifepristone were conducted to evaluate the efficacy and the

safety of this dose. The target population was patients with pregnancies having a gestational age ≤42 days of amenorrhea. A total of 2,459 patients were studied.

The advantage of combining mifepristone 600 mg with a prostaglandin (sulprostone 250μg I.M. 36-48 hours later) for pregnancy interruption was demonstrated in 1985. A series of ten clinical trials were conducted between 1987 and 1991 to confirm and extend these initial observations. In addition to sulprostone, other prostaglandins including gemeprost, 15MePGF 2a, and prostine E_2 were evaluated. During the ten studies, a total of 19,947 patients were exposed to mifepristone administered as a single 600 mg dose. One of these studies enrolled over 16,000 patients. Very rare cases of hypotension and one myocardial infarction were reported. Successful termination of early pregnancy was achieved in 82.6 to 100% of the patients enrolled in these studies and the safety of mifepristone was confirmed.

The efficacy and safety of mifepristone given as a single 600 mg oral dose in combination with misoprostol 0.4 mg orally administered approximately 36 to 48 hours after mifepristone for termination of pregnancy was evaluated in two historically controlled, pivotal clinical trials conducted in France. The first study included women with intrauterine pregnancies of ≤ 49 days and the second study included women with intrauterine pregnancies of ≤63 days. In the second study, a second dose of 200 μg of misoprostal was given 3 hours after the first dose if complete abortion had not occurred. In the first study of 1205 evaluable patients, the complete abortion rate was 95.4% and in the second study of 1104 evaluable patients, the complete abortion rate was 92.8%. These two studies were evaluated in the review of a new drug application that was submitted March 16, 1996.

V. Regulatory Background:

2 **Page(s) Redacted**

Deliberative Process

VI. Statistical Consultation: None required

VII. Clinical Studies:

The efficacy and safety of mifepristone was evaluated in two prospective, open-label, multicenter clinical trials in the United States according to two identical protocols (166A and 166B) at 17 centers (University hospitals, Planned Parenthood clinics, and free-standing clinics). The studies were conducted at centers that could perform abortions by either vacuum aspiration or dilatation and curettage and had access to facilities that provided blood transfusions and performed routine emergency resuscitation procedures. The studies included patients in three gestational age groups:

Group 1: amenorrhea of ≤49 days
Group 2: amenorrhea of 50-56 days
Group 3: amenorrhea of 57-63 days

Data from the two studies were combined in the following evaluation.

A. Investigators:

Dr. Paul Blumenthal	Baltimore, Maryland
Dr. Lynn Borgatta	White Plains, New York
Dr. Mitchell Crenin	Pittsburgh, Pennsylvania
Dr. Catherine Dean	St. Louis, Missouri
Dr. Susan Haskell	Des Moines, Iowa
Dr. Tyrone Mallory	Atlanta, Georgia
Dr. Daniel Mishell, Jr.	Los Angeles, California
Dr. Mark Nichols	Portland, Oregon
Dr. Alfred Poindexter	Houston, Texas
Dr. Suzanne Poppema	Seattle, Washington

Dr. Eugene Rothenberg	Shrewsbury, New Jersey
Dr. Katherine Sheehan	San Diego, California
Dr. Laszlo Sogor	Cleveland, Ohio
Dr. Judith Tyson	Burlington, Vermont
Dr. Peter Vargas	Aurora, Colorado
Dr. Carolyn Westhoff	New York, New York

B. Objectives of the Study:

The study was conducted to evaluate the effectiveness, safety, acceptability, and feasibility of using mifepristone and misoprotol in a variety of clinical settings within the United States health care system for the induction of abortion in women whose duration of amenorrhea was no more than 63 days.

C. Rationale for the Study:

Extensive experience has been gained outside the United States with the use of mifepristone and various prostaglandin analogs, including misoprostol, for the termination of pregnancies up to 63 days, with complete abortion rates ranging from 92.7% to 99%. The applicant wished to confirm the efficacy and safety of the regimen in the United States.

D. Method of Assignment to Treatment:

Eligible patients fulfilling all of the inclusion criteria and none of the exclusion criteria were assigned to one of the three treatment groups, based on gestational age.

E. Number of Subjects:

A total of 2,121 patients were enrolled including 859 patients in groups 1,722 patients in group 2, and 540 patients in group 3.

F. Duration of Clinical Trial:

Patients were to receive mifepristone on day 1 and misoprostol on day 3 and were to be observed in the clinical setting for at least 4 hours after misoprostol administration. Patients were to return for evaluation on day 15.

G. Inclusion Criteria:

1. Was at least 18 years of age and in good general health.

2. Requested a voluntary termination of pregnancy.

3. Had a positive urine pregnancy test.

4. Had an intrauterine pregnancy with a duration of amenorrhea of ≤63 days (from the first day of her last menstrual period) that was confirmed by uterine size on pelvic examination and by vaginal ultrasound evaluation.

5. Agreed to have a surgical termination of pregnancy if the study procedures failed to terminate her pregnancy.

6. Was a resident of the United States.

7. Gave written informed consent to participate in the study and was willing and able to participate.

H. Exclusion Criteria:

1. Had evidence of any disorder which represented a contraindication to the use of mifepristone (such as adrenal disease or a condition requiring chronic corticosteroid administration) or misoprostol (such as asthma, glaucoma, mitral stenosis, arterial hypotension, sickle cell anemia, or a known allergy to prostaglandins).

2. Had a history of severe liver, respiratory, or renal disease or thromboembolism.

3. Had a cardiovascular disease, e.g. angina, valve disease, arrhythmia, cardiac failure, or insulin dependent diabetes.

4. Had hypertension that was being treated on a chronic basis or had blood pressure of greater than 140/90mmHg.

5. Was anemic (hemoglobin < 10 g/dL or hematocrit < 30%).

6. Had a known clotting defect or was receiving anticoagulants.

7. Had an IUD *in situ*.

8. Was breastfeeding.

9. Had adnexal masses or tenderness on pelvic examination that suggested pelvic inflammatory disease.

10. Had an ectopic pregnancy or threatened abortion.

11. Was over 35 years of age and smoked more than 10 cigarettes per day, and

had another risk factor for cardiovascular disease such as diabetes mellitus, hyperlipidemia, hypertension, or a family history of ischemic heart disease.

12. Was unlikely to understand and comply with the requirements of the study.

13. Lived or worked more than one hour from the emergency care facility that served the abortion center.

I. Trial Period:

September 13, 1994 to September 12, 1995

J. Dosage and Mode of Administration:

Patients were not to eat during the one hour before and after the administration of mifepristone. In the presence of the investigator, each patient was administered three 200 mg mifepristone tablets by mouth with no more than 240 mL of water. Patients were informed that they should not smoke during the 48 hours following mifepristone administration and on the day misoprostol was to be administered. Unless the investigator could verify unequivocally that complete abortion had occurred, patients were administered two 200 μg misoprostol tablets by mouth with no more than 240 mL of water in the presence of the investigator 36 to 60 hours after the administration of mifepristone.

K. Efficacy Assessments:

Pelvic examinations were performed before mifepristone administration at visit 1, before misoprostol administration at visit 2, during the 4 hour observation period after misoprostol administration, and at the visit 3 evaluation. At visit 1, patients also had transvaginal ultrasound examinations and quantitative hCG β subunit pregnancy tests performed. At visits 2 and 3, ultrasound examinations were performed at the discretion of the investigator.

The outcome of treatment was classified as follows:

1. Complete abortion: pregnancy termination and complete expulsion of the products of conception without the need of surgical intervention.

2. Incomplete abortion: pregnancy termination with either partial expulsion or nonexpulsion of the products of conception diagnosed at visit 3 or at study end if later than visit 3 with surgery required.

3. Ongoing pregnancy: a viable pregnancy diagnosed at visit 3 based on fetal heartbeat and/or fetal growth indicating gestations that are

two weeks older than at visit 1; surgery required.

4. Medical intervention: before visit 3, the investigator judged that a surgical intervention was medically indicated.

5. Patient request: before visit 3, the patient chose not to proceed with the medical method of abortion and requested surgical intervention.

In the analyses of treatment outcome, complete abortion only was classified as a treatment success. All other categories resulted in a surgical procedure and , therefore, were classified as treatment failures.

L. Safety Assessments:

Adverse events were summarized and evaluated.

M. Disposition of Patients:

A total of 2121 patients were enrolled. Of these, 2015 (95.0%) were included in the efficacy analyses. There were 106 patients excluded from the efficacy analyses because of failure to show up for visit 3, thus preventing confirmation of a final outcome. For 92 of these patients, there was some information suggesting a successful outcome. For one excluded patient, there was evidence that suggested failure. The remaining 13 women were lost to followup; 5 had continuing pregnancies when last seen at visit 2. All 2121 patients were evaluable for safety. A total of 827 patients in Group 1, 678 patients in Group 2, and 510 patients in Group 3 were included in the efficacy evaluation.

N. Demographic Characteristics:

Most patients were Caucasian (71%), 20-29 years of age (61%; mean age of 26.9 years), of normal body mass index (71%), nulliparous (55%) and had a previous elective abortion (51%). The differences among the three gestational age groups in race distribution and mean age, weight, and body mass index were small and not of clinical significance.

O. Results:

1. Efficacy:

Success and failure rates are summarized in Table 1.

Table 1
(Sponsor's Table 4.1)
Treatment Outcomes by Gestational Age (Evaluable Patients)

Treatment Outcomes	Group 1 ≤ 49 days N = 827	Group 2 50-56 days N = 678	Group 3 57-63 days N = 510
Total Successes	762 (92%)	563 (83%)	395 (77%)
RU-486 alone	40 (5%)	12 (2%)	4 (< 1%)
Plus misoprostol	722 (87%)	551 (81%)	391 (77%)
Total Failures	65 (8%)	115 (17%)	115 (23%)
Med intervention	13 (2%)	26 (4%)	21 (4%)
Patient request	5 (< 1%)	13 (2%)	12 (2%)
Incomplete ab	39 (5%)	51 (8%)	36 (7%)
Ongoing preg	8 (< 1%)	25 (4%)	46 (9%)

Failures are discussed in this review in the "Safety" section of "Results."

Complete abortion rates according to time of occurrence are displayed in Table 2 as confirmed by the investigators.

Table 2
(Sponsor's Table 5.1)
Time to Occurrence of Complete Abortion

Occurrence Time	Group 1 ≤ 49 days N =827	Group 2 50-56 days N=678	Group 3 57-63 days N=510
Mifepristone alone	40 (4.8%)	12 (1.8%)	4 (0.8%)
≤ 4h after misoprostol	376 (45.5%)	312 (46.0%)	178 (34.9%)
> 4h & < end of day 4	178 (21.5%)	118 (17.4%)	118 (23.1%)
After day 4	168 (20.3%)	121 (17.8%)	95 (18.6%)
Surgical intervention	65 (7.9%)	115 (17.0%)	115 (22.5%)

2. Safety:

Adverse events, regardless of causality, were reported for at least 99% of the patients in each gestational age group. More than one adverse event was reported for most patients. The majority of adverse events were of mild or moderate severity. Approximately 23% of the adverse events in each gestational age group were judged to be severe. The most common adverse event was abdominal pain, including uterine cramping. This was to be expected since the treatment procedure is designed to induce the uterine cramping (and bleeding) necessary to produce an abortion.

Other commonly reported adverse events were nausea, vomiting, headache, diarrhea, and dizziness. No serious adverse events were reported in tolerance studies in healthy non-pregnant female and healthy male subjects where mifepristone was administered in single doses greater than threefold that recommended for termination of pregnancy. Table 3 shows that the rates of most, but not all, adverse events that occurred in patients whose gestational age was ≤ 49 days were not significantly different from the rates across all gestational age groups.

Table 3

Most Commonly Reported Adverse Events

Adverse Event	Group 1 ≤ 49 days N=859 Percentage	Groups 1, 2, and 3 ≤ 63 days N=2121 Percentage
Abdominal pain (cramping)	96	97
Nausea	61	67
Headache	31	32
Vomiting	26	34
Diarrhea	20	23
Dizziness	12	12
Fatigue	10	9
Back pain	9	9
Uterine hemorrhage	5	7
Fever	4	4
Viral infections	4	4
Vaginitis	3	4
Rigors (chills/shaking)	3	3
Dyspepsia	3	3
Insomnia	3	2
Asthenia	2	2
Leg pain	2	2
Anxiety	2	2
Anemia	2	2
Leukorrhea	2	2
Sinusitis	2	2
Syncope	1	2

Table 4 shows the rates of adverse events in any gestational age group which were significantly different across gestational age groups.

Table 4
Adverse Events Significantly Different Across Gestational Age Groups

Adverse Event	Group 1 ≤ 49 days Percentage	Group 2 50-56 days Percentage	Group 3 57-63 days Percentage
Nausea	61	71	72
Vomiting	26	38	41
Diarrhea	20	23	26
Uterine hemorrhage	5	8	10

No patient was discontinued from the study because of an adverse event and there were no deaths.

The median bleeding duration for group 1 was 14 days and 15 days for groups 2 and 3.

The proportions of patients who received any medications for bleeding increased with increasing gestational age form 5.7% in group 1 to 10.7% in group 3. A total of 146 patients (6.9%) received uterotonics (ergot-type medications or oxytocin) for bleeding.

Fourteen patients (0.7%) were hospitalized for an adverse event. Of these patients, 2 of 4 in the ≤ 49 days group, 3 of 5 in the 50-56 days group, and 3 of 5 in the 56-63 days group had adverse events (severe excessive bleeding) which were considered to be study drug related. The other patients were hospitalized for reasons unrelated to study treatment (pneumonia, meningitis, automobile accident, depression, shooting injury, endometritis).

Nineteen patients (0.9%) had emergency room visits that did not result in hospitalization. Sixteen of these 19 patients had excessive bleeding (2, ≤ 49 days; 7, 50-56 days; 7, 57-63 days). The other three visits were for chest pain, nausea and vomiting, and cramping.

Four patients received blood transfusions (1, ≤ 49 days; 2, 50-56 days; 1, 57-63 days). Three of these patients were hospitalized.

IV fluids were administered for various reasons to 9 (1.0%) patients in the ≤ 49 days group, 19 (2.6%) in the 50-56 days group, and 18 (3.3%) in the 57-63 days group.

The following five potentially serious adverse events occurred:

A 34 year old patient with a 20 year history of seizures and a pregnancy of

46 days gestational age had a mild seizure (convulsion) on the day of mifepristone administration and received 250 mg of dilantin. In the opinion of the investigator, the patient's seizure was not related to treatment with mifepristone and she received misoprostol 47 hours after the mifepristone.

A 28 year old of 54 days gestational age with a negative gastrointestinal history reported possible blood in her stool a month after misoprostol administration. In the opinion of the investigator, the patient's melena was not related to study treatment.

A 23 year old of 57 days gestational age developed moderate purpura (body bruises) that lasted for one day without treatment ten days after receiving misoprostol. In the opinion of the investigator, the patient's purpura was not related to study treatment.

A 21 year old of 57 days gestational age developed severe viral meningitis 6 days after receiving misoprostol and was hospitalized. In the opinion of the investigator, the patient's meningitis was not related to study treatment.

A 27 year old of 60 days gestational age with a negative gastrointestinal history reported blood in her stool 3 days after receiving misoprostol. At the time of last contact with the patient three weeks later, no further incidents of melena had been reported. In the opinion of the investigator, the patient's melena was not related to study treatment.

The proportions of patients with a decrease in hemoglobin or hematocrit of more than 20% from their pre-mifepristone administration levels increased significantly with increasing gestational age, from 3.1% in the ≤ 49 days group to 8.0% in the 57-63 days group.

Of the 1028 patients with hemoglobin measurements before and after misoprostol administration, 131 had a decrease of at least 2mg/dL (7.8%, ≤49 days; 15.0%, 50-60 days; 17.4% 57-63 days).

Hypotension after administration of misoprostol occurred in 0.3% - 1.4% of all treated patients.

Hypertension after administration of misoprostol occurred in 1.5% - 1.7% of all treated patients.

Decrease in heart rate by > 20% after administration of misoprostol occurred in 18.2% - 21.3% of all patients.

Increase in heart rate by >20% after administration of misoprostol occurred in 11.8% - 14.1% of all patients.

For the subgroup of patients with a full panel of laboratory tests, the median changes were small and not of clinical significance.

Failure of the mifepristone - misoprostol procedure required surgical intervention which is an additional safety concern, albeit small. A total of 295 patients were classified as having failed medical abortion. Of these patients, 79 (27%) had ongoing pregnancies, 126 (43%) had incomplete abortions, 30 (10%) requested and had surgical terminations, and the remaining 60 (20%) patients had surgical terminations performed because of medical indications directly related to the medical procedure. In group 1 (≤ 49 days gestation), of the 65 failures, 8 (12%) patients had ongoing pregnancies, 39 (60%) patients had incomplete abortions, 5 (8%) requested and had surgical terminations performed, and the remaining 13 (20%) patients had surgical terminations directly related to the medical procedure. The failure rates for medical intervention, patient request, incomplete abortion, and ongoing pregnancy were significantly higher in groups 2 and 3 than in group 1.

For each gestational age group, the adverse event rates were highest at Planned Parenthood clinics and lowest at Free-Standing clinics, with university hospital clinics in the middle.

VIII. Reviewer's Comments, Evaluation, and Conclusions:

Two studies were conducted according to two identical protocols at 17 centers to evaluate a mifepristone - misoprostol regimen for the termination of pregnancies in the United States health care system. The studies included patients in three gestational age groups:

Group 1: amenorrhea of ≤ 49 days
Group 2: amenorrhea of 50-56 days
Group 3: amenorrhea of 57-63 days

The studies included women who requested a voluntary termination of pregnancy, had a positive pregnancy test, and a documented intrauterine pregnancy. Women with liver, respiratory, renal, adrenal, or cardiovascular disease, thromboembolism, hypertension, anemia, insulin-dependent diabetes mellitus, coagulopathy, or allergy to prostaglandins were excluded, as were women less than 18 years of age or those more than 35 years of age who smoked more than ten cigarettes per day and had another cardiovascular risk factor. Women were also excluded if they had intrauterine devices, were breast-feeding, were receiving anticoagulation or long-term glucocorticoid therapy, had adrenal masses, had

ectopic pregnancies, or had signs or symptoms suggesting that they might abort spontaneously. All the women agreed to undergo surgical termination of pregnancy if the medical method failed. A total of 2,121 women were enrolled in the two studies including 859 women who were in the ≤ 49 days group, which is the gestational age which is the subject of this application.

Pregnancy was measured from the first day of the last menstrual period according to menstrual history, pelvic examination, and vaginal ultrasonography and women were assigned to the appropriate gestational age group.

Three clinic visits were scheduled. At visit 1 (day 1), the women were assessed clinically and took three 200 mg tablets of mifepristone orally in the presence of the investigator. Patients did not eat for one hour before and after the consumption of the mifepristone. At visit 2 (day 3), they took 400 μg of misoprostol orally unless a complete abortion had already occurred. Patients did not smoke during the 48 hours following mifepristone consumption and on the day misoprostol was administered. Patients then remained at the clinics under observation for at least four hours. Adverse events such as nausea, vomiting, diarrhea, abdominal pain, and vaginal bleeding were rated by the women and recorded. Blood pressure and heart rate were measured at least hourly. Vaginal bleeding was recorded on a diary card and rated by each woman on days 1 through 15 as "spotting", "normal", or "heavy." During this period, the women were also monitored for the expulsion of the conceptus. At visit 3 (day 15), the treatment outcome was assessed.

Efficacy was defined as the termination of pregnancy with complete expulsion of the conceptus without the need for a surgical procedure. The need for a vacuum aspiration or dilatation and curettage constituted a failure. A surgical procedure was performed at any time if the investigator believed there was a threat to a woman's health (medically indicated), at a woman's request, or at the end of the study for an ongoing pregnancy or incomplete abortion.

A total of 106 women were excluded from the efficacy analysis because they did not return for visit 3. Evidence suggesting a successful outcome was available for 92 of these women, and evidence of failure for 1. The remaining 13 women were lost to followup; 5 had continuing pregnancies when last seen at visit 2. The efficacy analysis, therefore, included 2015 women. No additional information is available on the outcomes of the 5 women with continuing pregnancies who were lost to followup. All other women with continuing pregnancies were aborted surgically.

Efficacy was 92% in the ≤ 49 days group with a lower 95% confidence interval of 90%. This is somewhat less than the 95.5% efficacy with a lower 95% C.I. of 94.2% reported in the pivotal French studies upon which approval of this application was recommended.

Efficacy was 83% in the 50-56 days group with a lower 95% confidence interval of 80%. Efficacy was 77% in the 57-63 days group with a lower 95% confidence interval of 74%.

The 92% success rate in the ≤ 49 days group is an acceptable one.

The median duration of bleeding in the ≤ 49 days group was 14 days. The average duration of bleeding was 16 days. This is considerably longer than the average duration of 9 days reported in the French studies upon which approval of this application was recommended, but is an acceptable duration.

Excessive bleeding necessitated blood transfusion in only 1 patient in the ≤ 49 days group and required hospitalization of only 2 patients in the ≤ 49 days group. An additional 2 patients in the ≤ 49 days group were treated in the emergency room for excessive bleeding. Thirteen (2%) patients in the ≤ 49 days group required surgical intervention because of excessive bleeding. Bleeding was managed by the administration of uterotonic agents such as oxytocin, methylergonovine or vasopressin in 5% of patients in the≤ 49 days group.

The adverse event rates were higher in these studies than those in the pivotal French studies upon which approval of this application was recommended. This is shown in Table 5.

Table 5

Frequent Adverse Events (≤ 49 days) in French and U.S. Trials

Adverse Event	French Trials	U.S. Trials
Abdominal pain (cramping)	83%	96%
Nausea	43%	61%
Headache	2%	31%
Vomiting	18%	26%
Diarrhea	12%	20%
Dizziness	1%	12%

The majority of adverse events were of mild or moderate severity. The difference in the frequency of common adverse events noted above is acceptable.

In the pivotal French trials, 5.5% of subjects had a decrease in hemoglobin of greater than 2g/dL while in the U.S. trials, 7.8 % of patients in the ≤ 49 days group had such a decrease. This difference is an acceptable one.

The U.S. clinical trials confirmed the findings of the pivotal French trials that mifepristone and misoprostol are safe and effective in terminating pregnancies of up to 49 days gestation even though the success rate in the U.S. trials was lower

than that of the French trials. This lower success rate might be related to the lack of experience of most of the U.S. investigators with medical abortion. The lower success rate might also be attributable somewhat to the fact that in the U.S. trials, a woman's request for a surgical termination any time after receiving mifepristone was honored and classified as a failure rather than being excluded form the efficacy analysis. However, in the ≤ 49 days group, less than 8% of the failures (5 patients) were because of patient requests.

The success of medical termination of pregnancy decreased with advancing gestational age and the incidence of adverse events increased with advancing gestational age. The majority of surgical interventions were for incomplete abortion and excessive bleeding.

This method of pregnancy termination is of limited value because of the relatively short window of opportunity, in which it can be employed. Its safety and effectiveness is based on its use during the seven weeks following the first day of the last menstrual period. This means that most women would not suspect that they are pregnant and have a confirmatory pregnancy test until at least four weeks after the beginning of their last menses. This, then, leaves only a three week period for the women to secure this method of abortion.

Another disadvantage of this method of pregnancy termination is the need for at least three visits to the medical facility including at least a four hours stay after the administration of the misoprostol.

In addition, medical follow-up is required to ensure that surgical termination is performed in case the medical termination attempt fails since misoprostol has been reported to be teratogenic in humans (limb defects and skull defects).

In the U.S. clinical trials, an increase in the incidence of some adverse events (vomiting, nausea, diarrhea, uterine hemorrhage) occurred in the 50-56 and 57-63 days gestational age groups compared to the ≤ 49 days group. The safety profile of the ≤ 49 days group in the U.S. study did not differ significantly from the pivotal French studies, even though the incidence of common adverse events in the U.S. clinical trials was higher than that of the French trials in the ≤ 49 days group. The percentage of patients in the U.S. studies and the French studies requiring hospitalization, requiring blood transfusion and experiencing heavy bleeding was about the same. However, about 1.6% of the patients in the ≤ 49 days group in the U.S. study had surgical intervention because of heavy bleeding compared to less than 1% of patients in the French studies. The average duration of bleeding was 16 days in the U.S. studies compared to 9 days in the French studies.

While the U.S. clinical trials confirm the safety and efficacy of mifepristone and misoprostol found in the pivotal French studies for women seeking medical

abortions with gestations of 49 days duration or less, they demonstrate that with longer durations of gestation (50-56 days and 57-63 days), the treatment regimen is less effective and the incidence of adverse events is higher.

A comparison of medical termination of pregnancy with surgical termination is of interest in a polulation of women who are given a choice to select between medical and surgical termination of early pregnancy. Such a comparative clinical trial was conducted according to a uniform protocol from 1991 to 1993 in urban clinics in China, Cuba, and India, three countries where abortion is legal and available. A total of 1373 women with amenorrhea ≤ 56 days were given a choice of surgical abortion or mifepristone and misoprostol in the same dosage regimen as used in the U.S. studies. The results of this study were published in 1997. The medical regimen had more adverse events, particularly bleeding, than did surgical abortion. Failure rates for medical abortion exceeded those for surgical abortion (8.6% versus 0.4% in China, 16.0% versus 4.0% in Cuba, and 5.2% versus 0% in India). In each site failure rates of medical abortion increased with gestational age. Specific symptoms and adverse events, including cramping, nausea, and vomiting, were far more frequent among the medical than the surgical abortion patients. The only serious complication was excessive bleeding in medical abortion patients, which is a reason for surgical intervention and for dissatisfaction among medical abortion patients. Three patients (all medical abortions) received blood transfusions. This is a serious potential disadvantage of the medical method. On the whole, medical abortion patients reported significantly more blood loss than did surgical abortion patients. Slightly higher proportions of medical than surgical patients were dissatisfied (8.8% versus 3.8%). Despite the bleeding pattern and the failure rate of the medical abortion method, particularly in China, medical abortion by the mifepristone and misoprostol regimen was said by the authors of this published study to be safe, efficacious, and highly desired by and acceptable to women in developing countries.

The results of a smaller study published in 1999 comparing mifepristone to surgical abortion in U.S. women are consistent with the findings of the larger comparative clinical trial done in China, Cuba, and India. The study was a nonconcurrent, prospective, cohort analysis of 178 mifepristone - misoprostol and 199 suction curettage abortion subjects with intrauterine pregnancies ≤ 63 days gestational age. The medical abortion cohort represents all of the subjects enrolled at one U.S. clinical site for the mifepristone clinical trial between December, 1994 and August, 1995. The surgical abortion cohort was enrolled prospectively at the same clinical site between November, 1995 and December, 1996. Overall, 18.3% of medical and 4.7% surgical patients failed their primary procedure and received an unanticipated suction curettage (R.R. 3.93; 95% CI 1.87,8.29). The risk of failure demonstrated a statistically significant upward trend from 3.3 to 4.4 with advancing gestational age. Four mifepristone patients required curettage for acute bleeding while no surgical patients did. Nine

mifepristone patients required curettage to manage ongoing pregnancy while no surgical patients did. Five mifepristone patients required suction curettage because of incomplete abortion while no surgical patients did. Fourteen mifepristone and eight surgical patients required suction curettage for persistent bleeding. The median time delay for therapeutic curettage was significantly longer in the mifepristone group than in the surgical group (35 days versus 8 days). Mifepristone patients experienced significantly longer postprocedure bleeding than did surgical patients. The mean difference in bleeding days between cohorts was 9.6 days (95% CI, 6.8, 12.4). Mifepristone patients reported significantly longer bleeding in all three gestational age groups. Overall, mifepristone abortion patients reported significantly higher levels of pain, nausea, vomiting, and diarrhea during the actual abortion than did surgical patients. The use of antiemetic agents during the abortion procedure was significantly more common in mifepristone patients than surgical patients (31.1% versus 1%). Mifepristone patients were routinely offered oral narcotics for expulsion-related pain, and 78.5% used them. Mifepristone patients reported more problems during the follow-up interval than did surgical patients. Post-abortion pain occurred in 77.1% of mifepristone patients compared with only 10.5% of surgical patients (RR 7.4, 95% CI 4.7, 11.5). Nausea or vomiting in the follow-up interval was common in the mifepristone group (68.6%), but rare among surgical patients (0.6%) (RR 117.9, 95% CI 16.7, 834.7).

Although the mifepristone and surgical abortion techniques are both safe and effective, the abortion and post-abortion experiences differ significantly as reported in the two published studies above that permit direct comparison of the two techniques in a prospective manner.

IX. Labeling Evaluation:

Comments regarding labeling revisions were transmitted to the sponsor in a letter dated September 18, 1996. Revised draft labeling was submitted by the sponsor June 25, 1999 and currently is under review.

X. Conclusion:

The results of the U.S. studies do not adversely differ significantly from the results of the two pivotal French clinical trials which were the basis for the approvable letter to the sponsor September 18, 1996.

XI. Recommended Phase 4 Studies:

The medical officer, in his revised original NDA review, recommended that phase 4 studies with the following objectives be conducted:

A. To monitor the adequacy of the distribution and credentialing

system.

B. To follow-up on the outcome of a representative sample of mifepristone-treated women who have surgical abortion because of method failure.

C. To assess the long-term effects of multiple use of the regimen.

D. To ascertain the frequency with which women follow the complete treatment regimen and the outcome of those who do not.

E. To study the safety and efficacy of the regimen in women (1) under 18 years of age, (2) over age 35, and (3) who smoke.

F. To ascertain the effect of the regimen on children born after treatment failure.

The phase 4 recommendations were included in the approvable letter to the sponsor dated September 18, 1999.

XII. Consideration of Advisory Committee Members' Comments:

Part of the review process for this application included seeking expert advice from members of the FDA Reproductive Health Drugs Advisory Committee at a public meeting July 19, 1996. The committee voted 6-0 (with two abstentions) that the pivotal studies (French studies) presented at that time showed that the benefits of a mifepristone and misoprostol regimen for terminating early pregnancies outweighed its risks. The studies presented to the committee involved women treated within 49 days of the beginning of their last menstrual period.

Preliminary safety data from recently completed U.S. trials were also presented.

The committee recommended some phase 4 studies and individual committee members offered some individual comments for consideration by the FDA staff, particularly comments regarding labeling and the drug distribution system. All comments were carefully and fully considered and, to the extent possible, implemented.

The applicant was asked September 18, 1996 to submit a comprehensive description of the proposed distribution system. The following complete response from the applicant was submitted to FDA August 18, 1999 regarding the distribution system:

"The details of the distribution system for the product are in the process of being worked out with the proposed distributor. However, the following key principles will be adhered to in the final distribution arrangements:

- Product will only be available from one or two distributors nationwide and not through retail pharmacies or direct to physicians from the manufacturer.

- Each physician interested in obtaining the product must request the product from the distributors, register with them and open an account.

- Access to the distributors will be through the distributors' general order system and through a specially established toll free telephone number with product ordering as an option.

- Aside from standard credit checks run by the distributors to open a new account, each requesting physician will be required to register by providing their BNDD # and their state Medical License #, and signing a letter that they have the following:

  - The ability to accurately confirm the duration of pregnancy

  - The ability to determine blood Rh factor

  - Access to medical facilities equipped to provide emergency care should that become necessary.

In this same letter they will also be asked to indicate their agreement to:

- Obtain signed acknowledgment from the patient that they have been provided with the product label, that they have read and understood the patient information, have had the procedure, its risks and benefits explained to them, and that they agree to follow the treatment procedure.

- Place the dose # on the acknowlegement and in the patient record.

- Maintain complete records for each patient including blood tests, ultrasound examinations and progress noted.

- Fill out and return AE (Adverse Event) cards to the distributor, identifying patient by dose # only.

- Use every effort to ensure patients return for their follow up visit 14-20 days after taking the product.

- Provide the distributor with as much information as possible if there is an ongoing pregnancy following completion of the treatment procedure and this pregnancy is not terminated.

In addition, the toll free telephone number will enable providers to request training materials and information, and speak to an experienced medical consultant about either a non-emergency patient issue or an urgent medical problem or possible complication. Through a separate routing on the toll free telephone number, patients will have access to general information about the product, a provider location near them and web page addresses for more information.

The final distribution system will be more fully developed in the next few months but will always attempt to insure that the drug is only supplied to qualified physician/hospitals who register with the distributor, that the patient is given access to the product label and that the product # is placed on the acknowledgment in the patient's file and that the anonymity of the patient is maintained.

Market launch will not occur until the distribution system is finalized and there are adequate systems in place to track shipment and use."

FDA requested six phase 4 studies of the applicant's August 22, 1996 (and reminded them of their commitment to perform them in the approvable letter dated September 18, 1996). The requested studies are listed below:

1. To monitor the adequacy of the distribution and credentialing system.

2. To follow-up on the outcome of a representative sample of mifepristone-treated women who have surgical abortion because of method failure.

3. To assess the long-term effects of multiple use of the regimen.

4. To ascertain the frequency with which women follow the complete treatment regimen and the outcome of those who do not.

5. To study the safety and efficacy of the regimen in women (1) under 18 years of age, (2) over age 35, and (3) who smoke.

6. To ascertain the effect of the regimen on children born after treatment failure.

The applicant's complete response was submitted to FDA August 18, 1999 regarding the requested phase 4 studies as follows:
"We are mindful of our Phase 4 commitments as outlined in the Population Council's letter to FDA dated September 16, 1996. We plan to discuss in more detail and develop a consensus with the FDA post-NDA approval.

1. The Council recognizes the need for additional information about our proposed distribution and credentialing system and the necessity for making certain that it is designed to result in safe and efficacious abortions for women and in properly controlled access to the product. We will provide the FDA with a detailed product distribution and provider credentialing plan that describes our own monitoring indicators, and we would welcome additional discussion with the Agency at that time. We intend to monitor the distribution and credentialing system but we do not believe that the frequency of post-surgical complications will necessarily be a meaningful indicator of its effectiveness.

2. Although the Council cannot commit to a study that follows all women who have surgical abortions following failed mifepristone abortion, we would propose to investigate treatment failures among a representative sample of providers for a mutually agreeable period of time, for instance six months or one year. In such an investigation, we would classify women undergoing medical abortion according to whether they 1) completed their abortions successfully; 2) had a failed medical abortion and required a surgical abortion; 3) required surgical intervention for other reasons; or 4) were lost to follow-up.

   We are not able to commit to tracking down those women who are lost to follow-up because this would be very difficult and extraordinarily expensive. We are also concerned about the ethics of doing this, as it could violate women's privacy.

3. A prospective study of the long-term effects of multiple use of the regimen in all American women would be unduly burdensome, might result in an invasion of women's privacy and would not likely produce a meaningful scientific result for decades. However, the Council has been informed that central registries of mifeprostone users exist in Europe. We will examine these data sources to determine what can be learned about multiple use. In addition, in future studies of the regimen carried out by the Council in the U.S., we will attempt to develop a cohort of women who report more than one use of the regimen and agree to be followed.

4. We are willing to supply treatment failure data from a sample of providers for a mutually agreeable period to time, for instance six months or one

year, bearing in mind that such data will not include women lost to follow-up.

5. The Council agrees that it is desirable to have additional information on users of the regimen who are under age 18, or over age 35 or who are smokers. From the French and United States clinical trials, we do have some data on women who were more than 35 years old and on women who smoked. The French trials also included some subjects who were under age 18 years of age. We will submit an analysis of our safety and efficacy data on these subgroups. In addition, data on women under 18 or over 35 years of age and those who smoke will be collected in the sample of women we have agreed to study, as described in item Number 2 and 4 above.

6. Since live births are extraordinarily rare as outcomes of treatment with mifepristone (e.g. approximately 19 out of more than 250,000 in the French database) this issue is best approached by reporting through providers who utilize the regimen. We will instruct our distributor to include materials for providers that ask them to report to the distributor any treatment failure in which the woman decides to continue her pregnancy. The provider will ascertain which of these women agree to be followed to document the health of any children born of such pregnancies. In addition, any spontaneous reports of live births of children exposed to mifepristone *in utero* will be investigated."

Other issues raised by individual advisory committee members are addressed below:

While the DOSAGE AND ADMINISTRATION section of the labeling states that mifepristone may be administered by or under the supervision of a physician trained in abortion, able to assess the gestational age of an embryo and to diagnose ectopic pregnancies, and with access to emergency medical facilities, the applicant has not mentioned anything about conducting training seminars for use of mifepristone, without financial incentive to physicians, and distributing the drug only to those physicians who completed the training. Perhaps the applicant will address this point when the details of the distribution system are submitted to FDA.

The applicant should be able to assess compliance with return visits of patients in the phase 4 studies to be performed.

A surgical termination, if needed, should be provided at no additional cost to the patient. It should be part of the mifepristone-misoprostol method of abortion.

Reasonable attempts to contact patients who do not return to confirm the abortion should be made by the physician.

The applicant intends to monitor the distribution system to ensure that only qualified physicians are treating patients.

The applicant will monitor the number of failed medical terminations and any resulting surgical complication.

The applicant will examine central registries of mifepristone users in Europe to determine what can be learned about multiple use. In addition, the applicant proposes to attempt to develop a cohort of women in future studies in the United States who report more than one use of the regimen and agree to be followed.

The applicant has some data on women who were more than 35 years of age, on women who smoked, and on women under 18 years of age. They will submit an analysis of safety and efficacy data on these subgroups. In addition, data on these subgroups will be collected during the phase 4 studies.

The outcomes of pregnancies not terminated by medical or surgical abortion should be followed up and reported by the physician. This should be part of the credentialing and distribution system.

Conditions of exclusions in the clinical trials are in the labeling.

There is no age restriction in the labeling. Women under 18 years of age or over 35 years of age were arbitrarily excluded from the clinical trials, but there is no biologic reason to think that the efficacy and safety of drug administration to these age groups is any different from that of women 18-35 years of age.

The labeling states that misoprostol should be taken two days after ingesting mifepristone.

Women who smoked at least 10 cigarettes per day were excluded from the French studies. Women in the French studies were informed that they should neither smoke nor drink alcohol during the 48 hours following mifepristone administration and on the day misoprostol was to be administered.

Women in the U.S. studies were informed that they should not smoke during the 48 hours following mifepristone administration and on the day misoprostol was to be administered. Women were excluded from the U.S.

BEST POSSIBLE COPY

studies if they were over 35 years of age, smoked more than 10 cigarettes per day, and had another risk factor for cardiovascular disease. The labeling contains a cautionary statement that women who are more than 35 years of age and who also smoke 10 or more cigarettes per day should be treated with caution because such patients were generally excluded from clinical trials of mifepristone. The labeling does not contain a statement that alcohol and/or tobacco should be avoided during treatment. Myocardial infarction has been associated with the administration of an intramuscularly administered prostaglandin, sulprostone, but no such association has been reported with the administration of misoprostol. The labeling for misoprostol does not contain any statement regarding avoiding smoking.

Several comments regarding labeling were made by individual advisory committee members and have been throughly considered.

Overall, I do not think that the labeling imparts an impression to the physician or patient that the treatment regimen is "free of adverse effects and free of actually serious side effects."

The use of mifepristone and misoprostol extends the options available to women for the elective termination of early pregnancy, but it is inappropriate to directly compare this regimen with surgical termination in terms of adverse events. For example, bleeding and cramping are to be expected with mifepristone and misoprostol and not generally expected with surgical termination. The two methods are usually appropriate for abortion at different gestational ages. Medical abortions are done usually during the fifth to seventh weeks of gestation. Surgical terminations are usually not done before the sixth week of gestation.

Reference to drugs known to cause enzyme induction has been deleted.

The risk of malformation occurring if pregnancy is not terminated after drug administration appears in table 2 of the labeling.

The labeling states that a surgical termination must be recommended for patients who have an ongoing pregnancy because of the risk of fetal malformation resulting from the treatment procedure.

The physician labeling mentions that although specific drug interactions have not been studied, it is possible that interactions could occur with drugs like aspirin or other non-steroidal anti-inflammatory agents that modify or inhibit prostaglandin synthesis and metabolism. The only available study, however, found no evidence that non-steroidal antinflamatory drugs inhibit the ability of misoprostol to induce uterine

contractions and expulsions. In the patient labeling, the patient is instructed to advise her medical provider of all the medications she is taking and not to take any of them or any other medications during the treatment procedure without first telling her medical provider.

The mifepristone labeling states that since the effects of mifepristone on infants are unknown, and it is not known if misoprostol or its active metabolite is excreted in human milk, breast feeding women should consult with their medical provider to decide if they should discard their breastmilk for a few days following administration of the medications.

The labeling for misoprostol states that it is not known if the active metabolite (misoprostol acid) is excreted in human milk, and therefore, misoprostol should not be administered to nursing mothers because the potential excretion of misoprostol acid could cause significant diarrhea in nursing infants.

Two days is the optimal time to administer misoprostol after the administration of mifepristone because mifepristone requires 36-48 hours to sensitize the uterine muscle to prostaglandins. This information could be added to the labeling.

We do not know if, or to what extent, effectiveness decreases if administration of misoprostol is delayed past two days after the administration of mifepristone. We do know that administration of misoprostol 36-48 hours after the administration of mifepristone is well founded, based on the mechanism of action. The labeling does state that misoprostol should be administered two days after administration of the mifepristone.

Most of the data available are from women 18 years of age or older. However, the drug regimen is expected to be as safe and effective for pregnant women under the age of 18 years as it is for those over the age of 18 years.

Consideration should be given to including a statement under PRECAUTIONS in the physician labeling that the regimen is less effective and the incidence of adverse events is higher in women seeking abortion with pregnancies of greater than 49 days.

Consideration should also be given to including a statement in the patient labeling under "Are there any reasons that I should not have the treatment procedure?" that the regimen is less effective and the incidence of adverse events is higher in women seeking abortion with pregnancies greater than 49 days. This could follow the statements in the patient labeling that state,

"You should not have the treatment procedure if your medical provider determines that the duration of your pregnancy is more than 49 days. For many women this means that the first day of your last period was more than 49 days ago."

The physician labeling contains a PATIENT INFORMATION section that includes the statement, "Before giving you any medication, your medical provider will ask you to sign a statement that you have decided to terminate your pregnancy, and that you have read and understood this information." An ACKNOWLEGEMENT is included in the PATIENT INFORMATION section for the patient and medical provider to sign. Consideration should be given to adding the statement, "My medical provider has confirmed that I am pregnant and that the pregnancy is not greater than 49 days" and a statement that, " My medical provider has discussed with me alternatives to medical abortion including surgical abortion and continuation of this pregnancy."

Everyone who was a member of the advisory committee when mifepristone was presented and who is still a special government employee was sent the results of the U.S. studies in the form of a copy of the article, "Early Pregnancy Termination with Mifepristone and Misoprostol in the United States" by members of the Population Council published in the April 30, 1998 issue of the New England Journal of Medicine. The article accurately and succinctly summarizes the results of the studies.

XIII. Recommendation:

Approval of this application is recommended provided that the labeling is satisfactorily revised and the complete details of the distribution system which are yet to be submitted are acceptable.

Mifepristone Tablets, 200mg
NDA 20-687

Population Council
Safety Update Report #3

Medical Officer's Review of Safety Update No. 3 Dated March 31, 2000

This NDA Safety Update Report summarizes the body of information which has been obtained by the Population Council since the cut-off date for the previous NDA Safety Update Report submitted August 3, 1999. The primary source of new information for this report is the Periodic Safety Update Report #9 prepared by the manufacturer of mifepristone, as well as from foreign clinical studies sponsored by the Population Council and from the literature. The cut-off date for this third report is February 29, 2000.

The report from presents information from investigational and marketing experience with the product received by that company from worldwide sources. As stated in that report, there have been no specific actions taken with respect to the product for safety reasons such as rejection, withdrawal or suspension of marketing authorization, restrictions to distribution, suspension of clinical trials, modifications of dosage formulation, or changes in target population or indications. It is stated that in connection with new product approvals by European Union member countries via the mutual recognition procedure, some new textual changes were made to product labeling to reflect common usage practice and for purposes of accuracy and explanation.

One new area of safety concern is apparent in the new information presented in this NDA Safety Update Report. Following queries concerning the use of mifepristone in patients with acute hereditary hepatic porphyrias, conducted an experiment at The chick embryo liver in ovo is a validated model system and currently used to identify "inducing" effects of drugs by measuring increases in hepatic delta amino levulinate synthetase, a rate controlling enzyme, resulting in overproduction of porphyrin and cytochrome P 450. Mifepristone crystalline powder was tested on that model and appeared to be highly toxic on the chick embryo liver. Therefore, concluded that the drug should be contraindicated in patients with inherited porphyrias. This contraindication has been added to the updated Master Data Sheet dated December 1999 by It should be considered for inclusion in the labeling for Mifeprex as a contraindication, but since the contraindication would be based upon the results of a single nonclinical safety study, I am of the opinion that it does not warrant being in the labeling unless further confirmatory data becomes available.

The known number of subjects exposed to mifepristone in clinical studies for various indications is 32,439. Over patients have received mifepristone in commercial distribution since its initial marketing in France in 1989. No clinical studies were conducted in the U.S. by the Population Council during the period covered by this NDA

Safety Update Report.

Protocol 171 (not conducted under an IND) has recently been completed in India for pregnancy termination in 900 women. There were no hospitalizations and no unexpected adverse events. Losses to follow-up were 3.5% and 4.4%.

Protocol [redacted] not conducted under an IND) is ongoing [redacted]

Records have been maintained by [redacted] of ongoing pregnancies following administration of mifepristone and a prostoglandin for medical termination of the pregnancies. There are now reports of 107 ongoing pregnancies. Nine cases of fetal abnormalities have been reported as having occurred in association with these pregnancies. Eight of these occurred with the use of mifepristone and gemeprost. One occurred with the use of mifepristone alone.

Mifepristone is now approved for marketing in 21 countries.

The information contained in this Safety Update Report is consistent with the cumulative experience gained to date on mifepristone and does not reveal any unexpected, unanticipated safety issues that would change the benefit to risk ratio.

NDA 20-687
Population Council

Mifepristone 200 mg Oral Tablets
Review completed November 19, 1999

Medical Officer's Review of Safety Update Report No. 2 Dated August 3, 1999

This second NDA Safety Update Report includes accumulated information relative to the safety of mifepristone which has been obtained by the Population Council since Many 25, 1996, the cut-off date for the first Safety Update Report submitted on June 20, 1996. The cut-off for this second report is June 30, 1999.

Information in the report includes that obtained from recently completed and ongoing clinical trials with the product sponsored by the Population Council and by the manufacturers, Roussel Uclaf. Additionally, the report contains Periodic Safety Update Reports prepared by the French manufacturers to summarize the worldwide safety experience with the product, updated information on international regulatory approvals and new information obtained from the literature. The report also contains a Clinical Expert Report on mifepristone which was prepared by and which summarizes the accumulated clinical documentation on the efficacy and safety of the product.

Five periodic safety update reports are submitted covering the period December 1, 1995 - August 31, 1998. An estimated patients received mifepristone under marketing conditions during this period.

In addition to the periodic safety update reports, international reports of adverse reactions have been submitted in two other formats: 1) two quarterly safety line listings of safety reports from clinical trials and of the drug during the period of April 1, 1996 - September 30, 1996 when Roussel Uclaf was responsible for the drug and 2) five individual safety reports (and one follow-up report) received form Roussel Uclaf that were reported to IND.

The periodic safety update reports provide a comprehensive summary of the safety information received by Roussel Uclaf from worldwide sources during the covered time periods. Three of the five individual safety reports are also included in the periodic safety update reports. A total of 67 reports were received during a 32 month period when patients received mifepristone. This is one report per patients treated. A total of 28 of these adverse events were assessed as serious. This is one serious report per patients treated. Five of these adverse events were some sort of urticaria or allergic reaction. One instance of disseminated intravascular coagulation was reported from the United Kingdom. Five

of the reports were of fetal abnormalities. The other reports were diverse. No unexpected safety issues are raised by this safety update report. Overall safety results are similar to those seen in the pivotal French studies and in the U.S. studies.

In the period since 1987, Roussel Uclaf have received information on continuing pregnancies after administration of mifepristone or mifepristone and prostaglandins for medical termination of the pregnancies. A report, updated through June 1999, includes 87 reports of ongoing pregnancies, of which 26 followed the use of mifepristone alone and the remainder followed the use of mifepristone and a prostaglandin (or unknown). Nine reports of fetal anomalies have been received. Mifepristone alone was used in one report and mifepristone and gemeprost was used in eight reports. The one report of a fetal anomaly in a patient who received mifepristone alone resulted in a therapeutic termination of pregnancy with cleft palate and sirenomelia which was believed not to be drug related because of embryogenesis considerations. Of the nine reports of fetal anomalies, three occurred in babies at term. One had bilateral talipes (club foot), one had fingernail defect 3, and the third had a heart malformation. Fifteen of the 87 ongoing pregnancies were lost to followup.

A total of 33 normal babies have been born to women who received mifepristone alone (10), mifepristone plus misoprostol (11), or mifepristone plus some other prostaglandin (12). Data are too limited to determine whether mifepristone is a human teratogen.

Ninety articles published between 1996 and 1999 are submitted. These studies report the use of mifepristone in different clinical conditions, variable dosages, and for variable time durations. There is nothing reported in any of these articles that would change the safety profile of mifepristone for early abortion.

In the reports of early pregnancy termination, adverse events and efficacy reported are similar to that reported in the pivotal French studies and in the U.S. studies.

Unrelated to pregnancy termination, but of interest, are two reports where mild elevations in hepatic transaminases were noted in some subjects. Kettel reported 7 subjects with endometriosis treated with mifeprisone, 5 mg daily for six months. Subjects with liver function abnormalities were excluded from treatment. One of the 7 subjects experienced a mild increase in liver transaminases. Perrault reported 28 subjects with untreated metastatic breast carcinoma treated with mifepristone, 200 mg daily. Mild elevations of AST were reported in 6 of the 28 subjects. (Six subjects had metastatic liver disease. It is not known how many, if any, of these subjects with metastatic liver disease were among the six reports of elevated AST.) These mild elevations in hepatic transaminases are of interest because some such changes were noted very early in abortion dose finding studies. However, 248 subjects in the U.S. studies had a full panel of laboratory tests at baseline and at visit 3 including alkaline phosphatase, AST, ALT, and LDH. The median changes noted were small and not of clinical significance.

The Clinical Expert Report on Mifepristone in Termination of Pregnancy is a review of the clinical documentation forming the basis for approval, key results from the published trials, and post-marketing surveillance data. It contains no new information.

We are informed that mifepristone was approved in eight countries (including Germany) July 6, 1999 under the mutual recognition procedure of the European Union.

No new areas of safety concern are apparent. Information contained in this safety update report is consistent with the cumulative experience gained to date from the pivotal French studies and the U.S. studies. The risk-benefit assessment remains unchanged.

NDA 20-687
Mifepristone

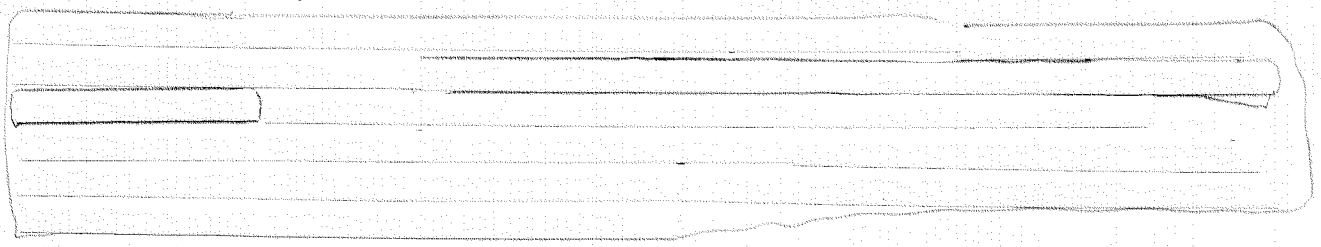
The Population Council
August 28, 1996

Medical Officer's Summary of Safety Update Dated
June 20, 1996

Included in the Safety Update Report received June 27, 1996 are two new clinical study reports as well as new information regarding study reports previously submitted.

The first new clinical study report is entitled, "The Efficacy and Safety of Mifepristone 600 mg in a Single Dose in Combination with Intravenously Administered Sulprostone (Nalador) in Therapeutic Termination of Second Trimester Pregnancy". The second new clinical report is entitled "Role of Cortisol in the Thermal Response to Alimentation: Effect of Mifepristone" and consisted of twelve healthy, male volunteers, six of whom received a single 600 mg tablet and six of whom received a placebo.

Neither of the two new clinical study reports reveal any additional safety concerns not identified in the two pivotal clinical studies.



Newly completed clinical trials include three studies of labor induction, two studies of breast cancer, and the United States clinical trials of early pregnancy termination. Laboratory data from these completed studies have not yet been analyzed and, therefore, no information on laboratory data are reported in this safety update. Final data analysis and study reports for these six studies have not been completed. The results for termination of pregnancy studies conducted in the United States are expected to be in full agreement with the two pivotal clinical studies. No unanticipated safety issues were raised in these studies. Preliminary examination of information from the United States studies as it was forwarded weekly from the clinics directly to the sponsor during the course of the trials indicates that the final, analyzed results will be similar to those obtained in similar clinical trials of the same medical regimen.

The literature update includes eleven articles published in 1995 and one article published in 1996. Three articles are of particular interest. One is the publication of one of the pivotal clinical studies (FF/92/486/24) by Aubeny et.al. The second is entitled "A Comparative Analysis of Fall in Hemoglobin Following Abortions Conducted By Mifepristone (600 mg) and Vacuum Aspiration" by Thonneau et. Al. The investigators found significant blood loss in the two weeks following abortions by the mifepristone/sulprostone protocol while hemoglobin concentrations remained stable in women who had vacuum aspiration. Women who took mifepristone experienced a mean fall of 0.7 g/dl in hemoglobin two weeks after the abortion. The third article entitled "Clinical, Hormonal, and Sonographic Predictors of Successful RU-486-Induced Abortions" was by Menashe et.al. A small hematoma, seen as a localized detachment of the gestational sac, was observed in the decidua capsularis in women who aborted successfully. A significant decrease in plasma levels of estradiol and progesterone and significantly increased cortisol levels in the plasma of the patients who aborted were observed by the seventh day following treatment.

Table four of the Safety Update Report contains adverse reactions from all sources reported to Roussel Uclaf which were summarized in the quarterly line listings covering July 1, 1995 to September 30, 1995; October 1, 1995 to December 31, 1995; January 1, 1996 to March 31, 1996 and reported in the Periodic Safety Update No. 3 dated January 1996 for the period June 1, 1995 to November 30, 1995.

Of a total of forty eight patient reports of adverse experiences listed in Table 4, twenty-eight were reported from patients enrolled in the United States studies (protocols 166A and B). Of these twenty-eight reports, nineteen were metrorrhagia, three were abdominal pain, two were dehydration, and there were one each of depression, viral meningitis, vomiting, and syncope. Vacuum aspiration or D&C was performed in twelve cases of metrorrhagia and a blood transfusion was given in one case of metrorrhagia. Concomitant hypotension was also reported in four patients with severe metrorrhagia. The patient with syncope presented with a marked vasovagal reaction fifteen minutes after misoprostol administration.

In the section of the Safety Update Report entitled "Tolerance of RU 486 During United States Studies" there is Table 1 which was submitted to the sponsor by Russell Uclaf June 7,1995 which indicates that there were forty-seven serious adverse events plus 8 non serious adverse events in the United States studies (protocols 166 A and B). Table 2 indicates that of the forty-seven serious adverse events forty-one were related to bleeding, two to hypotension, and one each to vomiting, chest pain, infection, and accidental injury.

Also included is a half page document entitled "Notifications Report to Roussel Uclaf from Study English PMS" which lists seven reactions occurring in five patients. There were three reports of uterine hemorrhage, one incomplete abortion with bleeding, one convulsion, one congenital nail disorder, and one report of lack of efficacy.

Also included is a section entitled "New Foreign Marketing Information" which consists only of a core product information document from the product manufacturer revised in March 1995.

Since the start of the use of mifepristone until November 30, 1995, Roussel Uclaf has recorded fifty-three cases of continued pregnancy after the intake of mifepristone for early pregnancy termination (alone or associated with a postaglandin analog).

Among these fifty-three cases:

Nineteen pregnancies were delivered at term (or close to it):
Fifteen were uneventful pregnancies with children normal at birth.
One was normal but born prematurely (33-34 weeks) from caesarean section
One was normal except for common slight bilateral talipes.
One case involves unilateral fingernail defects.
One child was reported as strictly normal at birth but it was known that when she was three months old, the infant was diagnosed as having an autoimmune disorder with chronic giant cell hepatitis and immunohemolytic anemia and later died of severe infectious pneumonia likely exacerbated by immuno-suppressive drugs. The reporting physician's opinion (an expert in teratogenicity) was that the onset of the autoimmune disorder was coincidental and that the role of mifepristone could be reasonably excluded.

In fifteen cases information on further condition of the fetus was made available, mainly in the cases where pregnancy is known to have been terminated later:

In nine cases, termination was performed voluntarily and information either from histologic examination or from ultrasound was that the fetus was normal.

In one case, at therapeutic termination the fetus was noted to have sirenomelia associated with other fetal malformations. The opinion of the consulting embryologists to whom the case was submitted by Roussel Uclaf was that the role of mifepristone was very unlikely. This case has been published (Pons J.C. and all : Lancet, 1991, 328: 763).

In five cases of ongoing pregnancy, the latest available information during second trimester examination indicated normal pregnancy and fetus development.

In six cases, no information on the fetus could be obtained but pregnancy was known to have been terminated later.

In thirteen cases, no further information was made available; in most cases patients were lost to follow-up, and in some cases pregnancy is still ongoing.

Comment: This Safety Update does not reveal any unexpected, unanticipated safety issues that were not made known in the original submission of the NDA.

NDA 20-687
Mifepristone

The Population Council
August 29, 1996

Medical Officer's Review of Safety Update Including a Summary Of International Post-Marketing Surveillance Data Dated July 25, 1996.

Submission dated July 25, 1996 contains summaries of all the safety information available to the sponsor from Roussel Uclaf International (France, Sweden, United Kingdom) post-marketing surveillance reports, starting from 1989, the first year mifepristone was on the market in France.

Spontaneous notification of suspected adverse events reported in post-marketing surveillance of mifepristone from June 1989 to June 1995 are listed in Table 7 of the submission. Causality by mifepristone is judged to be "unlikely", "unrelated", "not assessable", "insufficient data", "misuse", or "rumor" in the vast majority of cases. Adverse events that were possibly or probably related to drug use were usually expected events such as metrorrhagia. The most commonly used prostaglandin analogue during this period was sulprostone, given by injection.

The Mifepristone Safety Report covering the period January 1, 1991 through December 31, 1992 covers the first eighteen months since the launching of mifepristone in the United Kingdom. It also includes the period of discontinuation of sulprostone and the introduction in France of misoprostol as a possible alternative prostaglandin analogue. The report also contains the entire safety information available since [redacted] early pregnancy termination. In July, 1992, two new indications of mifepristone were approved in France, "therapeutic termination of second trimester pregnancy" and "labor induction in utero fetal death". [redacted]

The International Safety Report Periodic Update from January 1, 1993 to May 31, 1995 contains no unexpected or unanticipated reports of adverse reactions that were not already known. There were no post-marketing phase IV or surveillance studies reported in final form during this period. There is mention of about three thousand four hundred and thirty-five patients enrolled in the post-marketing surveillance program conducted by Roussel Uclaf in the United Kingdom during the period of this report, but no additional information is available.

Periodic Safety Update Report No. 3 from June 1, 1995 to November 30, 1995 has been reviewed previously by the Food And Drug Administration Medical Officer and his comments are in his Safety Update Review dated August 28, 1996. No unexpected or unanticipated adverse reactions were found in this periodic report.

Comment: From the cumulative experience to date, no new special areas of concern have been identified. The assessment of the risk-benefit ratio of mifepristone is unaltered by the data included in this Safety Update Report.

NDA 20-687
Mifepristone

The Population Council
August 29,1996

Medical Officer's Review of United States Safety Data Dated July 14, 1996

Submission dated July 14, 1996 is a summary report of the serious adverse events from Protocols 166 A and B during the United States clinical trials. All of these reports have been submitted previously in IND

A total of fifty-two subjects had at least one SAE. There was more than one adverse event reported for most subjects. The most frequently reported SAE was hemorrhage (41 reports). This was followed by fainting/dizziness (20 reports) which includes all of the following events: fainting, feeling faint or lightheaded, dizziness, syncope, vasovagal reaction and passing out. Other serious adverse events that were reported by at least four subjects are listed in the summary below.

Total No. of Patients	Total No. of Clinics	Total No. of Adverse Events	Total Number of Treatments				Total No. Hospitalized
			D&C/ Asp.	Meth./ oxy.	IV Fluids	Transfusion	
52	13	Hemorrhage 41 Faint/Dizziness 20 Cramping 14 Vomiting 06 Hypotension 05 Tachycardia 04	34	15	28	04	26

These serious adverse events resulted in the hospitalization of twenty-six subjects. Four subjects received transfusions. A total of twenty-eight subjects received IV fluids (including 3 of the subjects that also had transfusions). A total of thirty-four subjects received a D&C or aspiration. All but two of the subjects who had a D&C or aspiration reported hemorrhage. Fifteen subjects recieved methergine or oxytocin for treatment of bleeding, although eleven of these subjects eventually had a surgical procedure.

It is not possible to make a complete comparison of the serious adverse events reported in the United States trial and the pivotal French studies in the NDA, due to different definitions of SAEs and different adverse event reporting requirements in the two countries. Also, the safety analysis of the United States trials has not been conducted, since the good clinical practice audit of the clinics is currently being completed. Therefore, t this time comparisons between the United States and NDA pivotal studies can only be made with the serious adverse events

reported from these fifty-two United States subjects, rather than other less serious adverse events that will be uncovered during the safety analysis of the entire United States database. However, some general comparisons can be made. The total number of subjects enrolled in United States Protocol 166A/B was 2,121. This is slightly less than the number of subjects (2480) enrolled in the pivotal French trials in the NDA. The number of transfusions is identical (4) in both studies and the number of hospitalizations is similar (26 in the United States trials and 21 in the pivotal trials). The number of reported cases of hemorrhage, metrorrhagia or excessive bleeding was similar in the two studies. Hemorrhage was reported by forty-one subjects in the United States studies. In the NDA pivotal studies, fifty-two subjects reported metrorrhagia or excessive bleeding, which was categorized as severe in twenty-one subjects. However, the manner in which the bleeding was treated differed in the two studies. In the Unites States trials, thirty-two of the thirty-four surgical interventions (D&C or aspiration) were performed on subjects experiencing hemorrhage. In the NDA pivotal trials, a total of fifteen subjects received surgical interventions for bleeding. The greater number of surgical interventions by United States investigators is not unexpected, due to their initial lack of experience in the control of bleeding during medical abortion. This was the first clinical trial of medical abortion in the United States, but medical abortion had been available in France for several years prior to the conduct of the French studies of mifepristone and misoprostol. The United States investigators have noted that as they gained experience with the bleeding that occurs during medical abortion, they were less likely to surgically intervene.

There were five cases of hypotension, in the United States trials, although blood pressure readings were given for only two of these subjects. There were seven cases of clinically relevant hypotension, one rated as severe, in the NDA pivotal trials. There were also a similar number of reports of tachycardia for United States subjects and in the pivotal trials (4 and 5 reports, respectively).

The incidence of other adverse events reported in the United States subjects, such as cramping or vomiting, cannot at this time be fairly compared to the numbers of these adverse events reported from all subjects in the NDA pivotal studies. This comparison must await the safety analysis of the United states database.

Conclusion:

The SAEs reported during the United States trial do not appear to differ significantly from those reported in the pivotal NDA trails, although a full comparison is not possible at this time. The higher incidence of surgical intervention in the United States trials may be explained by the initial inexperience of United States clinicians in providing medical abortion. Investigators in the United States trials have indicated that there was a learning curve associated with the treatment of bleeding during the trial. The incidence of other events such as hemorrhage, transfusions, and hospitalizations were similar in the two studies.

In summary, the current comparison of SAEs between the United States trial and the NDA pivotal trials indicated that medical abortion can be safely delivered in a wide variety of United States settings.

NDA 20-687

SEP 28 2000

Population Council
Attention: Sandra P. Arnold
Vice President, Corporate Affairs
1230 York Avenue
New York, NY 10021

Dear Ms. Arnold:

Please refer to your new drug application (NDA) dated March 14, 1996, received March 18, 1996, submitted under section 505(b) of the Federal Food, Drug, and Cosmetic Act for MIFEPREX™ (mifepristone) Tablets, 200 mg.

We acknowledge receipt of your submissions dated April 19, June 20, July 25, August 15 and September 16 and 26, 1996; January 30, March 31, July 28, August 5, September 24, November 26, 1997; January 30 (2), February 19, April 27, June 25, October 26, December 8, 1998; February 8 and 22, March 31, April 28, May 10 and 20, June 3 (2), 15, 23, 25, and 30, July 14 (2) and 22, August 3, 13, 18 and 30, September 3, 8, 13 and 30, October 5, 26 and 28, November 16 and 29 (2), December 6, 7 and 23, 1999; and January 11, 21 and 28 (2), February 16 and 24, March 3, 6, 9, 10, 30 and 31 (2), April 20, May 3, 11 and 17, June 22 and 23, July 11, 13, 25 and 27, August 18, 21 and 24, September 8, 12, 15 (2), 19 (2), 20, 21, 22, 26 (2), and 27 (2), 2000. Your submission of March 30, 2000 constituted a complete response to our February 18, 2000 action letter.

This new drug application provides for the use of Mifeprex™ for the medical termination of intrauterine pregnancy through 49 days' pregnancy.

We have completed the review of this application, as amended, and have concluded that adequate information has been presented to approve Mifeprex™ (mifepristone) Tablets, 200 mg, for use as recommended in the agreed upon labeling text. The application is approved under 21 CFR 314 Subpart H. Approval is effective on the date of this letter. Marketing of this drug product and related activities are to be in accordance with the substance and procedures of the referenced regulations.

The final printed labeling (FPL) [including the professional labeling (Package Insert), the Medication Guide required for this product under 21 CFR Part 208, the Patient Agreement Form, and the Prescriber's Agreement Form] must be identical to the submitted draft labeling (Package Insert, Medication Guide, Patient Agreement Form, and the Prescriber's Agreement Form submitted September 27, 2000; and the immediate container and carton labels submitted July 25, 2000). Marketing the product with FPL that is not identical to the approved labeling text may render the product misbranded and an unapproved new drug.

Please submit 20 paper copies of the FPL as soon as it is available, in no case more than 30 days after it is printed. Please individually mount ten of the copies on heavy-weight paper or similar material. Alternatively, you may submit the FPL electronically according to the guidance for industry titled *Providing Regulatory Submissions in Electronic Format - NDAs* (January 1999). For administrative

purposes, this submission should be designated "FPL for approved NDA 20-687." Approval of this submission by FDA is not required before the labeling is used.

Under 21 CFR 314.520, distribution of the drug is restricted as follows:

Mifeprex™ must be provided by or under the supervision of a physician who meets the following qualifications:

- Ability to assess the duration of pregnancy accurately.
- Ability to diagnose ectopic pregnancies.
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through other qualified physicians, and are able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the prescribing information of Mifeprex™.
- Must provide each patient with a Medication Guide and must fully explain the procedure to each patient, provide her with a copy of the Medication Guide and Patient Agreement, give her an opportunity to read and discuss both the Medication Guide and the Patient Agreement, obtain her signature on the Patient Agreement and must sign it as well.
- Must notify the sponsor or its designate in writing as discussed in the Package Insert under the heading DOSAGE AND ADMINISTRATION in the event of an ongoing pregnancy, which is not terminated subsequent to the conclusion of the treatment procedure.
- Must report any hospitalization, transfusion or other serious events to the sponsor or its designate.
- Must record the Mifeprex™ package serial number in each patient's record.

With respect to the aspects of distribution other than physician qualifications described above, the following applies:

- Distribution will be in accordance with the system described in the March 30, 2000 submission. This plan assures the physical security of the drug product and provides specific requirements imposed by and on the distributor including procedures for storage, dosage tracking, damaged product returns, and other matters.

We also note the following Phase 4 commitments, specified in your submission dated September 15, 2000. These commitments replace all previous commitments cited in the September 18, 1996 and the February 18, 2000 approvable letters. These Phase 4 commitments are:

1. A cohort-based study of safety outcomes of patients having medical abortion under the care of physicians with surgical intervention skills compared to physicians who refer their patients for surgical intervention. Previous study questions related to age, smoking, and follow-up on day 14 (compliance with return visit) will be incorporated into this cohort study, as well as an audit of signed Patient Agreement forms.

2. A surveillance study on outcomes of ongoing pregnancies.

You have agreed to provide the final Phase 4 protocols for these studies within six months.

Protocols, data, and final reports should be submitted to your IND for this product and a copy of the cover letter sent to this NDA. If an IND is not required to meet your Phase 4 commitments, please submit protocols, data and final reports to this NDA as correspondence. In addition, under 21 CFR 314.81(b)(2)(vii), we request that you include a status summary of each commitment in your annual report to this NDA. The status summary should include the number of patients entered in each study, expected completion and submission dates, and any changes in plans since the last annual report. For administrative purposes, all submissions, including labeling supplements, relating to these Phase 4 commitments must be clearly designated "Phase 4 Commitments."

We also remind you that, under 21 CFR 314.550, after the initial 120 day period following this approval, you must submit all promotional materials, including promotional labeling as well as advertisements, at least 30 days prior to the intended time of initial dissemination of the labeling or initial publication of the advertisement.

Be advised that, as of April 1, 1999, all applications for new active ingredients, new dosage forms, new indications, new routes of administration, and new dosing regimens are required to contain an assessment of the safety and effectiveness of the product in pediatric patients unless this requirement is waived or deferred (63 *FR* 66632). We are waiving the pediatric study requirement for this action on this application.

Please submit one market package of the drug product when it is available.

We remind you that you must comply with the requirements for an approved NDA set forth under 21 CFR 314.80 and 314.81.

If you have any questions, call [redacted]

Sincerely,

/S/

U.S. FOOD & DRUG ADMINISTRATION

ANDA 091178/S-004

PRIOR APPROVAL SUPPLEMENT APPROVAL

GenBioPro, Inc.
(b) (6), (b) (4)

Attention: (b) (6), (b) (4)

Dear Sir or Madam:

This is in reference to your supplemental abbreviated new drug application (sANDA) received for review on June 22, 2022, submitted pursuant to section 505(j) of the Federal Food, Drug, and Cosmetic Act (FD&C Act), for Mifepristone Tablets, 200 mg.

Reference is also made to any amendments submitted prior to the issuance of this letter.

The sANDA, submitted as "Prior Approval Supplement," provides for modification to the approved single, shared system (SSS) risk evaluation and mitigation strategy (REMS) for mifepristone 200 mg tablets in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation, as well as corresponding labeling revisions to the prescribing information and the Medication Guide to align with the modification to the Mifepristone REMS Program. This SSS REMS is known as the Mifepristone REMS Program.

APPROVAL & LABELING

We have completed the review of this sANDA, as amended, and it is **approved**.

RISK EVALUATION AND MITIGATION STRATEGY (REMS) REQUIREMENTS

In order to ensure the benefits of Mifepristone Tablets, 200 mg. outweigh its risks and to minimize burden on the healthcare delivery system of complying with the REMS, we determined that you were required to make the REMS modifications outlined in our REMS Modification Notification letter dated December 16, 2021. In addition the following modifications were communicated during the course of the review:

- Revisions to the REMS goal to align with the updated REMS requirements.

U.S. Food & Drug Administration
10903 New Hampshire Avenue
Silver Spring, MD 20903
www.fda.gov

- Replacing serial number with recording of NDC and lot number of mifepristone dispensed.

- Additional edits for clarification and consistency in the REMS Document and REMS materials (*Prescriber Agreement Forms, Patient Agreement Form,* and *Pharmacy Agreement Forms*).

Your proposed modified REMS, received on June 22, 2022, and amended is approved and will be posted on the FDA REMS website: http://www.fda.gov/rems.

The modified REMS consists of elements to assure safe use and an implementation system.

The modification of the approved REMS must be fully implemented within 120 calendar days of this letter.

Other products may be added in the future if additional NDAs or ANDAs are approved.

Under section 505-1(g)(2)(C) of the FD&C Act, FDA can require the submission of a REMS assessment if FDA determines an assessment is needed to evaluate whether the REMS should be modified to ensure the benefits of the drug outweigh the risks or to minimize the burden on the healthcare delivery system of complying with the REMS.

We remind you that you must include an adequate rationale to support a proposed REMS modification for the addition, modification, or removal of any goal or element of the REMS, as described in section 505-1(g)(4) of the FD&C Act.

We remind you that section 505-1(f)(8) of the FD&C Act prohibits holders of an approved covered application with elements to assure safe use from using any element to block or delay approval of an application under section 505(b)(2) or (j) of the FD&C Act. A violation of this provision in 505-1(f) of the FD&C Act could result in enforcement action.

Prominently identify any submission containing the REMS assessments or proposed modifications of the REMS with the following wording in bold capital letters at the top of the first page of the submission as appropriate:

PROPOSED MAJOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR ANDA 091178/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED REMS MODIFICATIONS DUE TO SAFETY LABELING CHANGES SUBMITTED IN SUPPLEMENT XXX

Should you choose to submit a REMS revision, prominently identify the submission containing the REMS revisions with the following wording in bold capital letters at the top of the first page of the submission:

REMS REVISIONS FOR ANDA 091178

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, are only in PDF format, they may be submitted as such, but the preference is to include as many as possible in Word format.

SUBMISSION OF REMS DOCUMENT IN SPL FORMAT

In addition to submitting the proposed REMS as described above, you can also submit the REMS document in Structured Product Labeling (SPL) format. If you intend to submit the REMS document in SPL format, include the SPL file with your proposed REMS submission.

For more information on submitting REMS in SPL format, please email REMSWebsite@fda.hhs.gov.

REPORTING REQUIREMENTS

Postmarketing reporting requirements for this ANDA are set forth in 21 CFR 314.80-81 and 314.98 and at section 506I of the FD&C Act. The Agency should be advised of any change in the marketing status of this drug or if this drug will not be available for sale after approval. In particular, under section 506I(b) of the FD&C Act, you are required to notify the Agency in writing within 180 days from the date of this letter if this drug will not be available for sale within 180 days from the date of approval. As part of such written notification, you must include (1) the identity of the drug by established name and proprietary name (if any); (2) the ANDA number; (3) the strength of the drug; (4) the date on which the drug will be available for sale, if known; and (5) the reason for not marketing the drug after approval.

If your product is a combination product as defined by 21 CFR 3.2(e) and is comprised of drug and device constituent parts, we remind you that you must comply with the postmarking safety reporting requirements for an approved combination product (21 CFR Part 4, Subpart B). Additional information on combination product postmarketing safety reporting is available at https://www.fda.gov/combination-products/guidance-regulatory-information/postmarketing-safety-reporting-combination-products.

ANNUAL FACILITY FEES

The Generic Drug User Fee Amendments of 2012 (GDUFA) (Public Law 112-144, Title III) established certain provisions[1] with respect to self-identification of facilities and payment of annual facility fees. Your ANDA identifies at least one facility that is subject to the self-identification requirement and payment of an annual facility fee. Self-identification must occur by June 1 of each year for the next fiscal year. Facility fees must be paid each year by the date specified in the Federal Register notice announcing facility fee amounts.

All finished dosage forms (FDFs) or active pharmaceutical ingredients (APIs) manufactured in a facility that has not met its obligations to self-identify or to pay fees when they are due will be deemed misbranded. This means that it will be a violation of federal law to ship these products in interstate commerce or to import them into the United States. Such violations can result in prosecution of those responsible, injunctions, or seizures of misbranded products. Products misbranded because of failure to self-identify or pay facility fees are subject to being denied entry into the United States.

If you have any questions, call (b) (6)

Sincerely,

{See appended electronic signature page}

(b) (6)

Center for Drug Evaluation and Research

[1] Some of these provisions were amended by the Generic Drug User Fee Amendments of 2017 (GDUFA II) (Public Law 115-52, Title III).

DEPARTMENT OF HEALTH AND HUMAN SERVICES

Food and Drug Administration
Silver Spring MD 20993

NDA 020687/S-014

SUPPLEMENT APPROVAL

Danco Laboratories, LLC
(b) (6)
P.O. Box 4816
New York, NY 10185

Dear (b) (6):

Please refer to your Supplemental New Drug Application (sNDA) dated September 16, 2008, received September 17, 2008, submitted under section 505(b) of the Federal Food, Drug, and Cosmetic Act (FDCA) for MIFEPREX® (mifepristone) Tablets. We note that NDA 020687 is approved under the provisions of 21 CFR 314.520 (Subpart H).

This supplemental application provides for a proposed risk evaluation and mitigation strategy (REMS) for MIFEPREX (mifepristone) and was submitted in accordance with section 909(b)(1) of the Food and Drug Administration Amendments Act of 2007 (FDAAA). Under section 909(b)(1) of FDAAA, we identified MIFEPREX (mifepristone) as a product deemed to have in effect an approved REMS because there were in effect on the effective date of FDAAA, March 25, 2008, elements to assure safe use required under 21 CFR 314.520.

We acknowledge receipt of your amendments dated December 9, 2008, November 8, 2010, and May 19 and 27, 2011.

In accordance with section 505-1 of the FDCA, we have determined that a REMS is necessary for MIFEPREX (mifepristone) to ensure the benefits of the drug outweigh the risks of serious complications by requiring prescribers to certify that they are qualified to prescribe MIFEPREX (mifepristone) and are able to assure patient access to appropriate medical facilities to manage any complications.

Your proposed REMS, as amended and appended to this letter, is approved. The REMS consists of a Medication Guide, elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS.

We remind you that section 505-1(f)(8) of FDCA prohibits holders of an approved covered application with elements to assure safe use from using any element to block or delay approval of an application under section 505(b)(2) or (j). A violation of this provision in 505-1(f) could result in enforcement action.

The REMS assessment plan will include the information submitted to FDA on May 27, 2011, and should include the following information:

a. Per section 505-1(g)(3)(A), an assessment of the extent to which the elements to assure safe use are meeting the goal or goals to mitigate a specific serious risk listed in the labeling of the drug, or whether the goal or goals or such elements should be modified.
b. Per section 505-1(g)(3)(B) and (C), information on the status of any postapproval study or clinical trial required under section 505(o) or otherwise undertaken to investigate a safety issue. With respect to any such postapproval study, you must include the status of such study, including whether any difficulties completing the study have been encountered. With respect to any such postapproval clinical trial, you must include the status of such clinical trial, including whether enrollment has begun, the number of participants enrolled, the expected completion date, whether any difficulties completing the clinical trial have been encountered, and registration information with respect to requirements under subsections (i) and (j) of section 402 of the Public Health Service Act. You can satisfy these requirements in your REMS assessments by referring to relevant information included in the most recent annual report required under section 506B and 21 CFR 314.81(b)(2)(vii) and including any updates to the status information since the annual report was prepared. Failure to comply with the REMS assessments provisions in section 505-1(g) could result in enforcement action.

We remind you that in addition to the assessments submitted according to the timetable included in the approved REMS, you must submit a REMS assessment and may propose a modification to the approved REMS when you submit a supplemental application for a new indication for use as described in Section 505-1(g)(2)(A) of FDCA.

Prominently identify future submissions containing the REMS assessments or proposed modifications with the following wording in bold capital letters at the top of the first page of the submission:

NDA 020687 REMS ASSESSMENT

NEW SUPPLEMENT FOR NDA 020687
PROPOSED REMS MODIFICATION
REMS ASSESSMENT

NEW SUPPLEMENT (NEW INDICATION FOR USE) FOR NDA 020687
REMS ASSESSMENT
PROPOSED REMS MODIFICATION (if included)

If you do not submit electronically, please send 5 copies of REMS-related submissions.

As part of the approval under Subpart H, as required by 21 CFR 314.550, you must submit all promotional materials, including promotional labeling as well as advertisements, at least 30 days

before the intended time of initial distribution of the labeling or initial publication of the advertisement. Send one copy to the (b) (6) and two copies of the promotional materials and the package insert directly to:

Food and Drug Administration
Center for Drug Evaluation and Research
Division of Drug Marketing, Advertising, and Communications
Food and Drug Administration
5901-B Ammendale Road
Beltsville, MD 20705-1266

REPORTING REQUIREMENTS

We remind you that you must comply with reporting requirements for an approved NDA (21 CFR 314.80 and 314.81).

If you have any questions, (b) (6)

Sincerely,

{See appended electronic signature page}

(b) (6)

NDA 020687/S-020

SUPPLEMENT APPROVAL

Danco Laboratories, LLC
(b) (4), (b) (6)
P.O. Box 4816
New York, NY 10185

Dear (b) (4), (b) (6):

Please refer to your Supplemental New Drug Application (sNDA) dated May 28, 2015, received May 29, 2015, submitted pursuant to section 505(b)(2) of the Federal Food, Drug, and Cosmetic Act (FDCA) for Mifeprex (mifepristone) Tablets.

We acknowledge receipt of your risk evaluation and mitigation strategy (REMS) assessment dated July 17, 2015.

This "Prior Approval" supplemental new drug application proposes to provide for use through 70 days gestation, revise the labeled dose and dosing regimen and modify the REMS.

APPROVAL & LABELING

We have completed our review of this supplemental application, as amended. It is approved, effective on the date of this letter, for use as recommended in the enclosed, agreed-upon labeling text.

CONTENT OF LABELING

As soon as possible, but no later than 14 days from the date of this letter, submit the content of labeling [21 CFR 314.50(l)] in structured product labeling (SPL) format using the FDA automated drug registration and listing system (eLIST), as described at http://www.fda.gov/ForIndustry/DataStandards/StructuredProductLabeling/default.htm. Content of labeling must be identical to the enclosed labeling (text for the package insert, text for the patient package insert, Medication Guide), with the addition of any labeling changes in pending "Changes Being Effected" (CBE) supplements, as well as annual reportable changes not included in the enclosed labeling.

Information on submitting SPL files using eList may be found in the guidance for industry titled "SPL Standard for Content of Labeling Technical Qs and As at http://www.fda.gov/downloads/DrugsGuidanceComplianceRegulatoryInformation/Guidances/UCM072392.pdf

The SPL will be accessible from publicly available labeling repositories.

Also within 14 days, amend all pending supplemental applications that includes labeling changes for this NDA, including CBE supplements for which FDA has not yet issued an action letter, with the content of labeling [21 CFR 314.50(l)(1)(i)] in MS Word format, that includes the changes approved in this supplemental application, as well as annual reportable changes and annotate each change. To facilitate review of your submission, provide a highlighted or marked-up copy that shows all changes, as well as a clean Microsoft Word version. The marked-up copy should provide appropriate annotations, including supplement number(s) and annual report date(s).

We request that the labeling approved today be available on your website within 10 days of receipt of this letter.

REQUIRED PEDIATRIC ASSESSMENTS

Under the Pediatric Research Equity Act (PREA) (21 U.S.C. 355c), all applications for new active ingredients, new indications, new dosage forms, new dosing regimens, or new routes of administration are required to contain an assessment of the safety and effectiveness of the product for the claimed indication(s) in pediatric patients unless this requirement is waived, deferred, or inapplicable.

We are waiving the pediatric study requirement for pre-menarcheal patients because the use of this product before menarche is not indicated, and we have determined that you have fulfilled the pediatric study requirement for post-menarcheal patients.

RISK EVALUATION AND MITIGATION STRATEGY REQUIREMENTS

The REMS for Mifeprex (mifepristone) Tablets was originally approved on June 8, 2011. The REMS consisted of a Medication Guide, elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS. Your proposed modifications to the REMS included revisions to both the prescriber and patient agreement forms.

Other changes proposed in the efficacy supplement prompted additional revisions to the Mifeprex REMS materials. During review of this efficacy supplement, we also assessed the current REMS program to determine whether each Mifeprex REMS element remains necessary to ensure that the drug's benefits outweigh the risks.

After consultations between the Office of New Drugs (OND) and the Office of Surveillance and Epidemiology (OSE), we have determined that the approved REMS for Mifeprex should be modified to continue to ensure that the benefits of Mifeprex outweigh its risks and to minimize the burden on the healthcare delivery system of complying with the REMS. The REMS modifications submitted by you on March 29, 2016 are approved.

We have determined that it is no longer necessary to include the Medication Guide as an element of the approved REMS to ensure that the benefits of Mifeprex outweigh its risks. The

Medication Guide will continue to be part of the approved labeling in accordance with 21 CFR 208. Like other labeling, Medication Guides are subject to the safety labeling change provisions of section 505(o)(4) of the FDCA.

Your proposed modified REMS, submitted on July 17, 2015, and appended to this letter, is approved as amended. The modified REMS consists of elements to assure safe use (A, C and D), an implementation system, and a timetable for submission of assessments of the REMS.

The timetable for submission of assessments of the REMS remains the same as that approved on June 8, 2011.

The REMS assessment plan will include the information submitted to FDA on March 29, 2016.

The revised REMS assessment plan must include, but is not limited to, the following:

REMS Assessment Plan

1. Number of prescribers enrolled (cumulative)
2. Number of new prescribers enrolled during reporting period
3. Number of prescribers ordering Mifeprex during reporting period
4. Number of healthcare providers who attempted to order Mifeprex who were not enrolled; describe actions taken (during reporting period and cumulative).
5. Number of women exposed to Mifeprex (during reporting period and cumulative)
6. Summary and analysis of any program deviations and corrective action taken
7. Based on the information reported, an assessment and analysis of whether the REMS is meeting its goals and whether modifications to the REMS are needed

The requirements for assessments of an approved REMS under section 505-1(g)(3) include with respect to each goal included in the strategy, an assessment of the extent to which the approved strategy, including each element of the strategy, is meeting the goal or whether 1 or more such goals or such elements should be modified.

We remind you that in addition to the REMS assessments submitted according to the timetable in the approved REMS, you must include an adequate rationale to support any proposed REMS modification for the addition, modification, or removal of any of goal or element of the REMS, as described in section 505-1(g)(4) of the FDCA.

We also remind you that you must submit a REMS assessment when you submit any future supplemental application for a new indication for use as described in section 505-1(g)(2)(A) of the FDCA. This assessment should include:

a) An evaluation of how the benefit-risk profile will or will not change with the new indication;

b) A determination of the implications of a change in the benefit-risk profile for the current REMS;

c) *If the new indication for use introduces unexpected risks*: A description of those risks and an evaluation of whether those risks can be appropriately managed with the currently approved REMS.

d) *If a REMS assessment was submitted in the 18 months prior to submission of the supplemental application for a new indication for use*: A statement about whether the REMS was meeting its goals at the time of that the last assessment and if any modifications of the REMS have been proposed since that assessment.

e) *If a REMS assessment has not been submitted in the 18 months prior to submission of the supplemental application for a new indication for use:* Provision of as many of the currently listed assessment plan items as is feasible.

f) *If you propose a REMS modification based on a change in the benefit-risk profile or because of the new indication of use, submit an adequate rationale to support the modification, including*: Provision of the reason(s) why the proposed REMS modification is necessary, the potential effect on the serious risk(s) for which the REMS was required, on patient access to the drug, and/or on the burden on the health care delivery system; and other appropriate evidence or data to support the proposed change. Additionally, include any changes to the assessment plan necessary to assess the proposed modified REMS. *If you are not proposing REMS modifications*, provide a rationale for why the REMS does not need to be modified.

If the assessment instruments and methodology for your REMS assessments are not included in the REMS supporting document, or if you propose changes to the submitted assessment instruments or methodology, you should update the REMS supporting document to include specific assessment instrument and methodology information at least 90 days before the assessments will be conducted. Updates to the REMS supporting document may be included in a new document that references previous REMS supporting document submission(s) for unchanged portions. Alternatively, updates may be made by modifying the complete previous REMS supporting document, with all changes marked and highlighted. Prominently identify the submission containing the assessment instruments and methodology with the following wording in bold capital letters at the top of the first page of the submission:

NDA 020687 REMS CORRESPONDENCE
(insert concise description of content in bold capital letters, e.g.,
UPDATE TO REMS SUPPORTING DOCUMENT - ASSESSMENT METHODOLOGY

An authorized generic drug under this NDA must have an approved REMS prior to marketing. Should you decide to market, sell, or distribute an authorized generic drug under this NDA, contact us to discuss what will be required in the authorized generic drug REMS submission.

We remind you that section 505-1(f)(8) of FDCA prohibits holders of an approved covered application with elements to assure safe use from using any element to block or delay approval of an application under section 505(b)(2) or (j). A violation of this provision in 505-1(f) could result in enforcement action.

Prominently identify any submission containing the REMS assessments or proposed modifications of the REMS with the following wording in bold capital letters at the top of the first page of the submission as appropriate:

NDA 020687 REMS ASSESSMENT

PROPOSED REMS MODIFICATION (if included)

Should you choose to submit a REMS revision, prominently identify the submission containing the REMS revisions with the following wording in bold capital letters at the top of the first page of the submission:

REMS REVISIONS FOR NDA 020687

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, are only in PDF format, they may be submitted as such, but the preference is to include as many as possible in Word format.

If you do not submit electronically, please send 5 copies of REMS-related submissions.

PROMOTIONAL MATERIALS

You may request advisory comments on proposed introductory advertising and promotional labeling. To do so, submit the following, in triplicate: (1) a cover letter requesting advisory comments, (2) the proposed materials in draft or mock-up form with annotated references, and (3) the package insert(s) to:

OPDP Regulatory Project Manager
Food and Drug Administration
Center for Drug Evaluation and Research
Office of Prescription Drug Promotion (OPDP)
5901-B Ammendale Road
Beltsville, MD 20705-1266

Alternatively, you may submit a request for advisory comments electronically in eCTD format. For more information about submitting promotional materials in eCTD format, see the draft Guidance for Industry (available at: http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/UCM443702.pdf).

You must submit final promotional materials and package insert(s), accompanied by a Form FDA 2253, at the time of initial dissemination or publication [21 CFR 314.81(b)(3)(i)]. Form FDA 2253 is available at http://www.fda.gov/downloads/AboutFDA/ReportsManualsForms/Forms/UCM083570.pdf. Information and Instructions for completing the form can be found at http://www.fda.gov/downloads/AboutFDA/ReportsManualsForms/Forms/UCM375154.pdf. For more information about submission of promotional materials to the Office of Prescription Drug Promotion (OPDP), see http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm090142.htm.

REPORTING REQUIREMENTS

We remind you that you must comply with reporting requirements for an approved NDA (21 CFR 314.80 and 314.81).

If you have any questions, call (b) (6) .

Sincerely,

{See appended electronic signature page}

(b) (6)

(b) (6)

03/29/2016

U.S. FOOD & DRUG ADMINISTRATION

NDA 020687/S-025

SUPPLEMENT APPROVAL

Danco Laboratories, LLC
(b) (4), (b) (6)
P.O. Box 4816
New York, NY 10185

Dear (b) (4), (b) (6):

Please refer to your supplemental new drug application (sNDA) dated and received June 22, 2022, and your amendments, submitted under section 505(b) of the Federal Food, Drug, and Cosmetic Act (FDCA) for Mifeprex (mifepristone) Tablets, 200 mg.

This Prior Approval sNDA provides for modification to the approved single, shared system (SSS) risk evaluation and mitigation strategy (REMS) for mifepristone 200 mg tablets, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation, as well as corresponding labeling revisions to the prescribing information and the Medication Guide to align with the modification to the Mifepristone REMS Program. This SSS REMS is known as the Mifepristone REMS Program.

APPROVAL & LABELING

We have completed our review of the supplemental application, as amended. It is approved effective the date of this letter.

CONTENT OF LABELING

As soon as possible, but no later than 14 days from the date of this letter, submit the content of labeling [21 CFR 314.50(l)] in structured product labeling (SPL) format using the FDA automated drug registration and listing system (eLIST), as described at FDA.gov.[1] Content of labeling must be identical to the enclosed labeling (text for the Prescribing Information and Medication Guide), with the addition of any labeling changes in pending "Changes Being Effected" (CBE) supplements, as well as annual reportable changes not included in the enclosed labeling.

[1] http://www.fda.gov/ForIndustry/DataStandards/StructuredProductLabeling/default.htm

Information on submitting SPL files using eList may be found in the guidance for industry *SPL Standard for Content of Labeling Technical Qs and As*.[2]

The SPL will be accessible from publicly available labeling repositories.

Also within 14 days, amend all pending supplemental applications that include labeling changes for this NDA, including CBE supplements for which FDA has not yet issued an action letter, with the content of labeling [21 CFR 314.50(l)(1)(i)] in Microsoft Word format, that includes the changes approved in this supplemental application, as well as annual reportable changes. To facilitate review of your submission(s), provide a highlighted or marked-up copy that shows all changes, as well as a clean Microsoft Word version. The marked-up copy should provide appropriate annotations, including supplement number(s) and annual report date(s).

We request that the labeling approved today be available on your website within 10 days of receipt of this letter.

REQUIRED PEDIATRIC ASSESSMENTS

Under the Pediatric Research Equity Act (PREA) (21 U.S.C. 355c), all applications for new active ingredients (which includes new salts and new fixed combinations), new indications, new dosage forms, new dosing regimens, or new routes of administration are required to contain an assessment of the safety and effectiveness of the product for the claimed indication in pediatric patients unless this requirement is waived, deferred, or inapplicable.

Because none of these criteria apply to your application, you are exempt from this requirement.

RISK EVALUATION AND MITIGATION STRATEGY (REMS) REQUIREMENTS

The Mifepristone REMS Program, of which Mifeprex is a member, was originally approved on April 11, 2019, and the most recent REMS modification was approved on May 14, 2021. The Mifepristone REMS Program consists of elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS.

In order to ensure the benefits of Mifeprex outweigh its risks and to minimize burden on the healthcare delivery system of complying with the REMS, we determined that you were required to make the REMS modifications outlined in our REMS Modification

[2] We update guidances periodically. For the most recent version of a guidance, check the FDA Guidance Documents Database https://www.fda.gov/RegulatoryInformation/Guidances/default.htm.

Notification letter dated December 16, 2021. In addition the following modifications were communicated during the course of the review:

- Revisions to the REMS goal to align with the updated REMS requirements.
- Replacing serial number with recording of NDC and lot number of mifepristone dispensed.
- Additional edits for clarification and consistency in the REMS Document and REMS materials (*Prescriber Agreement Forms, Patient Agreement Form,* and *Pharmacy Agreement Forms*).

Your proposed modified REMS, received on June 22, 2022, amended and appended to this letter, is approved. The modified REMS consists of the elements to assure safe use, implementation system, and a timetable for submission of assessments of the REMS.

The modification of the approved REMS must be fully implemented within 120 calendar days of this letter.

This shared system REMS, known as the Mifepristone REMS Program, currently includes those products listed on the FDA REMS website[3].

Other products may be added in the future if additional NDAs or ANDAs are approved.

The timetable for submission of assessments of the REMS must be revised to one year from the date of the approval of the modified SSS REMS (1/3/2023) and annually thereafter.

The revised REMS assessment plan must include, but is not limited to, the following:

Program Implementation and Operations

1. REMS Certification Statistics
   a. Prescribers
      i. Number of certified prescribers who have certified with the Sponsor's distributor(s) and number who have submitted *Prescriber Agreement Forms* to Certified Pharmacies
      ii. Number and percentage of newly certified prescribers
      iii. Number and percentage of active certified prescribers (i.e., who ordered mifepristone or submitted a prescription during the reporting period)

   b. Pharmacies

[3] https://www.accessdata.fda.gov/scripts/cder/rems/index.cfm

i. Number of certified pharmacies
ii. Number and percentage of newly certified pharmacies
iii. Number and percentage of active certified pharmacies (i.e., that dispensed mifepristone during the reporting period)

c. Wholesalers/Distributors
i. Number of authorized wholesalers/distributors
ii. Number and percentage of newly authorized wholesalers/distributors
iii. Number and percentage of active authorized wholesalers/distributors (i.e. that shipped mifepristone during the reporting period)

2. Utilization Data
a. Total number of tablets shipped by wholesalers/distributors, stratified by Certified Prescriber or Certified Pharmacy location
b. Number of prescriptions dispensed from pharmacies

3. REMS Compliance Data
a. Audits: Summary of audit activities for each stakeholder (i.e., certified pharmacies and wholesalers/distributors) including but not limited to:
i. A copy of the final audit plan for each stakeholder type (provide for the current reporting period)
ii. The number of audits expected, and the number of audits performed
iii. The number and type of deficiencies noted
iv. For those with deficiencies noted, report the corrective and preventive actions (CAPAs) required, if any, to address the deficiencies, including the status (e.g., completed, not completed, in progress) (provide for the current reporting period)
v. For any stakeholders that did not complete the CAPA within the timeframe specified in the audit plan, describe actions taken (provide for the current reporting period)
vi. A summary report of all resulting changes to processes and procedures necessary to ensure compliance with the REMS requirements (provide for the current reporting period)

b. A summary report of non-compliance, associated corrective action plans (CAPAs), and the status of CAPAs including but not limited to:
i. A copy of the final non-compliance plans for Pharmacies and Distributors (provide for the current reporting period)
ii. For each instance of noncompliance below (iii-v), report the following information (provide for the current reporting period):
1. A unique, anonymized ID for the stakeholder(s) associated with the non-compliance event to enable tracking over time
2. The source of the non-compliance data (e.g., self-reported, audit, other)
3. A root cause analysis of the non-compliance

4. Actions to prevent future occurrences and outcomes of such actions

iii. Prescriber compliance

1. Number and percentage of certified prescribers who became decertified as a result of non- compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
2. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

iv. Pharmacy compliance

1. Number and percentage of prescriptions dispensed that were written by prescriber(s) who did not submit a Prescriber Agreement to the dispensing Certified Pharmacy
2. Number and percentage of mifepristone tablets dispensed by non-certified pharmacies
3. Number and percentage of pharmacies that became decertified as a result of non- compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
4. An assessment of prescription delivery timelines, including percentage delivered more than four days after receipt of the prescription, duration and causes for delay. A proposal for this assessment will be submitted within 60 days of the approval of the REMS Modification.
5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

v. Wholesaler/distributor compliance

1. Number of healthcare providers who successfully ordered mifepristone who were not certified
2. Number of non-certified pharmacies that successfully ordered mifepristone
3. Number of shipments sent to non-certified prescriber receiving locations
4. Number of shipments sent to non-certified pharmacy receiving locations
5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

Overall Assessment of REMS Effectiveness

The requirements for assessments of an approved REMS under section 505-1(g)(3) include with respect to each goal included in the strategy, an assessment of the extent to which the approved strategy, including each element of the strategy, is meeting the goal or whether one or more such goals or such elements should be modified.

We remind you that in addition to the REMS assessments submitted according to the timetable in the approved REMS, you must include an adequate rationale to support a

proposed REMS modification for the addition, modification, or removal of any goal or element of the REMS, as described in section 505-1(g)(4) of the FDCA.

We also remind you that you must submit a REMS assessment when you submit a supplemental application for a new indication for use, as described in section 505-1(g)(2)(A) of the FDCA. This assessment should include:

a) An evaluation of how the benefit-risk profile will or will not change with the new indication;

b) A determination of the implications of a change in the benefit-risk profile for the current REMS;

c) *If the new indication for use introduces unexpected risks*: A description of those risks and an evaluation of whether those risks can be appropriately managed with the currently approved REMS.

d) *If a REMS assessment was submitted in the 18 months prior to submission of the supplemental application for a new indication for use*: A statement about whether the REMS was meeting its goals at the time of that last assessment and if any modifications of the REMS have been proposed since that assessment.

e) *If a REMS assessment has not been submitted in the 18 months prior to submission of the supplemental application for a new indication for use:* Provision of as many of the currently listed assessment plan items as is feasible.

f) *If you propose a REMS modification based on a change in the benefit-risk profile or because of the new indication of use, submit an adequate rationale to support the modification, including*: Provision of the reason(s) why the proposed REMS modification is necessary, the potential effect on the serious risk(s) for which the REMS was required, on patient access to the drug, and/or on the burden on the health care delivery system; and other appropriate evidence or data to support the proposed change. Additionally, include any changes to the assessment plan necessary to assess the proposed modified REMS. *If you are not proposing REMS modifications*, provide a rationale for why the REMS does not need to be modified.

If the assessment instruments and methodology for your REMS assessments are not included in the REMS supporting document, or if you propose changes to the submitted assessment instruments or methodology, you should update the REMS supporting document to include specific assessment instrument and methodology information at least 90 days before the assessments will be conducted. Updates to the REMS supporting document may be included in a new document that references previous REMS supporting document submission(s) for unchanged portions. Alternatively,

updates may be made by modifying the complete previous REMS supporting document, with all changes marked and highlighted.

Prominently identify the submission containing the assessment instruments and methodology with the following wording in bold capital letters at the top of the first page of the submission:

NDA 020687 REMS ASSESSMENT METHODOLOGY
(insert concise description of content in bold capital letters, e.g.,
ASSESSMENT METHODOLOGY, PROTOCOL, SURVEY METHODOLOGIES, AUDIT PLAN, DRUG USE STUDY)

An authorized generic drug under this NDA must have an approved REMS prior to marketing. Should you decide to market, sell, or distribute an authorized generic drug under this NDA, contact us to discuss what will be required in the authorized generic drug REMS submission.

We remind you that section 505-1(f)(8) of FDCA prohibits holders of an approved covered application with elements to assure safe use from using any element to block or delay approval of an application under section 505(b)(2) or (j). A violation of this provision in 505-1(f) could result in enforcement action.

Prominently identify any submission containing the REMS assessments or proposed modifications of the REMS with the following wording in bold capital letters at the top of the first page of the submission as appropriate:

NDA 020687 REMS ASSESSMENT

or

NEW SUPPLEMENT FOR NDA 020687/S-000
CHANGES BEING EFFECTED IN 30 DAYS
PROPOSED MINOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR NDA 020687/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED MAJOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR NDA 020687/S-000/
PRIOR APPROVAL SUPPLEMENT

PROPOSED REMS MODIFICATIONS DUE TO SAFETY LABELING CHANGES SUBMITTED IN SUPPLEMENT XXX

or

NEW SUPPLEMENT (NEW INDICATION FOR USE)
FOR NDA 020687/S-000
REMS ASSESSMENT
PROPOSED REMS MODIFICATION (if included)

Should you choose to submit a REMS revision, prominently identify the submission containing the REMS revisions with the following wording in bold capital letters at the top of the first page of the submission:

REMS REVISIONS FOR NDA 020687

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, or website screenshots are only in PDF format, they may be submitted as such, but Word format is preferred.

SUBMISSION OF REMS DOCUMENT IN SPL FORMAT

FDA can accept the REMS document in Structured Product Labeling (SPL) format. If you intend to submit the REMS document in SPL format, as soon as possible, but no later than 14 days from the date of this letter, submit the REMS document in SPL format using the FDA automated drug registration and listing system (eLIST).

For more information on submitting REMS in SPL format, please email FDAREMSwebsite@fda.hhs.gov
.

PATENT LISTING REQUIREMENTS

Pursuant to 21 CFR 314.53(d)(2) and 314.70(f), certain changes to an approved NDA submitted in a supplement require you to submit patent information for listing in the Orange Book upon approval of the supplement. You must submit the patent information required by 21 CFR 314.53(d)(2)(i)(A) through (C) and 314.53(d)(2)(ii)(A) and (C), as applicable, to FDA on Form FDA 3542 within 30 days after the date of approval of the supplement for the patent information to be timely filed (see 21 CFR 314.53(c)(2)(ii)). You also must ensure that any changes to your approved NDA that require the submission of a request to remove patent information from the Orange Book are submitted to FDA at the time of approval of the supplement pursuant to 21 CFR 314.53(d)(2)(ii)(B) and 314.53(f)(2)(iv).

REPORTING REQUIREMENTS

We remind you that you must comply with reporting requirements for an approved NDA (21 CFR 314.80 and 314.81).

If you have any questions, call (b) (6)

Sincerely,

{See appended electronic signature page}

GUIDANCE FOR INDUSTRY [1]

FOR THE SUBMISSION OF AN ENVIRONMENTAL ASSESSMENT IN HUMAN DRUG APPLICATIONS AND SUPPLEMENTS

I. INTRODUCTION

The National Environmental Policy Act of 1969 (NEPA) requires all Federal agencies to assess the environmental impacts of their actions and to ensure that the interested and affected public is informed of environmental analyses. The Food and Drug Administration (FDA) is required under NEPA to consider the environmental impact of approving drug product applications as an integral part of its regulatory process. FDA's regulations in 21 CFR Part 25 specify that environmental assessments (EA's) or abbreviated environmental assessments (AEA's) must be submitted as part of certain new drug applications (NDA's), antibiotic applications, abbreviated new drug applications (ANDA's), abbreviated antibiotic applications (AADA's), investigational new drug applications (IND's) and for various other actions (see 21 CFR § 25.22(a)).

This guidance provides information on how to prepare EA's for submission to the Center for Drug Evaluation and Research (CDER) for these drug product applications. Topics covered include: 1) when categorical exclusions apply; 2) when to submit an EA or AEA; 3) the content and format of EA's or AEA's; 4) approaches to determining the environmental fate and effects of substances; 5) test methods; 6) treatment of confidential information submitted in support of an EA; 7) special considerations associated with EA's for genetically altered organisms and materials and products

WITHDRAWN

---

[1] This guidance has been prepared under the auspices of the Office of Pharmaceutical Science of the Center for Drug Evaluation and Research (CDER) at the Food and Drug Administration. The guidance is an informal communication under 21 CFR § 10.90(b)(9) that reflects the best judgment of CDER employees at this time. It does not create or confer any rights, privileges or benefits for or on any person, nor does it operate to bind or obligate FDA in any way. For further information about this guidance, contact Nancy B. Sager, Center for Drug Evaluation and Research, HFD-357, 5600 Fishers Lane, Rockville, MD 20857 (Phone: 301-594-6740; FAX: 301-594-6197, Internet: SAGERN@CDER.FDA.
GOV). For additional copies of this guidance contact the Consumer Affairs Branch, HFD-210, Center for Drug Evaluation and Research, 7500 Standish Place, Rockville, MD, 20855, 301-594-1012. An electronic version of this guidance is also available via Internet by connecting to the CDER file transfer protocol (FTP) server (CDVS2.CDER.FDA.GOV).

derived from natural sources; 8) EA documentation for foreign manufacturing facilities; and 9) Drug Master Files (DMF's).

Information in this guidance, in addition to the Code of Federal Regulations (CFR) and the FDA EA Technical Handbook (NTIS Publication Number PB 87 175345/AS) which provides information on acceptable test methods, represents the core information available from CDER to assist industry in preparing an EA.

Under the President's reinventing government (REGO) initiatives announced in April, 1995, CDER is reevaluating its environmental regulations and plans to revise the regulations to reduce the number of EA's required to be submitted by industry and, consequently, the number of finding of no significant impacts (FONSI's) prepared by the agency under NEPA. FDA will issue for public comment a notice of proposed rulemaking that will propose additional categorical exclusions for those actions CDER has determined normally do not individually or cumulatively have a significant effect on the quality of the human environment. This guidance, explaining how to prepare an EA when required by current regulations, will remain in effect until superseded by revised final regulations or new CDER guidance.

II. WHEN IS AN ACTION CATEGORICALLY EXCLUDED?

Certain actions are subject to categorical exclusion and, therefore, ordinarily do not require the preparation of an EA because, as a class, these actions will not normally have significant effects on the environment (21 CFR § 25.24).

Submissions to CDER that are ordinarily categorically excluded under the regulations are actions on the majority of: 1) ANDA's and AADA's; 2) NDA supplements; and 3) IND's. ANDA's/AADA's and NDA supplements are categorically excluded from the requirement for preparation of an EA if they meet certain criteria (21 CFR 25.24(c)). The criteria include that the drug product will not be administered at higher dosage levels, for longer duration, or for different indications than were previously in effect, and if data available to the agency do not establish that, at the expected levels of exposure, the substance may be toxic to organisms in the environment. In such cases, no EA or AEA need be submitted unless the agency has sufficient evidence to establish that the specific proposed action may significantly affect the quality of the human environment. Supplements for chemistry, manufacturing and controls changes, such as manufacturing site changes, typically meet the categorical exclusion criteria.

WITHDRAWN

Action on an IND is categorically excluded from the requirement for preparation of an EA (21 CFR § 25.24(c)(4)) if the drug shipped under such notice is intended to be used for clinical studies or research in which waste will be controlled or the amount of waste expected to enter the environment may reasonably be expected to be nontoxic.

When requesting a categorical exclusion, the applicant should cite the categorical exclusion used and certify that the drug product meets the criteria for the categorical exclusion defined in the regulations. An applicant ordinarily need not provide data to demonstrate that it qualifies for a categorical exclusion. CDER will deny a categorical exclusion, however, and require an EA if there is sufficient available information that suggests that the substance may be toxic to organisms in the environment at the expected levels of exposure. Available information includes information submitted as part of the application as well as data available to the agency on the same or similar drugs. CDER will request additional information when warranted. If an applicant has information that indicates that a substance may be toxic to organisms in the environment at the expected level of exposure, the information should be provided to CDER.

CDER considers any action that, directly or indirectly, affects a species or the critical habitat of a species determined under the Endangered Species Act (ESA) or the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES) to be endangered or threatened, or that affects properties listed in or eligible for listing in the United States' Register of Historic Places, to be an action that may significantly affect the quality of the human environment. For such actions, CDER may request additional information if a categorical exclusion is claimed.

III. PREPARING AN EA FOR SUBMISSION TO CDER

A. When is an EA or AEA required under the regulations?

Preparation of an environmental assessment is ordinarily required unless the proposed action qualifies for exclusion under 21 CFR §§ 25.23 and 25.24. EA's are submitted to CDER for among other actions: 1) NDA's and 2) efficacy or other supplements to existing NDA's or actions on ANDA's or AADA's, if the approved drug product will be administered at higher dosage levels, for longer duration, or for different indications than were previously in effect, or if data available to the agency establish that at the established levels of exposure, the substance may be toxic to organisms in the environment.

WITHDRAWN

1. NDA's

Type 1 NDA's are for new molecular entities. NDA Types 2-7 are for drug products which have already been marketed or approved in the same form or very similar form in the U.S. **The regulations require that an EA or AEA be provided for all NDA's.**

2. NDA Supplements

Under FDA's NEPA procedures, an EA or AEA must be prepared if the supplemental application does not qualify for a categorical exclusion. If an EA or AEA has previously been submitted for the same active moiety by the applicant, the EA or AEA for the supplement need only include a copy of the original EA/AEA and a discussion of the differences/changes from the original application and the impact of these differences on the environment from those described in the original EA/AEA. For each EA format item that does not differ from the original EA/AEA, this should be stated and a reference to the previously submitted EA provided. If the applicant is abstracting information from an environmental assessment/FONSI released under the Freedom of Information Act (FOIA), a copy of the document should be included with the submission. If no previous EA/AEA can be referenced, an EA or AEA, as appropriate, should be provided in accordance with the content and format information provided in section III.D.

3. ANDA/AADA's

Under FDA's NEPA procedures, an EA or AEA must be prepared if the ANDA/AADA application or supplement to an ANDA/AADA does not qualify for categorical exclusion. If an EA or AEA has previously been submitted for the same active moiety by the applicant, the EA or AEA need only include a copy of the original EA/AEA and a discussion of the differences/changes from the original application and the impact of these differences on the environment from those described in the original EA/AEA. For each EA format item that does not differ from the original EA/AEA, this should be stated and a reference to the previously submitted EA provided. If the applicant is abstracting information from an environmental assessment/FONSI released under the Freedom of Information Act (FOIA), a copy of the document should be included with the submission. If no previous EA/AEA can be referenced, an EA or AEA, as appropriate, should be provided in accordance with the content and format information provided in section III.D.

WITHDRAWN

4. IND's

Under FDA's NEPA procedures, an EA or AEA must be prepared if the action does not qualify for a categorical exclusion.

B. What type of EA should be submitted?

FDA's NEPA procedures provide for two types of EA's: "full" EA's or abbreviated EA's. A "full" EA consists of 15 format items, including characterization of the fate and effects in the environment of the compound which is the subject of the proposed action. AEA's exclude or limit some of the information required including that in EA format items 7 and 8, fate and effects testing. The information to be provided for each of the format items is described in 21 CFR § 25.31a and in section III.D of this document.

FDA believes that, as stated in 21 CFR § 25.1(b), environmental documents are to concentrate on timely and significant issues, not to amass needless detail. FDA 's regulations (21 CFR § 25.31a(b)) provide that for various actions, certain format items of the EA may be abbreviated. For other drug product approvals requiring an EA pursuant to 21 CFR § 25.31a(a), the EA generally should address format items 1-15, but in some cases, not all format items may apply (see section III.D.7 for additional information). If a preparer of an EA believes that not all items in the format apply, the applicant may consult the Environmental Assessment Team at CDER to agree on a different format.

FDA's regulations at 21 CFR §25.31a(b) describe three types of CDER actions which are eligible for an AEA: 1) infrequent uses; 2) naturally occurring substances; and 3) products approved by the Environmental Protection Agency (EPA).

The basis for an AEA should be stated in EA format item 4.a. After CDER evaluates the environmental information submitted in an EA in which one or more EA format items are abbreviated, CDER may require the submission of additional information.

1. Infrequent Use AEA's

The infrequent use provision allows for preparation of an AEA when the drug product is intended for the prevention, treatment, or diagnosis of a rare disease or for a similarly infrequent use; for ophthalmic or topical application; or for local or general anesthesia (21 CFR § 25.31a(b)(3)).

WITHDRAWN

For infrequent use AEA's, documentation for EA format items 7-11 and 15 is ordinarily not required. Questions have arisen regarding the interpretation of rare disease or condition under this provision. CDER is providing guidance regarding this provision as follows: "Rare disease or condition" is defined in the Federal Food, Drug and Cosmetic Act, 21 U.S.C. § 360bb(a)(2) as "any disease or condition which (A) affects less than 200,000 persons in the United States, or (B) affects more than 200,000 in the United States and for which there is no reasonable expectation that the cost of developing and making available in the United States a drug for such disease or condition will be recovered from sales in the United States of such a drug." Criterion A may be supported by designation as an Orphan Drug by FDA's Office of Orphan Products Development or by providing the estimated patient population and supporting information from an independent source (*e.g.,* Centers for Disease Control and Prevention (CDC)). If a drug has been designated as an Orphan Drug under criterion B, an infrequent use AEA may be used.

2. Naturally Occurring Substances AEA's

An AEA may be submitted for organic or inorganic drug substances, whether obtained from a natural resource or synthesized, that will exist in the environment in the same form as a substance found naturally in the flora, fauna, atmosphere, water or soil. A modified active moiety (*e.g.,* salt) which does not occur naturally also may be supported by an AEA filed under § 25.31a(b)(5) if it is established that, *in vivo* and in the environment, the active moiety exists in a form that is found naturally.

AEA's for substances that occur naturally in the environment should discuss whether the use of the product can reasonably be expected on the basis of all available evidence to alter significantly the concentration and distribution of the product, its metabolites, degradation products or its constituent parts in the environment (EA format item 7). These AEA's may rely on **existing** data (*i.e.,* from literature or data previously generated by the applicant) to fulfill the reporting requirements of EA format item 8 (effects). If a substance does not occur naturally in the geographic area of proposed drug use and disposal, additional information may be needed.

More information is available in section V regarding drug substances that are obtained from natural resources.

3. AEA's for Products Approved by EPA

AEA's for products that have been approved by the Environmental Protection Agency (EPA) under section 4 or 5 of the Toxic Substances Control Act (TSCA) or under the Federal Insecticide, Fungicide, and Rodenticide Act (FIFRA) should rely on environmental information in studies submitted to EPA, in the application/ petition submitted for FDA approval, and in the scientific literature to fulfill the requirements of EA format items 7, 8 and 15 (21 CFR § 25.31a(b)(6)). The AEA should contain a

WITHDRAWN

description of any potential adverse environmental impact determined by the EPA.

C. What EA information should be provided in an application?

The applicant should determine whether a categorical exclusion, AEA or EA is appropriate for their submission and provide the required information in the initial filing. **Failure to provide: 1) a claim of categorical exclusion with certification of compliance with the categorical exclusion criteria; or 2) an adequate EA or AEA (*e.g.,* information for each required EA format item), is grounds for refusing to file the application (21 CFR §314.101(d)(4) and §25.23(d)).**

If the submission is eligible for more than one type of environmental assessment format (*e.g.,* a naturally occurring substance for a rare disease for which one could prepare an AEA either under 21 CFR § 25.31a(b)(3) or (5)), the applicant should submit the information in the format with the fewest reporting requirements and state which EA format is being used. CDER will request additional information if warranted.

D. Content and Format

This section describes the basic information that should be submitted for each format item in an EA or AEA and follows the formats described in FDA's NEPA procedures (21 CFR § 25.31a). Attachment A contains an outline of the format for an EA.

1. Date

The EA should include the date the EA was originally prepared and the date(s) of any subsequent amendments.

2. Name of Applicant/Petitioner

The EA should identify the applicant who is submitting the application.

3. Address

The EA should contain the address where all correspondence is to be directed.

4. Description of Proposed Action

a. Requested Approval

The description of the requested approval should include the drug product application number (if available), drug product name, dosage form, strength, a brief description of the drug product packaging, whether an EA or AEA is provided and, if applicable, the basis for the AEA. For example, "XYZ Pharmaceuticals has filed an NDA pursuant to

WITHDRAWN

section 505(b) of the Federal Food, Drug, and Cosmetic Act for TRADE NAME® (established name), 250 mg and 500 mg, packaged in OHDPE bottles. An EA has been submitted pursuant to 21 CFR § 25.31a(a)."

b. Need for Action

The EA should briefly describe the drug's intended uses in the diagnosis, cure, mitigation, treatment or prevention of disease. If attempting to qualify an action for an abbreviated environmental assessment because it is used to treat a rare disease or condition (see section III.B.1), it should be indicated if the drug is for acute or long-term use, the current and/or expected patient population (*i.e.,* total patient population, not marketing estimate) and Orphan Drug status, if applicable.

c. Production Locations

The EA should identify the location of both the drug substance and the drug product manufacturing facilities. The location of production facilities for isolated drug substance intermediates should also be provided if the intermediates are not commercially available to all parties in the open marketplace (*i.e.*, proprietary drug substance intermediates). The EA should include a statement whether any intermediates are considered proprietary. The specific street address(es) should be provided. A brief description of the environments at and adjacent to the facilities should be provided. The zoning (*e.g.*, industrial, commercial, residential) and any geographic features (*e.g.*, mountains, lakes, rivers, forests) in proximity to the manufacturing facilities should be identified.

If primary packaging operations are conducted at locations other than the drug product manufacturing facility, the sites of those operations should be identified.

Information ordinarily need not be provided for secondary packaging operations, labeling, testing, quality control, distribution and warehousing operations which are performed at locations other than the manufacturing facilities, or primary packaging facilities where the introduction of drug substance, proprietary drug substance intermediate or drug product into the environment is minimal (*e.g.*, due to accidental breakage, emission from nondestructive testing). If standard procedures at any of these facilities allow for introduction of other than incidental quantities of these compounds into the environment, then information should also be included for those facilities.

The names and addresses of manufacturers or suppliers that are excluded from public release under FOIA procedures may be treated as confidential information when preparing an environmental assessment and may be included in a confidential appendix (see section III.G for a discussion of confidential and non-confidential

WITHDRAWN

information). All other information regarding these facilities (*e.g.,* EA format item 6) should be included in the non-confidential EA summary document and identified in such a manner to clearly indicate the operation conducted at the facility (*e.g.,* Contract Manufacturer - Drug Substance, Contract Primary Packager #1, Contract Primary Packager #2).

Note that for each facility identified in this section, information should be provided under EA format item 6 unless it is a foreign site with appropriate certification (see section VI).

d. Locations of Use

The EA should identify the location(s) of end use of the drug product. Typically, the locations of use are identified as hospitals, clinics and/or patients in their homes. If use is expected to be concentrated in a particular geographic region, this fact should be included.

e. Disposal Sites

The EA should describe the method(s) of disposal of rejected, expired, returned or waste drug substance, proprietary drug substance intermediate, and drug product. The applicant should provide a brief, general description of the method(s) of disposal including whether the facilities that will be used are permitted by an appropriate authority to destroy hazardous or non-hazardous material. The company/facility currently responsible for disposal should be identified as should: 1) the license or permit number; 2) the EPA or other issuing authority's identification number, if any; 3) the license or permit expiration dates; and 4) the issuing agent. For example, "Returned, expired or rejected drug product will be disposed of by high temperature incineration at a facility which is licensed by the EPA or an appropriate state authority to destroy hazardous materials. The facility currently being used is XYZ Incinerators, 1234 Good Ave., Burn, AK which is licensed by the EPA to destroy hazardous material under permit 1234 (expiration date 12/1999))." **Copies of the actual permits/licenses do not need to be submitted.** A reference to EA format item 6.b, "Controls Exercised," may be provided if the disposal operations are described there. Specific information regarding contract disposal facilities (*e.g.,* identification, licensing information) may be included in a confidential appendix. (See section III.G for a discussion of confidential and non-confidential information).

Unless other disposal methods by the end user are anticipated, it is sufficient to state that at U.S. hospitals, pharmacies or clinics, empty or partially empty packages will be disposed of according to hospital, pharmacy or clinic procedures and/or that in the home, empty or partially empty containers will typically be disposed of by a community's solid waste management system which may include landfills, incineration and recycling, although minimal quantities of unused drug may be disposed of in the

WITHDRAWN

sewer system.

5. Identification of Chemical Substances that are the Subject of the Proposed Action

The EA should contain information to allow for accurate location of data about the chemical in scientific literature and to allow for identification of closely related compounds. At a minimum, the information listed below should be provided. Other information, such as the International Nonproprietary Name (INN) or nonsystematic/ semisystematic chemical names, should be included if deemed useful in the identification of the compounds.

Usually this information need only be provided for the drug substance, but the same information should also be provided for the form of the active ingredient in the drug product if it is different from the drug substance (*e.g.*, a salt formed *in situ* from a free base) or for a pharmacologically active related substance formed by conversion from a pharmacologically inactive parent compound (*e.g.*, a prodrug product is converted to the pharmacologically active form). Although the following information is generally self-explanatory, explanation is provided, where appropriate:

a. Nomenclature

i. Established Name (U.S. Adopted Name-USAN)

ii. Brand/Proprietary Name

iii. Chemical Names

(1) Chemical Abstracts (CA) Index Name (inverted form)

WITHDRAWN

(2) Systematic Chemical Name (uninverted form)

b. Chemical Abstracts Service (CAS) registration number

c. Molecular Formula

d. Molecular Weight

e. Structural (graphic) Formula

f. Physical Description

For example, white to off-white powder

g. Additives

The EA should identify by name and CAS registration number any substance added to the described chemical substance in relatively small amounts to impart or improve desirable properties or suppress undesirable properties (*e.g.,* formulation excipients, preservatives) which is expected to be emitted into the environment. A reference to EA format item 6.a is acceptable as long as the additives are included in the list of "Substances Expected to be Emitted."

h. Impurities

Impurities in drug substances and products are controlled and are typically found at very low levels (*i.e.,* much less than 1%). The EA should only identify impurities likely to be found in the described chemical substance at levels > than 1%. CAS registration numbers should be provided, if available. Reference in the EA document to a confidential appendix which provides this information is adequate. Identification in this section of the EA of potential residual solvents is not necessary if solvents are adequately addressed in EA format item 6.a.

WITHDRAWN

6. Introduction of Substances into the Environment

Information should be provided in EA format items 6.a through 6.e for all facilities identified in EA format item 4.c, unless a facility is a foreign facility with appropriate certification (see section VI). The information should be presented separately for each facility. The extent/detail of information necessary for primary packaging operations depends on the dosage form and the potential for introduction of chemical substances into the environment.

The obligation for a company to obtain the proper emission permits and comply with all applicable Federal, State and local emission requirements is not negated by FDA review of an environmental assessment or approval of an application.

a. Substances Expected to be Emitted

The substances expected to be emitted from the facilities should be listed. Substances that are emitted at low levels need not be listed unless they are likely to have a significant environmental impact. The list(s) should include the CAS registration number for each and the manner in which they are expected to be emitted (*e.g.*, organic solvent waste stream). Reference in the EA document to a confidential appendix which provides this information is adequate.

b. Controls Exercised

The EA should contain a brief description of the controls associated with the air, liquid, and solid emission waste streams identified in EA format item 6.a. Descriptions of control efficiencies (*e.g.*, emission of airborne particulate material is controlled by HEPA filtration with a 99.9% operating efficiency) or treatment prior to emission (*e.g.*, neutralization of aqueous waste streams) should be included, if applicable. Disposition of unused product or rejected packaged goods, including those at contract packagers, should be discussed in EA format item 6.b if it has not been described in EA format item 4.e. Disposal of manufacturing aids, emission controls or other items (*e.g.*, resins, filters, clothing) which may contain residual drug substance or proprietary drug substance intermediates should be discussed.

c. Citation of and Statement of Compliance with Applicable Emission Requirements

A citation (*i.e.*, list of regulations/laws) of all applicable Federal, State and local emission requirements, including occupational, should be provided, as well as a statement of compliance with, or being on an enforceable schedule to be in

WITHDRAWN

compliance with, all emission requirements set forth in permits, consent decrees and administrative orders applicable to the manufacturing operations.

Material safety data sheets (MSDS) should be provided in a non-confidential appendix for the drug substance and if appropriate, drug product.

A list of emission permits and/or licenses should be provided along with the number, authorizing agency and expiration dates. **Inclusion of the actual permit and/or license is not necessary.** Any of the requested information that is not applicable or not current for a specific permit/license (*e.g.*, expired permit) should be explained. If no permits are required, this should be stated (e.g., air emissions are below the level that requires a permit). For ease of review, CDER prefers that this information be presented in a table format (see Attachment B for a sample table).

d. Discussion of the Effect of Approval on Compliance with Current Emission Requirements

The EA should state whether approval and the subsequent increase in production at the facility is expected to affect compliance with current emission requirements and should contain a brief supporting discussion based on the estimated fifth year production volume (*e.g.*, waste water emission will increase to approximately 60% of the permit limit).

e. Expected Introduction Concentrations

For the drug substance and/or active moiety entering the environment as a result of use and disposal, expected introduction concentrations for use and disposal should be estimated, either through use of calculations or direct measures. The estimates for use should be based on total fifth year production estimates for all dosage forms and strengths included in the application or related (companion) applications. All concentrations should be reported as the concentration of active moiety rather than, for example, the salt or complex. The specific calculations and the basis for the calculations (*e.g.,* 5th year production estimates) may be included in a confidential appendix.

Based on the identification of and literature about emitted substances other than the drug substance/active moiety, CDER can determine whether it needs more information about the potential environmental impacts of these other emissions (see EA format item 6.a). Such additional information generally will not be needed.

WITHDRAWN

Note: for substances occurring naturally in the environment, calculations may aid in preparing the discussion of the concentration and distribution of the substance in the environment which is called for in EA format item 7 (21 CFR § 25.31a(b)(5)) .

i. Expected Introduction Concentration from Use

The calculation of the expected introduction concentration (EIC) entering into the aquatic environment from patient use may include consideration of metabolism to less pharmacologically active or inactive compounds and the environmental depletion mechanisms that occur in the waste treatment process (*e.g.,* adsorption, degradation, hydrolysis), if the information is available. Information should be provided regarding the metabolic profile and pharmacological activity of the metabolites relative to the active moiety if metabolism is considered.

The EIC for the aquatic environment, assuming all drug substance produced is used, even distribution throughout the U.S. per day, and no metabolism or depletion mechanisms, should be calculated as follows:

EIC-Aquatic (ppm) = A x B x C x D

where A = kg/year production
B = 1/liters per day entering POTW's*
C = year/365 days
D = 10^6 mg/kg (conversion factor)

* 1.115 x 10^{11} liters per day entering publicly owned treatment works (POTW's), Source: 1992 Needs Survey, Report to Congress, September 1993, EPA 832-R-93-002

This equation should be used when determining if the Tier 0 approach will be used unless localized use is expected (see section III.D.7.c). If an alternative calculation is used in addition to the equation provided above, it should be clearly indicated in the EA and the source and/or basis for the alternative calculation provided. An alternative calculation should be used if localized use of the drug product is expected.

Some drug substance and/or active moiety may enter the terrestrial environment when sludge from waste water treatment facilities, which contains adsorbed material, is applied to land. Although application of sludge to land is regulated by EPA or an appropriate State authority, controls similar to those at landfills are not in place to limit the release of materials in the environment after application. Sludge is generally subjected to some form of aerobic or anaerobic digestion in the waste treatment facility, and only a fraction of the sludge may be applied to soil while the remainder is incinerated or landfilled. The EIC for the terrestrial compartment should be estimated if, based on the available physical/chemical properties of the compound, significant

WITHDRAWN

quantities of the active moiety are expected to adsorb to sludge and typical POTW procedures allow for significant quantities of sludge to be disposed of in this manner. The calculations used depend on the treatment/disposal process. Depletion mechanisms (*e.g.,* biodegradation, hydrolysis) that occur in the waste treatment process may be considered when calculating the EIC for the terrestrial compartment, if the information is available.

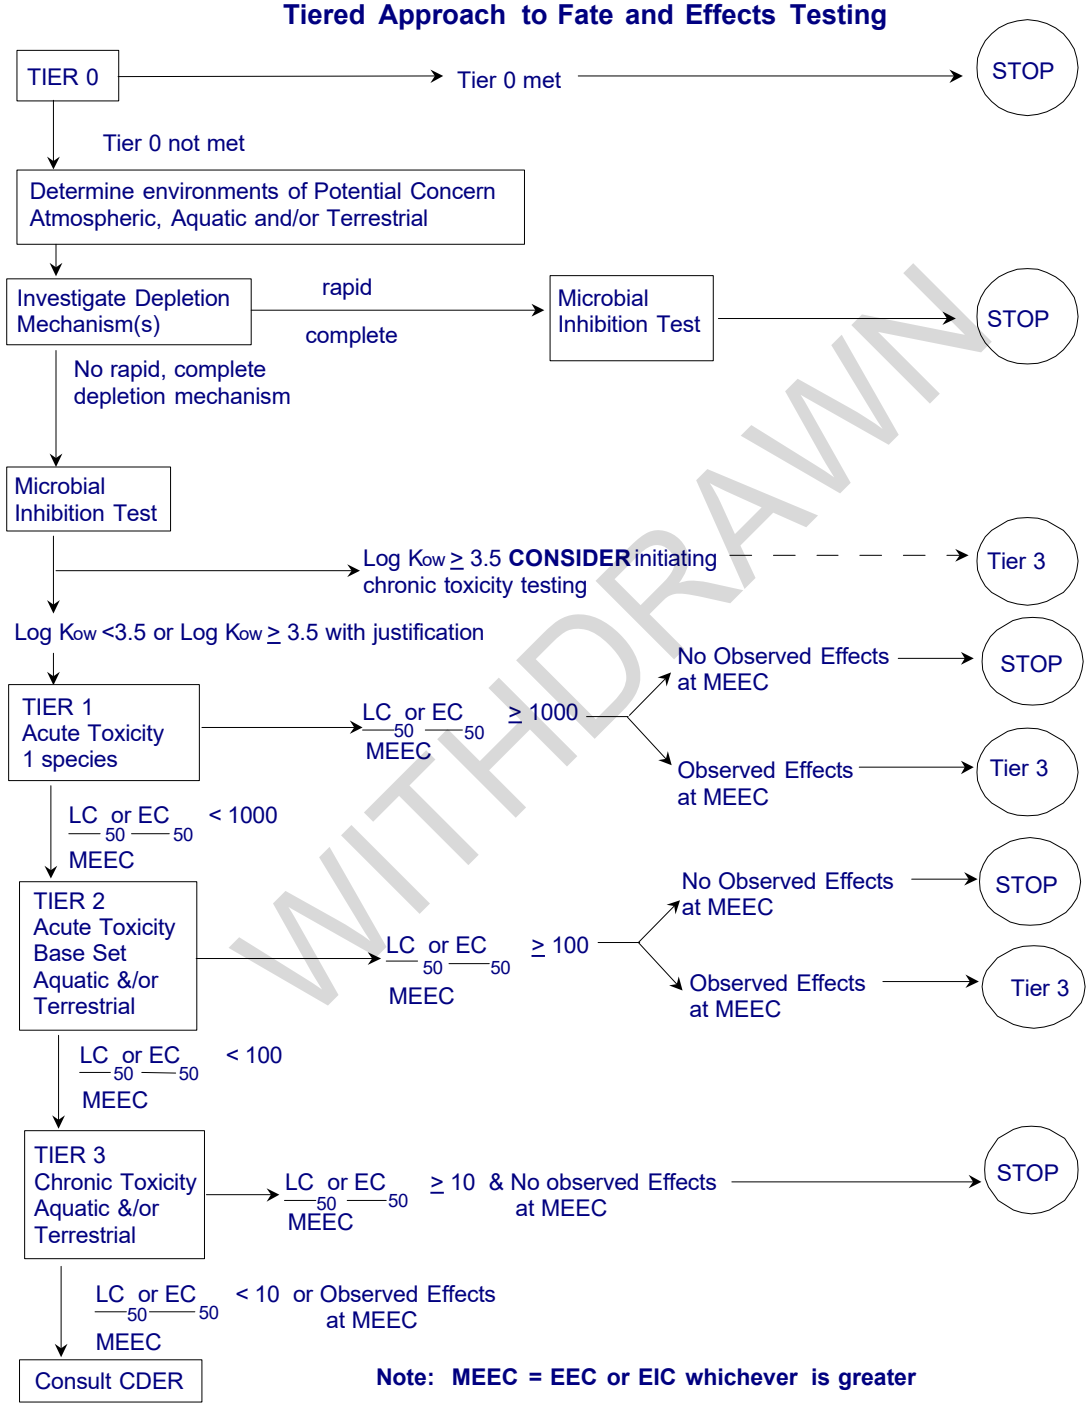
The concentration expected in the atmospheric compartment should be considered for products that are released primarily into the air (*e.g.,* medical gases).

ii. Expected Introduction Concentration from Disposal

Normally, the EIC from disposal need not be calculated since the majority of pharmaceutical waste will be disposed of in landfills or at incineration facilities which are regulated by the EPA or appropriate State agencies. These agencies have considered the environmental impacts from the operation of these facilities in their licensing process and require controls (*e.g.,* scrubbers, lined landfills, migration tests) to limit the release of materials into the environment. The EIC for disposal should be calculated if significant quantities of material (*e.g.,* rejected batches) are expected to be disposed of in the sewer system.

7. Fate of Emitted Substances in the Environment

a. Tiered Approach to Determining Environmental Fate (EA format item 7) and Effects (EA format item 8)



The Center encourages the use of a logical, tiered approach to testing so that adequate information is available to assess the potential environmental fate (EA format item 7) and effects (EA format item 8) of pharmaceuticals while minimizing the cost to industry. Information is provided in EA format item 7.c (Tier 0) and EA format item 8 (Tiers 1-3) regarding an acceptable approach to tier testing. Figure 1 provides an illustration of this tiered approach. Alternative, scientifically justified approaches may also be used.

If EA format items 7 and 8 are needed, the information provided should focus on the fate and effect of the drug substance and/or structurally related substances (SRS's) rather than, for example, excipients, solvents or raw materials used in producing the drug substance, proprietary drug substance intermediate, or drug product. Based on the identification of and literature about emitted substance

WITHDRAWN

other than the drug substance or SRS's, CDER can determine whether it needs more information about the potential environmental impacts of these other emissions. Such additional information generally will not be needed.

Figure 1
Tiered Approach to Fate and Effects Testing

WITHDRAWN

Information submitted under EA format items 7 and 8 may include specific data generated on the test substance or relevant information on analogous compounds from the submitter or from the peer reviewed literature as appropriate. Actual experimental data regarding base parameters are generally preferable to computer modeling; however, in some circumstances computer modeling may be appropriate. FDA may be consulted if a company believes computer modeling is appropriate and wishes to use modeling in an EA.

b. Type of Fate Information to be Submitted

i. EA's filed pursuant to 21 CFR § 25.31a(a)

Information listed in section III.D.7.d may not be needed if an applicant follows a tiered approach to preparing an environmental assessment (see Tier 0 approach described in section III.D.7.c).

ii. EA's filed pursuant to 21 CFR § 25.31a(b)(3)

Fate information normally need not be submitted in AEA's for drugs intended for the prevention, treatment, or diagnosis of a rare disease or for a similarly infrequent use; for ophthalmic or topical application; or for local or general anesthesia (21 CFR § 25.31a(b)(3)).

iii. EA's filed pursuant to 21 CFR § 25.31a(b)(5)

AEA's for substances that occur naturally in the environment should contain a discussion of whether, on the basis of all available evidence, the use of the product can reasonably be expected to alter significantly the concentration and distribution of the product, its metabolites, degradation products, or its constituent parts in the environment (21 CFR § 25.31a(b)(5)). The natural source of the substance (*e.g.*, endogenous to all mammalian cells), and the production volume relative to the estimated quantity occurring naturally in the environment, if known, should be provided. Information in section III.D.7.d may not be needed if an applicant follows a tiered approach to preparing an environmental assessment (see Tier 0 approach described in section III.D.7.c).

WITHDRAWN

iv. EA's filed pursuant to 21 CFR § 25.31a(b)(6)

AEA's for products that have been approved by the Environmental Protection Agency (EPA) under section 4 or 5 of the TSCA or under FIFRA should rely on environmental information in studies submitted to EPA, in the application/ petition submitted for FDA approval and in the scientific literature (21 CFR § 25.31a(b)(6)).

c. Tier 0

CDER has performed a retrospective review of toxicity information available in EA's previously submitted in support of NDA's and NDA supplements. Data are available from each reviewing division and are representative of pharmacological drug classifications. The data have routinely shown no observed effects on relevant standard environmental test organisms at drug concentrations below 1 part per billion (ppb). Because CDER has routinely found that drugs at concentrations less than 1 ppb have no significant effect on relevant standard test organisms, and, therefore, are unlikely to have a significant effect on the environment, CDER has determined that information for EA format items 7, 8, 9, 10, 11 and 15 will normally not be needed for drugs whose maximum expected environmental concentration (EEC or EIC whichever is greater) is less than 1 part per billion.

EA format items 7, 8, 9, 10, 11 and 15 will normally not be needed when the expected environmental concentration due to entry into the environment is less than one (1) ppb from use and/or disposal or at any point where higher concentrations are expected as a result of bioaccumulation or other types of concentration processes. Additionally, for those actions involving genetically modified organisms and cells, the applicant should be using a containment class for manufacturing established by a recognized authority (*e.g.,* National Institutes of Health's Recombinant DNA Advisory Committee) or consideration of the fate and effects of the use of the modified organisms or cells should be included as an integral part of the CDER application review process (*e.g.,* manufacturing process validation) if the Tier 0 approach is used to limit the information submitted in EA format items 7, 8, 9, 10, 11 and 15.

Under specific circumstances, such as those identified in section II as reasons for denying a categorical exclusion, EA format items 7, 8, 9, 10, 11 and 15 may have to be submitted even if the Tier 0 approach is used. CDER encourages consultation if there are any questions regarding the applicability of Tier 0 to a particular drug product.

See EA format items 6.e and 7.d.iv for information regarding concentration calculations.

WITHDRAWN

d. Fate information to be submitted for an EA filed pursuant to 21 CFR § 25.31a(a)

If the Tier 0 approach (see section III.D.7.c) cannot be used by an applicant, the following information should be provided.

i. Identification of Substances of Interest

The actual substances which will enter or exist in the environment (*i.e.,* atmospheric, aquatic, terrestrial) may include the parent compound (*i.e.*, drug substance) or SRS's such as the dissociated parent compound, metabolites or degradants. The EA should list the drug substance and the **predominant** SRS's expected to enter or exist in the environment, provide the name, chemical structure and CAS number when possible, and provide a rationale for the decision as to which substance(s) will be studied. Predominant SRS's should be considered those greater than 10% of dose.

In most cases, fate (and effects) information should be provided on the parent (or active) drug substance, as representative of substances entering the environment. Such information is relevant to SRS's when these possess the same fundamental structure and are comparably or more polar than the parent drug substance. At a minimum, the EA should contain a discussion of the potential fate and effects of the predominant SRS's based on their structural differences/similarities to the parent compound *(e.g.*, due to a functional group change, the metabolite should be more soluble than the parent compound, the SRS is more polar). Computerized structure/activity relationship modeling programs may be useful in supporting extrapolation of fate and effects information from the parent (or active) drug substance to the SRS. Relevant available pharmacologic activity and toxicity information should be provided for the SRS's. Specific toxicity/activity information for SRS's may be included in a confidential appendix. Additional environmental information on a predominant SRS may be warranted, following consultation with the Environmental Assessment Team at CDER, if the fate of the compound is expected to differ from the parent compound or there is an indication that the SRS's effect on the environment would be substantially greater than from the parent drug substance.

ii. Physical/Chemical Characterization

The following tests should be conducted to determine if the compound is most likely to amass predominantly in aquatic, terrestrial and/or atmospheric environments:

WITHDRAWN

(a) Water Solubility

(b) Dissociation Constant(s)

(c) Octanol/Water Partition Coefficient

(d) Vapor Pressure or Henry's Law Constant

If there is a scientific basis for not performing a test, the justification should be included in the EA (*e.g.*, water solubility was not determined because the compound is hydrolytically unstable). For a test compound that associates or dissociates in water, water solubility and the octanol/water partition coefficient may have to be determined at pH 5 and 9 as well as pH 7.

The octanol/water partition coefficient (K_{ow}) is an indicator of a nonionized compound's potential to adsorb to the organic fraction of soil, sediment or sludge in addition to being an indicator of a compound's lipophilicity. It is not as good a predictor for inorganic chemicals, metal organic complexes, dissociating, ionic organic compounds or compounds with other mitigating structural features such as molecular size. Further study of the sorption/desorption properties (K_{oc}) of a substance to sludge should be **considered** if log K_{ow} is greater than 3 or other properties indicate that sorption/desorption may occur.

iii. Environmental Depletion Mechanisms

Depletion mechanisms should be investigated to determine if there is degradation of the compound in the environment(s) of interest. **It is not necessary to go to extraordinary effort to identify a depletion mechanism once the typical depletion mechanisms (i.e., hydrolysis, photolysis, biodegradation) have been investigated nor to continue investigating all potential depletion mechanisms once one has been identified.** Consideration should be given to the nature and extent of the degradation. If a rapid, complete depletion mechanism is identified (degradants are relatively simple, polar by-products), no testing to determine the environmental effects of the compound should be performed except for a microbial inhibition test or other appropriate test to assess the potential for the compound to disrupt waste treatment processes. Based on the estimated time prior to emission from a treatment facility, CDER considers the following to be rapid depletion mechanisms:

Hydrolysis $t_{½}$ (pH 5-9):	≤ 24 hours
Aerobic Biodegradation $t_{½}$:	≤ 8 hours
Soil Biodegradation $t_{½}$:	≤ 5 days

WITHDRAWN

It is usually sufficient to provide basic supporting information that identifies the potential for a compound to be removed from the environment by a depletion mechanism (*e.g.,* photolysis or hydrolysis based on information developed for analytical methods validation or from stability studies). If the depletion mechanism is being used to reduce the expected introduction concentration (EA format item 6.e) or to eliminate effects testing, a formal, detailed analysis of the depletion mechanism should be provided (*e.g.,* according to a standard test method, rate determination, analysis of expected exposure time in the environment).

Direct and indirect photolysis, although significant under laboratory conditions, may not be a rapid depletion mechanism in the environment due to significant variation in light intensity (*e.g.*, related to weather, latitude, depth penetration) and duration of exposure. Efforts to characterize photolysis as a depletion mechanism should take these factors into consideration.

iv. Expected Environmental Concentration (EEC)

The expected environmental concentration is the expected concentration of the active moiety or other compound of interest (see EA format item 7.d.i) that organisms would be exposed to in the environment (*e.g.,* surface water) after consideration of, for example, spatial or temporal concentration or depletion factors such as dilution, degradation, sorption and/or bioaccumulation. A brief discussion comparing the EEC to the EIC (see EA format item 6.e) should be provided. In the majority of cases the EEC would be expected to be significantly less than the EIC due to dilution in the aquatic environment.

v. Summary

A summary discussion of the environmental fate of the substance(s) of interest should be provided for the following environmental compartments based on the information and data provided in EA format items 7.d.i-iv. In some circumstances, transport between environmental compartments should be considered when determining the fate of the substance(s) of interest in the environment.

Aquatic Environment: In general, pharmaceutical substances are expected to enter predominantly into the aquatic environment and, therefore, the focus of any effects studies will most likely be on aquatic organisms. If the substance(s) of interest rapidly degrades (see EA format item 7.d.iii) or adsorbs completely and irreversibly to sludge, then fate and effects in the aquatic environment should not usually be considered.

Terrestrial Environment: In general, substances enter the terrestrial environment predominantly from sludge removed from waste water treatment plants that is subsequently applied to land (see EA format item 6.e.i). Therefore, effects on the

WITHDRAWN

terrestrial environment are more likely if a compound adsorbs to sludge. Sludge is generally subjected to some form of aerobic or anaerobic digestion in the waste treatment facility and only a fraction of the sludge may be applied to soil while the remainder is incinerated or landfilled. Fate and effects testing in the terrestrial environment should be **considered** if testing indicates that the substance(s) of interest will significantly adsorb to sludge (*e.g.*, $K_{oc} \geq 1000$) and if based on typical POTW processes, a significant quantity of sludge is expected to be applied to land.

Atmospheric Environment: In general, substances that do not adsorb readily to soils, have a high vapor pressure and have a low water solubility are likely to volatilize significantly from the aquatic or terrestrial environments, although actual volatilization rates will depend on environmental conditions (*e.g.*, dispersion away from the evaporation site) and on factors that can lessen or enhance the effective vapor pressure or behavior of the chemical at a liquid-air or solid-air interface. The atmospheric compartment may be of interest for medical gases. But based on the polarity of the majority of compounds at relevant aquatic environmental conditions, it is unlikely that there would be substantive partitioning from the aquatic to the atmospheric environment for other pharmaceuticals. Any potential for a substance to volatilize and recycle into the aquatic or terrestrial environments should be discussed based on the information and data available for the substance.

8. Environmental Effects of Released Substances

EA's filed pursuant to 21 CFR § 25.31a(a): Information in EA format item 8 may not be needed if an applicant follows a tiered approach to preparing an environmental assessment (see Tier 0 approach described in section III.D.7.c). Guidance is provided below regarding the tiered approach to effects testing, when testing is indicated.

EA's filed pursuant to 21 CFR § 25.31a(b)(3): Effects information normally need not be submitted for AEA's for drugs intended for the prevention, treatment, or diagnosis of a rare disease or for a similarly infrequent use, for ophthalmic or topical application, or for local or general anesthesia (21 CFR § 25.31a(b)(3)).

EA's filed pursuant to 21 CFR § 25.31a(b)(5): AEA's for substances that occur naturally in the environment should report **existing** data relating to the environmental effects of substances expected to be emitted into the environment as a consequence of use of the product and report information obtained from the scientific literature on the toxicity of the product to laboratory animals, *e.g.*, that information used to satisfy human safety requirements, and to organisms in the environment, *e.g.*, fish invertebrates, plants, fungi, and bacteria, that may be exposed to the product. Information in EA format item 8 may not be needed if an applicant follows a tiered approach to preparing an environmental assessment (see Tier 0 approach described in section III.D.7.c).

WITHDRAWN

EA's filed pursuant to 21 CFR § 25.31a(b)(6): AEA's for products that have been approved by the Environmental Protection Agency (EPA) under section 4 or 5 of TSCA or under FIFRA should rely on environmental information in studies submitted to EPA, in the application/petition submitted for FDA approval and in the scientific literature (21 CFR § 25.31a(b)(6)). The EA should contain a description of any potential adverse environmental impact determined by the EPA.

Tiered approach to environmental effects testing (see below, Microbiological Inhibition Testing through Tier 3 Testing): If effects data are needed and no rapid, complete depletion mechanism has been identified, it should be assumed that the compound will persist in the environment for some time and, therefore, the toxicity of the released substances to environmental organisms should be evaluated. The fate of the substance as determined in EA format item 7 should be considered when designing the studies. For those compounds which enter the atmospheric environment, testing should be designed based on the extent to which the substance recycles into the aquatic or terrestrial environments. All toxicity test results for the drug substance should be reported in terms of the quantity/concentration of the active moiety. The results of the toxicity testing should be compared to the maximum expected environmental concentration (MEEC: EIC or EEC whichever is greater) and the difference between the values discussed (*e.g.,* in terms of the assessment factor, > 1000, > 100). When using this tiered approach to effects testing, it is important to design the test conditions appropriately so that a no observed effects concentration is determined.

Microbial Inhibition Testing: A microbial inhibition test or other appropriate test (*e.g.*, respiration inhibition testing) should be performed to assess a chemical compound's potential to inhibit microorganisms and subsequently disrupt waste treatment processes.

Assessment Factors: These assessment factors are intended to provide a consistent regulatory basis for determining when additional ecotoxicity testing should be performed (tiered approach). They are directly related to the amount of valid ecotoxicity data available. If the LC_{50} or EC_{50} or other appropriate test endpoint divided by the MEEC is less than the assessment factor, additional testing should be performed. The use of EC_{50} or test end point other than the LC_{50} should be limited to those test organisms for which the LC_{50} is not the test endpoint.

TEST TIER	ASSESSMENT FACTOR
1	1000 (see below)
2	100 (see below)

WITHDRAWN

3	10 (see below)

Alternative scientifically justified approaches may also be used.

Tier 1 Testing: Acute ecotoxicity testing should be performed on a minimum of one suitable test organism (see base set for Tier 2 Testing). If the EC_{50} or LC_{50} divided by the MEEC is greater than 1000, no further testing should be conducted unless sublethal effects are observed at the MEEC. If the EC_{50} or LC_{50} divided by the MEEC is less than 1000, Tier 2 testing should be performed. Sublethal effects (observed effects) at the MEEC indicate that chronic toxicity testing (Tier 3) should be performed. The use of the assessment factor of 100 could be used for Tier 1 Testing if there is evidence (*e.g.,* Tier 2 Testing on a similar compound) to support that the single test organism used would be expected to be the most sensitive of the base set test organisms.

Tier 2 Testing: Acute ecotoxicity testing should be performed on the minimum base set of aquatic and/or terrestrial organisms. The aquatic base set usually consists of: 1) a fish acute toxicity test; 2) an aquatic invertebrate acute toxicity test; and 3) an algal species bioassay. The terrestrial base set usually consists of: 1) plant early growth tests; 2) earthworm toxicity test; and 3) soil microbial toxicity test. Usually only an earthworm toxicity study is indicated if the substance binds tightly to soil. A rodent acute toxicity is not included in the terrestrial base set since there is usually a significant quantity of mammalian (*e.g.,* mice, rat, dog, monkey, humans) toxicity testing performed, both acute and chronic, to support the underlying application and to demonstrate the safety of the drug product. **Consultation with the Environmental Assessment Team at CDER is suggested prior to initiating any terrestrial studies.** If the EC_{50} or LC_{50} for the most sensitive organism in the base set divided by the MEEC is greater than 100, no further testing should be conducted unless sublethal effects are observed at the MEEC. If the EC_{50} or LC_{50} divided by the MEEC is less than 100, Tier 3 testing should be performed. Sublethal effects (observed effects) at the MEEC indicate that chronic toxicity testing (Tier 3) should be performed.

Tier 3 Testing: Chronic toxicity testing should be considered if the compound has the potential to bioaccumulate or bioconcentrate, if indicated based on Tier 1 and/or Tier 2 Testing, or if there are other indications that the compound undergoes biotransformation to more toxic compounds.

Bioaccumulation or bioconcentration is a complex, dynamic process which is dependant on the availability, persistence and physical/chemical properties of a compound in the environment. In general, pharmaceuticals tend not to be very lipophilic and are produced/used in relatively low quantities compared to industrial chemicals. The majority of pharmaceuticals are metabolized to some extent in humans to SRS's that are more polar, less toxic and less pharmacologically active than the parent

WITHDRAWN

compound. These factors suggest that there should be a low potential for bioaccumulation or bioconcentration of pharmaceuticals, but because of the length of time it takes to conduct chronic toxicity studies, applicants are encouraged to identify compounds which are candidates for these studies as early as possible. A primary determinant of the potential for a compound to bioaccumulate is the octanol/water partition coefficient (K_{ow}). A high octanol/water partition coefficient indicates that the compound will tend to be lipophilic. Chronic toxicity testing should be **considered** if log K_{ow} of a compound is greater than or equal to 3.5 under relevant environmental conditions (*e.g.,* pH 7), and a justification should be provided if chronic toxicity testing is not performed. Structural features (*e.g.,* molecular size, polarity) that limit passage across biological membranes or the lack of bioavailability to environmental organisms (*e.g.,* strong adsorption to soil) are mitigating factors which could be considered when determining if bioaccumulation/bioconcentration would be a concern for compounds with a K_{ow} greater than or equal to 3.5. It may be necessary to obtain acute toxicity data for the organism to be tested in order to set the concentrations for the chronic studies properly. **If the preparer of an EA is considering initiating chronic toxicity studies, consultation with the Environmental Assessment Team at CDER is recommended to ensure that such studies are appropriate and properly designed.**

For chronic toxicity testing, If the EC_{50} or LC_{50} divided by the MEEC is greater than 10, no further testing should be conducted unless sublethal effects are observed at the MEEC. CDER should be consulted if the EC_{50} or LC_{50} divided by the MEEC is less than 10 or there are sublethal effects at the MEEC.

Test Methods/Test Organisms: Studies should be performed using test organisms and methods which have been identified by the FDA EA Technical Assistance Handbook, the EPA (40 CFR § 797), the Organisation for Economic Co-operation and Development (OECD) or other peer reviewed literature as appropriate for use in environmental studies. If the drug product is intended to act upon an environmental organism (*e.g.*, antiparasitic, antibiotic), information regarding the toxicity to the target organism(s) should be included.

WITHDRAWN

9. Use of Resources and Energy

a. Natural Resources and Energy

The EA should provide the approximate energy usage associated with the manufacturing operations as a percent of the total plant consumption, or other appropriate evaluations. If the drug substance, proprietary drug substance intermediates, or precursors are derived from a natural resource (*e.g.*, plants), the source should be identified, and other pertinent information provided, if applicable, such as geographic region of source, whether the resource is cultivated or harvested from the wild and/or relevant permits (See section V).

b. Effect on Endangered or Threatened Species

The EA should state whether approval is expected to affect, directly or indirectly, endangered or threatened species. If the drug substance, proprietary drug substance intermediates or precursors are derived from a natural resource, the EA should specifically state whether the natural resource is listed as endangered or threatened under the U.S. Endangered Species Act (ESA) or the Convention on International Trade in Endangered Species of Wild Flora and Fauna (CITES). Endangered or threatened species in the immediate vicinity of any of the production facilities should be identified.

c. Effect on Property Listed in or Eligible for Listing in the National Register of Historic Places

The EA should state whether approval is expected to affect properties listed in or eligible for listing in the United States' National Register of Historic Places. Historic properties in the immediate vicinity of any of the U.S. production facilities should be identified.

10. Mitigation Measures

The EA should contain a summary of measures used routinely in production to mitigate the release of materials into the environment (*e.g.*, compliance with Federal, State and local environmental laws, spill prevention plans). If applicable, a brief description of special measures used to mitigate the release of toxic or potentially toxic materials into the environment should be provided (*e.g.*, special handling information in the product labeling, Occupational Safety and Health Administration (OSHA) requirements, incineration, containment procedures). If there is a discussion of any of these mitigation measures in another section of the

WITHDRAWN

EA, reference to that information is adequate. **Actual copies of mitigation measures *e.g.*, standard operating procedures (SOP's), plans, corporate policies should not be included in the EA.**

11. Alternatives to the Proposed Action

If no potential adverse environmental impacts have been identified for the proposed action, the EA should so state. If potential adverse environmental impacts have been identified for the proposed action, the EA should contain a detailed description of the environmental impact of all reasonable alternatives to the proposed action (including no action, and including measures that FDA or another government agency could undertake as well as those the applicant/petitioner would undertake). The EA should include a description of those alternatives that will enhance the quality of the environment and avoid some or all of the adverse environmental impacts of the proposed action. The environmental benefits and risks of the proposed action and the environmental benefits and risks of each alternative should be discussed.

12. List of Preparers

The EA should include the name, job title, and qualifications (*e.g.,* educational degrees) of those persons preparing the assessment, and should identify any persons or agencies consulted. Contract testing laboratories should be included in the list of consultants, although this may be included in a confidential appendix. ***Curriculum vitae* may be included in lieu of a description of an individual's qualifications, but are not necessary.**

13. Certification

A dated certification should be signed by the responsible official, include the official's title. The following language is recommended:

> "The undersigned official certifies that the information presented is true, accurate and complete to the best of the knowledge of the firm or agency responsible for preparation of the EA.
>
> The undersigned official certifies that the EA summary document (pages x-x) and Appendices x-x (pages x-x) contain non-confidential information and acknowledges that this information will be made available to the public in accordance with 40 CFR § 1506.6."

WITHDRAWN

The applicant is responsible for the contents of the EA and for signing the certification, whether or not a consultant was used to prepare the EA. The certification should not predate the EA.

14. References

The EA should include a list of citations for all referenced material and standard test methods used in generating data in support of the EA. Copies of referenced articles not generally available which are used to support specific claims in the EA document should be attached in a non-confidential appendix.

15. Appendices

Both confidential and non-confidential appendices may be included (see section III.G for additional information about treatment of confidential information). A list of the appendices should be included in the EA summary document with a designation of confidential or non-confidential following each of the listings. Typically, the non-confidential appendices include Material Safety Data Sheet(s), certification and compliance statements, data summary tables, and copies of referenced articles that are not generally available or which were used in support of specific claims in the EA. Proprietary/confidential information such as emissions or identification of contract facilities and test reports should be included in the confidential appendices.

E. Data Summary Table

To facilitate review, the EA should include a data summary table in a non-confidential appendix (EA format item 15). Attachment C provides an example of a suitable data summary table. Results should not be needed for all items listed if a tiered approach to determining the environmental fate and effects of compounds is used. The table should be modified as appropriate.

F. Test Methods and Report Formats

Test methods and report formats are provided in the FDA EA Technical Assistance Handbook. Equivalent tests, such as those provided by the EPA (40 CFR §§ 796 and 797), the Organisation for Economic Co-operation and Development (OECD) or other validated, peer reviewed methods may be used. The expected minimum level of test performance and test reporting for studies performed to fulfill the requirements of EA format item 7 (fate) is the standards of good scientific practice. The reports submitted in support of fate testing (EA format item 7) should include a description of the test method sufficient for a reviewer to determine the scientific merit of the methodology. The expected minimum level of test performance and test reporting for studies performed to fulfill the requirements of EA format item 8 (effects) is the standards of

WITHDRAWN

FDA's Good Laboratory Practice (GLP) regulations. Guidance on test reporting formats is included in the FDA EA Technical Assistance Handbook or 40 CFR §§ 796 and 797. **Raw test data (*e.g.*, copies of notebook pages, HPLC chromatograms for each assay) should not be included in the EA.**

G. Confidential/Non-Confidential Information

Some of the information that is submitted in an EA is available elsewhere in an application or in a publicly available document. This information may be cross-referenced in the EA, if the information is publicly available. However, the EA should be a stand-alone document, summarizing information that is available elsewhere. The EA will be made public by the FDA as required by regulations issued by the Council on Environmental Quality. Therefore, the EA should contain three distinct parts: 1) the EA summary document which is non-confidential; 2) non-confidential appendices; and 3) appendices with confidential information used to support the EA. All confidential appendices should be at the end of the environmental assessment document. References to non-confidential and confidential appendices may be included in the EA summary document, as appropriate. Confidential data and information which are pertinent to the environmental review of a proposed action and which are submitted in confidential appendices should be summarized in the EA summary document to the extent possible. The EA summary document, non-confidential appendices and FONSI are normally made available for public inspection.

Attachment D provides general guidance as to which information may be included in confidential appendices of the EA. It is the applicant's responsibility to clearly identify the information in the EA which it believes is confidential.

IV. EA'S INVOLVING BIOTECHNOLOGY PRODUCTS

Actions for drugs derived from biotechnology products raise specific concerns regarding the release into the environment of genetically modified microorganisms and cells (*e.g.,* rDNA, bacteria, yeast and plant and animal cells), and fermentation and tissue culture waste media. The EA should: 1) clearly identify that the action involves the use of such materials (EA format item 4.a); 2) describe the biological production system including the host microorganism or cell line and genetic construct(s) (EA format item 5); 3) where appropriate, describe the physical containment and procedures used to prevent release of these materials to the environment as well as relate the containment level to that recommended in the National Institutes of Health (NIH) Guidelines for Research Involving Recombinant

WITHDRAWN

DNA Molecules (*e.g.,* 59 FR 34496, 59 FR 40170, 60 FR 20726) which provides guidance for both research and large scale (Good Large Scale Practices-GLSP) use of organisms containing recombinant DNA molecules (EA format item 6.b);
4) include a description and validation report of the process used to inactivate these materials prior to their release into the environment (EA format item 6.b); 5) discuss the mitigation measures to be taken if the production organism becomes contaminated with other biological agents (*e.g.,* virus, prions, mycoplasma, bacteria, fungi) during production (EA format item 10); and 6) discuss the environmental fate and effect of both the active and inactivated materials if they are to be released into the environment (EA format items 7 and 8).

The discussion for actions involving genetically modified microorganisms and cells should focus on their survivability and colonization potential in the environment and their ability to transfer some or all parts of their genetic material to indigenous organisms. If live microorganisms or cells may be released post-activation or as a result of accidental release during production, studies should be performed to adequately characterize these attributes. The fate of other potentially harmful components (*e.g.,* bacterial toxins) from the genetically modified microorganisms or cells after their release into the environment should be addressed.

V. EA'S INVOLVING DRUGS DERIVED FROM NATURAL RESOURCES

Under the U.S. Endangered Species Act (ESA), Congress declared, "the United States has pledged itself as a sovereign state in the international community to conserve to the extent practicable the various species of fish or wildlife and plants facing extinction, pursuant to the Convention on International Trade in Endangered Species of Wild Fauna and Flora" [CITES] (16 U.S.C. § 1531(a)(4)(F)). Identification as an endangered or threatened species does not preclude the use of material but may necessitate submission of additional information. Under the ESA, if a species has been determined to be endangered or threatened, a federal agency is required to consult with the Secretary of Interior or Commerce to ensure that the agency's actions are not likely to jeopardize the continued existence of threatened or endangered species or their critical habitats (16 U.S.C. § 1536).

When a drug substance, drug substance intermediate, or precursor is derived from a natural resource, the source should be identified. Pertinent information, such as geographic region of source or whether the resource is cultivated or harvested from the wild, should be provided in EA format item 9.a of the EA. In EA format item 9.b it should be specifically stated whether the natural resource is subject to the U.S. ESA/CITES. For natural resources covered under CITES, CDER may request copies of relevant permits.

WITHDRAWN

VI. FOREIGN MANUFACTURING FACILITIES

Executive Order 12114, "Environmental Effects Abroad of Major Federal Actions," directs FDA to consider the environmental effects of approving drug product applications on the environment outside the United Sates. The responsible company official at each of the foreign facilities should certify that the manufacturing facilities are: 1) in compliance with all local and national environmental laws; 2) in compliance with, or are on an enforceable schedule to be in compliance with, all emission requirements set forth in all permits; and 3) that approval and the subsequent increase in production at the facility is not expected to affect compliance with current emission requirements or compliance with environmental laws. The statement should be signed and dated by the responsible company official and, if not in English, a certified English translation should be provided. FDA will request additional information if such information is needed to evaluate environmental effects outside the U.S.

VII. DRUG MASTER FILES

CDER does not take action on DMF's, *i.e.,* CDER does not approve or disapprove submissions to a DMF (21 CFR § 314.420(a)). Therefore, NEPA does not apply and no environmental assessment needs to be submitted for a DMF. However, CDER does take action on applications that incorporate by reference information regarding the manufacture of the drug substance or proprietary drug substance intermediates that may be submitted in Type II DMF's. In these instances, the drug product applicant should include the environmental assessment information for the manufacture of drug substance or proprietary drug substance intermediates in the EA if an EA or AEA is required for their particular application. The DMF holder may be the drug product applicant or an independent manufacturer who may want to limit the applicant's access to proprietary manufacturing information. The non-confidential information regarding the manufacture of the drug substance or proprietary drug substance intermediates should be included in the EA summary document. A DMF reference may be provided for the information which is defined as confidential in this guide (*e.g.,* substances expected to be emitted, EA format item 6.a) although this information must be summarized to the extent possible and included in the EA for public release. CDER prefers that copies of confidential information from DMF's be submitted in the EA by the drug product applicant as a confidential appendix, whenever possible, to expedite review of the EA. If a letter of authorization is provided to reference confidential information in a DMF, the specific information which is being referenced, and the submission date and page number where the information can be located, should be identified. References to DMF's should be included in a confidential appendix since such references are considered confidential commercial information under FOIA.

WITHDRAWN

ATTACHMENT E

GLOSSARY OF TERMS

Active Moiety: The molecule or ion, excluding those appended portions of the molecule that cause the drug to be an ester, salt (including a salt with hydrogen or coordination bonds), or other noncovalent derivative (such as a complex chelate, or clathrate) of the molecule, responsible for the physiological or pharmacological action of the drug substance (21 CFR § 314.108(a)). The active moiety is the entire molecule or ion, not the "active site."

Bioaccumulation: The process by which industrial waste, chemicals and other substances gradually accumulate in living tissue.

Bioconcentration: The process by which industrial waste, chemicals and other substances accumulate directly from water into and onto aquatic organisms.

Drug product: A finished dosage form, for example, tablet, capsule, or solution, that contains a drug substance, generally, but not necessarily, in association with one or more ingredients (21 CFR § 314.3(b)).

Drug Substance: An active ingredient that is intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease or to affect the structure or any function of the human body, but does not include intermediates used in the synthesis of such ingredient (21 CFR § 314.3(b)).

Expected environmental concentration (EEC): The expected concentration of the active moiety or other structurally related substance of interest that organisms would be exposed to in the environment (*e.g.,* surface water) after consideration of spatial or temporal concentration or depletion factors such as dilution, degradation, sorption, bioaccumulation. This is sometimes referred to as the predicted environmental concentration (PEC).

Expected introduction concentration (EIC) for disposal: The expected introduction concentration of the active moiety which may enter the environment due to disposal. Depletion mechanisms that occur prior to introduction into the environment may be considered in the calculation.

WITHDRAWN

Expected introduction concentration (EIC) for use: The expected introduction concentration, based on fifth year marketing estimates, of the active moiety which may enter the environment due to use. Depletion mechanisms that occur prior to introduction into the environment and human metabolism may be considered in the calculation.

Half-life ($t_{½}$): Time required to reduce by one-half the concentration of a material.

Lowest observed effect concentration (LOEC): The lowest concentration of a material used in a toxicity test that has a statistically significant adverse effect on the exposed population of the test organisms as compared with the controls.

Maximum expected environmental concentration (MEEC): The expected introduction concentration (EIC) or expected environmental concentration (EEC), whichever is greater.

Median effective concentration (EC_{50}): The concentration of material to which organisms are exposed that is estimated to be effective in producing some sublethal response in 50% of the test organisms. The EC_{50} is usually expressed as a time-dependent variable (*e.g.,* 24 hour EC_{50}).

Median lethal concentration (LC_{50}): The concentration of material to which organisms are exposed that is estimated to be lethal to 50% of the test organisms. The LC_{50} is usually expressed as a time-dependent variable (*e.g.,* 24 hour LC_{50}).

Minimum inhibitory concentration (MIC): The lowest concentration of a chemical that inhibits the visible growth of the test organisms.

No observed effect concentration (NOEC): The highest concentration of a material used in a toxicity test that has no statistically significant adverse effect on the exposed population of test organisms as compared with the controls.

Octanol/water partition coefficient (K_{ow}): The ratio of a chemical's solubility in n-octanol and water at equilibrium; also expressed as P. A measurement of a drug's lipophilicity and an indication of its ability to cross cell membranes. The logarithm of P or K_{ow} is used as an estimate of the tendency of the chemical to bioaccumulate or adsorb to soil or sediments.

Parts per billion (ppb): One unit of chemical (usually expressed as mass) per 1,000,000,000 (10^9) units of medium (*e.g.,* water) or organism (*e.g.,* tissue) in which it is contained. For water 1 µg/L = 1 ppb; for tissue 1 µg/kg = 1 ng/g = 1 ppb.

Parts per million (ppm): One unit of chemical (usually expressed as mass) per

WITHDRAWN

1,000,000 (10^6) units of medium (*e.g.,* water) or organism (*e.g.,* tissue) in which it is contained. For water 1 mg/L = 1 ppm; for tissue 1 mg/kg = 1 µg/g = 1 ppm.

Parts per trillion (pptr): One unit of chemical (usually expressed as mass) per 1,000,000,000,000 (10^{12}) units of medium (*e.g.,* water) or organism (*e.g.,* tissue) in which it is contained. For water 1 ng/L = 1 pptr; for tissue 1 ng/kg = 1 pptr.

Primary packaging operations: Manufacturing operations which result in the drug product being placed into the immediate container (*i.e.,* container which is in direct contact with the drug product).

Secondary packaging operations: All packaging operations other than the primary packaging operation.

Soil or sediment/water partition coefficient (K_{oc}): The ratio of chemical adsorbed per unit weight of organic carbon in soil or sediment to the concentration of the chemical in solution at equilibrium.

"Substance that occurs naturally in the environment": In the context of § 25.31a(b)(5) this refers to organic or inorganic drug substances, whether obtained from a natural resource or synthesized, that will exist in the environment in the same form as the substance found naturally in the flora, fauna, atmosphere, water or soil.

Toxicity: The inherent potential or capacity of a material to cause adverse effects in a living organism.

Type 1 NDA[2]**:** A new drug application (NDA) for a drug for which the active moiety (present as the unmodified base [parent] compound, or an ester or a salt, clathrate, or other noncovalent derivative of the base [parent] compound) has not been previously approved or marketed as the active moiety in the United States for use in a drug product, either as a single ingredient or as part of a combination product or as part of a mixture of stereoisomers.

WITHDRAWN

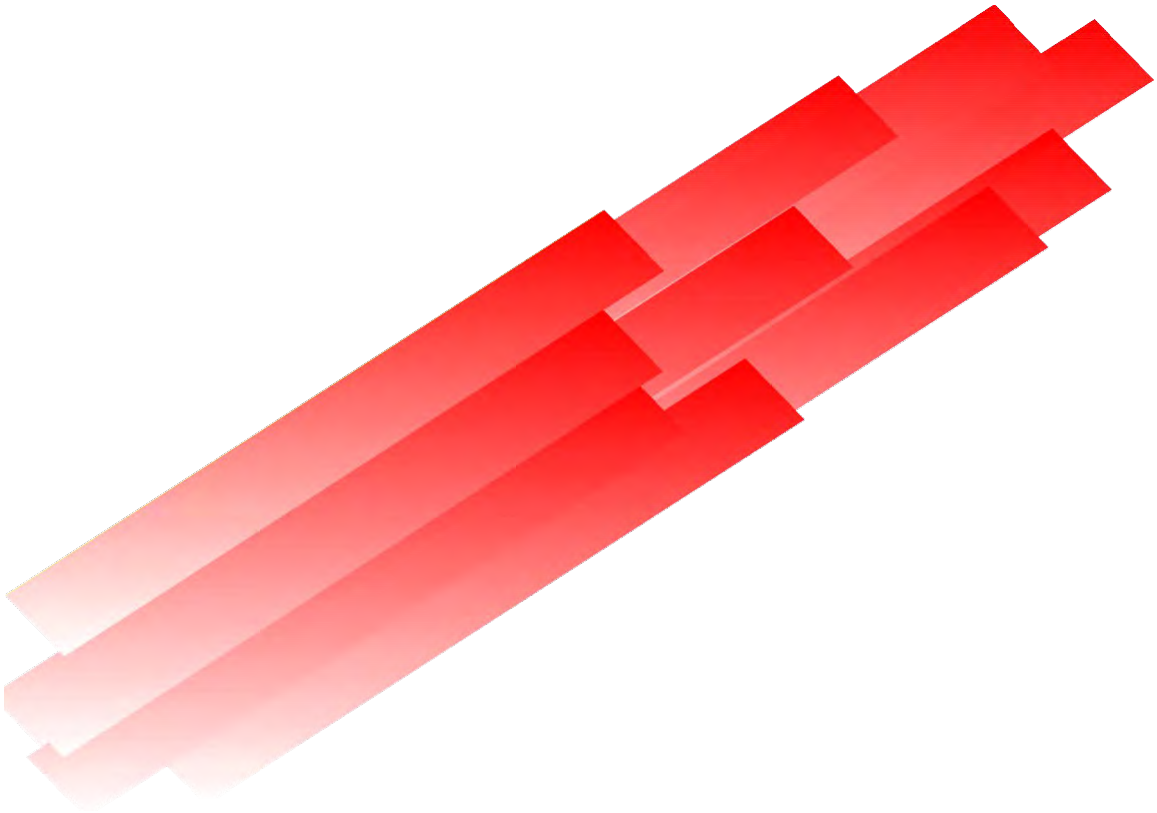
[2]For complete definitions of Type 1-7 NDA's see Center for Drug Evaluation and Research, Staff Manual Guide, 4820.3, “Drug Classification and Priority Review.”

Type 2 NDA: A new drug application (NDA) for a drug for which the active moiety has been previously approved or marketed in the United States but for which the particular ester, or salt, clathrate, or other noncovalent derivative or unmodified base (parent) compound has not yet been approved or marketed in the United States, either as a single ingredient, part of a combination product, or part of a mixture of stereoisomers.

Type 3 NDA: A new drug application (NDA) for a new dosage form or formulation, including a new strength, where the drug has already been approved or marketed in the United States by the same or another manufacturer. The indication may be the same as that of the already marketed drug product or may be new.

Type 4 NDA: A new drug application (NDA) for a drug product containing two or more active moieties that have not been previously approved or marketed together in a drug product by any manufacturer in the United States. The new product may be a physical or a chemical (ester or non-covalent) combination of two or more active moieties.

Type 5 NDA: A new drug application (NDA) for a drug product that duplicates a drug product already approved or marketed in the United States by another firm.



Type 6 NDA: A new drug application (NDA) for a drug product that duplicates a drug product (same active moiety, same salt, same formulation, or same combination) already approved or marketed in the United States by the same or another firm except that it provides for a new indication.

Type 7 NDA: The first new drug application (NDA) for a drug product containing one or more drugs marketed at the time of application or in the past without an approved NDA.

GUIDANCE FOR INDUSTRY[1]

Environmental Assessment of Human Drug and Biologics Applications

I. INTRODUCTION

The National Environmental Policy Act of 1969 (NEPA) requires all Federal agencies to assess the environmental impacts of their actions and to ensure that the interested and affected public is informed of environmental analyses. The Food and Drug Administration (FDA) is required under NEPA to consider the environmental impacts of approving drug and biologics applications as an integral part of its regulatory process. FDA's regulations in 21 CFR part 25 specify that environmental assessments (EAs) must be submitted as part of certain new drug applications (NDAs), abbreviated applications, applications for marketing approval of a biologic product, supplements to such applications, investigational new drug applications (INDs) and for various other actions (see 21 CFR 25.20), unless the action qualifies for categorical exclusion.

Under the President's reinventing government (REGO) initiatives, announced in April 1995, FDA reevaluated and revised its environmental regulations to reduce the number of EAs required to be submitted by industry and, consequently, the number of findings of no significant impact (FONSIs) prepared by the Agency under NEPA. FDA issued for public comment a notice of proposed rulemaking on April 3, 1996 (61 FR 14922) (republished May 1, 1996 (61 FR 19476)), that proposed additional categorical exclusions for those actions that have been identified as normally not having a significant effect, individually or cumulatively, on the quality of the human environment. The final rule was published on July 29, 1997 (62 FR 40569), and became effective August 28, 1997. All applications or petitions requesting Agency action (e.g., NDAs, abbreviated new drug applications (ANDAs), INDs, biologics license applications (BLAs), supplements to such applications) must be accompanied by either an EA or a claim of categorical exclusion. Failure to provide (1) a claim of categorical exclusion or (2) an adequate EA, is sufficient grounds for ***refusing to file or approve*** the application (21 CFR 314.101(d)(4), 601.2(a) and (c), and 25.15(a)). An EA that is adequate for filing is one that addresses the relevant environmental issues. An EA adequate for approval is one that contains sufficient information to enable the Agency to determine whether the proposed action may affect significantly the quality of the human environment. This guidance provides information on when an EA should be submitted; it also makes recommendations on how to prepare EAs for submission of drug or biologics applications to the Center for Drug Evaluation and Research (CDER) and the Center for

[1] This guidance has been prepared under the direction of the Chemistry Manufacturing Controls Coordinating Committee, Center for Drug Evaluation and Research (CDER), and the Center for Biologics Evaluation and Research (CBER) at the Food and Drug Administration. This guidance represents the Agency's current thinking on environmental assessments. It does not create or confer any rights for or on any person and does not operate to bind FDA or the public. An alternative approach may be used if such approach satisfies the requirements of the applicable statute, regulations, or both.

Biologics Evaluation and Research (CBER). Topics covered include (1) when categorical exclusions apply, (2) when to submit an EA, (3) the content and format of EAs, (4) specific guidance for the environmental issues that are most likely to be associated with human drugs and biologics, (5) test methods, (6) an applicant's treatment of confidential information submitted in support of an EA, and (7) master files for drugs and biologics.

This guidance, which is based on the July 1997 final rule, will remain in effect until superseded by new regulations or new guidance. The guidance is intended to supersede CDER's *Guidance for Industry For the Submission of an Environmental Assessment in Human Drug Applications and Supplements,* which was published in November 1995. Information in this guidance, along with information in the Code of Federal Regulations (CFR) at 21 CFR part 25 and 40 CFR parts 1500-1508 and the FDA *Environmental Assessment Technical Handbook* (NTIS Publication Number PB 87 175345/AS), which provides information on acceptable test methods, represents the core information available from CDER and CBER to assist industry in preparing an EA.

II. WHAT TYPES OF ACTIONS ARE SUBJECT TO CATEGORICAL EXCLUSION?

Certain classes of actions are subject to categorical exclusion and, therefore, ordinarily do not require the preparation of an EA because, as a class, these actions, individually or cumulatively, do not significantly affect the quality of the human environment (21 CFR 25.5(c)). However, as required under 21 CFR 25.21 and 40 CFR 1508.4, FDA will require "at least an EA" for any specific action that ordinarily would be excluded if extraordinary circumstances indicate that the specific proposed action may significantly affect the quality of the human environment.[2] See section III.C for additional information regarding extraordinary circumstances.

Submissions to CDER or CBER that ordinarily are excluded categorically under the regulations include actions on (1) NDAs, abbreviated applications, applications for marketing approval of a biologic product, and supplements to such applications if FDA's approval of the application does not increase the use of the active moiety; (2) NDAs, abbreviated applications, and supplements to such applications if FDA's approval of the application increases the use of the active moiety, but the estimated concentration of the substance at the point of entry into the aquatic environment will be below 1 part per billion (ppb); (3) NDAs, abbreviated applications, applications for marketing approval of a biologic product, and supplements to such applications for substances that occur naturally in the environment when the approval of the application does not alter significantly the concentration or distribution of the substance, its metabolites, or degradation products in the environment; (4) INDs; and (5) applications for marketing approval of a biologic product for transfusable human blood or blood components and plasma. An applicant is eligible

[2] Regulations would require an EIS (environmental impact statement) when "evaluation of data or information in an EA or otherwise available to the agency leads to a finding by the responsible agency official that a proposed action may significantly affect the quality of the human environment (21 CFR 25.22(b)).

to file a claim of categorical exclusion from the requirement to submit an EA if the action meets the criteria of at least one categorical exclusion.

A person submitting an application or petition of a type subject to categorical exclusion under 21 CFR 25.31 is not required to submit an EA if the person states that the action requested qualifies for categorical exclusion, citing the particular categorical exclusion that is claimed, and states that to the applicant's knowledge, no extraordinary circumstances exist (21 CFR 25.15(d)). An applicant ordinarily need not provide data to demonstrate that the action qualifies for categorical exclusion. CDER and CBER can rely on other information submitted in an application to evaluate the appropriateness of a claim for categorical exclusion. In the limited instances when it may be necessary, CDER or CBER will request additional information as needed to establish to their satisfaction that the criteria for categorical exclusion have been met.

III. WHEN IS AN EA REQUIRED?

Preparation of an environmental assessment ordinarily is required unless the proposed action qualifies for an exclusion under 21 CFR 25.30 or 25.31. An EA would also be required if extraordinary circumstances indicate that the specific proposed action may significantly affect the quality of the human environment (21 CFR 25.21).

Detailed information is provided below for the most common situations when actions would not qualify for categorical exclusion.

A. NDAs, Abbreviated Applications, and Supplements

Note: Section 1, below, should be used to assess increased use of a biological product as referenced in 21 CFR 25.31(a). Section 2 does not apply to biologics license applications (BLAs) because BLAs are not included in the categorical exclusion on which this section is based (21 CFR 25.31(b)). BLAs should be evaluated for whether they are eligible for categorical exclusion using 21 CFR 25.31(a) or (c) or other appropriate categorical exclusions found in 21 CFR 25.30 and 25.31.

NDAs, abbreviated applications, and supplements to such applications would not qualify for categorical exclusion if FDA's approval of the application increases the use of the active moiety ***and*** the estimated concentration of the substance at the point of entry into the aquatic environment will be 1 ppb or greater.

1. Increased Use

Increased use of an active moiety may occur if the drug will be administered at higher dosage levels, for longer duration, or for different indications than were previously in effect, or if the drug is a new molecular entity. The term *use* also encompasses disposal of FDA-regulated articles by consumers.

Attachment A contains examples of actions that would not be considered to increase the use of a drug and Attachment B contains examples of actions that would be considered to increase the use of a drug or biologic. These lists are not inclusive. An applicant is encouraged to contact the appropriate Center if any questions arise as to whether a particular action is considered to increase the use of a drug or biologic.

2. Estimating the Concentration of a Substance at the Point of Entry into the Aquatic Environment

The expected introduction concentration (EIC) of an active moiety into the aquatic environment should be calculated as follows:

EIC-Aquatic (ppb) = A x B x C x D where

A = kg/year produced for direct use (as active moiety)
B = 1/liters per day entering POTWs*
C = year/365 days
D = 10^9 µg/kg (conversion factor)

* 1.214 x 10^{11} liters per day entering publicly owned treatment works (POTWs), Source: *1996 Needs Survey, Report to Congress.* Information regarding the *Needs Survey* is available on the Internet at http://www.epa.gov/owm. It is updated periodically.

This calculation assumes:

- All drug products produced in a year are used and enter the publicly owned treatment works (POTW) system.

- Drug product usage occurs throughout the United States in proportion to the population and amount of waste water generated.

- There is no metabolism.

The estimate of the kilogram/year active moiety should be based on or include (1) the highest quantity of the active moiety expected to be produced for direct use in any of the next five years. *Produced for direct use* means the quantity intended for use in humans during a given year (i.e., excludes any quantity produced for inventory buildup), (2) the quantity used in all dosage forms and strengths included in the application, and (3) the quantity used in an applicant's related applications. Related applications include those for other dosage forms using the same active moiety and for products using different forms of the active moiety (e.g., level of hydration, salt, free acid/base). All concentrations should be reported as the

concentration of active moiety, rather than the salt or complex.

The calculation of the expected introduction concentration (EIC) of an active moiety entering into the aquatic environment from patient use can consider the extent of metabolism of the active moiety to less pharmacologically active or inactive compounds, if that information is available. The pharmacological activity of metabolites relative to the active moiety should be considered when calculating the EIC. The weighted contribution of the metabolite to the EIC should be calculated (e.g., kg/year active moiety x 10% x 0.5 for a metabolite found at a level of 10% and that has half the pharmacological activity of the active moiety). If the pharmacological activity of the metabolite is unknown, it can be assumed to be the same as the active moiety.

An alternative calculation should be used if the drug product is intended for use in a specific geographic location (e.g., use an alternative value for the amount of liters per day entering POTWs — term B in the EIC calculation above). Moreover, if an alternative calculation is used to estimate localized use, or for any other reason, the calculation and the source and basis for the alternative calculation should be provided when filing an EA or a claim of categorical exclusion and would be subject to review.

B. Applications for Substances that Occur Naturally in the Environment

NDAs, abbreviated applications, applications for marketing approval of a biologic product and supplements to such applications for substances that occur naturally in the environment would not qualify for categorical exclusion under 21 CFR 25.31(c) when FDA's approval of the application alters significantly the concentration or distribution of the substance, its metabolites, or degradation products in the environment. This might be the case when the use and disposal occur in a geographic area where the substance does not naturally occur. However, the application may be eligible for a categorical exclusion under other provisions in 21 CFR 25.31.

In addition to drug and biologic products derived from natural sources or from biological systems, substances can be considered naturally occurring even if they are chemically synthesized. The Agency will consider the form in which the FDA-regulated article will exist in the environment when determining whether the drug or biologic is a naturally occurring substance. For example, a modified active moiety (e.g., salt) that does not occur naturally could be considered a naturally occurring substance if it is established that, in vivo and in the environment, the active moiety exists in a form that is found naturally.

Biological and biotechnological products will be similarly evaluated. For example, a protein or DNA comprising naturally occurring amino acids or nucleosides, but having a sequence different from that of a naturally occurring substance, will normally qualify as a

naturally occurring substance after consideration of metabolism. The same principle would apply to synthetic peptides and oligonucleotides and living and dead cells and organisms. CDER and CBER may rely on other information submitted in an application (e.g., information about metabolism, excretion, and stability; viability (if applicable); and physical and/or chemical characteristics of the product) in determining whether the FDA-regulated article would be considered a naturally occurring substance.

CDER and CBER will evaluate on a case-by-case basis the appropriateness of categorical exclusions claiming that the quantity of the naturally occurring substance that is expected to enter the environment as a result of an action will not alter significantly the concentration or distribution of the substance, its metabolites, or degradation products in the environment.

C. Extraordinary Circumstances

As stated in 21 CFR 25.21 and 40 CFR 1508.4, FDA will require at least an EA for any specific action that ordinarily would be categorically excluded if extraordinary circumstances indicate that the specific proposed action could significantly affect the quality of the human environment. Extraordinary circumstance can be shown by data available either to the Agency or the applicant and can be based on the production, use, or disposal from use of the FDA-regulated article. Data available to the Agency can include public information, information submitted in the application, and data available to the Agency on the same or similar products.

1. Actions for which available data establish that there is a potential for serious harm to the environment at the expected level of exposure.

FDA considers harm to the environment to include not only toxicity to environmental organisms but also environmental effects other than toxicity, such as lasting effects on ecological community dynamics.

2. Actions that adversely affect a species or the critical habitat of a species determined under the Endangered Species Act or the Convention on International Trade in Endangered Species of Wild Fauna and Flora to be endangered or threatened, or wild fauna or flora that are entitled to special protection under some other Federal law.

Actions that adversely affect a species or the critical habitat of a species determined under the Endangered Species Act to be endangered or threatened, wild fauna or flora listed in the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES), or wild fauna or flora that are entitled to special protection under some other Federal law or international treaty to which the United States is a party would be considered an extraordinary circumstance, and an EA should be submitted unless there are specific exemptions relating to the

pharmaceutical substances or FDA action. An example of an exception would be when a species is afforded special protection under Federal law or international treaty, but the pharmaceutical is derived only from nonwild specimens. If nonwild specimens are exempted from Federal law or treaty, the action would be eligible for categorical exclusion as indicated in section III.C.3.a. Both direct effects (e.g., pharmaceuticals derived from fauna or flora, see section III.C.3) and indirect effects (e.g., adverse effects from manufacturing site emissions) should be considered.

Under the U.S. Endangered Species Act (ESA), Congress declared, "[T]he United States has pledged itself as a sovereign state in the international community to conserve to the extent practicable the various species of fish or wildlife and plants facing extinction, pursuant to the Convention on International Trade in Endangered Species of Wild Fauna and Flora" (16 U.S.C. 1531(a)(4)(F)). Identification as an endangered or threatened species does not preclude the use of such fauna or flora. However, under the ESA, if a species has been determined to be endangered or threatened, a Federal agency is required to consult with the Secretary of Interior or the Secretary of Commerce to ensure that the agency's actions are not likely to jeopardize the continued existence of endangered or threatened species or their critical habitats (16 U.S.C. 1536).

3. Use of Fauna or Flora

FDA intends to examine closely the proposed actions for FDA-regulated articles obtained from fauna and flora and will use the extraordinary circumstances provision to require an EA in any instance in which it appears from an examination of the proposed action that the action may jeopardize the continued existence of a species. The following sections discuss CDER's and CBER's current position on when the use of fauna or flora normally would constitute an extraordinary circumstance for which an EA should be submitted to support the application.[3]

a. Cultivated Specimens

Actions involving drug or biologic products derived from cultivated plants (e.g., plantation, nursery stock) or bred or domestic animals (e.g., laboratory breed, cows, pigs) are not normally considered an extraordinary circumstance that would require an EA for an action that is normally categorically excluded (see section III.C.2 for a possible exception).

b. Wild Specimens

[3] FDA may clarify the environmental information that must be submitted to the Agency in marketing applications for specific drug or biologic products derived from plants or animals (e.g., paclitaxel, 61 FR 58694).

i. NDAs, abbreviated applications, applications for marketing approval of a biologic product, or certain supplements to such applications.

NDAs, abbreviated applications and applications for marketing approval of a biologic product where the drug or biologic product is derived from plants or animals taken from the wild, supplements to such applications that relate to changes in the source of the wild biomass (e.g., species, geographic region where biomass is obtained), or supplements to such applications that are considered to increase the use of an active moiety or biologic substance (see Attachment B) and which will cause more harvesting than what was described in the original EA would be considered an extraordinary circumstance, and an EA should be submitted.

ii. INDs

INDs generally involve relatively small quantities of a drug or biologic product and treatment of a limited number of patients. Many INDs never result in the filing of an NDA or application for marketing approval of a biologic product, which would allow for the wide-spread commercial sale of the product. CDER and CBER will evaluate INDs on a case-by-case basis where the drug or biologic product is derived from wild plants or animals to determine whether the extraordinary circumstance provision in 21 CFR 25.21 is invoked.

To facilitate Center review, when submitting a claim of categorical exclusion for actions where the drug or biologic product is derived from plants or animals, CDER and CBER request that the applicant provide the following information with the claim, or specifically identify where the information can be located (e.g., page number of application): (1) biological identification (i.e., common names, synonyms, variety, species, genus and family); (2) a statement as to whether wild or cultivated specimens are used; (3) the geographic region (e.g., country, state, province) where the biomass is obtained; and (4) a statement indicating whether the species is (a) determined under the Endangered Species Act or the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) to be endangered or threatened, (b) entitled to special protection under some other Federal law or international treaty to which the United States is a party, or (c) the critical habitat of a species that has been determined to be endangered or threatened under the Endangered Species Act or the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) or is entitled to

special protection under some other Federal law or international treaty to which the United States is a party. CDER and CBER will use this information to evaluate whether the claim of categorical exclusion is appropriate.

4. Production and Disposal Sites

FDA has found that regulated articles produced and disposed of in compliance with all applicable emission requirements do not significantly affect the environment and has determined it is unnecessary to review a company's compliance with Federal, State, and local environmental laws. In addition, both CDER and CBER routinely require as part of their safety evaluations that live organisms be inactivated following production and prior to release into the environment if there is a reasonable possibility that the living system may be harmful to the environment. Therefore, CDER and CBER will not routinely request submission of manufacturing and disposal information in an EA. However, if information available to the Agency or the applicant establishes that the general or specific emission requirements promulgated by Federal, State, or local environmental protection agencies do not address unique emission circumstances and the emissions may harm the environment, this would be sufficient grounds for requesting manufacturing or disposal information in an EA. Actions that threaten a violation of Federal, State, or local law or requirements imposed for the protection of the environment may constitute a significant impact (40 CFR 1508.27(b)(10)).

5. Significant Effects as Defined in 40 CFR 1508.27

The Council on Environmental Quality has provided a definition of "significantly" to aid in determining if an action may significantly affect the quality of the human environment. These examples should be considered when evaluating whether extraordinary circumstances exist that may warrant submission of at least an EA (See Attachment C).

IV. PREPARING AN EA FOR SUBMISSION TO CDER or CBER

A. Content and Format

This section describes the basic information that should be submitted in an EA if an EA is required. Attachment D contains an outline of the format for an EA. Alternative formats may be used, but the applicant should recognize that use of a standard format, such as described in this guidance, promotes efficiency in the review process.

1. Date

The EA should include the date the EA was originally prepared and the date(s) of any subsequent amendments.

2. Name of Applicant or Petitioner

The EA should identify the applicant who is submitting the application.

3. Address

The EA should contain the address where all correspondence is to be directed.

4. Description of Proposed Action

a. Requested Approval

The description of the requested approval should include the drug or biologic application number (if available), the drug or biologic product name, the dosage form and strength, and a brief description of the product packaging. For example, "XYZ Pharmaceuticals has filed an NDA pursuant to section 505(b) of the Federal Food, Drug, and Cosmetic Act for TRADE NAME (established name), 250 mg and 500 mg, packaged in OHDPE bottles. An EA has been submitted pursuant to 21 CFR part 25."

b. Need for Action

The EA should briefly describe the drug's or biologic's intended uses in the diagnosis, cure, mitigation, treatment, or prevention of disease.

c. Locations of Use

The EA should identify the location(s) where the product will be used. Depending on the type of product and its use, the locations of use are typically identified as hospitals, clinics and/or patients in their homes. If use is expected to be concentrated in a particular geographic region, this fact should be included.

d. Disposal Sites

Unless other disposal methods by the end user are anticipated, it is sufficient to state that at U.S. hospitals, pharmacies, or clinics, empty or partially empty packages will be disposed of according to hospital, pharmacy, or clinic procedures and/or that in the home, empty or partially empty containers will typically be disposed of by a community's solid waste management system, which may include landfills, incineration, and

recycling, although minimal quantities of the unused drug could be disposed of in the sewer system.

5. Identification of Substances that are the Subject the Proposed Action

The EA should contain information that allows for the accurate location of data about the substance in the scientific literature and for identification of closely related compounds. At a minimum, the information listed below should be provided, if available. For many biological products, format items 5.a.iii, b, c, and d will not apply. Other information, such as the international nonproprietary name (INN) or nonsystematic or semisystematic chemical names should be included if deemed useful in the identification of the compounds.

Usually this information need only be provided for the drug or biologic substance, but the same information also should be provided for the form of the active ingredient in the drug or biologic product if it is different from the drug or biologic substance (e.g., a salt formed in situ from a free base) or for a pharmacologically active related substance formed by conversion from a pharmacologically inactive parent compound (e.g., a prodrug product is converted to the pharmacologically active form).

a. Nomenclature

i. Established Name (U.S. Adopted Name-USAN)

ii. Brand/Proprietary Name/Tradename

iii. Chemical Names or Genus/Species of Biologic Product (e.g., virus)

- Chemical Abstracts (CA) Index Name (inverted form)
- Systematic Chemical Name (uninverted form)

b. Chemical Abstracts Service (CAS) registration number

c. Molecular Formula

d. Molecular Weight

e. Structural (graphic) Formula/Amino Acid Sequence

6. Environmental Issues

The type of information provided will vary depending on the environmental issues associated with the particular action. In general, the EA should include a succinct description of the environmental issues. The affected environment and the environmental effects and their significance should be discussed. Data and analyses to support the discussions should be provided as appropriate. Specific guidance is provided in section IV.B for the environmental issues that are most likely to be associated with human drugs and biologics. For environmental issues not specifically addressed in section IV.B (e.g., those included in sections III.C.4 and 5), applicants are encouraged to consult the appropriate Center prior to preparing the EA.

7. Mitigation Measures

Describe measures taken to avoid or mitigate any potential adverse environmental effects associated with the proposed action. If no adverse environmental effects have been identified, it should be so stated and indicated that, therefore, no mitigation measures are needed. See section IV.B.2.b for additional information regarding the discussion of mitigation measures for actions involving fauna and flora.

8. Alternatives to the Proposed Action

If no potential adverse environmental effects have been identified for the proposed action, the EA should state this. If potential adverse environmental effects have been identified for the proposed action, the EA "shall discuss any reasonable alternative course of action that offers less environmental risk or that is environmentally preferable to the proposed actions" (21 CFR 25.40(a)). The discussion should include the no-action alternative and measures that FDA or another government agency could undertake as well as those the applicant or petitioner would undertake. The EA should include a description of those alternatives that will enhance the quality of the environment and avoid some or all of the adverse environmental effects of the proposed action. The environmental benefits and risks of the proposed action and the environmental benefits and risks of each alternative should be discussed. See section IV.B.2.c for additional information regarding the discussion of alternatives for actions involving fauna and flora.

9. List of Preparers

The EA should include the name, job title, and qualifications (e.g., educational degrees) of those persons preparing the assessment and should identify any persons or agencies consulted. Contract testing laboratories should be included in the list of consultants, although this may be included in a confidential appendix. Curriculum vitae can be included in lieu of a description of an individual's

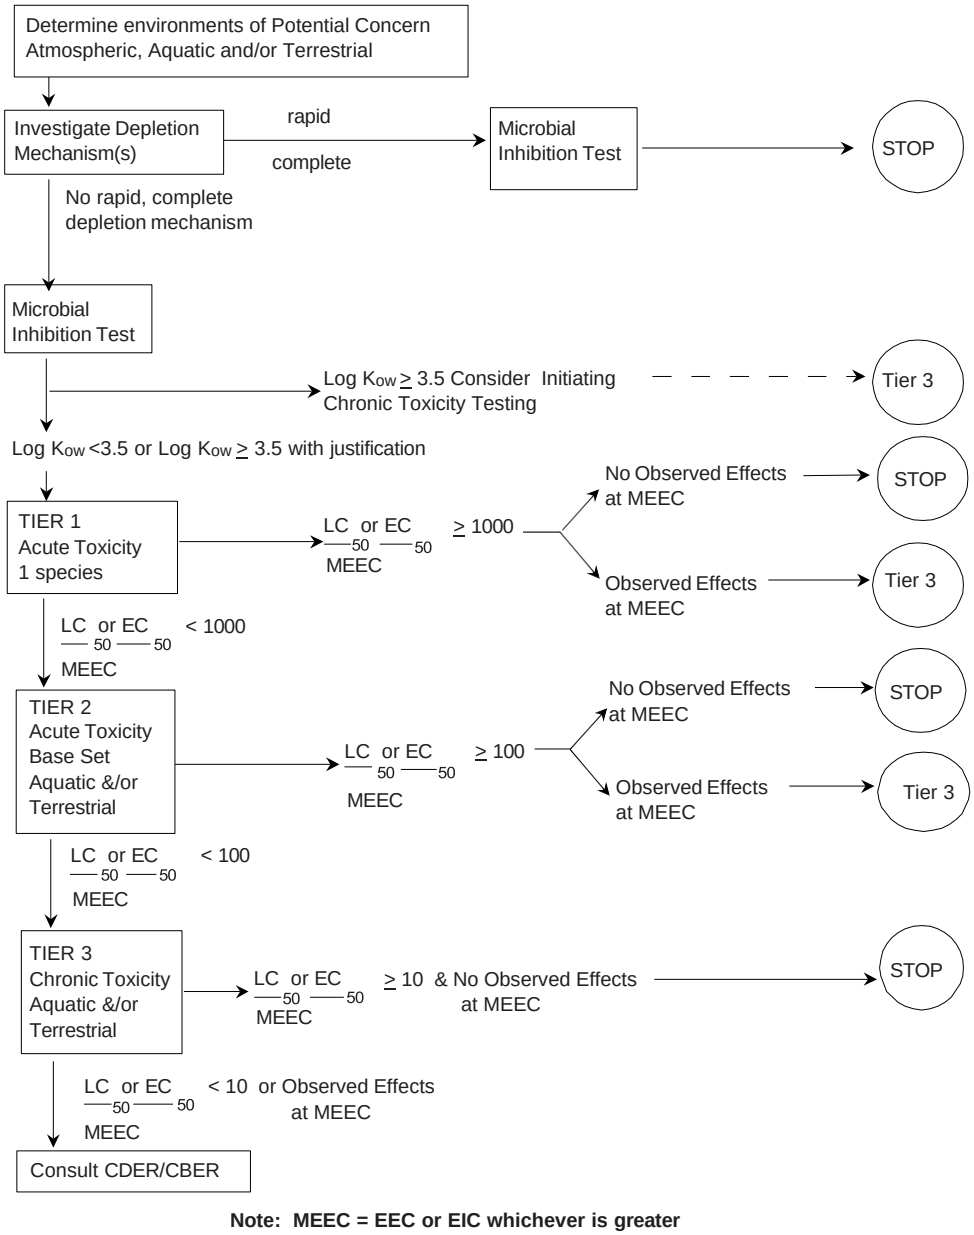
qualifications.

10. References

The EA should include a list of citations for all referenced material and standard test methods used in generating data in support of the EA. Copies of referenced articles that are not generally available and that are used to support specific claims in the EA document should be attached in a nonconfidential appendix.

11. Appendices

Both confidential and nonconfidential appendices can be included. See section IV.E for additional information about the treatment of confidential information. A list of the appendices should be included in the EA summary document with a designation of confidential or nonconfidential following each of the listings. Typically, the nonconfidential appendices include data summary tables and copies of referenced articles that are generally unavailable or that were used to support specific claims in the EA. Proprietary or confidential information, such as use estimates and test reports, should be included in the confidential appendices.



B. Specific Guidance — Environmental Issues

1. Assessing Toxicity to Environmental Organisms

If an EA is required, it normally should focus on characterizing the fate and effects of the compound of interest in the environment (1) when FDA's approval of the application increases the use of an active moiety and the estimated concentration of the active moiety at the point of entry into the aquatic environment is 1 ppb or greater (see section III.A); (2) when the substance occurs naturally in the environment and FDA's approval of the application alters significantly the concentration or distribution of the substance, its metabolites, or degradation products in the environment (see section III.B); or (3) in some cases, when data available to the Agency or applicant establish that at the expected level of exposure, there is the potential for serious harm to the environment (see section III.C.1). The provided information should focus on the fate and effects of the active moiety and/or structurally related substances (SRSs), rather than on excipients, for example.

The Centers encourage the use of a logical, tiered approach to testing so that adequate information is available to assess the potential environmental fate and effects of pharmaceuticals while minimizing the cost to industry. Figure 1 provides an illustration of a tiered approach. Alternative, scientifically justified approaches also can be used.

Figure 1
Tiered Approach to Fate and Effects Testing

Note: MEEC = EEC or EIC whichever is greater

Information submitted for fate and effects can include specific data generated on the test substance or relevant information on analogous compounds from the submitter or from peer-reviewed literature as appropriate. Actual experimental data regarding base parameters are generally preferable to computer modeling; however, in some circumstances computer modeling may be appropriate. FDA should be consulted if a company believes computer modeling is appropriate and wishes to use modeling in an EA.

a. Environmental Fate of Released Substances

i. Identification of Substances of Interest

The actual substances that will enter or exist in the environment (i.e., atmospheric, aquatic, terrestrial) can include the parent compound (i.e., drug or biologic substance) or SRSs such as the dissociated parent compound, metabolites, or degradants. The EA should list the drug or biologic substance and the predominant SRSs expected to enter or exist in the environment; provide the name, chemical structure and CAS number when possible; and provide a rationale for the decision as to which substance(s) will be studied. Predominant SRSs should be considered those greater than 10 percent of dose.

In most cases, fate (and effects) information should be provided on the parent (or active) drug or biologic substance, as representative of substances entering the environment. Such information is relevant to SRSs when the SRSs possess the same fundamental structure as the parent drug or biologic substance and are comparably or more polar. At a minimum, the EA should contain a discussion of the potential fate and effects of the predominant SRSs based on their structural differences and/or similarities to the parent compound (e.g., due to a functional group change, the metabolite should be more soluble than the parent compound, or the SRS is more polar). Computerized structure-activity relationship modeling programs may be useful in supporting extrapolation of fate and effects information from the parent (or active) drug or biologic substance to the SRS. Relevant available pharmacologic activity and toxicity information should be provided for the SRSs. Specific toxicity-activity information for SRSs may be included in a confidential appendix. Additional environmental information on a predominant SRS may be warranted, following consultation with the appropriate Center, if the fate of the compound is expected to differ from the parent compound, or there is an indication that the

SRSs effect on the environment would be substantially greater than from the parent drug or biologic substance.

ii. Physical and Chemical Characterization

The following tests should be conducted to determine if the compound is most likely to amass predominantly in aquatic, terrestrial, and/or atmospheric environments:

- Water Solubility
- Dissociation Constant(s)
- Octanol/Water Partition Coefficient
- Vapor Pressure or Henry's Law Constant

If there is a scientific basis for not performing a test, the justification should be included in the EA (e.g., water solubility was not determined because the compound is hydrolytically unstable). For a test compound that associates or dissociates in water, water solubility and the octanol/water partition coefficient may have to be determined at pH 5 and 9 as well as pH 7.

The octanol/water partition coefficient (K_{ow}) is an indicator of a nonionized compound's potential to adsorb to the organic fraction of soil, sediment, or biosolids (i.e., sludge) in addition to being an indicator of a compound's lipophilicity. It is not as good a predictor for inorganic chemicals, metal organic complexes, dissociating, ionic organic compounds, or compounds with other mitigating structural features such as molecular size. Further study of the sorption and/or desorption properties (K_{oc}) of a substance to biosolids should be considered if log K_{ow} is greater than 3 or other properties indicate that sorption or desorption may occur.

iii. Environmental Depletion Mechanisms

Depletion mechanisms should be investigated to determine if there is degradation of the compound in the environment(s) of interest. It is usually sufficient to provide basic supporting information that identifies the potential for a compound to be removed from the environment by a depletion mechanism (e.g., photolysis or hydrolysis based on information developed for analytical methods validation or from stability studies). It is unnecessary to go to

extraordinary effort to identify a depletion mechanism once the typical depletion mechanisms (i.e., hydrolysis, photolysis, biodegradation) have been investigated or to continue investigating other potential depletion mechanisms once one has been identified.

If the depletion mechanism is being used to reduce the expected introduction concentration or to eliminate effects testing, a formal, detailed analysis of the depletion mechanism should be provided (e.g., according to a standard test method, rate determination, analysis of expected exposure time in the environment).

Consideration should be given to the nature and extent of the degradation. If a rapid, complete depletion mechanism is identified (degradants are relatively simple, polar by-products), no testing to determine the environmental effects of the compound should be performed except for a microbial inhibition test or other appropriate test to assess the potential for the compound to disrupt waste treatment processes. Based on the estimated time prior to emission from a treatment facility, the following would be considered rapid depletion mechanisms:

Hydrolysis $t_{½}$ (pH 5-9):	:, 24 hours
Aerobic Biodegradation $t_{½}$:	:, 8 hours
Soil Biodegradation $t_{½}$:	:, 5 days

Direct and indirect photolysis, although significant under laboratory conditions, may not be as rapid a depletion mechanism in the environment due to significant variation in light intensity (e.g., related to weather, latitude, depth penetration) and duration of exposure. Efforts to characterize photolysis as a depletion mechanism should take these factors into consideration.

iv. Environmental Concentrations

Expected Introduction Concentration (EIC): The environmental introduction concentrations into those environments (i.e., aquatic, terrestrial, atmospheric) where the substance(s) of interest is most likely to amass (see section IV.B.1.a.ii) should be estimated. A method of calculating the expected introduction concentration of a substance into the aquatic environment is described in section III.A.2. The calculation of the expected introduction concentration (EIC) entering into the aquatic environment from patient use, in addition to considering metabolism as described in section III.A.1, may include consideration of the environmental depletion

mechanisms that occur in the waste treatment process (e.g., adsorption, degradation, hydrolysis), if the information is available (see section IV.B.1.a.iii).

Some drug or biologic substance and/or active moiety may enter the terrestrial environment when biosolids from waste water treatment facilities, which contain adsorbed material, are applied to land. Application of biosolids to land is subject to regulation by the Environmental Protection Agency (EPA) or an appropriate State authority. Biosolids are generally subjected to some form of aerobic or anaerobic digestion in the waste treatment facility. The EIC for the terrestrial compartment should be estimated if, based on the available physical or chemical properties of the compound, significant quantities of the active moiety are expected to adsorb to biosolids. The calculation used will depend on the typical treatment, disposal, and application processes. Currently, approximately 6.8 million tons of biosolids (dry basis) are generated per year with 54 percent of that quantity being applied to land. The remaining biosolids are incinerated, landfilled or disposed of by other means. Depletion mechanisms (e.g., biodegradation, hydrolysis) that occur in the waste treatment process can be considered when calculating the EIC for the terrestrial compartment, if the information is available. Additional information regarding land application of biosolids is available from EPA's Office of Wastewater Management (on the Internet at http://www.epa.gov/owm/bio.htm).

The concentration expected in the atmospheric compartment need not be routinely calculated for pharmaceutical products administered through inhalation because, for the majority of these, the active moiety or other compound of interest is not released into the air. However, the EIC should be considered for products that are released primarily into the air (e.g., medical gases).

CDER and CBER have defined *use* to encompass disposal of FDA-regulated articles by consumers. Normally, the EIC from disposal need not be calculated since the majority of pharmaceutical products will be totally consumed, and any residual waste will typically be disposed of in landfills or at incineration facilities that are regulated by the EPA or appropriate State agencies. These agencies have considered the environmental impacts from the operation of these facilities in their licensing process and require controls (e.g., scrubbers, lined landfills, migration tests) to limit the release of materials into the environment. The EIC for disposal

should be calculated if significant quantities of material are expected to be disposed of other than by landfill, incineration or other procedures regulated by the EPA or appropriate State agencies.

Expected Environmental Concentration (EEC): The expected environmental concentration (EEC), sometimes referred to as the *predicted environmental concentration* (PEC), is the concentration of the active moiety or other compound of interest that organisms would be exposed to in the environment (e.g., surface water) after consideration of, for example, spatial or temporal concentration or depletion factors such as dilution, degradation, sorption and/or bioaccumulation. Adjustments to the expected introduction concentration may be made, based on spatial and temporal concentration or depletion factors, to provide an expected environmental concentration. Supporting information and/or discussion should be provided to explain the factors used in calculating the expected environmental concentration. The concentration should be provided for each environmental compartment (aquatic, terrestrial, atmospheric) expected to be affected based on the physical and/or chemical characterization of the compound of interest. In the majority of cases, the EEC for the aquatic environment would be expected to be significantly less than the EIC for the aquatic environment due to dilution. Based on dilution factors for POTWs available from the EPA, applying a dilution factor of 10 to the EIC-aquatic to estimate the EEC-aquatic is normally appropriate.

v. Summary

A summary discussion of the environmental fate of the substance(s) of interest should be provided for each environmental compartment based on the information and data provided in the EA, and the environmental compartment(s) in which the substance is expected to predominantly amass should be identified. In some circumstances, transport between environmental compartments should be considered when determining the fate of the substance(s) of interest in the environment.

Aquatic Environment: In general, pharmaceutical substances are expected to enter predominantly into the aquatic environment and, therefore, the focus of any effects studies most likely will be on aquatic organisms. If the substance(s) of interest rapidly degrades (see section IV.B.1.a.iii) or adsorbs completely and irreversibly to

biosolids, then fate and effects in the aquatic environment should not usually be considered.

Terrestrial Environment: In general, substances enter the terrestrial environment predominantly from biosolids removed from waste water treatment plants that are subsequently applied to land. Therefore, effects on the terrestrial environment are more likely if a compound adsorbs to biosolids (see section IV.B.1.a.ii). Biosolids are generally subjected to some form of aerobic or anaerobic digestion in the waste treatment facility; only a fraction of the biosolids may be applied to land, while the remainder is incinerated or land filled. Fate and effects testing in the terrestrial environment should be considered if testing indicates that the substance(s) of interest will significantly adsorb to biosolids (e.g., K_{oc} ;„ 1000).

Atmospheric Environment: In general, substances that do not adsorb readily to soils, have a high vapor pressure, and have a low water solubility, are likely to volatilize significantly from the aquatic or terrestrial environments, although actual volatilization rates will depend on environmental conditions (e.g., dispersion away from the evaporation site) and on factors that can lessen or enhance the effective vapor pressure or behavior of the chemical at a liquid-air or solid-air interface. The atmospheric compartment may be of interest for medical gases. But, based on the polarity of the majority of compounds at relevant aquatic environmental conditions, it is unlikely that there would be substantive partitioning from the aquatic to the atmospheric environment for other pharmaceuticals. Any potential for a substance to volatilize and recycle into the aquatic or terrestrial environments should be discussed based on the information and data available for the substance.

b. Environmental Effects of Released Substances

Tiered approach to environmental effects testing (see below, Microbiological Inhibition Testing through Tier 3 Testing and Figure 1): If no rapid, complete depletion mechanism has been identified, it should be assumed that the compound will persist in the environment for some time and, therefore, the toxicity of the released substances to environmental organisms should be evaluated. The fate of the substance should be considered when designing the studies. For those compounds that enter the atmospheric environment, testing should be designed based on the extent to which the substance recycles into the aquatic or terrestrial environments. All toxicity test results for the drug or biologic substance

should be reported in terms of the quantity and/or concentration of the active moiety. When using this tiered approach to effects testing, it is important to design the test conditions appropriately so that a no-observed-effects concentration is determined.

Microbial Inhibition Testing: A microbial inhibition test or other appropriate test (e.g., respiration inhibition testing) should be performed to assess the substance(s) of interest's potential to inhibit microorganisms and subsequently disrupt waste treatment processes.

Assessment Factors: The assessment factors are intended to provide a consistent regulatory basis for determining when additional ecotoxicity testing should be performed (tiered approach). They are directly related to the amount of valid ecotoxicity data available. If the LC_{50} or EC_{50} or other appropriate test endpoint divided by the maximum expected environmental concentration (MEEC: EIC or EEC, whichever is greater) is less than the assessment factor, additional testing should be performed. The use of EC_{50} or test end point other than the LC_{50} should be limited to those test organisms for which the LC_{50} is not the test endpoint.

TEST TIER	ASSESSMENT FACTOR
1	1000 (see below)
2	100 (see below)
3	10 (see below)

Alternative scientifically justified approaches also can be used.

Tier 1 Testing: Acute ecotoxicity testing should be performed on a minimum of one suitable test organism (see base set for Tier 2 testing). If the EC_{50} or LC_{50} divided by the MEEC is greater than or equal to 1000, no further testing should be conducted unless sublethal effects are observed at the MEEC. If the EC_{50} or LC_{50} divided by the MEEC is less than 1000, Tier 2 testing should be performed. Sublethal effects (observed effects) at the MEEC indicate that chronic toxicity testing (Tier 3) should be performed. The use of the assessment factor of 100 could be used for Tier 1 testing if there is evidence (e.g., Tier 2 testing on a similar compound) to support that the single test organism used would be expected to be the most sensitive of the base set test organisms. If the compound is expected to partition to both the aquatic and terrestrial environments, usually testing of an aquatic test organism is sufficient since CDER has routinely observed lower toxicity results reported for aquatic test organisms as compared to terrestrial test organisms.

Tier 2 Testing: Acute ecotoxicity testing should be performed on the minimum base set of aquatic and/or terrestrial organisms. The aquatic base set usually consists of (1) a fish acute toxicity test, (2) an aquatic invertebrate acute toxicity test, and (3) an algal species bioassay. The terrestrial base set usually consists of (1) plant early growth tests, (2) earthworm toxicity tests, and (3) soil microbial toxicity tests. Usually only an earthworm toxicity study is indicated if the substance binds tightly to soil. A rodent acute toxicity is not included in the terrestrial base set since there is usually a significant quantity of mammalian (e.g., mouse, rat, dog, monkey, human) toxicity testing performed, both acute and chronic, to support the underlying applicacton and to demonstrate the safety of the drug or biologic product. Consultation with CDER or CBER is suggested prior to initiating any terrestrial studies.

If the EC_{50} or LC_{50} for the most sensitive organism in the base set divided by the MEEC is greater than or equal to 100, no further testing should be conducted unless sublethal effects are observed at the MEEC. If the EC_{50} or LC_{50} divided by the MEEC is less than 100, Tier 3 testing should be performed. Sublethal effects (observed effects) at the MEEC indicate that chronic toxicity testing (Tier 3) should be performed.

Tier 3 Testing: Chronic toxicity testing should be considered if the compound has the potential to bioaccumulate or bioconcentrate, if indicated based on Tier 1 and/or Tier 2 testing, or if there are other indications that the compound undergoes biotransformation to more toxic compounds.

Bioaccumulation, or bioconcentration, is a complex, dynamic process that depends on the availability, persistence, and physical and/or chemical properties of a compound in the environment. In general, pharmaceuticals tend not to be very lipophilic and are produced and/or used in relatively low quantities compared to industrial chemicals. In humans, the majority of pharmaceuticals are metabolized to some extent to SRSs that are more polar, less toxic, and less pharmacologically active than the parent compound. This suggests that there is a low potential for bioaccumulation or bioconcentration of pharmaceuticals; however, because of the length of time it takes to conduct chronic toxicity studies, applicants are encouraged to identify as early as possible compounds that are candidates for these studies.

A primary indicator of the potential for bioaccumulation is a compound's octanol/water partition coefficient (K_{ow}). A high octanol/water partition coefficient indicates that the compound will tend to be lipophilic. Chronic toxicity testing should be considered if log K_{ow} of a compound is greater

than or equal to 3.5 under relevant environmental conditions (e.g., pH 7), and a justification should be provided if chronic toxicity testing is not performed. Structural features (e.g., molecular size, polarity) that limit passage across biological membranes or the lack of bioavailability to environmental organisms (e.g., strong adsorption to soil) are mitigating factors that could be considered when determining if bioaccumulation (bioconcentration) would be a concern for compounds with a K_{ow} greater than or equal to 3.5. It may be important to obtain acute toxicity data for the organism to be tested to set the concentrations for the chronic studies properly. If the preparer of an EA is considering initiating chronic toxicity studies, consultation with CDER or CBER is recommended to ensure that such studies are appropriate and properly designed.

For chronic toxicity testing, if the EC_{50} or LC_{50} divided by the MEEC is greater than or equal to 10, no further testing should be conducted unless sublethal effects are observed at the MEEC. CDER or CBER should be consulted if the EC_{50} or LC_{50} divided by the MEEC is less than 10 or there are sublethal effects at the MEEC.

Test Methods and Test Organisms: Studies should be performed using test organisms and methods that have been identified by the FDA *Environmental Assessment Technical Handbook*, the EPA (40 CFR 797), the Organization for Economic Cooperation and Development (OECD), or other peer-reviewed literature, as appropriate, for use in environmental studies. If the drug or biologic product is intended to act upon an environmental organism (e.g., antiparasitic, antibiotic), information regarding the toxicity to the target organism(s) should be included.

c. Summary

A summary discussion of the environmental fate and effect of the substance(s) of interest should be provided. Discussion of the affected environments (aquatic, terrestrial, or atmospheric) should be included. The toxicity test results should be compared to the MEEC and the difference between the values discussed (e.g., in terms of the assessment factor, > 1000, > 100). It also may be appropriate to relate the toxicity test results to other estimated environmental concentrations (see section IV.B.1.a.iv).

2. Use of Fauna or Flora

If an EA is to be submitted for an action because the use of fauna or flora is the environmental issue (see section III.C.2 or 3), the EA should include specific information regarding the source of the fauna or flora, the mitigation measures associated with the harvesting of the resources, and a discussion of the reasonable

alternatives.

a. Use of Resources

Information relating to the source of the plant or animal, such as biological identification, government oversight of harvesting, geographic region where biomass is obtained, and harvesting methods and techniques should be included in the EA. The EA should include, but not be limited to, the following types of information:

- Biological identification (i.e., common names, synonyms, variety, species, genus, and family).
- A statement as to whether wild or cultivated specimens are used.
- The geographic region (e.g., country, state, province) where biomass is obtained and whether harvesting occurred on public or private land.
- A brief description of government oversight of the harvesting including, if applicable, the identity of the authority permitting harvesting and identity of authorities consulted regarding the harvesting. Submission of copies of permits or harvesting regulations relating to the specific species is helpful. For species covered under CITES, CDER or CBER could request copies of relevant permits.
- A brief description of the applicant's oversight of the harvesting.
- A statement indicating whether the species is (1) determined under the Endangered Species Act or the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) to be endangered or threatened, (2) entitled to special protection under some other Federal law or international treaty to which the United States is a party, or (3) the critical habitat of a species that has been determined to be endangered or threatened under the Endangered Species Act or the Convention on International Trade in Endangered Species of Wild Fauna and Flora (CITES) or is entitled to special protection under some other Federal law or international treaty to which the United States is a party.
- A statement describing the part of plant or animal used and whether it is a renewable resource.

- A detailed description of the method of harvest including such information as the type of harvesting (e.g., clear cut, gleaning from timber stands destined for clear cutting, salvaging, pruning), frequency of harvest, whether the harvesting technique will affect the ecosystem (and if so, how), and whether the harvesting is conducted in accordance with government regulations or guidances (include citations to applicable regulations or guidances).

- Bulk weight or other appropriate measure of biomass needed to yield one kilogram of active moiety or biologic substance, the amount that has been harvested to date to support the proposed Agency action for the product, and the amount expected to be harvested in the future.

- The amount of biomass needed to produce the active moiety or biological substance used to treat the average patient. This should be provided in terms easy to understand (e.g., 2-3 trees per patient). The expected patient population and number of kilograms of active moiety or biologic substance needed per year should be provided.

- An estimate of the total number of plants or animals in the geographic region where the biomass is obtained.

- Any uses of the plant or animal other then for the proposed use (humans, food source, habitat for fauna).

- Plant or animal growth rate and/or life span and, if applicable, the rate of reproduction/regeneration.

- A discussion of whether the harvesting provides for sustained yield (e.g., percentage of sustainable harvest needed to supply annual needs based on the proposed use and any prior approved uses).

b. Mitigation Measures

Mitigation measures taken before (e.g., developing a process that uses a renewable part of a plant), during (e.g., limiting/selecting specimens to be harvested), and after harvesting (e.g., reforestation) should be included in the discussion of mitigation measures (see 40 CFR 1508.20).

c. Alternatives to the Proposed Action

A discussion must be provided of the reasonable alternatives that were considered when deciding which biomass source would be used to produce the active moiety or biologic substance (21 CFR 25.40(a)). All alternatives that were considered (e.g., other species, wild or cultivated sources, chemical synthesis) should be discussed. A brief discussion of the factors (e.g., environmental effects) that were considered in deciding whether or not the alternative would be used should be provided. The no-action (i.e., no approval) alternative should also be discussed. It should be indicated if any of the alternatives not currently used are planned for use in the future.

C. Data Summary Table

To facilitate review, the EA, if appropriate, should include a data summary table in a nonconfidential appendix (EA format item 11). Attachment E provides an example of a suitable data summary table.

D. Test Methods and Report Formats

Test methods and report formats are provided in the FDA *Environmental Assessment Technical Handbook*. Equivalent tests, such as those provided by the EPA (40 CFR 796 and 797), the Organization for Economic Cooperation and Development (OECD), or other validated, peer-reviewed methods can be used. Environmental fate studies should be compliant with either FDA's current Good Manufacturing Practice (cGMP) regulations (21 CFR 211.194) or FDA's Good Laboratory Practice (GLP) regulations (21 CFR part 58). The reports submitted in support of fate testing should include a description of the test method sufficient for a reviewer to determine the scientific merit of the methodology. Test performance and test reporting for environmental effects studies should meet FDA's GLP standards. Guidance on test reporting formats is included in the FDA *Environmental Assessment Technical Handbook* or 40 CFR parts 796 and 797. Raw test data (e.g., copies of notebook pages, HPLC chromatograms for each assay) should not be included in the EA.

E. Confidential and Nonconfidential Information

Some of the information that is submitted in an EA may be available elsewhere in an application or in a publicly available document. This information may be incorporated by reference in the EA (21 CFR 25.40(d)). However, the EA summary document, the document that contains the information recommended in section IV.A, should be a stand-alone document that contains a summary of the public information that is incorporated by reference and, to the extent possible, a summary of the confidential information that is either incorporated by reference or included in confidential appendices to the EA (21 CFR 25.51(a)). The EA will be made public by the FDA as required by regulations issued by

the Council on Environmental Quality. Therefore, the EA should contain, if appropriate, three distinct parts: (1) the EA summary document (see section IV.A), which is nonconfidential; (2) nonconfidential appendices; and (3) appendices with confidential information used to support the EA. Confidential data and information pertinent to the environmental review of a proposed action should be included in confidential appendices whenever possible to facilitate review of the EA. All confidential appendices should be at the end of the environmental assessment document. References to nonconfidential and confidential appendices may be included in the EA summary document, as appropriate. The EA summary document, nonconfidential appendices, and FONSI are made available for public inspection to the extent allowed by applicable laws (21 CFR 25.50(a) and (b)).

Attachment F provides general guidance as to which information can be included in confidential appendices of the EA. It is the applicant's responsibility to clearly identify the information in the EA that it believes is confidential.

F. Master Files for Drugs and Biologics

CDER and CBER do not take action on drug master files (DMFs) or master files (MFs) (i.e., they do not approve or disapprove submissions to a DMF (21 CFR 314.420(a)) or MF). Therefore, NEPA does not apply, and no EA needs to be submitted for a master file.

However, if an EA is required for the particular application, certain information that is included in a master file may be needed to address the relevant environmental issue(s). In these instances, the applicant seeking marketing approval should include the nonconfidential information in the EA summary document, rather than provide reference to the master file. The master file holder may be the applicant or an independent manufacturer who wants to limit the applicant's access to proprietary information. A master file reference may be provided for the confidential information, although this information must be summarized to the extent possible and included in the EA for public release. To expedite review of the EA, CDER and CBER prefer that copies of confidential information from master files be submitted in confidential appendices to the EA, whenever possible. If a letter of authorization is provided to reference confidential information in a master file, the specific type of information that is being referenced, the submission date, and page number where the information can be located should be stated. References to master files should be included in a confidential appendix since such references are considered confidential commercial information under the Freedom of Information Act (FOIA).

ATTACHMENT A: NO INCREASED USE

The following are types of actions that are not considered to result in increased use of an active moiety if approved by the Agency:

- Chemistry, manufacturing and control supplements (§§ 314.70, 601.12).
- Abbreviated applications.
- Lower doses than previously approved for the same indication (i.e., total daily dose).
- Shorter duration of use than previously approved for the same indication (e.g., number of days).
- Exclusion of a patient population in the labeling (e.g., by age, sex, complicating medical conditions).
- A prodrug for which the active metabolite is an approved product in the United States and which is intended to substitute directly[4] for that approved product. An active moiety which is the active metabolite of an approved prodrug in the United States would be considered similarly.
- New dosage forms that substitute directly for an approved product.
- Product reformulations in which the labeled amount of active moiety/biologic substance remains constant.
- Packaging changes/dosage form product line extensions that substitute directly for an approved product (e.g., new delivery system, addition of a different vial fill size).
- Combination drugs in which the single product substitutes directly for two approved products that would be administered separately.

[4] In context of Attachments A and B, substitute directly means that the drug or biologic product (i.e., active moiety or biologic substance) will be used for the same indication, at the same or lower dosage levels (i.e., total daily dose), and for the same or shorter duration of use (e.g., number of days) as previously approved by the Agency for the same active moiety or biologic substance.

ATTACHMENT B: INCREASED USE

The following are types of actions that are considered to result in increased use of an active moiety if approved by the Agency:

- New molecular entities.
- A new indication for a drug that was previously approved. This includes those actions requesting approval of off-label uses and switches from a second-line to first-line indication.
- R to OTC switches.
- Higher doses than were previously approved (i.e., total daily dose).
- Longer duration of use than previously approved (e.g., number of days).
- Inclusion of a patient population in the labeling that had previously been ***specifically excluded*** (e.g., by age, sex, complicating medical conditions).
- New dosage forms/routes of administration that increase the amount of active ingredient/biologic substance used. For example, the use of the active moiety or biologic substance for the same indication will normally increase if a switch is made from an injectable dosage form to an oral dosage form.

ATTACHMENT C: 40 CFR 1508.27

§ 1508.27 Significantly.

"Significantly" as used in NEPA requires considerations of both context and intensity:

(a) *Context.* This means that the significance of an action must be analyzed in several contexts such as society as a whole (human, national), the affected region, the affected interests, and the locality. Significance varies with the setting of the proposed action. For instance, in the case of a site-specific action, significance would usually depend upon the effects in the locale rather than in the world as a whole. Both short- and long-term effects are relevant.

(b) *Intensity.* This refers to the severity of impact. Responsible officials must bear in mind that more than one agency may make decisions about partial aspects of a major action. The following should be considered in evaluating intensity:

(1) Impacts that may be both beneficial and adverse. A significant effect may exist even if the Federal agency believes that on balance the effect will be beneficial.

(2) The degree to which the proposed action affects public health or safety.

(3) Unique characteristics of the geographic area such as proximity to historic or cultural resources, park lands, prime farmlands, wetlands, wild and scenic rivers, or ecologically critical areas.

(4) The degree to which the effects on the quality of the human environment are likely to be highly controversial.

(5) The degree to which the possible effects on the quality of the human environment are highly uncertain or involve unique or unknown risks.

(6) The degree to which the action may establish a precedent for future actions with significant effects or represents a decision in principle about a future consideration.

(7) Whether the action is related to other actions with individually insignificant but cumulatively significant impacts. Significance exists if it is reasonable to anticipate a cumulatively significant impact on the environment. Significance cannot be avoided by terming an action temporary or by breaking it down into small component parts.

(8) The degree to which the action may adversely affect districts, sites, highways, structures, or objects listed in or eligible for listing in the National Register of Historic Places or may cause loss or destruction of significant scientific, cultural, or historical resources.

(9) The degree to which the action may adversely affect an endangered or threatened species or its habitat that has been determined to be critical under the Endangered Species Act of 1973.

(10) Whether the action threatens a violation of Federal, State, or local law or requirements imposed for the protection of the environment.

ATTACHMENT G: GLOSSARY OF TERMS

Active Moiety: The molecule or ion, excluding those appended portions of the molecule that cause the drug to be an ester, salt (including a salt with hydrogen or coordination bonds), or other noncovalent derivative (such as a complex, chelate, or clathrate) of the molecule, responsible for the physiological or pharmacological action of the drug substance (21 CFR 314.108(a)). The active moiety is the entire molecule or ion, not the "active site."

Bioaccumulation: The process by which industrial waste, chemicals, and other substances gradually accumulate in living tissue.

Bioconcentration: The process by which industrial waste, chemicals, and other substances accumulate directly from water into and onto aquatic organisms.

Biological (biologic) product: Any virus, therapeutic serum, toxin, antitoxin, vaccine, blood, blood component, derivative, allergenic product, or analogous product applicable to the prevention, treatment, or cure of a disease or condition of human beings (section 351 of the Public Health Service Act).

Biomass: The plant, plant part (e.g., bark, leaves, flower, seed), animal, or animal part (e.g., skin, liver, stomach) that is collected for processing into a drug or biologic.

Drug product: A finished dosage form, for example, tablet, capsule, or solution, that contains a drug substance, generally, but not necessarily, in association with one or more ingredients (21 CFR 314.3(b)).

Drug substance: An active ingredient that is intended to furnish pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment, or prevention of disease or to affect the structure or any function of the human body, but does not include intermediates used in the synthesis of such ingredient (21 CFR 314.3(b)).

Expected environmental concentration (EEC): The expected concentration of the active moiety or other structurally related substance of interest that organisms would be exposed to in the environment (e.g., surface water) after consideration of spatial or temporal concentration or depletion factors such as dilution, degradation, sorption, bioaccumulation. This is sometimes referred to as the predicted environmental concentration (PEC).

Expected introduction concentration (EIC) for disposal: The expected introduction concentration of the active moiety that may enter the environment due to disposal. Depletion mechanisms that occur prior to introduction into the environment may be considered in the calculation as indicated in the text.

Expected introduction concentration (EIC) for use: The expected introduction concentration, based on fifth-year marketing estimates, of the active moiety that can enter the environment due to use. Depletion mechanisms that occur prior to introduction into the environment and human metabolism may be considered in the calculation as indicated in the text.

Half-life ($t_{½}$): Time required to reduce by one-half the concentration of a material.

Lowest observed effect concentration (LOEC): The lowest concentration of a material used in a toxicity test that has a statistically significant adverse effect on the exposed population of the test organisms as compared with the controls.

Master file: A submission of information to the FDA by a person who intends it to be referenced during the review of an application. See 21 CFR 314.420 for specific information on drug master files.

Maximum expected environmental concentration (MEEC): The expected introduction concentration (EIC) or expected environmental concentration (EEC), whichever is greater.

Median effective concentration (EC_{50}): The concentration of material to which organisms are exposed that is estimated to be effective in producing some sublethal response in 50 percent of the test organisms. The EC_{50} is usually expressed as a time-dependent variable (e.g., 24 hour EC_{50}).

Median lethal concentration (LC_{50}): The concentration of material to which organisms are exposed that is estimated to be lethal to 50 percent of the test organisms. The LC_{50} is usually expressed as a time-dependent variable (e.g., 24 hour LC_{50}).

Minimum inhibitory concentration (MIC): The lowest concentration of a chemical that inhibits the visible growth of the test organisms.

New molecular entity: An active moiety (present as the unmodified base [parent] compound, or an ester or a salt, clathrate, or other noncovalent derivative of the base [parent] compound) that has not been previously approved or marketed as the active moiety in the United States for use in a drug product, either as a single ingredient or as part of a combination product, or as part of a mixture of stereoisomers.

No observed effect concentration (NOEC): The highest concentration of a material used in a toxicity test that has no statistically significant adverse effect on the exposed population of test organisms as compared with the controls.

Octanol/water partition coefficient (K_{ow}): The ratio of a chemical's solubility in n-octanol and water at equilibrium; also expressed as P. A measurement of a drug's or biologic's lipophilicity and an indication of its ability to cross cell membranes. The logarithm of P or K_{ow} is used as an estimate of the tendency of the chemical to bioaccumulate or adsorb to soil or sediments.

Parts per billion (ppb): One unit of chemical (usually expressed as mass) per 1,000,000,000 (10^9) units of medium (e.g., water) or organism (e.g., tissue) in which it is contained. For water 1 µg/L = 1 ppb; for tissue 1 µg/kg = 1 ng/g = 1 ppb.

Parts per million (ppm): One unit of chemical (usually expressed as mass) per 1,000,000 (10^6) units of medium (e.g., water) or organism (e.g., tissue) in which it is contained. For water 1 mg/L = 1 ppm; for tissue 1 mg/kg = 1 µg/g = 1 ppm.

Parts per trillion (pptr): One unit of chemical (usually expressed as mass) per 1,000,000,000,000 (10^{12}) units of medium (e.g., water) or organism (e.g., tissue) in which it is contained. For water 1 ng/L = 1 pptr; for tissue 1 ng/kg = 1 pptr.

Soil or sediment/water partition coefficient (K_{oc}): The ratio of chemical adsorbed per unit weight of organic carbon in soil or sediment to the concentration of the chemical in solution at equilibrium.

Toxicity: The inherent potential or capacity of a material to cause adverse effects in a living organism.

Real-World Data: Assessing Electronic Health Records and Medical Claims Data to Support Regulatory Decision-Making for Drug and Biological Products
Guidance for Industry[1]

This guidance represents the current thinking of the Food and Drug Administration (FDA or Agency) on this topic. It does not establish any rights for any person and is not binding on FDA or the public. You can use an alternative approach if it satisfies the requirements of the applicable statutes and regulations. To discuss an alternative approach, contact the FDA office responsible for this guidance as listed on the title page.

I. INTRODUCTION AND SCOPE

The 21st Century Cures Act (Cures Act),[2] signed into law on December 13, 2016, is intended to accelerate medical product development and bring innovations faster and more efficiently to the patients who need them. Among other provisions, the Cures Act added section 505F to the Federal Food, Drug, and Cosmetic Act (FD&C Act) (21 U.S.C. 355g). Pursuant to this section, FDA created a framework for a program to evaluate the potential use of real-world evidence (RWE) to help support the approval of a new indication for a drug[3] already approved under section 505(c) of the FD&C Act or help support or satisfy postapproval study requirements.

FDA is issuing this guidance as part of its RWE Program[4] and to satisfy, in part, the mandate under section 505F of the FD&C Act to issue guidance about the use of RWE in regulatory decision-making.[5] The RWE Program will cover clinical studies that use real-world data (RWD) sources, such as information from routine clinical practice, to derive RWE.

[1] This guidance has been prepared by the Center for Drug Evaluation and Research (CDER) in cooperation with the Center for Biologics Evaluation and Research (CBER) and Oncology Center for Excellence (OCE) at the Food and Drug Administration.

[2] Public Law 114-255.

[3] For the purposes of this guidance, all references to *drugs* include both human drugs and biological products. This guidance does not apply to medical devices. For information on medical devices, see the guidance for industry and FDA staff *Use of Real-World Evidence to Support Regulatory Decision-Making for Medical Devices* (August 2017). We update guidances periodically. For the most recent version of the guidance, check the FDA guidance web page at https://www.fda.gov/regulatory-information/search-fda-guidance-documents.

[4] See *Framework for FDA's Real-World Evidence Program*, available at https://www.fda.gov/media/120060/download. The framework and RWE Program also cover biological products licensed under the Public Health Service Act.

[5] See section 505F(e) of the FD&C Act.

This guidance is intended to provide sponsors and other interested parties with considerations when proposing to use electronic health records (EHRs) or medical claims data[6] in clinical studies[7] to support a regulatory decision on effectiveness or safety of a drug.

For the purposes of this guidance, FDA defines RWD and RWE as follows:[8]

- RWD are data relating to patient health status or the delivery of health care routinely collected from a variety of sources.

- RWE is the clinical evidence regarding the usage and potential benefits or risks of a medical product derived from analysis of RWD.

Examples of RWD include data derived from EHRs, medical claims data, data from product and disease registries,[9] patient-generated data including from in-home use settings, and data gathered from other sources that can inform on health status, such as digital health technologies.[10] This guidance focuses on health-related data recorded by providers that can be extracted from two sources: EHRs and medical claims data. EHRs and medical claims data are types of electronic health care data that contain patient health information, and these data are widely used in safety studies and increasingly being proposed for use in effectiveness studies. EHRs and medical claims data can be considered as data sources in various clinical study designs.

This guidance discusses the following topics related to the potential use of EHR and medical claims data in clinical studies to support regulatory decisions:

(1) Selection of data sources that appropriately address the study question and sufficiently characterize study populations, exposure(s), outcome(s) of interest, and key covariates.

(2) Development and validation of definitions for study design elements (e.g., exposures, outcomes, covariates).

---

[6] For purposes of this guidance, the term *medical claims data* (sometimes referred to as *administrative healthcare claims data*) refers to information submitted to insurers to receive payment for treatments (e.g., pharmacy claims data) and other interventions.

[7] For the purposes of this guidance, the term *clinical studies* refers to all study designs, including, but not limited to, interventional studies where the treatment is assigned by a protocol (e.g., randomized or single-arm trials, including those that use RWD as an external control arm) and non-interventional (observational) studies where treatment is determined in the course of routine clinical care (e.g., case-control or cohort studies). Throughout the guidance, FDA uses the terms *clinical studies*, *studies*, and *study* interchangeably.

[8] See *Framework for FDA's Real-World Evidence Program*, available at https://www.fda.gov/media/120060/download.

[9] For additional discussion, see the guidance for industry *Real-World Data: Assessing Registries to Support Regulatory Decision-Making for Drug and Biological Products* (December 2023).

[10] For additional discussion, see the guidance for industry, investigators, and other stakeholders *Digital Health Technologies for Remote Data Acquisition in Clinical Investigations* (December 2023).

(3) Data traceability[11] and quality during data accrual, data curation, and incorporation into the final study-specific dataset.

This guidance does not provide recommendations on choice of study design or type of statistical analysis, and it does not endorse any type of data source or study methodology. For all study designs, it is important to ensure the reliability and relevance of the data used to help support a regulatory decision. For the purposes of this guidance, the term *reliability* includes accuracy, completeness, and traceability. The term *relevance* includes the availability of data for key study variables (exposures, outcomes, covariates) and sufficient numbers of representative patients for the study.

In general, FDA's guidance documents do not establish legally enforceable responsibilities. Instead, guidances describe the Agency's current thinking on a topic and should be viewed only as recommendations, unless specific regulatory or statutory requirements are cited. The use of the word *should* in FDA guidances means that something is suggested or recommended, but not required.

II. BACKGROUND

The FDA guidance for industry and FDA staff *Best Practices for Conducting and Reporting Pharmacoepidemiologic Safety Studies Using Electronic Healthcare Data* (May 2013) focuses on the use of electronic health care data in pharmacoepidemiologic safety studies. The 2013 guidance includes recommendations for documenting the design, analysis, and results of pharmacoepidemiologic safety studies to optimize FDA's review of protocols and study reports that are submitted to FDA.

This guidance complements the 2013 guidance by expanding on certain aspects of that guidance relating to the selection of data sources, and provides additional guidance for evaluating the relevance and reliability of both EHRs and medical claims data for use in a clinical study. This guidance also provides a broader overview of considerations relating to the use of EHRs and medical claims data in clinical studies more generally, including studies intended to inform FDA's evaluation of product effectiveness.

III. GENERAL CONSIDERATIONS

For all studies using EHRs or medical claims data that will be submitted to FDA to support a regulatory decision, sponsors should submit protocols and statistical analysis plans before conducting the study. Sponsors seeking FDA input before conducting the study should request comments or a meeting to discuss the study with the relevant FDA review division. All essential elements of study design, analysis, conduct, and reporting should be predefined, and, for each study element, the protocol and final study report should describe how that element was

[11] For the purposes of this guidance, traceability is the method (e.g., audit trail) that allows for knowledge of data provenance (i.e., the origin of a piece of data and how it got to the electronic health record or medical claim).

ascertained from the selected RWD source, including applicable validation studies. More information about study elements is provided in section V, Study Design Elements.

This guidance provides recommendations on selecting data sources to maximize the completeness and accuracy of the data derived from EHRs and medical claims for clinical studies. The use of certain study design features or specific analyses to address misclassified or missing information, as well as methods to achieve covariate balance are out of scope of this guidance. Instead, this guidance addresses issues that are essential to determining the reliability and relevance of the data and that should be addressed in the protocol, including:

(1) The appropriateness and potential limitations of the data source for the study question and to support key study elements.

(2) Time periods for ascertainment of study design elements.

(3) Conceptual definitions and operational definitions for study design elements (e.g., inclusion/exclusion criteria for study population, exposures, outcomes, covariates) and the results of validation studies. See section V, Study Design Elements, for examples of conceptual and operational definitions for study design elements.

(4) Quality assurance and quality control (QA/QC) procedures for data accrual, curation, and incorporation into the final study-specific dataset.

IV. DATA SOURCES

Protocols submitted to FDA should identify all data sources proposed for the study, as well as other relevant descriptive information (discussed below). FDA does not endorse one data source over another or seek to limit the possible sources of data that may be relevant to answering study questions.

Each data source should be evaluated to determine whether the available information is appropriate for addressing a specific study question. Given that existing electronic health care data were not developed for research purposes or to support regulatory submissions to FDA, it is important to understand their potential limitations when they are used for that purpose. Examples of potential limitations include:

(1) The purpose of medical claims data is to support payment for care; claims may not accurately reflect a particular disease or the comprehensive management of a disease (e.g., the transcription and classification practices of clinical coders may differ), or a patient may have a particular disease or condition that is not reflected or well-reflected in claims data. In addition, medical claims data can change during the run-off period and claims adjudication process, as initial submissions may be adjusted or corrected, leading to variations in reported diagnoses and procedures over time.

(2) EHR data are generated for use in clinical care and may also serve as a basis for billing and for auditing of practice quality measures. Structured and unstructured data recorded in an EHR system depend on each health care system's practices for patient care, the clinical and documentation practices of its providers, and the functionality and configuration of the EHR system. In addition, data collection is limited to the data captured within an EHR system or network, and may not represent comprehensive care (e.g., care obtained in different facilities in the same or outside of the health care system). Similar to claims data, EHR data may not accurately reflect the presence, characteristics, or severity of a particular disease.

(3) For prospective clinical studies proposing to use EHRs, it may be possible to modify the EHR system for the purpose of collecting additional patient data during routine care through an add-on module to the EHR system. However, given the limited ability to add modules to collect extensive additional information, EHR-based data collection may still not be comprehensive.

(4) Information regarding continuity of care depends on patients remaining within the specific health care system and engaging with the health care system for continuing care.

Prior use of the selected data source for research purposes (e.g., previous submissions to FDA by the sponsor or relevant examples in the published literature) should be described in the protocol. This description should include how well the selected data source has been shown to capture study variables (e.g., inclusion and exclusion criteria, exposures, outcomes, key covariates) and how the study variables can be validated for a particular research activity.

A. Relevance of the Data Source

There are differences in the practice of medicine around the world and between health care systems that may affect the relevance of the data source to the study question. Patients in different types of commercial or government health care payment programs can differ in a range of characteristics, such as age, socioeconomic status, health conditions, risk factors, and other potential confounders. Various factors in health care systems and insurance programs, such as patient out-of-pocket expenses, formulary decisions, and patient coverage, can influence the degree to which patients on a given therapy in one health care system might differ in disease severity, or other disease characteristics, from patients on the same therapy in another health care system. It is also important to identify whether the data sources cover all populations relevant to the study if those sources are to be used to address the study question. Differences in terminology and coding systems used in different health care systems should also be considered.

FDA recommends including the following in the protocol:

(1) The reason for selecting the particular data sources, and the time frame of data that are available, to address the specific study question.

(2) Relevant background information about the health care system(s), including (if available) any specified method of diagnosis and preferred treatments for the disease of interest, and

the degree to which such information is collected and validated in the proposed data sources.

(3) A description of any available information on prescribing and utilization practices (e.g., stepped therapy, prior authorizations, formulary restrictions) that may impact feasibility of the study in the data source or interpretation of study findings.

(4) A discussion on how factors relating to the health care system, including its practices, might affect the generalizability of the study findings from the selected data sources. When non-U.S. data sources are proposed, additional explanation (e.g., demographic factors, standard of care) should be provided to support the generalizability to the U.S. population.

B. Data Capture: General Discussion

A record in EHR systems or medical claims databases is generated only if there is an interaction of the patient with the health care system. Because EHRs and medical claims data are collected during routine care and not according to a prespecified research protocol, information needed to address certain questions in a proposed study may not be present in EHRs and medical claims data sources. Sponsors should demonstrate that the proposed data source(s) contain the detail and completeness needed to capture the study populations, exposures, key covariates, outcomes of interest, and other important parameters (e.g., time periods) that are relevant to the study question and design.

1. Enrollment and Comprehensive Capture of Care

The capture of patients' health care information in a medical claim or EHR data source depends on *continuity of coverage* (i.e., enrollment and disenrollment from the health insurance plan) and *continuity of care* (i.e., continuous interaction with the health care system). When using medical claims data sources, continuity of coverage should be addressed, given that patients often enroll and disenroll in different health plans when they experience changes in employment, or other life circumstances. When using EHR data sources, continuity of care should be discussed**,** specifically, whether patients receive all types of health care services within the same health system or network of facilities that contribute to the same EHR data source. The validity of findings from a study using these data depends in part on the documentation of the migration of patients into and out of health plans and health care systems. Such documentation allows for the identification of time periods during which data are and are not available on the patients of interest. Definitions of continuity of coverage and continuity of care should be developed and documented in the protocol. Of note, information on continuity of care may be difficult to accurately capture (e.g., data do not differentiate discontinuation of care and lack of encounters due to worsening or resolution of existing health conditions) and might need to be approximated in an EHR data source.

FDA recommends addressing the comprehensiveness of the data sources in capturing aspects of care and outcomes that are relevant to the study question. This information will help evaluate the likelihood that all exposures and outcomes of interest will be captured for

regulatory decision-making. For example, outpatient data sources that do not include hospitalization data would generally not be appropriate for studying outcomes likely to result in hospitalization. A second example is a study where an outcome is dependent on a specific frequency of laboratory tests, and clinicians do not typically order those tests at such a frequency.

FDA recommends specifying how all relevant populations, exposures, outcomes, and covariates will be captured during the study period, particularly in situations where data availability varies greatly over time. The data sources should contain adequate numbers of patients with adequate length of continuous follow-up to ascertain outcomes of interest based on the biologically plausible time frame when the outcome, if associated with the exposure, might be expected to occur. Information should be provided about the distribution of length of follow-up for patients in the data sources because the length of follow-up may inform whether the selected data sources are adequate or whether additional supportive data are needed to ascertain long latency outcomes.

In general, EHRs and medical claims data may not systematically capture the use of nonprescription drugs or drugs that are not reimbursed under health plans, episodes of medical tourism outside the U.S., or immunizations offered in the workplace, at pharmacies or public health clinics, or through government immunization programs. If these exposures are particularly relevant to the study question, the data source may not be suitable, or the protocol should describe how this information gap will be addressed (e.g., by building additional modules into the EHR system, linking, or collecting additional data).

Obtaining comprehensive drug coverage and medical care data on patients with certain types of privacy concerns (e.g., sexually transmitted infection, substance abuse, mental health conditions) can be challenging and failure to do so can result in incomplete or erroneous information. Patients with these conditions may receive treatment in federally qualified health centers, or in private clinics where an insurance claim may not be generated if self-payment is used. In addition, certain populations (e.g., patients with rare cancers) more often enroll in experimental clinical trials. In such cases, patients' health data may not be fully captured in electronic health care data. If these issues are relevant to the study question of interest, the protocol should describe how the issues will be addressed.

2. Data Linkage and Synthesis

Data linkages can be used to increase the amount of data available to capture the longitudinal patient journey, increase the amount of data available on individual patients, and provide additional data for validation purposes. If the study involves establishing new data linkages within the same data sources (e.g., mother-infant linkages) or across different data sources (e.g., vital records, disease and product registries, biobank data), the protocol should describe each data source, the information that will be obtained, linkage methods, and the accuracy and completeness of data linkages over time. Probabilistic and deterministic approaches to data linkage may result in different linkage quality, albeit both approaches can have value depending on the scenario. The deterministic approach for data linkage uses records that have an exact match to a unique or set of common identifiers. The probabilistic approach for data linkage uses less restrictive steps in which the linkage can be established by exact matching of

fewer identifiers or matching part of the information on the identifiers (e.g., the first several letters of a name) (Carreras et al., 2018). When a probabilistic approach is used, the analysis plan should include testing the impact of the degree of match and robustness of findings. In addition, if the study involves generating additional data (e.g., interviews, mail surveys, computerized or mobile-application questionnaires, measurements through digital health technologies), the protocol should describe the methods of data collection and the methods of integrating the collected data with the proposed EHRs or medical claims data.

For studies that require combining data from multiple data sources or study sites, FDA recommends demonstrating whether and how data from different sources can be obtained and integrated with acceptable sample size and quality, given the potential for heterogeneity in clinical and coding practices across data sources or systems.

Because patients typically visit multiple health care sites, especially in geographically contiguous areas, the inclusion of de-identified data from many sites creates the possibility that there will be multiple records from different health care sites for a single individual. The existence of multiple records of the same person in different sites can result in overcounts of a particular data measure or, alternatively, if some site records are not available, can result in a collection of patient histories that reflect only a fraction of the patient's total health care history. Specific attention to data curation[12] including individual level and population level linkages and understanding of many-to-one and 1:1 linkage is fundamental to assessing the appropriateness of a new data linkage. Even where multiple data sources are linked by a unique patient identifier or where the patient information is coming from only one data source, there still can be an issue with multiple records or duplicate records. FDA recommends considering and documenting the type of curation performed to address duplication or fragmentation issues and documenting approaches taken to address issues that cannot be fully rectified by curation. See section VI, Data Quality During Data Accrual, Curation, and Transformation into the Final Study-Specific Dataset.

3. Distributed Data Networks

Distributed data networks (or systems) of EHRs and medical claims data systems, often combined with the use of common data models (CDM), have been increasingly used for medical product safety surveillance and research purposes. A CDM standardizes a variety of electronic health care data sources into a common format to ensure interoperability across all sites providing data. The primary benefit of using a distributed network in which data from multiple sites are transformed into a single CDM, is the ability to execute an identical query (without any or substantial modifications) on multiple datasets. In some distributed data networks, queries can be run simultaneously at all network sites or at each site asynchronously, with results combined at a coordinating center for return to the end user. There are a number of the commonly used operational models employed by distributed data networks. Some networks are managed by a single business entity using a consistent EHR system or medical claims database structure and while data are maintained at many locations, they are structured and managed in a consistent manner (e.g., the U.S. Department of Veterans Affairs Veterans Health

[12] For the purposes of this guidance, data curation is the processing of source data through the application of standards for exchange, integration, sharing, and retrieval.

Administration). Another approach is a hybrid distributed model in which a subset of data from many remote sites is sent to a centralized repository that allows for research to be conducted on a combined dataset (e.g., U.S. Centers for Disease Control and Prevention's National Syndromic Surveillance System). A third commonly used approach is seen in networks of data systems with multiple owners and database structures, with data structured and managed differently from location to location (e.g., the member sites of FDA's Sentinel system). In this model, research queries are sent to the various network member sites and results returned to a central location for collation and reporting.

The latter type of networks, comprised of disparate data systems such as the Sentinel system, are facilitated by the use of CDMs. Networks using CDMs also typically provide tools and methodologies for analysis, a consistent level of data curation, unified QA/QC procedures, and periodic revision of the data model to incorporate new data concepts as needed. Additionally, methodologies have been developed that allow the ability to translate data from one CDM to another, however these involve additional data transformations,[13] which present added quality considerations. Data curation and transformation into a CDM, as well as general QA/QC procedures, are discussed in section VI, Data Quality During Data Accrual, Curation, and Transformation into the Final Study-Specific Dataset.

Distributed data networks are typically comprised of EHR, medical claim, or registry data. Nevertheless, combining many data sources, especially with the addition of data transformation into a CDM, adds a layer of complexity that should be considered. Because there are many different configurations of distributed health data networks, the configurations discussed in this guidance should not be considered comprehensive.

Transforming disparate database structures into a common health network with a CDM allows research across health care sites that would otherwise be more complex and costly. However, CDMs can introduce additional challenges to consider. Many CDMs, including those developed for FDA's Sentinel system, Biologics Effectiveness and Safety Initiative, and the National Patient-Centered Clinical Research Network, were created to satisfy a specific set of research purposes; the choice of data captured in a CDM is optimized for the types of data measures and detail needed for the intended use (e.g., Sentinel system for postmarket safety surveillance to inform regulatory decision-making, the National Patient-Centered Clinical Research Network for patient-centered outcomes research). Therefore, data in CDM-driven networks rarely contain all the source information present at the individual health care sites, and the data elements chosen for a given CDM network may not be sufficient for all research purposes or questions. Furthermore, CDMs often have many data elements within the model that are optional—that is, although the model has such data elements available to be filled with data, the individual sites can choose whether to put their original data into the optional fields.

Before using a CDM-driven network, data elements collected by the CDM should be considered—including whether needed data elements exist in the model and, if so, whether they are required or optional elements—to determine suitability for the study and whether identified deficiencies can be addressed by supplementing with customized study-specific data elements,

[13] For the purposes of this guidance, data transformation is the process of converting data from one format or structure into another format or structure.

collecting additional data, or using other data elements present in the dataset that are reasonable proxies for the missing information. It should be noted, however, that such workarounds involve additional considerations by the sponsor such as the work involved with validating proxy endpoints or any human subject research considerations that involve additional data. Suitability may also be improved with more flexible CDMs that are frequently expanded for new uses. For information on proxy variables, see section IV.C, Missing Data: General Considerations.

4. Computable Phenotypes

A computable phenotype identifies a clinical condition or characteristic using a computerized query to an EHR system or clinical data repository (including disease registries, claims data) using a defined set of data elements and logical expressions. Standardized computable phenotypes enable efficient selection of study populations and ascertainment of outcomes of interest or other study variables for large-scale clinical studies across multiple health care systems. A computable phenotype definition should include metadata and supporting information about the definition, its intended use, the clinical rationale or research justification for the definition, and data assessing validation in various health care settings (Richesson et al. 2016). The computable phenotype definition, composed of standardized and mapped data elements and phenotype algorithm, if applicable, should be described in the protocol and study report and should also be available in a computer-processable format. Clinical validation of the computable phenotype definition should be described in the protocol and study report. For additional information on validation, see section IV.D, Validation: General Considerations.

5. Unstructured Data

Although medical claims data are typically in structured fields, large amounts of key clinical data are unstructured data within EHRs, either as free text data fields (such as physician notes) or as other non-standardized information in computer documents (such as PDF-based radiology reports). To enhance the efficiency of data abstraction, a range of approaches, including both existing and emerging technologies and strategies, are increasingly being used to convert unstructured data into a computable format. More recent innovations include technology-enabled abstraction whereby software provides a mechanism for human data abstractors (e.g., tumor registrars) to do their work in a consistent and scalable fashion.

Technological advances in the field of artificial intelligence (AI) may permit more rapid processing of unstructured electronic health care data. AI is a branch of computer science, statistics, and engineering that uses algorithms or models to perform tasks and exhibit behaviors such as learning, making decisions, and making predictions.[14] Advances include natural language processing, machine learning, and particularly deep learning to: (1) extract data elements from unstructured text in EHRs; (2) develop computer algorithms that identify outcomes; or (3) evaluate images or laboratory results. FDA does not endorse any specific AI technology.

[14] See IMDRF/AIMD WG/N67 Machine Learning-enabled Medical Devices: Key Terms and Definitions, May 6, 2022.

All these methods are computer-assisted to various levels but require a significant amount of human-aided curation and decision-making, injecting an additional level of data variability and quality considerations into the final study-specific dataset. If the protocol proposes to use AI or other derivation methods, the protocol should specify the assumptions and parameters of the computer algorithms used, the data source from which the information was used to build the algorithm, whether the algorithm was supervised (i.e., using input and review by experts) or unsupervised, and the metrics associated with validation of the methods. Relevant impacts on data quality from use of AI or other computerized extraction methods should be documented in the protocol and analysis plan.

C. Missing Data: General Considerations

There are two broad scenarios in which information may be absent from data sources. The first scenario is when the information was intended to be collected (e.g., structured field present in EHRs), but is absent from the data sources. This is an example of traditional missing data.[15] The second case is when the information was not intended to be collected in EHRs and medical claims data and is therefore absent. The second scenario affects the relevance of the data source. Although both can have an impact on study validity, it is helpful to distinguish between these two scenarios and understand the reasons why information is present or absent in EHRs and medical claims. For example, lack of information about the result of a laboratory test could be caused by different circumstances: (1) the test might not have been ordered by the health care provider; (2) the test might have been ordered but not conducted; (3) the test might have been performed, but the result was not stored or captured in the data source; or (4) the test might have been performed and the result was stored in the data source, but data were not in an accessible format, or lost in the transformation and curation process when the final study-specific dataset was generated. Because providers might order a laboratory test based on a patient's characteristics, the decision not to order the test or a patient's decision to forgo the test may have implications on the data's fitness for use in a proposed study. An understanding of the reasons for missing data may help assess the impact of missing data on study findings.

As discussed above, data linkage is one way to address certain types of missing data. It may also be possible to identify a variable that is a proxy for the missing data. An example of a potential proxy variable includes maternal education as a proxy for socioeconomic status that often is an important confounder when evaluating child-health outcomes.

The protocol and the statistical analysis plan should be developed and based on an understanding of reasons for the presence and absence of information. Descriptive analyses should be included to characterize the missing data. Assumptions regarding the missing data (e.g., missing at random, missing not at random) underlying the statistical analysis for study endpoints and important covariates should be supported and the implications of missing data considered in the design and analysis of the study. Sensitivity analysis should be conducted to evaluate the robustness of findings.

[15] For the purposes of this guidance, missing data are data that would have been used in the study analysis but were not observed, collected, or accessible. This refers to information that is intended to be collected but is absent and information that is not intended to be collected and is therefore absent.

D. Validation: General Considerations

1. Conceptual and Operational Definitions of Study Variables

Studies using EHRs and medical claims data sources should include conceptual definitions for important study variables, including study population inclusion and exclusion criteria, exposure, outcome, and covariates. A conceptual definition should reflect current medical and scientific thinking regarding the variable of interest, such as: (1) clinical criteria to define a condition for population selection or as an outcome of interest or a covariate; or (2) measurement of drug intake to define an exposure of interest.

An operational definition should be developed based on the conceptual definition to extract the most complete and accurate data from the data source. In many studies using EHRs or medical claims data, the operational definition will be a code-based electronic algorithm using structured data elements. In other studies, the operational definition may be derived from extracting relevant information from unstructured data or constructing an algorithm that combines structured and unstructured data elements. Operational definitions can also specify additional data collection, such as a patient survey, when appropriate.

2. Selection of Study Variables for Validation

Given that operational definitions are usually imperfect and cannot accurately classify the variable of interest for every subject, a resulting misclassification can lead to false positives and false negatives (Table 1) and may bias the association between exposure and outcome in a certain direction and degree.[16] Misclassification may occur in any study variable (e.g., exposure, outcome, covariate). Understanding the implications of potential misclassification for study internal validity and study inference is the key step in determining what variables of interest might require validation and to what extent, based on the necessary level of certainty. For example, in a study to quantify a drug effect, internal validity should be optimized, and misclassification of key study variables should be minimized to accurately measure the association. Some misclassification might be tolerable in some studies when the presence of misclassification is not expected to change the interpretation of results (e.g., for signal detection, or when the hypothesized effect size is large and the impact of misclassification on the measure of association is deemed minimal).

To understand how potential misclassification of a variable of interest (e.g., exposure, outcome, covariate) might impact the measure of association and the interpretation of results, sponsors should consider: (1) the degree of misclassification; (2) differential versus non-differential misclassification (e.g., whether the degree of misclassification of an outcome may differ across treatment groups being compared); (3) dependent versus independent misclassification (e.g., correlated misclassifications of exposure and outcome when both are self-reported in the same

[16] For categorical variables, the performance of operational definitions can be measured by indices such as sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV). For continuous variables, indices may be based on the correlation with, or the pairwise comparison to, the reference standard. These measures inform the presence and degree of misclassification or measurement error of a variable that may in turn bias the study findings from the truth.

survey); and (4) the direction toward which the association between exposure and outcome might be biased.

3. Validation Approaches

Validation refers to the process of determining if a study variable (e.g., exposure, outcome, covariate) is correctly measured, usually according to a reference standard (Porta, 2014). Examples of validation approaches include: (1) complete verification[17] of a key study variable for all subjects; (2) verification of a study variable for all those identified by an operational definition as positive (e.g., all those identified as exposed for exposure status, or all those identified as a case for outcome status), or as negative (e.g., all those identified as unexposed for exposure status, or all those identified as a non-case for outcome status, but not necessarily all subjects; or (3) assessing the performance of an operational definition (e.g., internally in a sample of the study population for the proposed study, or externally in a prior study). The extent of effort required for validation depends on the necessary level of certainty and the implication of potential misclassification on study inference. Although complete verification of a study variable is considered the most rigorous approach, there are scenarios where verifying a key study variable for every subject might not be feasible (e.g., a very large study population, lack of reference standard[18] data for all study subjects) and assessing the performance of the variable's operational definition might suffice. Based on the performance measures described in Table 1, sponsors should consider whether validating the variable to a greater extent (e.g., all positives classified by the operational definition) is necessary and discuss options with the relevant review division.

Because the performance of an operational definition is dependent on various factors, such as data source, study population, study time frame, and choice of reference standard, FDA recommends assessing the performance of operational definitions in an adequately large and representative sample of the study population as part of the proposed study, using justified sampling methods (e.g., random sampling, stratified sampling). If sponsors propose to use an operational definition that has been assessed in a prior study, ideally, those definitions should have been assessed using the same data source and in a similar study population as the proposed study. In addition, secular trends in disease, diagnosis, and coding may necessitate assessment of the operational definition using more recent data. The quality of prior studies used to establish sensitivity, specificity, and predictive values should always be evaluated.

Choice of a reference standard may vary by study design and question, variable of interest, and the necessary level of certainty. For example, subject matter experts' review of medical records (including structured and unstructured data) may be a preferred reference standard for validation of clinical events identified by diagnosis codes or automated algorithms, or drug intake diary may be

[17] For the purposes of this guidance, complete verification involves assigning an accurate value to the variable of interest for each study subject based on a reference standard of choice. For example, medical record review can be used in conjunction with a conceptual definition to determine whether a subject meets a critical inclusion criterion or has experienced the outcome event (adjudication may be involved in this process).

[18] For the purposes of this guidance, reference standard is the best available benchmark, also referred to as a *gold standard*. When a gold standard is not clearly identified, validation may indicate concordance between methods assessed by a Kappa statistic, precent agreement, or other indices.

used to assess the validity of medication exposures identified in pharmacy dispensing data. Other examples may include broadly accepted external reference data sources, such as national or state vital statistics data sources, if appropriate. Sometimes the reference standard of choice itself may have important limitations and not be entirely valid, in which case caution should be used when interpreting validation results.

The protocol should include a detailed description of the planned validation, including justification for the choice of a validation approach, reference standard, methods, processes, and sampling strategy (if applicable). If a previously assessed operational definition is proposed, additional information should be provided, including in what data source and study population and during what time frame the assessment was conducted, the value of the assessed performance measures, and a discussion of whether the performance measures are applicable to the proposed study. FDA also recommends using quantitative approaches, such as quantitative bias analyses, either *a priori* for feasibility assessment, or to facilitate interpretation of study results, or for both purposes, to demonstrate whether and how misclassification, if present, might impact study findings. The protocol should pre-specify the indices (e.g., sensitivity, specificity) that will be used for quantifying bias and describe how the selected indices will be measured during validation.

For further discussion about the validation of study design elements, see section V.C.5, Validation of Exposure; section V.D.3, Validation of Outcomes; and section V.E.3, Validation of Confounders and Effect Modifiers.

Table 1: Schematic Representation of the Calculation of Sensitivity, Specificity, Positive Predictive Value (PPV), and Negative Predictive Value (NPV) for a Binary Variable

Condition based on proposed operational definition	Condition based on reference standard: Yes	Condition based on reference standard: No	Total	
Yes	a (true positive)	b (false positive)	a+b	PPV = a/(a+b)
No	c (false negative)	d (true negative)	c+d	NPV = d/(c+d)
Total	a+c	b+d	N	
	Sensitivity = a/(a+c)	Specificity = d/(b+d)		

V. STUDY DESIGN ELEMENTS

The ascertainment and validation of study design elements are discussed in detail below. The study questions of interest should be established first, and then the data source and study design most appropriate for addressing these questions should be determined. The study should not be

designed to fit a specific data source, because the limitations of a specific data source may restrict the options for study design and limit the inferences that can be drawn.

A. Definition of Time Periods

FDA recommends clearly defining the various time periods pertinent to the study design in the protocol (e.g., time periods for identifying study population, defining inclusion and exclusion criteria, assessing exposure, assessing outcome, assessing covariates, following up with patients, "washout" time period if applicable). The focus of the time scale (e.g., calendar time, age, time since exposure) should be explicitly described with adequate detail on data availability of the time unit (e.g., year, month, day, hour, minute) required to answer the study question.

The protocol should demonstrate the data availability, accuracy, and completeness for the proposed time periods and the potential impact on study validity. For example, justification should be provided regarding how data for the time period before exposure are adequate for identifying the study population and the important baseline covariates, or for the follow-up period to consider the biologically plausible time frame when the outcome (e.g., long latency events), if associated with the exposure, might be expected to occur. When the proposed outcome definition distinguishes disease onset (e.g., early symptoms) from a confirmed diagnosis, justification should be provided regarding whether the timing of disease onset can be accurately captured (e.g., for an insidious disease). In addition, when the study design involves time-varying covariates, description should be provided regarding the data availability of the time unit to capture the changes of the variable of interest (e.g., age in month as a time-varying covariate in a study among infants). The protocol should also address potential temporal changes in the standard of care, the availability of other treatments, diagnosis criteria, and any other relevant factors that are pertinent to the accuracy and completeness of data for study variables. For example, healthcare avoidance or limited access to healthcare during a pandemic may adversely impact the assessment of patients' underlying conditions for studies using RWD during or after the pandemic. Other relevant factors may include payer or provider policies (if known), such as formulary changes, step therapy, and laboratory assay changes. Before developing the study approach, sponsors should discuss with the relevant FDA review division the capability of data to capture such potential temporal changes and the impact of the potential temporal changes on internal validity.

B. Selection of Study Population

The protocol should include a detailed description of methods for determining how inclusion and exclusion criteria (e.g., demographic factors, medical condition, disease status, severity, biomarkers) will be implemented to identify appropriate patients meeting these criteria from the data source. The protocol should include a detailed description of operational definitions for inclusion and exclusion criteria to identify the eligible study population from the data source. The identification of the study population may rely on information recorded in multiple data fields such as diagnosis and procedure codes (e.g., International Classification of Diseases (ICD)-9-CM, ICD-10), laboratory tests (e.g., Logical Observation Identifier Names and Codes (LOINC)) and values, or unstructured data (e.g., physician's encounter notes, radiology and

pathology reports). The protocol should address the accuracy and completeness of the information collected in the proposed data source to fulfill the inclusion and exclusion criteria.

Operational definitions of key inclusion and exclusion criteria used to select the study population should be validated. As one example, to assess the drug effect in patients with immune thrombocytopenic purpura, the disorder ascertained by operational definition ICD-9-CM diagnosis code 287.31 or ICD-10 code D69.3 should be validated based on the conceptual definition of the disorder, which includes signs and symptoms, levels of platelets, and exclusion of other possible causes of thrombocytopenia.

In certain circumstances, key inclusion and exclusion criteria (e.g., gestational age for pregnancy studies) may be generated by the information recorded at the point of care by the health care providers. For example, health care providers may enter the calculated gestational age in EHRs based on patient self-reported last menstrual period, ultrasound dating, and other relevant information. If such data are used, the protocol should describe the source of information and the methods health care providers use to generate the data (if known).

FDA also recommends including quantitative approaches, such as quantitative bias analyses, in the protocol to demonstrate whether and how misclassification of inclusion and exclusion criteria, if present, might impact study findings. The approach can be applied *a priori* for feasibility assessment, to facilitate interpretation of study results, or for both purposes. The protocol should pre-specify the indices (e.g., sensitivity, specificity) that will be used for quantifying bias and describe how the selected indices will be measured in key inclusion/exclusion criteria validation.

C. Exposure Ascertainment and Validation

Considerations discussed in this section regarding exposure ascertainment in EHRs or medical claims data primarily apply to noninterventional studies, given that the assignment of exposure is documented in interventional studies.

1. Definition of Exposure

For the purposes of this guidance, the term *exposure* applies to the medical product or regimen of interest being evaluated in the proposed study. The product of interest is referred to as *the treatment*, and may be compared to no treatment, a placebo, standard of care, another treatment, or a combination of the above. Other variables that could affect the study outcome are considered covariates and are discussed in section V.E, Covariate Ascertainment and Validation. The exposure definition should include information about the drug dose, formulation, strength, route, timing, frequency, and duration of use for the product studied (if relevant). It may also be necessary to describe the specific manufacturer of a product (e.g., when a proper name for a vaccine is used by different manufacturers).

The description of exposure should include the intended or prescribed use of the product (e.g., the number, frequency, route of administration, and specific doses), the period between initiation of exposure and the earliest time one might reasonably expect to see an effect, and the expected duration of effect. This will usually require an understanding of the pharmacological properties

(e.g., half-life) and mechanism of action of the drug —for example, that a onetime infusion to prevent osteoporosis may have an effect for several months. See section V.C.3, Ascertainment of Exposure: Duration, and section V.C.4, Ascertainment of Exposure: Dose.

2. Ascertainment of Exposure: Data Source

Sponsors should be able to demonstrate an ability to identify the specific products of interest in the proposed data source, demonstrating that the data source contains data fields and codes that allow identification of the specific products of interest (e.g., through specific coding). For example, it is not always possible to infer a specific vaccine formulation from the billing or diagnostic code alone, such as in systems where a single billing code is used for multiple vaccines. The protocol should describe the coding system used, the level of granularity represented (e.g., using RxNorm concept unique identifiers (CUIs) mapped to the National Drug Code [NDC] codes), and the specificity attained by the coding system.

When relying on coded data, the operational exposure definitions should be based on the coding system of the selected data source and reflect an understanding of the prescription, delivery, and reimbursement characteristics of the drug (if applicable) in that data source over time. For example, in the United States, the operational definition should include the appropriate pharmacy codes (NDC or Healthcare Common Procedure Coding System (HCPCS) or other applicable codes) to capture the use of the drug in various settings. This approach is particularly important in the case of non-oral drugs that may be assigned different codes depending on how they are obtained. For example, patients using an injectable drug can obtain it from the pharmacy, in which case the NDC code would be recorded, or it can be administered by the provider, in which case the drug and its administration would be recorded using the HCPCS J code.[19]

It is also essential to report operational definitions and methods when combining information from unstructured and structured data. Emerging methods may involve review of unstructured information in medical records combined with pharmacy dispensing and physician prescribing data and notes to provide an assessment of whether a person was prescribed and received the medication of interest, as well as whether there are problems with the patient continuing the medication. An example of such methods is found in ascertainment of aspirin exposure in a retrospective cohort study of veterans undergoing usual care colonoscopy (Bustamante et al. 2019).

When using a medical claims data source, it is important to consider that there could be dispensed prescriptions that were not associated with insurance claims if these uncaptured prescriptions are relevant exposures for the study. Uncaptured prescriptions might include low-cost generic drugs, drugs obtained through discount programs, samples provided by pharmaceutical companies and dispensed by health care providers, and drugs sold via the internet or patient out-of-pocket purchases. An individual can seek care outside of the healthcare system(s), and exposure to medication prescribed by out-of-system providers would not be captured in the EHR. Lastly, nonprescription drugs and dietary supplements are not generally

[19] A drug's J code is a Healthcare Common Procedure Coding System (HCPCS) Level II code used in medical claims to report injectable drugs that ordinarily cannot be self-administered; chemotherapy, immunosuppressive drugs, and inhalation solutions; and some orally administered drugs.

captured, nor well-captured in electronic health care databases. It is important to address the likelihood of incomplete exposure ascertainment and its effect on study validity, see section V.C.5, Validation of Exposure.

3. Ascertainment of Exposure: Duration

The data source should capture the relevant exposure duration (anticipated use of a product over time). Given that some medical products are designed as onetime exposures (e.g., vaccines), and other products may be intended for use over extended periods of time, the suitability of a data source will vary with the specific medical product under investigation or the medical conditions the product is intended to treat (e.g., acute versus chronic conditions, treated daily versus as needed, or prophylaxis versus active treatment). FDA recommends describing the duration of exposure as well as the period during which the exposure is having its effect relative to the outcome of interest. Duration may refer to continuous exposure or cumulative exposure, depending on the study question. For some products, an immediate or near-immediate effect is expected; for other products, an effect is expected after a time interval (e.g., drugs that promote bone strength). FDA recommends considering the duration of continued drug effect after treatment discontinuation to include the entire period in which the drug effect may occur. For example, a vaccine effect may persist for years after vaccination, and persons might be considered exposed during that period. On the other hand, an anticoagulant's effects may not extend beyond several hours or days. FDA also recommends justifying the units (e.g., hours, days) selected for estimating the duration of exposure and ensuring the data are available in those units.

Because patients may not refill their prescriptions exactly on time or, alternatively, may refill their prescriptions early, gaps or stockpiling in therapy may exist and may be reflected in the dispensing medical claims data.[20] FDA recommends describing and justifying in the protocol how the study will measure use, address potential gaps in therapy in the data source, and handle refill stockpiling if there are early refills. Intermittent therapies (e.g., drugs used to treat pain on an as-needed basis) and therapies for which samples are often provided to patients (e.g., expensive drugs, drugs that are new to the market) present challenges in accurately assessing the actual exposure and duration of exposure, see section V.C.5, Validation of Exposure

4. Ascertainment of Exposure: Dose

Data about exposure should include information about dosing regimen (e.g., strength, dosing frequency, route of administration). Depending on the exposure and the question of interest in the study, it may be useful to describe the dose of each administration or a daily dose, as well as an estimated cumulative dose (i.e., the total amount of the drug of interest given to a patient over a specified period of time).

It is reasonable to begin with the dose information provided in the data source, and then discuss in the protocol or study report the specific assumptions made when estimating the dose of the exposures of interest, especially for pediatric patients. See section V.C.6, Dosing in Specific Populations. In addition to the dosing regimen, the data source should provide detailed and

[20] This guidance does not address issues related to medication adherence.

complete drug description information, including dosage formulation (e.g., oral solution versus injectable solution) to determine a patient's total daily dose, especially if the product has multiple formulations available.

5. Validation of Exposure

Other than for medications administered in hospital settings or infusion settings, electronic health care data capture prescriptions of drugs and the dispensing of drugs to patients, but generally do not capture actual patient drug exposure or dose consumption because this depends on patients obtaining and using the therapy as prescribed. Additionally, medical claims data do not capture dose adjustment of an existing treatment if the provider instructs patients in a clinic visit or by phone to adjust the dose without writing a new prescription. Dose adjustment for an existing treatment can be missed in the EHRs if the change was not noted in the patient's record.

Validation ideally involves a comparison of the exposure classification in the proposed data source with a reference data source,[21] and produces estimates of misclassification that can be used in qualitative or quantitative assessments of the impact on study validity. Validation might begin with defining the conceptual and operational definitions. For example, to define new use of drug X in a particular study, the conceptual definition may be "initiation of drug X and no exposure to drug X in the past 365 days," and the operational definition would be "at least one outpatient prescription claim for drug X (identified by NDC code xxx), and no claims for drug X in 365 days before the dispensing date of the prescription." For prescribed medications used in outpatient settings, dispensing or billing data would tend to be more accurate than most EHRs in reflecting exposure to a drug by documenting that the prescriptions were filled. In such cases, validation of EHRs prescribing data by examining medical claims data may be warranted. For drugs administered in the health care setting (e.g., vaccines, injectables, blood products), administration recorded in the EHRs may provide more complete information than is available in medical claims records. In these cases, it may be useful to validate medical claims data by examining the EHRs. In certain situations, when reference data sources are not available, additional studies conducted in the same population or published in the literature can provide estimates of potential misclassification of exposure status (e.g., survey of study participants to assess intake of drug, published reports of numbers of people obtaining vaccinations through pharmacies/workplaces/schools).

FDA recommends documenting the methods used to calculate and validate duration, dose, product switching, and other characteristics of exposure. Validation and misclassification issues should be addressed in appropriate study documents. FDA also recommends including in the protocol quantitative approaches, such as quantitative bias analyses, to demonstrate whether and how exposure misclassification, if present, might impact study findings. The approach can be applied *a priori* for feasibility assessment, to facilitate interpretation of study results, or for both purposes. The protocol should pre-specify the indices (e.g., sensitivity, specificity) that will be used for quantifying bias and describe how the selected indices will be measured in exposure validation.

[21] In certain cases, the RWD source may be the only reference. For example, if exposure is defined by whether the patient paid for the prescription, medical claims data may be used, and this information will be the reference source.

6. Dosing in Specific Populations

In addition to reporting validated information about the dose prescribed, dispensed, or administered, additional information may be necessary to permit an assessment of whether dosing was appropriate for specific populations (e.g., if there was significant underdosing or overdosing). For example, for patients with compromised renal function, it may be necessary to have access to measurements of serum creatinine, creatinine clearance, or estimated glomerular filtration rate to determine whether the recommended dose based on product labeling was used. Another example is when assessing exposure in pediatric populations where it may be necessary to obtain the patient's weight and describe the dose within weight categories. The need for additional data to permit appropriate assessment of dosing may occur more frequently with claims data, but can also occur when using EHRs, if necessary, data are absent.

7. Other Considerations

The patients providing comparator data should be defined clearly and with adequate detail in the protocol. The protocol should discuss the reasoning for selecting the: (1) source of comparator data; and (2) the time period (if the comparator group is not concurrent with the treatment group). Because a comparator agent may differ from the product of interest in specific indication within a disease, contraindication, safety profile, or user's disease severity or comorbidity, as well as other patient, physician, and healthcare system characteristics (e.g., timing of exposure relative to the onset of disease, disease status, prior treatment, patient's socioeconomic status, physician's prescribing behavior, drug availability and treatment guideline based upon particular healthcare system, etc.), it is important to ensure adequate data are available for FDA to assess the comparability of the exposed and comparator populations.

Relevant concomitant medication use (e.g., combination therapy components, standard of care therapy, etc.) should be described and ascertained from the data source. A study's definition of concomitant medication use should be described in detail. Definitions of concomitant medication use might include instances when drugs are dispensed on the same day, when drugs have overlapping days' supply, or when patients have filled prescriptions for two or more drugs during the study period. Limitations to ascertainment of concomitant drugs (e.g., nonprescription drugs) should also be described.

D. Outcome Ascertainment and Validation

A crucial step in selecting a data source is determining whether it captures the clinical outcome of interest. Because electronic health care data typically capture outcomes that are brought to the attention of a health care professional and documented in the medical record, outcomes representing mild symptoms or events occurring outside of medical care (e.g., out-of-hospital death) will not generally be well-captured. Conversely, discrete outcomes or acute events (e.g., stroke, myocardial infarction, new infection) are more likely to be captured than worsening of existing problems (e.g., depression, psoriasis, arthritis) that may not be discerned by a new diagnosis code. In general, the likelihood of capturing outcomes may vary by disease type and the extent to which the patient has ongoing encounters with health care professionals that could lead to additional information being documented in medical records. Unlike traditional clinical

trials, studies exclusively using electronic health care data to ascertain outcomes likely do not have protocol-defined follow-up visits and may not have monitoring of events at intervals necessary for outcome ascertainment; further, the severity of disease and responses to treatment may impact the frequency of follow-up visits, and hence the data available. In addition, the assessment of the outcome of interest is likely more standardized and comprehensive in traditional clinical trials. Therefore, the availability, accuracy, and completeness of data on the outcome of interest as well as the need for external data linkage should be carefully considered. Whether and to what degree a data source captures the outcome of interest should be assessed before study initiation and be independent of the exposure of interest.

1. Definition of Outcomes of Interest

Many outcomes involve diagnoses recorded by physicians as part of routine care. To minimize the effect of variability in practice by different physicians and over time (e.g., using different diagnosis and classification criteria, coding the same event in different ways), FDA recommends defining an outcome of interest based on the clinical, biological, psychological, and functional concepts of the condition, as appropriate. The conceptual definition for the outcome of interest (also referred to as the *case definition*) should reflect the medical and scientific understanding of the condition and might vary by study. For example, for anaphylaxis, the conceptual definition (or case definition) may include the following clinical criteria: sudden onset, rapid progression of signs and symptoms, ≥1 major dermatological criterion, and ≥ 1 major cardiovascular or respiratory criterion. The protocol should include a detailed description of the conceptual definition, including the signs, symptoms, and laboratory and radiology results that would confirm the outcome status.

Conceptual definitions should be able to be operationalized in RWD sources. For example, randomized controlled trials in oncology typically use tumor-based outcomes of interest in the setting of specific timing and frequency of follow-up assessment and often include molecular or other biomarker testing that may not be standard of care in all clinical practice settings. Since achievement of an objective response (tumor shrinkage), or the date of tumor progression based on standardized clinical trial criteria (e.g., RECIST 1.1) is not typically captured in RWD sources, proxy measures or multi-component definitions may need to be explored and their use justified. As mentioned above, it is more feasible to capture outcomes that have well-defined diagnostic criteria that are likely to be consistently captured in RWD. Sponsors should discuss the proposed outcomes definitions and the appropriateness of proxy measures with the FDA review division.

2. Ascertainment of Outcomes

To help identify potential cases in the selected data source and study population, operational definitions using diagnosis and procedure codes (e.g., ICD-9-CM, ICD-10), laboratory tests (e.g., LOINC) and values, or unstructured data (e.g., physician's encounter notes, radiology and pathology reports) should be developed based on the conceptual definition of the outcome of interest. If the operational definition includes information abstracted from unstructured data in the EHRs or another data source (e.g., mention of spina bifida in birth certificate records for the identification of neural tube defects in infants), the protocol should provide a detailed description

and rationale for the methods and tools used to process the unstructured data and the validation of those methods. See section IV.B.5, Unstructured Data, for additional information on unstructured data. When patient- or physician-generated data (e.g., data required for subjective end points) are proposed to assess the outcome of interest or to complement operational definitions, the protocol should specify how the outcome measure (e.g., sign score, severity index) will be defined and constructed and validated, if applicable, and how the data will be collected.

The sensitivity and specificity of an operational definition may both be reduced when there is outcome misclassification. Given that it is usually not possible for sensitivity and specificity to be perfect (i.e., 100%), outcome misclassification might result in both false positives and false negatives. FDA recommends considering the potential impact of outcome misclassification on study validity and inference when developing or selecting an operational definition for the proposed study. For example, when studying infrequently occurring outcomes in a cohort study, given the low prevalence of the outcome event, it is important to achieve high specificity to minimize false positive cases and high sensitivity so that more true cases can be captured. If the study is designed to estimate a risk ratio, selecting an operational definition with high specificity may be more important than high sensitivity, because imperfect sensitivity (some false negatives) may not bias the risk ratio, provided the outcome misclassification is non-differential and specificity is very high (almost no false positives), regardless of outcome prevalence. Thus, focusing on very high specificity in this scenario will help ensure the study result is correct even if data are imperfect, while high sensitivity is still important to ensure the precision of the estimates.

Operational definitions developed for one data source or study population might not perform as well in other sources or populations, due to database-specific sensitivity and specificity as well as variable disease prevalence. PPV and NPV are functions of sensitivity and specificity as well as prevalence of the outcome in the population in which the predictive values are measured. Therefore, PPV and NPV are variable by data source and study population characteristics (e.g., demographic factors, underlying diseases, comorbidities, clinical settings).

The protocol should include a detailed description of the operational definition, the coding system, the rationale, and associated limitations of information selected to construct the operational definition (e.g., selection of primary or secondary diagnosis codes for which the order may not correspond to their medical importance), and the potential impact on outcome misclassification. If the performance of the operational definition has been assessed in prior studies, the applicability to the proposed study should be discussed. Furthermore, because the case definition used in prior studies to establish sensitivity, specificity, and predictive values might include different diagnostic criteria from the conceptual definition developed for the proposed study, proper use of the performance measures assessed in prior studies should be carefully considered.

3. Validation of Outcomes

FDA expects validation of the outcome variable to address outcome misclassification. The extent of validation, such as complete verification of the outcome variable for all subjects, verification

of all potential cases (or non-cases) identified by an operational definition, or assessing the performance of an operational definition depends on the necessary level of certainty and the implication of potential misclassification on study inference.

Although complete verification of the outcome variable is considered the most rigorous approach, there are scenarios where verifying outcome for every subject might not be feasible and assessing the performance of the operational definition of the outcome might suffice. Outcome validation involves using a clinically appropriate conceptual outcome definition to determine whether a patient's status, classified by an operational definition, truly represents the outcome of interest, typically by reviewing clinical details recorded in the patient's medical records in either electronic or paper format.

FDA recommends using standardized medical record review processes, including the use of standardized tools, documentation of process, and training of personnel. A standard and reproducible process is critical for minimizing intra- and inter-rater variability, especially for multi-site studies in which medical records usually cannot be shared across systems and a centralized medical record review is not possible. Even with a centralized medical record review, a standardized process helps to ensure that the same criteria are applied by different adjudicators or a single adjudicator over time. Reporting of comparison metrics (e.g., kappa statistic) is useful to ensure replicability. An estimated medical record retrieval rate (e.g., when requesting medical records from health facilities for a study using claims-based databases) should be justified in the protocol, and the implications for internal and external validity should be discussed. In addition, because knowledge of a patient's exposure status may influence the observer and result in differential misclassification, blinding of the abstractor and adjudicator to exposure status should be considered by masking the study question or redacting the exposure information, especially when the abstractor or adjudicator may associate the exposure with the outcome of interest. The protocol should provide a description of how observer bias will be handled.

Ideally, through complete verification of the outcome variable, the outcome status is accurately classified for each subject to minimize outcome misclassification and improve study internal validity. In practice, a more commonly used approach is to assess the performance of an operational definition in validation studies. Performance measures, such as sensitivity, specificity, and predictive values, do not accurately classify cases and non-cases; rather, they inform the degree of outcome misclassification and facilitate the interpretation of results in the presence of misclassification.

PPV is often assessed in validation studies. PPV is the proportion of potential cases identified by an operational definition that are true positive cases. Therefore, PPV informs the degree to which false-positive cases are included among the identified cases. When the concern with false negative cases is negligible (e.g., when the sensitivity is deemed sufficiently high so that the number of false-negative cases is minimal), a high PPV might be adequate to provide confidence in the validity of the outcome variable, whereas a moderate-to-low PPV might warrant verification of the outcome variable for all potential cases. When the extent of false-positive cases and the extent of false-negative cases are both of concern, sponsors should consider assessing all performance measures needed for quantitative bias analysis to evaluate the impact of outcome misclassification on the measure of association or take a more rigorous

approach by validating the outcome variable for all potential cases and non-cases to accurately classify the outcome variable for each subject. Overall, the required extent of validation should be determined by the necessary level of certainty and the implication of potential misclassification on study inference.

In general, sponsors should consider the tradeoff between false-positive and false-negative cases when selecting an operational definition and identify the proper outcome validation approach to support internal validity. For example, to identify neural tube defects in infants, an operational definition that includes a spectrum of inpatient and outpatient diagnosis codes might have a high sensitivity, low specificity, and low PPV; restricting the operational definition to inpatient diagnosis codes only or a combination of diagnosis and procedure (e.g., surgical repair) codes might increase the PPV but miss a substantial proportion of true cases (low sensitivity). Because missing true cases is particularly a concern for infrequently reported outcomes, one approach is to select an operational definition of high sensitivity and perform verification of the outcome variable for all potential cases identified by the sensitive operational definition to maximize the likelihood that the true cases are all identified and that the false-positive cases are minimized through validation. Unlike rare disease outcomes, when an outcome of interest involves a more common event (e.g., disease-specific hospitalization) or improvement or worsening of a condition, the operational definitions for common diagnoses are likely to generate false-positive and false-negative cases to a considerable extent because both true cases and true non-cases are prevalent. Therefore, it might be difficult to obtain accurate and complete information (e.g., laboratory test results, functional measures) for the operational definition to accurately classify cases and non-cases. For such outcomes, measuring PPV alone will be inadequate to inform outcome misclassification.

In scenarios where complete verification of the outcome variable for each study subject is infeasible, the performance of an operational outcome definition should be assessed in the proposed study population using a justified sampling strategy. As stated earlier, use of an operational definition that has been assessed in a prior study should ideally be in the same data source and in a similar study population, because the performance of an operational definition may vary substantially by data source and study scenario, and more recent data may be needed if there are secular trends in disease, diagnosis, and coding. The quality of prior studies used to establish sensitivity, specificity, and predictive values should be evaluated. In particular, the case definition used in the prior study to establish these measures should be compatible with the conceptual outcome definition developed for the proposed study. The applicability of these measures to the proposed study should be justified, and sensitivity analyses can be considered.

Without complete patient information and complete verification of the outcome variable, outcome misclassification remains a threat to the study internal validity, and the impact on the measure of association between exposure and outcome varies depending on whether the degree of misclassification differs between the exposure groups. Differential misclassification involves a complex interplay of differences in sensitivity, specificity, and disease prevalence between the exposure groups, and thus may bias the association either toward or away from the null.[22] Because it is difficult to predict the direction of the bias, differential misclassification is a concern for both safety and effectiveness studies. Unlike differential misclassification, non-

[22] Null refers to no association between exposure and outcome of interest.

differential misclassification tends to bias the association toward the null; as a result, a true risk might be missed in safety studies, whereas a larger study population might be needed to demonstrate the drug effect in effectiveness studies.

Non-differential outcome misclassification might occur when the outcome definition is not adequately refined and includes conditions that have different magnitude of association with the exposure of interest. For example, neural tube defects include primary neurulation defects and post-neurulation defects. Primary neurulation defects are directly attributed to failure of primary neurulation (i.e., neural tube closure), which occurs between approximately 18 and 28 days after fertilization. The pathophysiology of post-neurulation defects is less understood. Therefore, drug exposure during the critical period for primary neurulation in gestation might not affect post-neurulation in the same manner. When the outcome definition includes both primary and post-neurulation defects, the risk of primary neurulation defects, if any, is likely not detected.

Differential outcome misclassification might be minimized in studies in which the exposure status is blinded. However, even when data collection methods seem to preclude the likelihood of differential outcome misclassification, it is not guaranteed that the only misclassification of the actual data will be non-differential outcome misclassification. For example, the physician who observed, diagnosed, and documented whether or not an outcome occurred could have been the same physician who made a decision as to which patients received the treatment meant to prevent that outcome, or the physician could have monitored disease progression or treatment side effects differently, given the knowledge as to which treatment they received. Therefore, the direction of the outcome misclassification might remain unpredictable when using RWD. In addition, when more than one misclassification exists in a study, sponsors should consider how they might be related to each other. For example, whereas non-differential exposure misclassification and non-differential outcome misclassification each might bias the association toward the null, when the two misclassifications are dependent, overall it can create a bias away from the null (Lash et al. 2009). Therefore, when evaluating the implication of potential misclassification on study inference, sponsors should consider how the individual non-differential misclassifications are interrelated, rather than assuming that the association is biased toward the null. Under such circumstances, assessing the performance of the operational outcome definition according to exposure status in the proposed study population might be necessary.

Regarding outcome validation, sponsors should justify the proposed validation approach, such as verifying the outcome variable for all potential cases or non-cases, versus assessing the performance of the proposed operational definition; if the latter will be done, justify what performance measures will be assessed. The protocol should include a detailed description of the outcome validation design, methods, and processes, as well as sampling strategy (if applicable). If a previously assessed operational definition is proposed, additional information should be provided, including: (1) data source and study population; (2) during what time frame validation was performed; (3) performance characteristics; (4) the reference standard against which the performance was assessed; and (5) a discussion of whether prior validation data are applicable to the proposed study.

FDA recommends including in the protocol quantitative approaches, such as quantitative bias analyses, to demonstrate whether and how outcome misclassification, if present, might impact study findings. The approach can be applied *a priori* for feasibility assessment, to facilitate interpretation of study results, or for both purposes. The protocol should pre-specify the indices (e.g., sensitivity, specificity) that will be used for quantifying bias and describe how the selected indices will be measured in outcome validation.

4. Mortality as an Outcome

In the United States, death and cause of death are generally not included in electronic health care data, with exceptions being made for death occurring while a patient is under medical care. Ascertainment of death (fact of death and cause of death) can be accomplished through linkage with public or commercial vital statistics data sources, to increase the completeness and recency of the death variables. The use of external mortality data, however, is subject to all of the limitations of such data and data linkage methods (Haynes 2019; Navar et al. 2019; Curtis et al. 2018). Careful documentation of mortality data quality and its implications should be included in the protocol.

If the death is not captured in the electronic health care data systems, patients who die after having been exposed to the study drug might be observed in electronic health care data as either not filing any further medical claims or not receiving any additional care past a particular date. For studies in which the outcome or outcomes of interest (e.g., myocardial infarction or stroke) include fatal outcomes, either excluding patients who appear to be lost to follow-up at any time following their exposure to the study drug or classifying patients who are lost to follow-up as deceased in the absence of data to the contrary, is likely to create bias. Searches of vital statistics systems may be considered to see whether their absence (disenrollment) from the system is because of death.

E. Covariate Ascertainment and Validation

For the purposes of this guidance, covariates in a particular study can include two types of elements: confounders and effect modifiers.

1. Confounders

Information on potential confounders is collected in a nonrandomized study to support appropriate efforts to balance treatment and comparator groups in the analysis.

After identifying the potential confounders in a study, the proposed data source should be evaluated to determine whether it is adequate to capture information on important factors which may contribute to confounding. These include confounders that are well-captured in the proposed data source (measured confounders) and those that are not well-captured (unmeasured or imperfectly measured confounders). Examples of confounders that can be unmeasured or imperfectly measured in electronic health care data, especially in claims data, include race/ethnicity, family history of disease, lifestyle factors (e.g., smoking, alcohol use, nutrition intake, physical activity), certain physical measurements (e.g., body mass index), drugs obtained

without insurance, and indication for drug use. FDA recommends considering potential linkages with other data sources or additional data collection to expand the capture of important confounders that are unmeasured or imperfectly measured in the original data source. The protocol should clearly disclose all known unmeasured confounders in the proposed data source(s), as well as approach(es) to supplement information on unmeasured confounders and justify the appropriateness of any proxy measure(s) for specific unmeasured confounder(s).

2. Effect Modifiers

Studies of drug effectiveness or safety usually report an average treatment effect, even though the same treatment can have different effects in different groups of people. Information on potential effect modifiers is used to better understand heterogeneity of treatment effect, the nonrandom, explainable variability in the direction and magnitude of treatment effects for individuals within a population (Velentgas et al. 2013). The potential for effect modification by demographic variables (e.g., age, sex, race, ethnicity) or pertinent comorbidities should be examined in the study, and relevant effect modifiers should be available in the chosen data source. The protocol should clearly disclose all known unmeasured effect modifiers, when relevant, in the proposed data source(s), as well as approach(es) to supplement information on unmeasured effect modifiers and justify the appropriateness of any proxy measure(s) for specific unmeasured effect modifier(s).

3. Validation of Confounders and Effect Modifiers

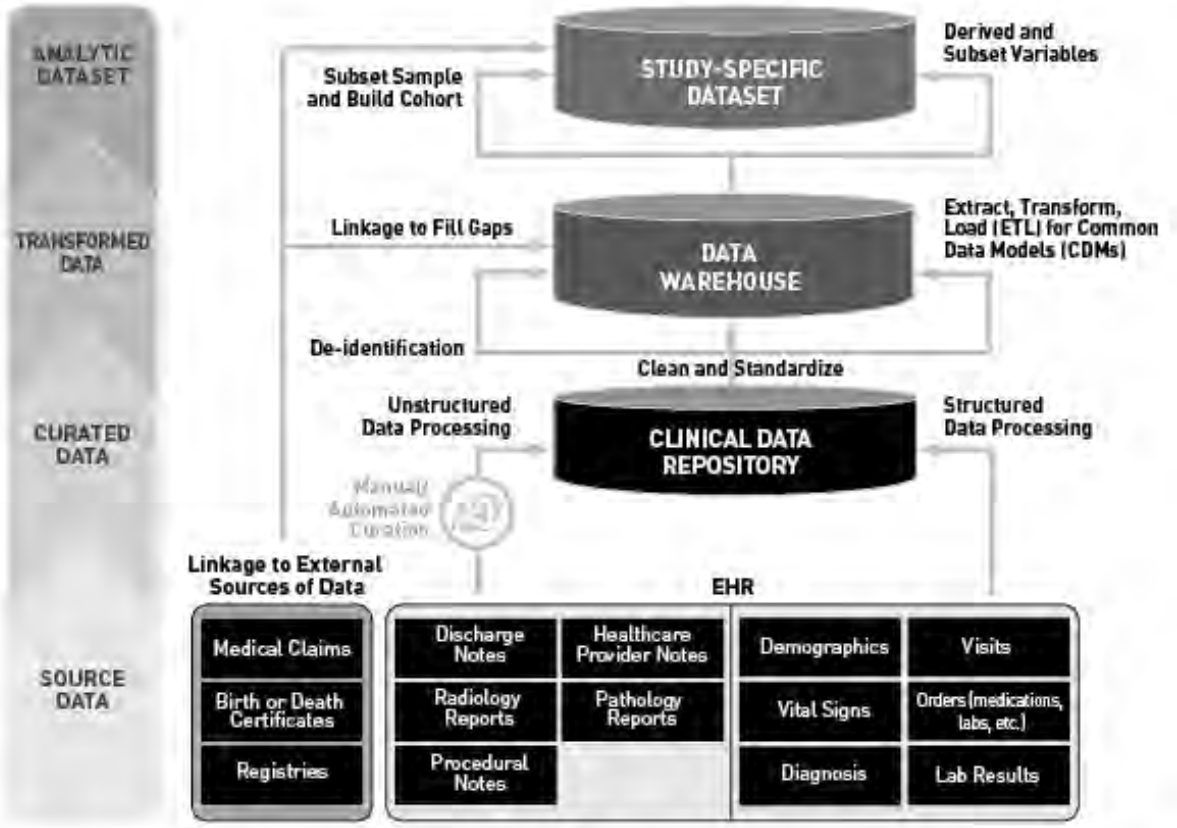
For all key covariates, including confounders and effect modifiers, FDA recommends providing and justifying the validity of operational definitions in the protocol and study report. Selection of such covariates depends on the study question, study design, and the impact of misclassification on study internal validity and study inference. For example, when a genetic factor is a key confounder for a study question, it may be implicitly adjusted as a time-fixed covariate in a self-controlled design, even if data are imperfect. If the measured covariates can change during a patient's follow-up period (time-varying covariates) and are important to the analysis, the protocol should describe whether and how frequently the information on time-varying covariates can be captured, particularly since capture of time-varying covariates in RWD can be differential by severity of illness (e.g., more testing in more seriously ill patients).

When evaluating the validity of covariate operational definitions, FDA recommends identifying the best reference data source based on the nature of the covariates. When validating operational definitions of covariates that are medical events or procedure utilizations (e.g., comorbidities, past medical history), the same principles apply as in section V.D.3, Validation of Outcomes. For discussion on validating operational definitions of covariates that are associated with drug uses, such as concurrent medications or past drug uses, see section V.C.5, Validation of Exposure. When assessing the validity of other covariate operational definitions, such as family history of disease, lifestyle factors, or indication for drug use, the appropriate reference may include a patient or provider survey or appropriate data linkages.

When supplemental information is needed to capture important covariates or is used for covariate validation, FDA recommends describing the likelihood of obtaining the supplemental

information for the overall study population. If this supplemental information is only available for part of the study population, FDA recommends discussing the potential effect on internal validity in relevant study documents.

Quantitative approaches, such as quantitative bias analyses, are encouraged to demonstrate whether and how misclassification of key covariate(s), if present, might impact study findings. The approach can be applied *a priori* for feasibility assessment, to facilitate interpretation of study results, or for both purposes. The protocol should pre-specify the indices (e.g., sensitivity, specificity) that will be used for quantifying bias and describe how the selected indices will be measured in key covariate(s) validation.



VI. DATA QUALITY DURING DATA ACCRUAL, CURATION, AND TRANSFORMATION INTO THE FINAL STUDY-SPECIFIC DATASET

This section discusses points for consideration when examining the quality of data over the course of the data life cycle. Although the data life cycle may vary depending on the type of data and setting (i.e., health care settings such as pharmacies, clinics, emergency departments and hospitals), in general, the life cycle involves multiple phases: data accrual from the original source data; curation of data to the clinical data repository; transformation and de-identification of data where necessary, creation of a data warehouse; and production of a study-specific dataset for analysis (see Figure 1).

The concept of the data life cycle illustrates the iterative nature of the process for examining the quality of data. The process is not a onetime assessment; rather, it is an ongoing process in which data quality checks, cleansing,[23] and monitoring occur at each phase in the cycle, and some checks may be repeated (i.e., occur in multiple phases of the cycle).

[23] Data cleansing (sometimes referred to as data scrubbing) is the process of correcting or removing inaccurate data (or improperly formatted, duplicate data or records) from a database. The data requiring correction/removal is sometimes referred to as "dirty data." Data cleansing is an essential task for preserving data quality.

Figure 1: Illustrative Example of the Life Cycle of EHR Data[24]

Guidelines that evaluate the quality of EHRs and medical claims data primarily focus on distributed data networks in which disparate data sources are aggregated, linked, and processed to create a comprehensive data warehouse (Miksad and Abernethy 2018; Girman et al. 2018; Daniel et al. 2018; Kahn et al. 2016; Wang et al. 2017; Mahendraratnam et al. 2019). Although FDA does not endorse any particular set of guidelines or checklists, sponsors should evaluate the completeness, accuracy, and plausibility of the data, including verifying data against its original source (e.g., discharge notes, pathology reports, registry records) and conforming to consensus-based data standards, where applicable. Sponsors should provide scientific justifications for choosing these standards and should articulate how these standards are adequate to ensure the completeness, accuracy, and plausibility of the relevant data source.

The study protocol and analysis plan should specify the traceability (curation and transformation procedures used throughout the data life cycle) and describe how these procedures could affect the integrity of the data and the overall validity of the study. Below are points for consideration when examining data at each step in the data life cycle, including (A) characterizing the data with respect to completeness, conformance, and plausibility of data values, (B) documenting the

[24] This figure illustrates some of the processes applied to EHR data to produce a dataset that may be appropriate for research use (i.e., steps from original source data through the final analytic dataset). This figure shows processes for EHR data; the process may differ for claims data. Quality checks for each process step are described in this section.

QA/QC plan that includes transformation processes; and (C) defining a set of procedures for ensuring integrity of the data.

A. Characterizing Data

The format and traceability of EHRs and medical claims data can vary significantly across health care entities (e.g., insurer, practice, provider, data vendor). In general, sponsors should address the procedures used to ensure completeness and accuracy of study data, as well as processes for data accrual, curation, and transformation over the data life cycle. The FDA recommends automated data quality reports that include the following characteristics and processes in a standardized way, when applicable to the chosen data source:

- Data accrual

  (1) Methods for data retrieval and processes to minimize missing data extraction, implausible values, and data quality checks in data captured at the point of care (e.g., during clinical practice for manual or automated health care data collection processes) to ensure accuracy and completeness of data elements.

  (2) Traceability of data elements to allow tracking of these elements back to their respective points of origin, with clear documentation of modifications that may have occurred.

  (3) Timeliness of data availability, data years spanned, and continuity of coverage (e.g., median duration of patient enrollment).

  (4) Handling data discrepancies and duplicate records. RWD may stem from multiple data streams, across various settings and platforms, which may present data discrepancies for the same variable (e.g., when the information for the same element is entered differently in different data sources) or even duplicate records for the same patient within the same data source.

  (5) The reason for and timing of data error corrections implemented by data holders during the relevant period of data collection.

  (6) The reason for and timing of changes in processes implemented by data holders during the relevant period of data collection that may impact data accrual and/or data quality checks.

  (7) Any updates or changes in coding practices and versioning (e.g., ICD diagnosis codes, Healthcare Common Procedure Coding System codes) across the study period that are relevant to variables of interest.

  (8) Any other changes in the data (e.g., collection, reporting, definitions) during the study period and their potential impact on the study results.

- Data curation

  (1) Routine migration of data from various sources over time.

  (2) QA testing and data quality checks employed across sites, as well as the criteria used in determining whether data quality techniques are appropriate for the intended purpose of the data.

  (3) Data elements that are well-defined with consistent and known clinical meaning and understanding of data traceability, as well as documentation of clinical definitions used.

  (4) Assessment of completeness of data elements including trends over time.

  (5) Unstructured and structured data processing (e.g., abstraction and conversion of unstructured data to structured data), including manual versus automated techniques.

  (6) Harmonization of structured data across systems.

  (7) Conformance to open, consensus-based data curation standards, when applicable.

  (8) Accuracy of mappings (e.g., in the presence of different coding systems, such as Systematized Nomenclature of Medicine—Clinical Terms [SNOMED CT] versus ICD-10-CM).

  (9) Additional harmonization and mapping considerations, if applicable (if data spans multiple countries—e.g., U.K. data used in addition to U.S. data).

- Data transformation[25]

  (1) Implementation of the extract, transform, and load process applied to the whole repository population as part of data warehouse creation.

  (2) De-identification of patient records and any process that could be used to re-identify unique patients in original source data without losing traceability (e.g., use of linkage tokens).

  (3) Algorithms used to transform and cleanse the data, as well as availability of standard operating procedures, including procedures for verifying the data against its original source.

  (4) Data standardization (e.g., data types, sizes, formats) for internal consistency of data elements and semantics, including semantics of local codes to a target terminology (e.g., for laboratory data).

[25] For purposes of this guidance, data transformation is the process of converting data from one format or structure into another format or structure.

(5) When converting multiple data sources into a CDM, processes used for data transformation into a CDM (e.g., common terminology and structure), the comprehensiveness of the CDM (e.g., does the CDM contain the key data elements), approaches (e.g., algorithms/methods) for identification and handling of duplicate records within and across data sources, and potential impact of restricting to CDM on sample size and duration of patient follow-up or duration of drug exposure. See section IV.B.3, Distributed Data Networks.

(6) Implementation of data checks pertaining to data model conformance errors.

(7) Data transformation processes used in preparation for data linkage. See section IV.B.2, Data Linkage and Synthesis.

(8) Quality of record linkage (i.e., linking records from multiple datasets) and deduplication (i.e., finding duplicate records in a dataset) process, which may vary depending on the accuracy of the data used to perform the matches and the accuracy of the linkage algorithm.

(9) Quantification of linkage errors (e.g., false matches, missed matches) that may lead to biased study findings. These are important when evaluating linkage quality (Harron et al. 2017). It is important to report details of the linkage algorithm and appropriate metrics (e.g., linkage error rates, match rates, comparison of characteristics of linked and unlinked data). Additional considerations include whether the error is random or nonrandom, potential bias, and impact on risk estimates and study findings.

(10) Procedures for adjudicating discrepancies in linked data as well as plans for handling linkage discrepancies (e.g., adjusting risk estimates for the linkage error).

Sponsors should also consider issues related to the study-specific analytic dataset:

(1) Adherence to data specifications outlined in the study protocol and statistical analysis plan when compiling the analytic dataset.

(2) Additional study-specific data transformations, such as data transformations that are only done for a subset of patients of interest and that are not applied to all patient records in the data warehouse (e.g., manual extraction of data from unstructured textual pathology reports).

(3) Data checks implemented on the final analytic dataset for implausible values for data elements (e.g., height, weight, blood pressure), how such values are addressed, and the completeness of data for key analytic variables.

(4) The extent, percentage, and pattern of missingness and implausible data. Depending on the analysis plan's proposed method for handling missing data, imputations may be performed and included in the final analytic dataset and the type of imputation described.

B. Documentation of the QA/QC Plan

A QA/QC plan for construction of analytical data, the planned approach for handling quality control issues during analysis, and contemplation of differing levels of data quality by data element (and the potential implications on study findings) should be described in the study protocol and analysis plan. In general, activities to ensure the quality of the data before data-related activities are developed during the design of the study, and such activities, which include standardizing procedures for how to collect the data, may be regarded as QA (Szklo and Nieto 2006). Quality control consists of the decisions and steps taken from data collection through compilation of the final analytic dataset to ensure it meets prespecified standards and to ensure the processes used are reproducible. A multidisciplinary approach that includes clinical input is necessary to ensure adequate capture and handling of data, particularly for electronic health care systems, which inherently incorporate nuances and intricacies of health care delivery.

C. Documentation of Data Management Process

All manual and automated data retrieval and transformation processes should be thoroughly assessed from data collection through writing of the final study report to ensure integrity of the data. Sponsors should ensure that curation and transformation processes do not alter the meaning of data or cause the loss of important contextual information. Descriptions of processes should include safeguards or checks to ensure that patient data are not duplicated or overrepresented. In addition, documentation of processes used to mine and evaluate unstructured data should describe the techniques employed (e.g., natural language processing) to abstract unstructured data (e.g., clinician notes) and supplement structured data (e.g., diagnostic codes).

Processes used for managing and preparing the final study-specific analytic dataset should be described in the study protocol or analysis plan. Analysts should have appropriate training or experience with the data and software used to compile the analytic datasets. To facilitate FDA review, all submitted programs (e.g., those written by analysts) should be thoroughly annotated with comments that describe the intent or purpose of each data management and analysis step written in the program (e.g., annotate each data step in a statistical analysis program).

MEDICAL REVIEW(S)

CLINICAL REVIEW

Application Type	SE-2 Efficacy Supplement
Application Number(s)	NDA 020687/S-020
Priority or Standard	Standard
Submit Date(s)	May 28, 2015
Received Date(s)	May 29, 2015
PDUFA Goal Date	March 29, 2016
Division / Office	(b) (6)
Reviewer Name(s)	(b) (6) and (b) (6)
Review Completion Date	March 29, 2016
Established Name	Mifepristone
(Proposed) Trade Name	Mifeprex
Therapeutic Class	Progestin antagonist
Applicant	Danco Laboratories, LLC
Formulation(s)	Oral Tablet
Dosing Regimen	For pregnancies through 70 days gestation: Mifeprex 200 mg tablet orally followed in 24-48 hours by 800 mcg buccal misoprostol.
Indication(s)	Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation.
Intended Population(s)	Pregnant women who desire a medical termination through 70 days gestation.

1 Recommendations/Risk Benefit Assessment

This NDA supplement from the Applicant, Danco Laboratories, LLC (called Danco or the Applicant throughout this clinical review), requested the following changes to the NDA for Mifeprex, approved 15 years ago in September 2000.

Changes proposed by the Applicant:

1. Change the dosing regimen: Decrease mifepristone dose from 600 to 200 mg, followed by misoprostol at a dose increased from 400 mcg to 800 mcg, administered buccally instead of orally
2. Remove the statement in labeling that administration of misoprostol must be done in-clinic, to allow for administration at home or other location convenient for the woman.
3. Administration of misoprostol at 24-48 hours instead of 48 hours after Mifeprex
4. Follow-up needed, but not restricted to in-clinic at 14 days after Mifeprex
5. Increase the gestational age from 49 days to 70 days
6. Change the labeled time for expulsion of the products of conception from 4-24 hours to 2-24 hours post misoprostol administration
7. Add that a repeat 800 mcg buccal dose of misoprostol may be used if needed
8. Change “physician” to “(b) (4) in the label and Risk Evaluation and Mitigation Strategies (REMS) document
9. Change indication to add reference to use of misoprostol: “Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of pregnancy through 70 days gestation.”
10. Remove references to “under Federal law” from the Prescriber’s Agreement
11. Address the Pediatric Research Equity Act (PREA) requirement for pediatric studies

Each of these 11 items will be discussed in the appropriate section of this review, generally under Section 6: Review of Efficacy and Section 7: Review of Safety. Four of the items, namely Number 8-11, are primarily regulatory and/or legal. They are discussed in Sections 1.3 and 9.4 (REMS recommendations and Prescriber’s Agreement), 7.6.4 (PREA), and 9.2 (Labeling recommendation). Additional information is found in Section 7.7 (2) on the change to “(b) (4) Section 7.7 (3) on “under Federal law”, and Section 7.7 (4) on the reference to use of misoprostol.

1.1 Recommendation on Regulatory Action

The clinical reviewers recommend an approval action for this efficacy supplement.

1.2 Risk Benefit Assessment

1. Decrease mifepristone dose from 600 to 200 mg, followed by misoprostol at a dose increased from 400 mcg to 800 mcg, administered buccally instead of orally.

   The Applicant has submitted sufficient evidence from the published medical literature to demonstrate that decreasing the dose of Mifeprex from 600 mg to 200 mg while increasing the dose of misoprostol from 400 to 800 mcg is safe and efficacious for termination of pregnancy through 70 days gestation. The risk/benefit balance favors approval.

   There is sufficient evidence that a dosing regimen with buccal administration of 800 mcg misoprostol is safe and effective. This change in the dosing regimen should be approved.

2. Allow administration of misoprostol outside of the clinic:

   Based on the evidence submitted by the Applicant, a dosing regimen that includes administration of misoprostol outside of the clinic is safe and effective for termination of pregnancy through 70 days gestation; labeling should be revised to remove the requirement for in-clinic dosing of misoprostol

3. Administration of misoprostol at 24-48 hours instead of 48 hours after Mifeprex:

   The available evidence supports that a dosing regimen that provides for administration of misoprostol 24-48 hours after administration of Mifeprex is safe and effective. The risk/benefit assessment demonstrates that this change in the dosing regimen should be approved.

4. Follow-up needed, but not restricted to in-clinic at 14 days after Mifeprex:

   Based on the evidence submitted by the Applicant supporting this change, flexibility in timing and method of follow-up after medical abortion is safe. Labeling should be revised to remove the requirement for in-clinic follow-up at 14 days.

5. Increase the gestational age from 49 days to 70 days:

   As detailed in the following review, the Applicant has submitted sufficient evidence for the safety and efficacy of medical abortion with Mifeprex, in a regimen with misoprostol, through 70 days gestation. The risk/benefit assessment supports the approval of the new dosing regimen up through 70 days gestation.

6. Change the labeled time for expulsion of the products of conception from 4-24 hours to 2-24 hours post misoprostol administration:

   The Applicant has submitted sufficient data from the published medical literature to support approval of a change in the label to note time to expulsion ranges from 2-24 hours.

7. Add that a repeat 800 mcg buccal dose of misoprostol may be used if needed:

The Applicant has submitted sufficient evidence to support that a repeat dose of misoprostol may be used through 70 days gestation to complete expulsion of the products of conception if needed. The risk/benefit assessment supports approval of this change. There have been rare reports of uterine rupture with use of misoprostol in women with prior uterine scar(s). This information should be added to the Mifeprex label.

8. Change "physician" to "(b) (4) in the labeling and Risk Evaluation and Mitigation Strategies (REMS) document:

   The Applicant has submitted sufficient data to support that Mifeprex is safe and effective when prescribed by midlevel practitioners as well as by physicians. Therefore, the term "licensed physician" was changed in the label and REMS materials to "healthcare provider who prescribes." This broader category of providers will still have to meet the certification criteria specified in the Prescriber Agreement Form.

9. Change the approved indication to add reference to use of misoprostol: "Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation." Based on current Agency labeling practice regarding drugs used together in a treatment regimen, the addition of misoprostol to the Indication Statement for Mifeprex should be approved.

10. Remove references to "under Federal law" from the Prescriber Agreement:

    The Agency has determined that there is no precedent for using this phrase in other REMS, nor is there any clinical rationale for including it; therefore, it is acceptable to remove "under Federal law" from the Prescriber Agreement Form.

11. Address the Pediatric Research Equity Act (PREA) requirement for pediatric studies:

    The Applicant has submitted sufficient evidence from the published medical literature to address the PREA requirement for this supplemental application. The Applicant has demonstrated that Mifeprex is safe and effective in postmenarchal females, including those under 17 years of age. (b) (6) concurred with granting a partial waiver under PREA in patients ages birth to 12 years of age who are premenarche.

1.3 Recommendations for Postmarket Risk Evaluation and Mitigation Strategies

Changes proposed in this efficacy supplement entailed a number of modifications to the current Risk Evaluation and Mitigation Strategy (REMS) for Mifeprex. See Section 9.4 for full details. The (b) (6) ((b) (6) concurs with the (b) (6) ((b) (6) evaluation of the REMS modifications, which include:

- Removal of "under Federal law" from the Prescriber Agreement Form is acceptable (see discussion in Additional Submissions / Issues).
- The term "healthcare providers who prescribe" is preferable to the Applicant's proposed "(b) (4) (see discussion in Additional Submissions / Issues).
- It is appropriate to modify the current adverse event reporting requirements under the REMS, which are currently outlined in the Prescriber's Agreement to include "hospitalization, transfusion or other serious event." Under these requirements, healthcare providers report certain adverse events to the Applicant, which then is required to report the adverse events to FDA. FDA has received such reports for 15 years, and it has determined that the safety profile of Mifeprex is well-characterized, that no new safety concerns have arisen in recent years, and that the known serious risks occur rarely. For this reason, ongoing reporting by certified healthcare providers to the Applicant of all of the specified adverse events is no longer warranted. . It should be noted that the Applicant will still be required by law, as is every NDA holder, to report serious, unexpected adverse events as 15-day safety reports, and to submit non-expedited individual case safety reports, and periodic adverse drug experience reports.

(b) (6) concurs with the following modifications recommended by (b) (6)

- Removal of the Medication Guide (MG) from the REMS. The MG will remain a required part of labeling and will be required to be provided to patients consistent with the requirements in 21 CFR part 208. FDA has been maintaining MGs as labeling but removing them from REMS when, as here, inclusion in REMS is not necessary to ensure that the benefits of a drug outweigh the risks, such as when the MG is redundant and not providing additional use or information to the patient about the risk(s) the REMS is intended to mitigate. This is consistent with ongoing efforts to streamline REMS by allowing for updates to the MG without need for a REMS modification.
- Removal of the Patient Agreement form (ETASU D). This decision was based on the well-established safety profile of Mifeprex, as well as the fact that the small numbers of practitioners who provide abortion care in the US use informed consent practices that are duplicated of the current Patient Agreement and thus the Patient Agreement is no longer necessary to ensure that the benefits of the drug outweigh the risks.
- Revision of the Prescriber Agreement Form to reflect changes to labeling revisions pursuant to the proposed efficacy supplement, and to improve the flow of the document.
- Revision of the REMS goals to reflect the above changes

1.4 Recommendations for Postmarket Requirements and Commitments

There are no recommendations for postmarket requirements or commitments for this efficacy supplement.

2 Introduction and Regulatory Background

2.1 Product Regulatory Information

On September 28, 2000, FDA approved Mifeprex for the medical termination of intrauterine pregnancy through 49 days' (7 weeks) pregnancy (NDA 20-687). The application was approved under 21 CFR part 314, subpart H, "Accelerated Approval of New Drugs for Serious or Life-Threatening Illnesses" (subpart H). This subpart applies to certain new drug products that have been studied for their safety and effectiveness in treating serious or life-threatening illnesses and that provide meaningful therapeutic benefit to patients over existing treatments." Specifically, § 314.520 of subpart H provides for approval with restrictions that are needed to assure the safe use of the drug product. In accordance with § 314.520, FDA restricted the distribution of Mifeprex as specified in the approval letter, including a requirement that Mifeprex be provided by or under the supervision of a physician who meets certain qualifications specified in the letter.

The September 28, 2000, approval letter also listed two Phase 4 commitments that the then-applicant of the Mifeprex NDA (i.e., the Population Council) agreed to meet:

1. A cohort-based study of safety outcomes of patients having medical abortion under the care of physicians with surgical intervention skills compared to physicians who refer their patients for surgical intervention. Previous study questions related to age, smoking, and follow-up on Day 14 (compliance with return visit) were incorporated into this cohort study, as well as an audit of signed Patient Agreement forms.
2. A surveillance study on outcomes of ongoing pregnancies.

In addition, the 2000 approval letter stated that FDA was waiving the pediatric study requirement in 21 CFR 314.55.

Effective October 31, 2002, the Population Council transferred ownership of the Mifeprex NDA to Danco Laboratories, LLC (Danco).

2.2 Tables of Currently Available Treatments for Proposed Indications

In the US there are no other approved products for the medical termination of first trimester pregnancy. Misoprostol alone or in combination with methotrexate has been used for early medical abortion (MAB), with much lower success than Mifeprex.[1]

[1] American College of Obstetricians and Gynecologists. Practice bulletin No. 143: medical management of first-trimester abortion. Obstet Gynecol 2014;123(3):676-92. doi:10.1097/01.AOG.0000444454.67279.7d.

2.3 Availability of Proposed Active Ingredient in the United States

Mifepristone: The only other FDA approval for mifepristone is the product Korlym, approved under NDA 202107 on February 17, 2012 for the control of hyperglycemia secondary to hypercortisolism in adult patients with endogenous Cushing's syndrome who have type 2 diabetes mellitus or glucose intolerance and have failed surgery or are not candidates for surgery.

2.4 Important Safety Issues with Consideration to Related Drugs

Korlym (mifepristone) is indicated to control hyperglycemia secondary to hypercortisolism in adult patients with endogenous Cushing's syndrome who have type 2 diabetes mellitus or glucose intolerance and have failed surgery or are not candidates for surgery. Korlym is taken in oral doses of 300 mg to 1200 mg daily. It is contraindicated in pregnancy, patients taking simvastatin, lovastatin and CYP3A substrates with narrow therapeutic ranges, patients on corticosteroids for lifesaving purposes, and women with unexplained vaginal bleeding or endometrial hyperplasia with atypia or endometrial carcinoma. The label[2] provides warnings and precautions regarding adrenal insufficiency, hypokalemia, vaginal bleeding and endometrial changes, QT prolongation, exacerbation or deterioration of conditions treated with corticosteroids, use of strong CYP3A inhibitors, and opportunistic infections with *Pneumocystis jiroveci* pneumonia in patients with Cushing's. Adverse reactions noted in ≥20% of patients in clinical trials with Korlym included nausea, fatigue, headache, hypokalemia, arthralgia, vomiting, peripheral edema, hypertension, dizziness, decreased appetite and endometrial hypertrophy.

Reviewer comment:

Some of the adverse events noted with Korlym are also seen with Mifeprex, such as nausea and vomiting. However, Korlym is taken in higher doses, in a chronic, daily fashion unlike the single 200 mg dose of Mifeprex that is the subject of this supplement; the rate of adverse events with Mifeprex is much lower.

Ella (ulipristal acetate) is a progesterone agonist/antagonist emergency contraceptive indicated for prevention of pregnancy following unprotected intercourse or a known or suspected contraceptive failure. The **ella** label[3] notes that in clinical trials, the most common adverse reactions (≥ 10%) in women receiving **ella** were headache (18% overall) and nausea (12% overall) and abdominal and upper abdominal pain (12% overall).

Due to **ella's** high affinity binding to the progesterone receptor, use of **ella** may reduce the contraceptive action of regular hormonal contraceptive methods. The label notes that after **ella** intake, menses sometimes occur earlier or later than expected by a few

[2] http://www.accessdata.fda.gov/drugsatfda_docs/label/2012/202107s000lbl.pdf

[3] https://www.accessdata.fda.gov/drugsatfda_docs/label/2010/022474s000lbl.pdf

days. In clinical trials, cycle length was increased by a mean of 2.5 days but returned to normal in the subsequent cycle. Seven percent of subjects reported menses occurring more than 7 days earlier than expected, and 19% reported a delay of more than 7 days. The label recommends that women rule out pregnancy if the expected menses is delayed by more than one week. Nine percent of women studied reported intermenstrual bleeding after use of **ella**.

Reviewer comment:

Ella is for occasional use and is not to be used as a regular contraceptive method. As such, the drug is not recommended for repeated use in the same menstrual cycle. The safety and efficacy of repeat use within the same cycle has not been evaluated. A single dose of ella does not appear to result in serious adverse events.

2.5 Summary of Presubmission Regulatory Activity Related to Submission

A pre-NDA meeting was held with the Applicant on January 29, 2015. The following items, among others, were discussed:

- New dosing regimen
- Proposal to have (b) (4)
- Use up to (b) (4) days' gestation
- Change in the interval between Mifeprex and misoprostol administration to 24-48 hours
- Revision of the labeled time to expulsion after misoprostol is administered
- Use of the term "(b) (4) in the approval and label to describe who may obtain and dispense Mifeprex
- Deletion of "under Federal law" in the Prescriber's Agreement
- PREA requirements
- Regulatory pathway for approval

2.6 Other Relevant Background Information

Since the approval in France and China in 1988, mifepristone for MAB is currently approved in 62 countries globally[4]; see the list and dates of approval in Appendix 9.7.

Prior to the Mifeprex approval by the FDA, mifepristone had also been approved in the UK in 1991. In the UK, the current therapeutic indications include:

- Medical alternative to surgical termination of intrauterine pregnancy up to 63 days gestation based on the first day of the last menstrual period
- Softening and dilatation of the cervix uteri prior to mechanical cervical dilatation for pregnancy termination during the first trimester

[4] Gynuity website, www.gynuity.org, Medical Abortion in Developing Countries- List of Mifepristone Approvals.

- For use with prostaglandin analogues for termination of pregnancy for medical reasons beyond the first trimester
- Labour induction in foetal death in utero[5]

The estimated cumulative use of Mifeprex in the US since the 2000 approval is 2.5 million uses. Estimated global occurence of MAB and SAB combined was 43.8 million abortionsin 2008 (Guttmacher Institute data)[6]. MAB has been increasingly used as its efficacy and safety have become well-established by both research and experience, and serious complications have proven to be extremely rare.[7] Medical abortion comprises 16.5% of all abortions in the US, 25.2% of all abortions at or before 9 weeks of gestation[1], and based on data from 40 reporting areas sending data to the CDC, 30.8% of all abortions at or before 8 weeks gestation (2012 data).[8] In 2011, approximately 239,400 medical abortions were performed, which was a 20% increase from 2008 data.[9] Data show that in the most recently reported 12 months (September 29, 2014-September 28, 2015), (b) (4) Mifeprex tablets were distributed in the US (NDA 20687 SD # 650, Annual Report-15, submitted October 09, 2015). Further, the vast majority of practitioners in the US who provide medical abortion services use a regimen other than the FDA-approved one. In 2008, Wiegerinck et al published a survey of members of the National Abortion Federation which showed that only 4% of facilities were using the current FDA-approved regimen.[10]

It is noteworthy that ten years ago, the combination of mifepristone and misoprostol for medical abortion was included on the World Health Organization (WHO) Model list of Essential Medicines for termination of pregnancy where legal and acceptable, up to 9 weeks of gestation.[11] Several other national and international organizations have also endorsed the safe use of medical abortion up to 9 and 10 weeks of gestation. This topic will be discussed thoroughly in the Efficacy and Safety Sections.

MAB is a choice that women have available in many areas, especially urban, in the US, although it should be noted that some geographical areas in the US have very limited availability of both the surgical and medical options or even one option for early pregnancy termination.

The primary advantages of having a MAB compared to a surgical abortion (SAB) are the following:

- Limited or no anesthesia
- Limited likelihood of any surgical intervention

Reviewer's Comment:

A very small number of physicians currently provide early medical terminations. In the most recent REMS update from the Applicant (stamp date June 3, 2015), the cumulative number of certified prescribers since 2000 is only (b) (4). Between May 1, 2012 and April 30, 2015, the number of new prescribers was (b) (4) and the number of prescribers ordering Mifeprex was (b) (4) during this 3-year period. The number of healthcare providers that are performing early SAB is not documented.

3 Ethics and Good Clinical Practices

3.1 Submission Quality and Integrity

Because this submission did not rely on datasets from any of the clinical trials, no FDA inspections were performed at clinical sites. The authors of the numerous articles, however, have published widely in peer-reviewed medical journals.

3.2 Compliance with Good Clinical Practices

This submission relies on findings from the published medical literature. The majority of the publications included a statement that the study was conducted under institutional review board (IRB) or Ethical Review Committee approval and the women gave informed consent.

3.3 Financial Disclosures

None were submitted or required.

4 Significant Efficacy/Safety Issues Related to Other Review Disciplines

4.1 Chemistry Manufacturing and Controls (CMC)

On March 10, 2016, a separate supplement approved the packaging of a single 200 mg tablet of mifepristone compared to the current 3 tablets in a blister pack. Each packet will have an individual barcode.

Reviewer comment:

The approval of single tablet packaging should make recording the barcode of the mifepristone tablet in the patient record (as provided in the REMS) easier as the new proposed dosing regimen uses only one 200 mg mifepristone tablet compared to the previously approved regimen of three tablets.

(b) (6), reviewed the PLR conversion of the label. Her review, dated January 11, 2016 states the following:

> "No changes have been made in the approved chemistry, manufacturing and controls. The approved 200 mg tablet will be used. This review evaluates the PLR conversion of the labeling. Sections 3, 11, and 16 of the PLR labeling, and the Highlights of Prescribing Information, have been evaluated from a chemistry perspective.
>
> **Overall Evaluation**: Acceptable. The labeling provided in Section 3, Section 11, and Section 16, and the Highlights of Prescribing Information, is identical in content to the approved information. The PLR conversion labeling, therefore, is acceptable from a chemistry perspective. The PLR label also corresponds to the content and format required in 21 CFR 201.57.

Reviewer comment:

We agree with the conclusions in the CMC review of the PLR conversion of the label.

4.2 Clinical Microbiology

The chemistry (CMC) reviewers determined that a microbiology review was not needed for this efficacy supplement.

4.3 Preclinical Pharmacology/Toxicology

Please refer to the Pharmacology/Toxicology review by (b) (6), dated March 2, 2016. No preclinical data were submitted for this efficacy supplement.The reviewer's only recommendations were labeling changes. His comments were conveyed to the Sponsor.

Per (b) (6) review, the supplement is approvable from a Pharmacology/Toxicology standpoint.

4.4 Clinical Pharmacology

The Clinical Pharmacology review by (b) (6) concluded with the following recommendation:

> "(b) (6), (b) (6) has reviewed the available clinical pharmacology information in relation to the newly proposed regimen for Mifeprex®. We find the application to be acceptable from a Clinical Pharmacology perspective, provided that an agreement on the language in the package insert is reached between the Sponsor and the Division."
>
> No postmarketing commitments or requirement are recommended.

4.4.1 Mechanism of Action

The original approved label states:

> "The anti-progestational activity of mifepristone results from competitive interaction with progesterone at progesterone-receptor sites. Based on studies with various oral doses in several animal species (mouse, rat, rabbit, and monkey), the compound inhibits the activity of endogenous or exogenous progesterone. The termination of pregnancy results.
>
> …..During pregnancy, the compound sensitizes the myometrium to the contraction-inducing activity of prostaglandins."

4.4.2 Pharmacodynamics

No new studies were submitted with this Application. See the original approved label.

4.4.3 Pharmacokinetics

(b) (6) review states the following:

> The pharmacokinetics (PK) of 200 mg mifepristone tablet has not been characterized in women. However, the PK data of 200 mg mifepristone tablet in men are available (1996 study): the mean maximum concentration (C_{max}) (± standard error) = 1.77 (±0.23) mg/L, the mean time to reach C_{max} (T_{max}) = 0.81 (±0.16) hour, and the mean area-under-the curve (AUC) = 25.8 (±2.2) mg·h/L. While the effects of sex on the disposition of mifepristone have not been evaluated using Mifeprex®, no sex differences in PK of mifepristone were seen with 300 mg mifepristone in a different NDA review (Korlym™, NDA 202107, Clinical Pharmacology review). Therefore, Section 12.3 of the proposed label in a PLR format should include the available PK data of mifepristone 200 mg tablet.
>
> Cytochrome P450 3A4 (CYP3A4) plays an important role in the metabolism of mifepristone. Therefore, concomitant intake of CYP3A4 inducers with mifepristone

is anticipated to have a significant effect on the disposition of mifepristone. However, the Sponsor did not conduct any *in vivo* studies to evaluate the effect of CYP3A4 inducers on the PK of Mifeprex®. Although the lowest effective therapeutic margin of mifepristone for termination of pregnancy has been not characterized clearly, the use of misoprostol in the regimen for Mifeprex® contributes to efficacy for inducing termination of pregnancy. In addition, concomitant intake of CYP3A4 inducers does not appear to affect the systemic exposure of misoprostol. In the proposed new regimen, another dose of misoprostol can be administered following day 7 to 14 of post-treatment of mifepristone if termination of pregnancy does not occur.

In summary, the contribution of misoprostol in termination of pregnancy and additional dosing option of misoprostol may compensate the possibly diminished efficacy of Mifeprex® in the users of CYP3A4 inducers. However, the labeling information should include the practical clinical guidance for the subject who has been exposed to CYP3A4 inducers.

Reviewers comments:

- **We agree with the Clinical Pharmacology conclusions and recommendations made by (b) (6).**

- **Within the last 10 years, administration of oral mifepristone followed by buccal misoprostol for early medical abortion has become the standard of care for MAB in many countries, including the US. This is based on 1) the PK profile of different doses and routes of administration for misoprostol, and 2) many clinical trials comparing the efficacy and safety of different dosing regimens.**

From Chen and Creinin (2015)[12]:

"With buccal administration, misoprostol is held in the buccal pouch between the teeth and gums for 30 minutes before swallowing any remaining tablets. Buccal misoprostol is slowly absorbed, unlike oral misoprostol, which is rapidly absorbed and undergoes extensive first-pass metabolism. After a dose of oral misoprostol, plasma misoprostol acid levels peak quickly at 30 minutes and decrease rapidly by 120 minutes. In contrast, after buccal administration, plasma misoprostol acid levels rise gradually to peak concentration after a median time of 75 minutes and fall slowly over several hours."

[12] Chen MJ, Creinin MD. Mifepristone with Buccal Misoprostol for Medical Abortion Obstet Gynecol: a Systematic Review. Obstet Gynecol 2015;126(1):12-21.

The PK profile of vaginal misoprostol is very similar to that of buccal misoprostol. These pharmacological differences between vaginal and buccal misoprostol do not have a clinically meaningful effect on the efficacy at different gestational weeks and the adverse event profile for the combination of mifepristone and misoprostol for early medical abortion. Those routes with rapid and significant absorption (e.g., sublingual) also have high efficacy (ACOG Bulletin[1]). This review, however, focuses primarily on the new dosing regimen proposed by the Applicant with some supportive data from studies that used vaginal and sublingual misoprostol.

5 Sources of Clinical Data

5.1 Tables of Studies/Clinical Trials

There were many studies that provided data for this NDA review. The original US trial that was reviewed for the Mifeprex approval in 2000 was performed over 20 years ago in 1994-95. Subsequently, there has been 20 years of experience with MAB, guidelines from professional organizations here and abroad, and clinical trials that have been published in the peer-reviewed medical literature. This review focuses on the information submitted by the Applicant for the change in the dosing regimen and follow-up.

For a complete list of all sources of information, see the extensive list of references in Appendix 9.6 at the end of this review.

Reviewer's comment:

Table 1 **above lists the major studies and review articles covering over 45,000 women who had an early MAB through 70 days gestation. Both retrospective and prospective studies were found to be valuable for this review. There are additional studies submitted by the Applicant that are not quoted or reviewed primarily because they did not use a dosing regimen relevant to that proposed by the Applicant or did not contain information pertinent to the other requested changes (e.g., less restrictive follow-up requirements or gestations through 70 days) in the NDA supplement. In some cases, studies that used variants of the proposed regimen were considered because PK, PD and clinical data indicate the relevance of data on vaginally-administered misoprostol, and because lower doses and certain other routes of administration of misoprostol are expected to have lower or similar levels of effectiveness.**

5.1.1 Submissions during the Review Process

During the course of the review, the Applicant submitted additional supportive articles from the peer-reviewed medical literature, and provided more detailed data from previously submitted articles based on direct communication with the authors. Further, the Applicant submitted changes to some of the original proposals. Below in Table 2 is a list of the clinical submissions to the NDA after the initial submission dated May 18, 2015.

Time (MAST Study Trial Group). Mifepristone and misoprostol administered simultaneously versus 24 hours apart for abortion a randomized controlled trial. Obstet Gynecol 2007;109:885-894.

REMS documents	Amendment #11, dated 3/21/2016

Source: Reviewer table.

5.2 Review Strategy

This is a joint review by two medical officers: (b) (6) reviewed the efficacy data and (b) (6) reviewed safety data and related issues. Other sections are jointly completed.

Within the last 10 years, use of buccal misoprostol with mifepristone for MAB has become commonplace. However, the published literature did not contain abundant information about medical abortion outcomes with buccal misoprostol at the time of the

original NDA review. In this review, we summarize clinical outcomes and adverse effects of medical abortion regimens consisting of oral mifepristone 200 mg followed in 24-48 hours by buccal misoprostol 800 mcg in pregnancies through 70 days of gestation.

5.2.1 Discussion of Individual Studies/Clinical Trials

Information and findings from individual clinical trials and reviews in the published medical literature, websites, the Applicant and other sources are discussed in different sections throughout this review. As acknowledged during pre-submission discussions between the Applicant and (b) (6) and as is typical for literature-based submissions, original datasets from the trials that are cited were not available for submission in this supplement.

6 Review of Efficacy

Efficacy Summary

This summary lists the final conclusions based on review of the data. Not all of the conclusions, regarding covariates such as ethnicity, parity, previous abortion, are specifically addressed in labeling, but the reviewers believe that it is important to show that we evaluated many different aspects and potential risk factors for safe and effective MAB:

- Medical termination of pregnancies through 70 days gestation is safe and effective and should be approved using the new proposed regimen.
- The original approved dosing regimen remains safe and effective but the new proposed dosing regimen is effective and should be approved for use in gestations through 70 days (10 weeks) gestation.
- 2015 Chen-Creinin review[12] of over 33,800 MABs concluded that regimens with a 24-hour time interval between mifepristone and buccal misoprostol administration are slightly less effective (94.2% success) compared to those with a 24-48-hour interval (96.8% success).
- 2013 Raymond review[18] of over 45,500 MABs using oral mifepristone 200 mg and various misoprostol doses concluded that the effectiveness decreases when:
    - misoprostol is taken orally compared to the three other routes of administration (buccal, sublingual, or vaginal)
    - the gestational age increases
    - the mifepristone-misoprostol interval is less than 24 hours
    - the total misoprostol dose is 400 mcg or less
- Efficacy in the adolescent population is the same or slightly better compared to non-adolescent women.

- Efficacy outcomes do not appear to be related to other baseline characteristics including age, race, body weight, gravidity and previous spontaneous abortions. (Spitz data[26] and many subsequent studies)
- Data from the original US trial (1994-95; Spitz 1998[26]) showed lower efficacy rates with the originally approved Mifeprex dosing than is reported in a large number of subsequent trials using different mifepristone-misoprostol dosing regimens for early MAB. There does not appear to be any change in the safety profile.
- Raymond (2013 systematic review[18]) found no significant association between abortion failure rates and the timing of the follow-up evaluation.
- Over 30% of women will completely expel the products of conception within 4-5 hours of taking the misoprostol for MAB with gestations of 57-70 days (Winikoff 2012[19]); this finding supports the proposal to allow women to choose the timing of (within the labeled range) and where to take the misoprostol.
    - Data from the original NDA review showed occurrence of a successful (complete) MAB occurred in ≤ 4 hours after misoprostol administration in 45-46% of women up to 56 days gestation and 34.9% of women at 57-63 days gestation.
- Home administration of misoprostol is efficacious, practical, and safe (see Safety Section)

Reviewer's overall comment:

Compared to the current Mifeprex approved label and regimen, the Applicant has requested less restrictive measures for location and timing of misoprostol administration and follow-up measures for early MAB. We believe that a regimen that includes these less restrictive measures is equally safe and effective, while offering women greater convenience and providing a less burdensome procedure for patients and providers.

6.1 Indication

In the initial submission of this efficacy supplement, the proposed new indication was the following: "Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy (b) (4)" In Amendment # 9, submitted on February 25, 2016, the Applicant proposed (b) (4) the gestational age through 70 days.

The proposed new modified regimen uses buccal (not oral) misoprostol administered 24-48 hours after taking a lower dose, 200 mg instead of 600mg, of oral mifepristone. The labeled dose of misoprostol is increased compared to the current approved regimen, from 400 mcg to 800 mcg. (b) (4) , the

(b) (4)
.

These requests were thoroughly reviewed by the Agency and we believe the product is safe and effective for the indication, which reads:

> "Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation."

6.1.1 Methods

There were numerous articles from the peer-reviewed medical literature that were submitted by the Applicant. Articles were also cited in three letters sent to CDER Center Director Janet Woodcock, MD from 1) ACOG, 2) a group of academic professionals and women's health non-profit organizations, and 3) thirty professional and academic organizations, all of which requested changes to the Mifeprex labeling and REMS. All relevant publications cited in those three letters were also submitted by the Applicant for our review. The articles and sources of data used for this review are listed in the Reference List in Appendix 9.6 at the end of this review.

The various studies noted in the articles had slightly different designs, inclusion criteria, dosing regimens and endpoints for safety and efficacy. The review focus is on clinical trials and follow-up methods for early medical abortion, including gestations through 70 days (10 weeks).

6.1.2 Demographics

Many of the trials were randomized and some were blinded to the actual dose of the two drugs that were administered. The route of misoprostol administration could not be easily blinded. Although there may have been some small differences in the demographic data for the different arms, it is doubtful that demographic differences such as race or ethnicity are clinically meaningful in relation to the safety and efficacy of medical abortion.

6.1.3 Subject Disposition

Most of the studies noted the number of women who were lost to follow-up and did not count them in the efficacy analysis. All women with any available safety data were included in the safety analyses. See Safety Section for further discussion.

6.1.4 Analysis of Primary Endpoint(s)

The studies analyzed for data used in this NDA review almost universally defined their primary efficacy endpoint as expulsion of the pregnancy from the uterus without need for any surgical evacuation or procedure for any reason (including patient request).

6.1.5 Analysis of Secondary Endpoints(s)

In addition to the final outcome of MAB success or lack of success (i.e., surgical or medical intervention needed), there are intermediate outcomes:

- Incomplete abortion: pregnancy no longer ongoing, but only partial or non-expulsion of the products of conception has occurred
- Ongoing pregnancy based on fetal heartbeat and/or growth

In the case of incomplete expulsion but where the pregnancy is no longer ongoing, there are in the US several safe options available to the healthcare provider and the patient:

- Expectant management (in many cases, complete expulsion will occur spontaneously given additional time)
- Additional dose of misoprostol
- Minor surgical procedure such as a vacuum aspiration in the clinic/office
- Surgical procedure under anesthesia such as a dilation and curettage (D&C)

For ongoing pregnancies following the initial MAB procedure, typically one of the surgical procedures is performed.

In addition to these two intermediate outcomes, there are other cases in which a surgical intervention might be performed:

- Intervention because of bleeding or other aspect of the patient's condition: the healthcare provider judges that surgical intervention is indicated
- Patient request: the patient requests surgical intervention for any reason

6.1.6 Proposal for a New Dosing Regimen

There are five major changes proposed by the Applicant in this supplement for which efficacy data will be discussed. The changes are interrelated and, in general, the same studies usually provide evidence to support multiple changes, although data from a given study may be more or less pertinent to a specific change (e.g., extending the approved gestational age, home administration of buccal misoprostol, etc.).

Summary of changes to dosing regimen, indication, and follow-up initially requested by the Applicant in the NDA Supplement:

1. **Addition of a new dosing regimen of Mifeprex 200 mg orally followed by the buccal administration of 800 mcg misoprostol at 24-48 hours instead of 48 hours**

2. **Increase in gestational age from (b) (4)**

3. **Option to administer misoprostol outside of the clinic**

4. **Option that a repeat dose of misoprostol may be used if needed for women using the new proposed dosing regimen**

5. **Follow-up timing and methods: follow-up is needed at 7-14 days after Mifeprex administration; the specific nature and timing of the follow-up to be agreed upon by the (b) (4) and patient. The current approved label states: "Patients will return for a follow-up visit approximately 14 days after the administration of Mifeprex."**

Discussion and analysis of the data supporting the five changes follows in five individual sections.

1. **Proposal of a new dosing regimen that:**

   1) decreases the oral dose of Mifeprex from 600 mg to 200 mg orally,

   2) increases the misoprostol dose from 400 mcg orally to 800 mcg misoprostol administered buccally, and

   3) revises the interval between Mifeprex and misoprostol dosing from 48 hours to "24-48 hours."

(b) (4)

Background on some dosing data and US practices:

There is ample medical evidence that the currently approved dose regimen (oral mifepristone 600 mg followed 2 days later with oral misoprostol 400 mcg) is safe and efficacious up to 49 days gestation. It was approved in September 2000 based on the US clinical trial of 1994-95 and two French trials. After 1995, however, more studies gradually became available using lower doses of mifepristone and different doses and routes of administration for misoprostol. These newer data were not submitted to or considered in the original NDA review. Studies also showed that with lower doses (< 600 mg) of oral mifepristone followed by oral misoprostol 400 mcg, the treatment success rate is greater than 95% up to 49 days gestation.

It is difficult to tell how many MABs in the US actually used the FDA-approved dosing regimen following the 2000 approval. It is clear that many clinics and individual practitioners did not. For example, from 2001 to March 2006, Planned Parenthood Federation of America (PPFA) health centers throughout the United States provided medical abortions principally using a regimen of oral mifepristone 200 mg, followed 24–48 hours later by 800 mcg misoprostol administered vaginally at home.[27] Of note, PPFA has been and continues to be the largest provider of MAB services in the US.

[27] Fjerstad M, Sivin I, Lichtenberg ES, Trussell J, Cleland K, Cullins V. Effectiveness of medical abortion

Reviewer's comment:

The 2009 Fjerstad article[28] states that PPFA was a federation of 97 independent local affiliates operating 880 health centers throughout the US; roughly 300 of those centers provided medical abortion. So, within one year of the FDA Mifeprex approval, PPFA was using a dosing regimen (actual doses and routes of administration) very similar to that proposed in this efficacy supplement.

Meanwhile, from September 2003 to June 2005, there were four fatalities in the US and one in August 2001 in a Canadian clinical trial, all due to a sudden and rapid sepsis secondary to the bacteria *Clostridium sordellii*. The five cases were with early MAB (all around 7 weeks gestation) in women who had used 800 mcg vaginal misoprostol. By late March 2006, consideration of these fatal uterine infections led PPFA to 1) change the route of administration of the 800 mcg misoprostol from vaginal to buccal (or, much less commonly, oral) and 2) employ additional measures (sexually transmitted infection [STI] testing and treatment if positive, or use of prophylactic antibiotics) to minimize the risk of subsequent serious uterine infections. In July 2007, PPFA began requiring routine treatment with antibiotics for all medical abortions at their health centers.[28]

Reviewer's comment:

As stated in currently approved labeling "No causal relationship between the use of Mifeprex and misoprostol and these events [serious and sometimes fatal infections and bleeding] has been established." There is no clear evidence that the vaginal use of misoprostol causes infection, and no causal association has been identified between the cases of sepsis and vaginal administration of misoprostol. While labeling was revised in November 2004 and July 2005 to recommend that providers have a high index of suspicion in order to rule out serious infection and sepsis, the Agency did not consider there was sufficient evidence to justify recommending prophylactic antibiotics.

A 2006 article showed that in pregnancies greater than 49 days gestation, compared to oral administration of misoprostol, the bioavailability and efficacy with use of misoprostol is increased by vaginal, sublingual and buccal administration, avoiding first-pass metabolism by the liver.[29] Furthermore, a 2009 review of MAB[30] noted that:

> "Consistent with other kinetic studies, clinical trials have demonstrated no change in efficacy when mifepristone doses are reduced from 600 to 200 mg. Multiple

> clinical studies, including a 2004 Cochrane meta-analysis, reported that a regimen of 200 mg of oral mifepristone followed 24 to 48 hours later by 800 mcg of vaginal misoprostol results in complete abortion in 96% of cases at gestations of up to 63 days and that increasing the mifepristone dose to 600 mg does not improve efficacy."

In a 2010 review article covering 25 years of the clinical development of mifepristone followed by a prostaglandin for MAB, Spitz[31] noted similar conclusions:

> "In the US, most investigators administer 200 mg rather than 600 mg mifepristone as many trials have shown equivalent results with these two dose schedules. A recent meta-analysis of four randomized controlled trials compared the two dose regimens. Endpoints were complete abortion, continuing pregnancy and side effects. The two doses *[600 v. 200 mg mifepristone]* result in similar rates of complete abortion with no difference in adverse events."

Another change in clinical practice was related to the labeling stipulation that women return to the clinic/office two days after Mifeprex was administered to take the misoprostol dose. Many experts involved with termination of early pregnancies also advocated misoprostol self-administration at home to mitigate the time, travel and inconvenience of this additional visit.

In the US, the American College of Obstetricians and Gynecologists (ACOG), National Abortion Federation[32], and PPFA currently all endorse the lower oral dose of mifepristone followed in 24-48 hours with misoprostol. According to the 2014 ACOG Practice Bulletin, the misoprostol route of administration may be oral, buccal, sublingual or vaginal; sublingual administration, however, has a more rapid absorption resulting in a higher incidence of adverse side effects.[1]

<u>European practice</u>:

In December 2011, the International Federation of Obstetrics and Gynaecology (FIGO) published revised guidelines for the use of mifepristone and misoprostol for MAB up to 63 days, 64-84 days, and after 84 days (12 weeks) gestation.[33] The FIGO recommended regimens using 200 mg of oral mifepristone followed by 800 mcg of misoprostol administered vaginally, buccally, or sublingually. Up to 57-63 days gestational age, misoprostol is taken 24-48 hours after mifepristone. Per the review of data available to them, FIGO decided additional doses of 400 mcg misoprostol may be

safely used depending on gestational age, and these combinations result in a complete termination in more than 95% of cases.

Similar guidelines using either vaginal, buccal, or sublingual misoprostol are endorsed by the World Health Organization (WHO), the United Kingdom Royal College of Obstetricians and Gynecologists[34], and a recent Cochrane Review (2011, Issue11).[35]

Reviewer's Comment:

From the above discussion, it is clear that the standard of care in the US for early MAB has deviated from the FDA-approved dosing regimen. PPFA provides the largest number of medical abortions each year in the US and as early as 2001, was already using the regimen of 200 mg oral mifepristone followed 24-48 hours later by 800 mcg vaginal misoprostol.

There are a large number of studies and reviews that support the efficacy of the proposed new dose regimen through 63-70 days gestation. Efficacy was defined in these studies as a complete expulsion of the pregnancy without need for surgical intervention for any reason during the follow up period. The 2015 review by Chen and Creinin summarized clinical outcomes and adverse effects from 20 MAB studies including a total of 33,846 women using regimens consisting of 200 mg oral mifepristone followed by buccal misoprostol through 70 days gestation. All studies except two used 800 mcg misoprostol. Two studies (827 women) used 400 mcg buccal misoprostol. Six studies used a 24-hour time interval between mifepristone and buccal misoprostol administration and 14 used a 24-48 hour window for the dosing interval. The table below lists the 15 studies using the proposed doses (200 mg plus 800 mcg) with a 24-48 hour dosing interval.

Reviewer's comments:

The data above in Table 3 and Table 4 from ~16,800 US women and ~18,400 non-US women in clinical studies of MAB through 70 days gestation with success rates of 97.4% (US) and 96.1% (non-US) strongly support the proposed new dosing regimen and the extension of the acceptable gestational age. The number of US and non-US studies, the number of evaluable women, and the overall complete abortion rates (termination with no surgical intervention) will be described in the efficacy table in Section 14 CLINICAL STUDIES in the new approved label. Additional discussion on increasing the gestational age through 70 days follows in the next major section.

Precise timing of the administration of misoprostol has not been shown to result in a higher success rate which is why the majority of the above studies allowed a range of hours between the mifepristone dose and misoprostol dose rather than one set time between the two drugs. The 2013 Raymond systematic review[18] of 87 studies that exclusively used a mifepristone 200 mg oral dose in over 45,000 women, followed by varying doses and routes of administration of misoprostol, concluded that if the mifepristone-misoprostol interval is < 24 hours, the procedure is less effective compared to an interval of 24-48 hours.

Another study[45] also looked at the question of the mifepristone-misoprostol interval. The authors conducted a systematic review of randomized controlled trials published from 1999 to 2008 to assess the evidence for a shorter mifepristone and misoprostol administration interval for first trimester medical termination. Searching strategy included MEDLINE, EMBASE, CLINAHL and Cochrane Library. The primary outcome measure was complete abortion without the need for a surgical procedure. "Five randomized controlled trials (RCTs) compared the efficacy of mifepristone-misoprostol administration intervals between 0 and 72 hours in 5,139 participants. The complete abortion rates varied between 90% and 98%. Although the meta-analysis of pooled data of all five RCTs showed no statistically significant difference in efficacy between

the shorter and longer dosing intervals, there was a trend toward slightly lower success rates with administration intervals < 8 hours." This study supports the finding that the proposed regimen is effective with the 24-48 hour flexible interval. Labeling will indicate that the regimen may not work as well if the misoprostol is taken earlier than 24 hours after Mifeprex.

Reviewer's Final Recommendation:

The new proposed regimen of 200 mg oral mifepristone followed in 24-48 hours with 800 mcg buccal misoprostol should be approved; there are sufficient data from the medical literature with over 35,000 women supporting the regimen's efficacy (termination without any additional surgical intervention) as being in the 91-98% range.

6.1.7 Increase in gestational age from 49 days to 70 days

Original NDA review:

The US clinical trial[31] was conducted from September 1994 to September 1995 and treated 2,121 women. A total of 2,015 women (95%) returned at the 14-day follow-up visit. The trial categorized women into three groups based on gestational age at the time of procedure, and evaluated the rates of "Success" (a complete pregnancy termination without use of any additional doses of misoprostol or surgical intervention), and the rates of "Failure" (with four sub-categories of incomplete abortion, ongoing pregnancy, intervention for medical reason, and intervention solely because of patient request). The success and failure data are shown in Table 5.

Table 5: Original NDA Efficacy Results

OUTCOME	≤ 49 Days N= 827 (%)	50-56 Days N= 678 (%)	57-63 Days N= 510 (%)
Success (mifepristone + misoprostol	**762 (92)**	**563 (83)**	**395 (77)*†**
Failure (any surgical intervention for any reason) N (%)			
Total failures	**8%**	**17%**	**23%*†**
Incomplete abortion	39 (5)	51 (8)‡	36 (7)
Ongoing pregnancy	8 (1)	25 (4)*	46 (9)* **§**
Medical indication for intervention	13 (2)	26 (4)‡	21 (4)‡
Patient's request for intervention	5 (0.6)	13 (2)	12 (2)‡

***P<0.001 for the comparison with the ≤ 49-days group.**

†P= 0.02 for the comparison with the 50 to 56-days group.

‡ 0.001 ≤ P<0.03 for the comparison with the ≤ 49-days group.

§ P<0.001 for the comparison with the 50 to 56-days group.

Source: Modified from Table 1, pg 1243 in the Spitz NEJM article (1998).

Reviewer's comments:

Looking at the results in the table above, it is reasonable that the approved use was only for women in the first 49 days' gestation, given the 8% "failure rate" in this subgroup, compared to 17% and 23% failure rates for the longer gestations. It is important to note that failure was defined as any case requiring surgical intervention for any of the following reasons:

- **incomplete abortion (incomplete expulsion)**
- **documented ongoing pregnancy**
- **medical reasons (usually heavy vaginal bleeding with or without retained products of conception)**
- **patient request (usually for bleeding)**

As has been pointed out, since the US trial data used for the FDA approval of Mifeprex, given the experience and data gained in the last 20 years from millions of women in the US and abroad, the success rates and overall outcomes are very different. Currently, when a "failure" occurs, using the original definition, options that are now commonly available include the following:

- **expectant management (wait and see) in the case of an incomplete abortion (i.e., pregnancy terminated but not fully expelled)***
- **medical treatment for bleeding, pain and other common symptoms**
- **clinical evaluation with the use of 1) office ultrasound and/or 2) hCG data determined by rapid, sensitive urine and/or serum testing***
- **additional doses of misoprostol for an incomplete abortion***
- **less invasive surgical intervention (vacuum aspiration) in the clinic/office instead of a D&C under anesthesia in an operating room**
- **continuing the pregnancy (although the medical recommendation is to proceed to a surgical abortion in such a case, we acknowledge that a woman could potentially decide to continue the pregnancy)**

*** per protocol, these options were NOT available in the original US trial**

It is also evident that the proposed new dosing regimen is considerably more effective for all gestations through 70 days [see data and discussion that follows for 57-63 and 64-70 days gestation], especially when compared to the original data using the FDA-approved regimen which had "success" rates of only 83% and 77% at 50-56 and 57-63 days gestation, respectively.

Current evidence for increasing the gestational age to 70 days

Current evidence demonstrates that the new proposed medical abortion regimen is effective for women in the range of 57-63 days and 64-70 days of gestation. A 2015

systematic review identified six published studies that recorded data on outcomes of medical abortions performed during gestational Days 64-70.[46]

The published studies were conducted in the United States, UK, Mexico, Curaçao, Vietnam, and the Republic of Georgia. All subjects were treated as outpatients between 2007 and 2015. The older UK study evaluated 127 women who were at 64-70 days gestation and treated with 200 mg oral mifepristone followed by 800 mcg vaginal misoprostol.[47]

Reviewer comment:

We evaluated the data separately for 57-63 and 64-70 days of gestation. The following two tables show the efficacy data for 57-63 and 64-70 days gestation (also known as Week 9 and Week 10).

Reviewer comments:

Although the Chong and Bracken studies do not use the exact proposed dosing regimen, it is felt that their efficacy results are relevant because both used a lower dose of misoprostol, which, if anything, would have been expected to provide lower efficacy.

After careful review of the above eight studies, we find the following results. A combined total of 3,072 women were treated at 57-63 days of gestation, with 2,730 (88.9%) providing outcome data. Of these women, 2,585 (94.7%) had a complete medical abortion (pregnancy termination without any surgical intervention), and 54 (2.0%) had ongoing pregnancies. This successful treatment rate is better (94.7% compared to 92.1%) than the rate in the data on which the 2000 FDA Mifeprex approval was based. The data are sufficient and acceptable for extending the approval of Mifeprex up to at least 63 days gestation.

The numbers here do not exactly match the results shown in the efficacy table for 57-63 gestational days that are in Section 14 CLINICAL STUDIES in the new approved label, which is limited to studies using the identical dosing regimen to that proposed in this supplement. The number of evaluable women here is higher because the Chong and Bracken data are included, as noted above in the comment. The label, however, states the same conclusion of a 94.7% complete medical abortion rate and a 2% ongoing pregnancy rate.

Data for 64-70 days gestation are found in the next table.

[Y]The Gouk study in 1996-97 included 253 women at 63-83 days gestation (Weeks 10-12).

Source: Table modified with data from published studies. See Abbas D et al. Contraception [MAB through 70 days gestation] 92 (2015):197-199.

Reviewer comments:

Use of the Chong and Bracken data is discussed above. Although the Gouk regimen used a different route of administration for misoprostol, the effectiveness of the vaginal route appears to be similar to that of the buccal route; therefore, these data are considered relevant. Data on sublingual administration of misoprostol may be less generalizable due to the different pharmacokinetic (PK) profile and higher AE frequency compared to buccal

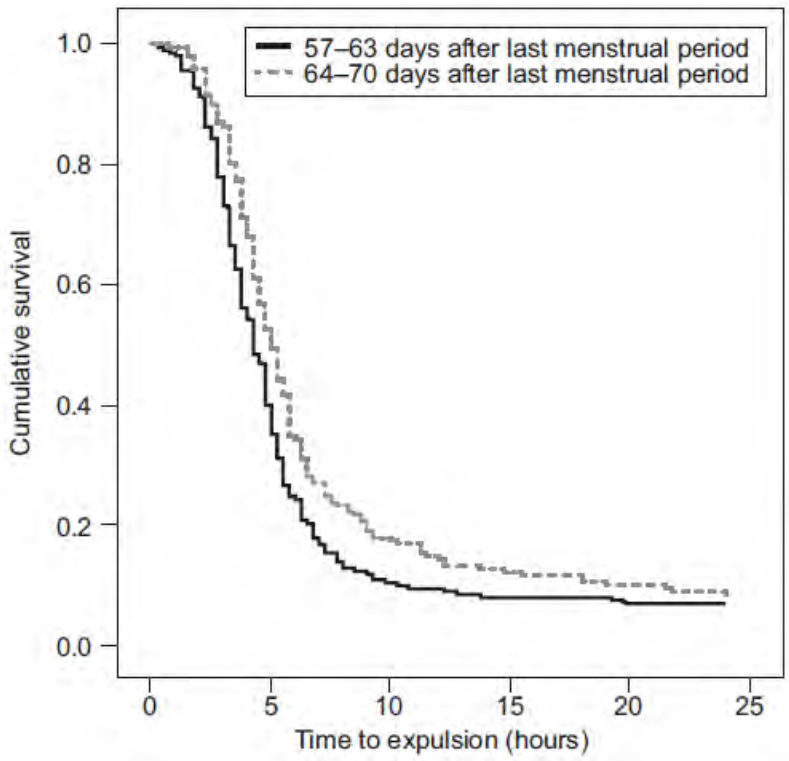
administration. Also, see Section 4.4.3 Pharmacokinetics and the Cross Discipline Team Leader review.

The abortion success rates shown above from seven studies are comparable to (and in several studies, greater than) the success rates for medical abortion in the initial 2000 decision for Mifeprex up to 49 days gestation. The proportion of subjects with complete success without any medical or surgical intervention in the US pivotal trial that supported the original approval was 92.1%, as shown in Table 5, in 827 women encompassing all gestational weeks up to 49 days. The data in the above two tables include 3,072 women treated at 57-63 days gestation and 987 women at 64-70 days gestation. We believe that this comprises a sufficient number of women in each gestational week upon which to make a clinical decision, and that the overall 94.7% and 92.6% success rates are acceptable for approval.

The data here clearly establish the efficacy of medical abortion with mifepristone and misoprostol through 70 days gestation. At least two Gynuity Health studies of outpatient medical abortion through 70 days are ongoing, so more information from clinical studies will be available in the future.

It is also worth noting that in November 2015, the National Medical Committee of PPFA approved medical abortion through 70 days, so this is currently their standard of care.

Reviewer's Final Recommendation:



The new proposed regimen of 200 mg oral mifepristone followed in 24-48 hours with 800 mcg buccal misoprostol should be approved for use through 70 days gestation (10 weeks from the first day of the LMP).

6.1.8 At-home Administration of Misoprostol

For the majority of women, the most significant cramping and bleeding will occur within 2-24 hours after taking misoprostol. Requiring women to take misoprostol in the office necessitates another visit and can interfere with the woman's ability to make reasonable plans for the expected bleeding and cramping. With the option to take misoprostol at home the woman can:

- **Plan to experience cramping and bleeding at a safe and convenient time when support is available**
- **Minimize loss of income (for childcare or missed days of work)**
- **Experience improved comfort, satisfaction and privacy**

Data (graph below) from Winikoff (2012)[19] shows the time in hours to complete expulsion of the pregnancy after misoprostol administration for gestations at 57-63 and 64-70 days. Within about 5 hours after misoprostol dosing, 50-60% of the MABs are complete.

Many studies have recorded data on home use in the US and elsewhere and "demonstrated that 87-97% of women find home use of misoprostol acceptable. Home use of misoprostol is now standard in the US."[50] The 2009-10 Swica comparative study focused on the option to take both mifepristone and misoprostol at home after being counseled at the office/clinic. There was no significant difference in either efficacy or safety for the 139 women (46%) who took both medications at home compared to 161 women who took mifepristone in the office and misoprostol at home.

Table 8 that follows is a list of studies where data are available on home use of misoprostol and the specific efficacy findings.

Source: FDA clinical reviewer table.

Reviewer comments:

The above table with data for home administration of misoprostol for 30,763 women in the US and other countries shows a success rate ranging from 91.9 to

97.7%. The two largest studies (Gatter and Goldstone) pooled showed 97% success using the new proposed dosing regimen with home use of buccal misoprostol. The lowest success rate above of 91.9% in the Bracken study is still supportive for approval and does not differ significantly from results with misoprostol taken in the clinic/office.

Of note is that 4 of the above studies provided data on home use of misoprostol through 70 days gestation.

Home use of misoprostol has been evaluated as part of the proposed protocol in studies including well over 30,000 patients, as well as in studies of home use of both mifepristone and misoprostol. The Raymond (2013) review[18] of early MAB with mifepristone 200 mg and misoprostol (different doses and routes of administration), analyzed 87 trials with 47,283 treated women up to 63 days gestation. The article concludes: "We found no evidence that allowing women to take the misoprostol at home increased the rate of abortion failure or serious complications." It is also notable that the NAF and ACOG guidances encourage home administration of misoprostol and it has been standard protocol for most PPFA clinics for since 2005.

While we do not have age-specific efficacy data for adolescents who took misoprostol at home, it is evident that many adolescents did take buccal misoprostol at home. In the Goldstone 2012 study, there were eight 14 year olds and 931 women ages 15-19 who took misoprostol at home. In the Gatter 2015 study, there were 24 adolescents age 11-14, 82 age 15, 216 age 16, and 435 age 17 who took misoprostol at home. The overall efficacy in these two large studies was excellent, as previously noted.

Reviewer's Final Recommendation:

There is no medical rationale against permitting the woman to be given the misoprostol on the day of the initial clinic/office visit and self-administer it at a convenient time in the next 24-48 hours at home. This would avoid another visit and the time, transportation, loss of work, inconvenience, etc. that such a visit would involve. Furthermore, given the fact that 22-38% of women abort within 3 hours and 50-60% within 5 hours of buccal misoprostol[19], it is preferable for the woman to be in a convenient, safe place (home or at a support person's location) for the expected uterine cramping and vaginal bleeding to occur. The new proposed regimen of 200 mg oral mifepristone followed in 24-48 hours with 800 mcg buccal misoprostol shows acceptable efficacy when misoprostol is self-administered at home.

6.1.9 Use of a Repeat Dose of Misoprostol if Needed

Several studies using buccal misoprostol allowed the option of repeat misoprostol at follow-up one week after mifepristone for persistent gestational sac; however, only a few

studies report specific outcomes. The Chen and Creinin 2015 review[12] of mifepristone with buccal misoprostol for MAB reported on four studies. Chong (2012)[40] provided additional information from 1,122 women. In the study protocols, women with an ongoing pregnancy at follow-up were recommended to undergo uterine suction curettage, whereas women who had retained products of conception were given the options of expectant management, suction curettage/aspiration, or a second dose of misoprostol. Limited additional data were provided by Gatter (2015)[13]: data on the use of a repeat dose of misoprostol were available from a subset of 7,335 women, of whom 87 (1.2%) received a repeat dose. Efficacy results, however, are not stated in the Gatter article, so this study is not included in Table 9, which highlights success rates after a repeat dose of misoprostol in seven published articles that included this specific outcome.

Table 9: Success with a Repeat Dose of Misoprostol - Incomplete MAB

***These 4 studies are in Table 4 of the Chen and Creinin 2015 review article.**

[Y]These data are directly from the Winikoff article; the Chen and Creinin review had incorrect data.

Source: table modified by FDA reviewer from Chen and Creinin 2015 article and 3 other studies.

[51] Raghavan S, et al. Comparison of 400 mcg buccal and 400 mcg sublingual misoprostol after mifepristone medical abortion through 63 days' LMP: a randomized controlled trial. Contraception 2010; 82:513-9.

Reviewer's comment:

The completion success rates shown above are high. While only 3.4% of the women took a second misoprostol dose, 90% of these women avoided a surgical procedure to complete their termination. We believe the option of a repeat dose of misoprostol is acceptable and safe in the case that complete expulsion has not occurred after initial dosing (provided that the pregnancy is not still ongoing): it offers a choice for the healthcare provider and the patient on how to manage an incomplete expulsion (retained products of conception) following the initial treatment. As noted above, the other options are expectant management, suction aspiration in the office, or a surgical D&C in the operating room. It is also of note that it is standard protocol in many US clinics to offer the choice of a repeat misoprostol dose, especially for women with an incomplete termination (retained tissue/clots or a documented non-viable pregnancy). A second dose of misoprostol is generally not offered in the case of a documented ongoing pregnancy following use of mifepristone and misoprostol.

Reviewer's Final Recommendation:

Use of a repeat dose of misoprostol may be offered when using the new dosing regimen if the pregnancy has ended, but the expulsion is incomplete.

6.1.10 Physician v Other Healthcare Provider Treatment

The Applicant provided data on the efficacy of medical abortion provided by non-physician healthcare providers, including four studies with 3,200 women in randomized controlled clinical trials and 596 women in prospective cohorts. These studies took place in varying settings (urban, rural, international, low resource). The efficacy results are as follows:

- Olavarietta[85] demonstrated efficacy of 97.9% when the MAB was provided by nurses as compared with 98.4% with physicians
- Kopp Kallner[84] showed efficacy of 99% with certified nurse midwives versus 97.4% with physicians
- Warriner[52] demonstrated efficacy of 97.4% with nurses versus 96.3% with physicians
- Puri[83] showed efficacy of 96.8% compared with 97.4% in the "standard care" group

Reviewer comment:

The above findings for MAB efficacy from 5 studies clearly demonstrates that efficacy is the same with non-physician providers compared to physicians or the

[52] Warriner IK, Wang D, Huong NTM, Thapa K, Tamang A, Shah I et al. Can midlevel health-care providers administer early medical abortion as safely and effectively as doctors? A randomized controlled equivalence trial in Nepal. Lancet 2011; 377: 1155-61.

"standard care" treatment.

6.1.11 Follow-up Timing and Method

Concerning follow-up timing and method, follow-up within the 7-14 day interval after mifepristone administration is universally recommended; however, follow-up does not necessarily need to be done as currently labeled "in the clinic or healthcare provider's office 14 days after Mifeprex administration."

One strong argument for flexibility in follow-up timing, location and method after the administration of Mifeprex and misoprostol is to avoid placing an undue burden on either the provider or the patient, while maintaining the ability to identify incomplete terminations. The currently approved labeling specifies three visits (two for dosing, one for follow-up) at fairly rigid times that are often not practical, convenient or necessary.

Several articles were submitted by the Applicant to support flexible follow-up. The most noteworthy article is the 2013 Raymond review[18] of over 45,000 MABs using 200 mg oral mifepristone that concluded: "we observed no significant association between abortion failure rates and the timing of the follow-up evaluation." This topic is discussed thoroughly in the Section Submission-Specific Primary Safety Concerns.

Reviewer comment:

Follow-up during the 7-14 day window after the administration of mifepristone is necessary to determine that the termination was successful and the woman is in good health. If for some reason the follow-up contact is not made (the woman is "lost to follow-up"), the clinical guidelines of NAF state that "all attempts to contact the patient (phone calls and letters) must be documented in the patient's medical record." This guideline emphasizes the importance of follow-up but accepts the fact that women are sometimes lost to follow-up and there is no mechanism that can guarantee 100% follow-up in the normal clinical setting.

Reviewer's Final Recommendation:

Follow-up after taking Mifeprex and misoprostol is necessary. The exact timing and method should be flexible and determined jointly by the healthcare provider and the individual woman being treated, and should follow the standard guidelines for the office/clinic where the Mifeprex is being dispensed. Fortunately, there are several choices/methods of follow-up that can be used and it appears that no single option is superior to the others. The woman should always have the option to be seen at the office/clinic.

6.1.12 Subpopulations

Parity

The Raymond (2013) review article[18] had 74 trials with parity data for ~ 32,000 women. In 34 trials whose study populations comprised > 50% nulliparous women, the MAB success rate was 96.4%; in 40 trials with ≤ 50% nulliparous women, the success rate was 94.9%. This suggests that women who have not had a previous term pregnancy

delivery have a slightly higher early MAB success rate. These data are not definitive, however, because such factors as the dosing regimen, route of administration, and gestational age could also influence the success rates.

Previous abortion

One study[26] found that success rates are slightly better in women who have not had a previous abortion. Prior abortion, however, did not appear to be an important risk factor for abortion failure or success (Raymond[18].

Race

There does not appear to be any efficacy difference based on race. Results are reported in studies enrolling a large number of women. Gatter (2015)[13] had five racial/ethnicity groups among over 13,000 women at the PPFA centers in the Los Angeles area; the success rates ranged from a low of 97.2% (African-American) to a high of 97.8% (White, Asian and Other), which is not clinically or statistically significant.

Adolescents v. Older Women

There are at least three articles that support the efficacy of MAB in adolescents; each study used the same definition of success as the need for no further medical or surgical intervention:

- Phelps et al. 2001[53] conducted a pilot study in 28 adolescents aged 14-17, at ≤ 56 days gestation, using Mifeprex 200 mg followed 48 hours later by misoprostol 800 mcg vaginally. All 28 had complete medical terminations without complications or surgical intervention. Five adolescents did not require any misoprostol.
- Niinimaki et al. April 2011:[54] Finnish Registry from 2000-06 comparing rates of AEs in adolescents and adult women with MAB at ≤ 20 weeks gestation, which included 3,024 women < age 18 and 24,006 women age 18 or older. By gestational age, 2,424 adolescents were < 64 days gestation and 139 were within 64-84 days gestation. The specific dose regimens are not stated and may have varied according to the gestational ages. The odds ratio for an incomplete abortion for adolescents under age 18 compared to the women ≥ age 18 was 0.69, meaning that the younger women had a lower rate of incomplete abortions.
- Gatter, Cleland and Nucatola (2015):[13] US data using the proposed regimen of mifepristone 200 mg and misoprostol 800 mcg buccally through 63 days included 283 women aged 17 years and 322 under age 17 (see Table 10). The 605 women under age 18 had a 98.7% success rate while the 6,674 18-24 year olds had a 98.1% success rate. The four older age groups had success rates that ranged from 96.5 to 97.5% without any need for a surgical procedure and additional treatment. In

[53] Phelps RH, et al. Mifepristone abortion in minors. Contraception 2001;64:339-343.

[54] Niinimaki M, et al. Comparison of rates of adverse events in adolescent and adult women undergoing medical abortion: population register based study. BJM 2011;342: d2111.

the pediatric population, there were no cases requiring transfusion, hospitalization or treatment for severe infection.

The table below shows the age distribution from the Gatter study. There were 24 adolescents between ages 11-14, 82 adolescents age 15, and 216 age 16 totaling 322 adolescents. As noted, 283 adolescents were age 17.

Table 10: MAB Success by Age Group

Age Group (years)	Total N Success (%)	Comment
< 18	**605 (98.7)**	**322 were age 11-16 283 were age 17**
18-24	6684 (98.1)	The age distribution here is representative of other US data on MAB - largest group is age 18-24 followed by age 25-29
25-29	3317 (97.5)	
30-34	1613 (96.5)	
35-39	855 (97.0)	
40+	299 (97.3)	
TOTAL	**13,373 97.7% overall success**	

Source: Data from Gatter 2015 review.

Reviewer comments:

Data from 3,657 adolescents under age 18 in the above three studies shows a MAB success rate that is consistently equal to or higher than that found in the women older than age 17. It is interesting that five (18%) of the adolescents in the Phelps study did not even need misoprostol. The percentage of women not needing any misoprostol is generally much lower, perhaps 1-3%, in other early MAB studies. From the articles reviewed, efficacy of early MAB in the adolescent population is not a concern.

Additional adolescent data were reported in the Goldstone 2012 study[20], where there were eight 14 year olds and 931 women ages 15-19 who took misoprostol at home for a MAB up to 63 days gestation. Efficacy and safety data by age groups were not reported in the article.

6.1.13 Analysis of Clinical Information Relevant to Dosing Recommendations

As noted in some of the reviewer comments and tables, there is evidence that lower doses of misoprostol (400 mcg), other ROAs (vaginal and sublingual), inclusion of more advanced gestational ages, and different dosing intervals between mifepristone and misoprostol have shown acceptable efficacy and safety results. However, for the purposes of this NDA review, our final recommendations are focused on the dosing regimen and other requests specifically made by the Applicant.

6.1.14 Discussion of Persistence of Efficacy and/or Tolerance Effects

There is no evidence that repeated medical or surgical abortion is unsafe or that there is a tolerance effect. Return to fertility is well-documented: in the Patient Counseling Information section, the labeling states "inform the patient that another pregnancy can occur following medical abortion and before resumption of normal menses" and "inform the patient that contraception can be initiated as soon as pregnancy expulsion has been confirmed, or before she resumes sexual intercourse."

6.1.15 Additional Efficacy Issues/Analyses

The Applicant has requested that revised labeling provide only for the new proposed regimen and that the original approved regimen be deleted.

Reviewer Final Recommendation:

While there are no safety or efficacy reasons that would lead us to withdraw approval of the currently labeled dosing regimen, we concur that it may be deleted from labeling because very few providers currently use it, and inclusion of two options for dosing could be confusing. Of note, PPFA and NAF guidelines have used mifepristone 200 mg oral and misoprostol 800 mcg (initially given vaginally and now buccally) since 2001.

7 Review of Safety

Safety Summary

- Medical abortion with the new proposed regimen of Mifeprex 200 mg followed 24-48 hours later by misoprostol 800 mcg buccally through 70 days gestation is safe. Major adverse events including death, hospitalization, serious infection, bleeding requiring transfusion and ectopic pregnancy with the proposed regimen are reported rarely in the literature on over 30,000 patients. The rates, when noted, are exceedingly rare, generally far below 0.1% for any individual adverse event. The number of postmarketing deaths associated with Mifeprex pharmacovigilance is very low. Non-vaginal routes of administration of misoprostol have increased and since the *C. sordellii* deaths associated with vaginal misoprostol, there have been no *C. sordellii* deaths. Given that the numbers of these adverse events appear to be stable or decreased over time, it is likely that these serious adverse events will remain acceptably low.

- Common adverse events associated with medical abortion occur at varying but acceptable rates.

- There are scarce cases of uterine rupture associated with early medical abortion. Medical abortion using mifepristone with or without misoprostol in the first trimester is safe from this perspective.

- There does appear to be an association between angioedema and mifepristone administration. The risks of anaphylaxis and angioedema should be included in the labeling for Mifeprex and there should be continued pharmacovigilance for anaphylaxis.

- Home use of misoprostol has been evaluated as part of the proposed dosing regimen in studies including well over 30,000 patients, demonstrating an acceptable safety profile, with rates of adverse events equal to or lower than those with the approved regimen requiring in-office dispensing of misoprostol. Home use of misoprostol can increase patient convenience, autonomy and privacy without increased burden on the healthcare system.

- In the articles about repeat misoprostol after mifepristone administration, there is little information provided about safety. The need for a second dose is a relatively uncommon occurrence. In studies of medical abortion using misoprostol alone, using two or more doses as compared to one dose of misoprostol does increase the risk of the common adverse event of diarrhea. There are a very few reports of uterine rupture with multiple doses of misoprostol, in almost all cases in women with prior uterine surgery, such as a cesarean section.

- The Applicant demonstrates that alternatives to in-clinic follow-up, including standardized questions, telephone follow-up, and use of low and high sensitivity urine pregnancy tests, serum pregnancy tests, and ultrasound are effective and safe. Loss-to-follow-up rates do not exceed those of in-clinic follow-up. This option can increase flexibility and accessibility of medical abortion for women.

- Medical abortion in adolescents appears to be at least as safe, if not safer, as in adult women. These data support the safety of Mifeprex in adolescents and satisfy requirements for PREA. No information on safety or efficacy if used in premenarchal girls is required, as the medication is not indicated in that subset of the pediatric population.

- Midlevel providers in the United States, such as nurse practitioners, nurse midwives and physician assistants currently provide family planning services and abortion care, including medical abortion care, under the supervision of physicians. In light of the REMS requirements, midlevel providers who are currently practicing abortion care are doing so under the supervision of physicians. Therefore, facilities that employ midlevel providers already have an infrastructure in place for consultation and referral if, as required under the REMS, a prescriber is unable to provide additional care, including surgical management if needed.

- It is appropriate to modify the current adverse event reporting requirements under the REMS, which are currently outlined in the Prescriber's Agreement to include "hospitalization, transfusion or other serious event." FDA has received

such reports for 15 years, and it has determined that the safety profile of Mifeprex is well-characterized, that no new safety concerns have arisen in recent years, and that the known serious risks occur rarely. For this reason, FDA does not believe ongoing reporting of all of the specified adverse events is warranted. The proposed Prescriber's Agreement Form (to replace the Prescriber's Agreement) will continue to require that qualified healthcare providers report any deaths. The Applicant will still be required by law, as is every NDA holder, to report serious, unexpected adverse events as 15-day safety reports, and to submit non-expedited individual case safety reports, and periodic adverse drug experience.

- Upon review of historical documents and of current guidelines for REMS materials, the phrase "under Federal law" can be removed from the Prescribers' Agreement. We concur with (b) (6) review of the REMS document.

- The revised Indication Statement should read:

"Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation." Safe use of Mifeprex would be enhanced when other information necessary to describe appropriate use (i.e., the need to use Mifeprex in a combined regimen with misoprostol and the gestational age for use) is included in the Indication Statement. This would be consistent with current FDA thinking (e.g., the internal Label Review Tool) which states that the indication and use statement should include "Information if drug is to be used only in conjunction with another therapy."

7.1 Methods

The assessment of the clinical safety of Mifeprex through 70 days gestation is based on the Applicant's submission of numerous articles from the peer-reviewed medical literature. The various studies have different designs, inclusion criteria, dosing regimens and endpoints for safety and efficacy. For the evaluation of safety, this reviewer focused on the studies that evaluated the proposed dosing regimen . All the articles used for this review can be found in the extensive list of references in Section 9.6 at the end of this review.

7.1.1 Studies/Clinical Trials Used to Evaluate Safety

The reviewer evaluated safety based on the studies that focused on the proposed dosing regimen, specifically Mifeprex 200 mg followed by misoprostol 800 mcg buccally 24-48 hours later, as listed in Table 11 below. Supportive data from studies that have less specific numerical data or studies that included other regimens, specifically with different routes of administration of misoprostol (vaginal, oral, sublingual) are not included in this portion of the review, but are discussed in Sections Major Safety Results and Supportive Safety Results. Table 11 lists the studies referenced in these discussions.

7.1.2 Categorization of Adverse Events

For the purposes of this review, adverse events categorized as serious include death; hospitalization; infection, including severe infection requiring hospitalization; bleeding requiring transfusion; and ectopic pregnancy. Other non-serious adverse events include: nausea, vomiting, diarrhea, fever, bleeding and cramping.

7.1.3 Pooling of Data Across Studies/Clinical Trials to Estimate and Compare Incidence

The data are not pooled across studies as the study designs are quite different. The incidence of individual adverse events is noted for each study, and can be used to provide an estimated range.

7.2 Adequacy of Safety Assessments

7.2.1 Overall Exposure at Appropriate Doses/Durations and Demographics of Target Populations

Per the Applicant, there have been approximately 2.5 million US uses of Mifeprex by US women since its approval in 2000. If evaluation is limited to the studies listed in Table 11 focusing specifically on the proposed new dosing regimen, exposure for this safety analysis is based on well over 30,000 patients. The exact number cannot be determined because two retrospective studies (Gatter[13] and Ireland[15]) are likely based on overlapping cohorts of patients from Planned Parenthood clinics in Los Angeles. There are likely some differences in the demographic data for the different studies; therefore, the descriptions are separated into US and international data. However, it is doubtful

that demographic differences such as race or ethnicity are clinically meaningful in relation to the safety and efficacy of medical abortion. The data do include adolescents exposed to Mifeprex; information on safety in this population is discussed in Section 7.4.5.

7.2.2 Explorations for Dose Response

NA for this review.

7.2.3 Special Animal and/or In Vitro Testing

NA for this review.

7.2.4 Routine Clinical Testing

From this reviewer's assessment of the literature, no routine clinical testing is needed to evaluate the proposed changes to the Mifeprex labeling.

7.2.5 Metabolic, Clearance, and Interaction Workup

NA for this review.

7.2.6 Evaluation for Potential Adverse Events for Similar Drugs in Drug Class

Please see Important Safety Issues with Consideration to Related Drugs for discussion of potential adverse events for drugs in this class.

7.3 Major Safety Results

7.3.1 Deaths

Deaths are rare with medical abortion. Most of the articles provided did not specifically report on deaths with medical abortion. Among the seven US studies, only one reported on deaths (Grossman, 2011[36]) and noted zero deaths among 578 subjects. Among the three international studies, only one[20] reported on deaths. In this retrospective review of 13,345 medical abortions with the proposed regimen, the authors reported only one death, yielding a rate of 0.007%. More information on deaths associated with medical abortion is found in Section 8 Postmarket Experience.

7.3.2 Nonfatal Serious Adverse Events

The nonfatal serious adverse events typically discussed in the literature are hospitalization, serious infection, bleeding requiring transfusion and ectopic pregnancy. See narratives below and Table 12, Table 13, and Table 14 for details.

Hospitalization data:

Most articles do not report hospitalization data. In the US studies, 19 patients were reported as being hospitalized out of a total of 16,696 subjects. The overall rates range

from 0.003-1.1%. Only three articles separated out hospitalizations by gestational age. In Gatter 2015[13], there were 3/8495 hospitalizations among women ≤ 49 days, 3/3142 among women at 50-56 days gestation and none among women at 57-63 days. In Winikoff 2012[19], there were only two hospitalizations, both among women at 57-63 days, and none in the 64-70 days gestation group. In Creinin[25] two of six total hospitalizations were in the 50-56 days group and two in the 57-63 days group. The two remaining hospitalizations in that study were unrelated to study drug and gestational age information was not provided for these two cases. There were none among women at 64-70 days gestation. See Table 12 below.

Among the international studies, only 3 of 15,109 women were hospitalized, with rates from 0.07-0.6%. These rates were not separated out by gestational age. See Table 12.

^ includes woman with sepsis noted in Table 13, and one woman with chronic pancreatitis, recurrent.

§includes subjects receiving transfusions noted in Table 14.

Source: NDA clinical reviewer table.

Serious infection:

Infections requiring hospitalization or IV antibiotics were rare in the studies. Only three US studies captured this information, with rates ranging from 0-0.015%. Two studies separated this information out by gestational age. In Gatter 2015[13], the two serious infections were in women ≤ 49 days gestation. There were no serious infections in

women at 50-56 or 57-63 days gestation. In Winikoff 2012[19], there was one serious infection in a woman at 57-63 days and none in women at 64-70 days. See Table 13.

Among the international studies, there were five women hospitalized with rates from 0.03-0.07%. This information was not broken down by gestational age. See Table 13.

Transfusion data:

With regard to bleeding requiring transfusion, five of the seven US studies included this information as shown in Table 14. The rates of transfusion range from 0.03-0.7%. Three of the studies provided a breakdown by gestational age. In Gatter 2015[13], there were the following: one woman in the ≤ 49 days group, three in the 50-56 days and zero in the 57-63 days group. In Winikoff 2012[19], there were: two in the 57-63 days group

and 1 in the 64-70 days group. In Creinin 2007[25], there were two women transfused each in the 50-56 days and 57-63 days. Only one international study[20] (Goldstone 2012) reported on transfusions and 11/13,345 women or 0.08% required transfusion.

Source: NDA clinical reviewer table.

Ectopic pregnancy:

Ectopic pregnancies were rarely reported in the supporting literature submitted with this efficacy supplement. Only one ectopic pregnancy was reported among 847 patients (0.12%) in Winikoff 2008[23].

Several studies also included less detailed, though still useful, information on adverse events. Ireland et al[15] conducted a retrospective review of 30,146 women undergoing

medical or surgical abortion at ≤ 63 days gestation at Planned Parenthood clinics in Los Angeles between November 1, 2010 and August 31, 2013. The authors reported that 29 women of 13,221 (0.1%) undergoing medical abortion experienced a major complication, which was defined as including: emergency department presentation, hospitalization, infection, perforation and hemorrhage requiring transfusion. The article did not specify the rate of each event. No deaths or ectopic pregnancies were reported in this study. In 2011, Grossman[36] reported on a study of medical abortion provided through telemedicine, in which 578 women seeking abortion services at Planned Parenthood of the Heartland clinics in Iowa were offered in-person services or telemedicine services. The serious adverse event outcomes are reported in Table 12, Table 13 and Table 14 above, but in addition, he reported on adverse events among all medical abortion patients from July 1, 2008 through October 31, 2009 (a wider time frame than the study itself). Four of 1,172 telemedicine patients (0.3%) required a blood transfusion compared to 0.1% of 2,384 in-person patients. These figures were reported in the paper to support study findings of low rates of serious adverse events, including transfusion. Pena (2014)[44] reported on 1,000 women in Mexico who had a medical abortion up to 63 days gestation. Their paper reported that "there were no serious complications as defined by any occurrence that was unexpected, serious, and related to the induced abortion." Upadhyay et al[55] used 2009 through 2010 patient-level billing data from Medi-Cal, California's state Medicaid program, to evaluate the incidence of complications after abortion, including medical abortion. Major complications were defined as those which required hospitalization, surgery or blood transfusion. There were 11,319 medical abortions, with 35 women (0.31%) having a major complication.

Winikoff (2012)[19] provides data on other serious adverse events through 70 days. Regarding hospitalization, there were zero hospitalizations among 350 women receiving medical abortion at 64-70 days compared with 2/379 women at 57-63 days (0.5% rate). There were no serious infections in the 64-70 day group, compared with 1/379 (0.3% rate) in the 57-63 day group. There was one transfusion (1/350=0.3% rate) in the 64-70 day group, compared with 2/379 (0.5% rate) in the 57-63 day group.

Reviewer comments:

(b) (4) **. Serious adverse events including death, hospitalization, serious infection, bleeding requiring transfusion and ectopic pregnancy with the proposed regimen are rarely reported in the literature. The rates, when noted are exceedingly rare, with rates generally far below 1.0% for any individual adverse event. This indicates that medical abortion with the proposed regimen up through 63 days is safe.**

[55] Upadhyay UD, Desai S, Lidar V, Waits TA, Grossman D, Anderson P, Taylor D. Incidence of emergency department visits and complications after abortion. Obstet Gynecol 2015;125(1):175-183.

Serious fatal or nonfatal adverse events in the 64-70 days gestation group, were evaluated in one US study (Winikoff 2012)[19]. This study with 379 women in the 64-70 day range is reassuring in that the rates of hospitalization, serious infection and transfusion are no higher than in the lower gestational age ranges. Based on the available safety data on medical abortion in totality, it appears that serious fatal or nonfatal adverse events are very rare through 70 days as well. This regimen should be approved for use through 70 days gestation.

Reviewer's Final Recommendation:

The regimen of mifepristone 200 mg followed by misoprostol 800 mcg buccally in 24-48 hours is safe to approve for use through 70 days gestation.

7.3.3 Dropouts and/or Discontinuations

The studies included in this safety review revealed a wide range of loss to follow-up, from 0.6% loss to follow-up in the study with telephone follow-up (Ngoc 2014[16]) to 22% in the Grossman[36] study using telemedicine to deliver medical abortion services. One study noted no differences in demographics between the subjects on whom follow-up was available, compared with those on whom no follow-up information was available. Only two studies evaluated other subgroups of women lost to follow-up. Gatter et al 2015[13] found a higher odds of loss to follow-up with age <18 and with income at or below the federal poverty level. Additionally they noted increased odds of loss to follow-up with increasing gestational age. As compared with women 43-49 days gestation, the Odds Ratio (OR) for loss to follow-up at 50-56 days was 1.17 (95% CI 1.05-1.31) and at 57-63 days was 1.28 (95% CI 1.10-1.48). The Boersma study[22] had a 7% loss to follow-up rate. The rate of loss to follow-up was 6.5% at ≤ 49 days, 7.6% at 50-63 days and 7.7% at 64-70 days. No tests for significance were applied to these numbers. Only one study reported on withdrawals: Winikoff 2012[19] reported that 0.27% of patients withdrew and noted this was similar to rates previously reported in the literature.

Reviewer comment:

There is a wide range of loss to follow-up in the studies submitted with the efficacy supplement. The loss to follow-up rate cannot be reliably linked to method of follow-up, though it is notable that the lowest rate of loss-to-follow-up occurred in the Ngoc trial with telephone follow-up (0.6%) and the highest with abortion services provided via telemedicine (22%). The range of loss to follow-up is well-within the range documented in literature covering real-world abortion practice.[1]

7.4 Significant Adverse Events

The label for misoprostol currently includes a boxed warning against the use past 8 weeks gestation, due to the risk of uterine rupture. The (b) (6) safety reviewer and

(b) (6) conducted separate literature searches on this topic. Chen et al 2008[56] evaluated 488 women with a mean gestational age of 7.8 weeks who received 800 mcg misoprostol as part of a randomized study of misoprostol vs. curettage for early pregnancy failure. They found that 78 (16%) of women in the misoprostol group had previous uterine surgery (>1 C-section or myomectomy). There were no uterine ruptures in that study. Gautam et al[57] reported in 2003 on 66 women up to 60 days' gestation and with previous Caesarean section scar, who received misoprostol 800 mcg for termination and found no uterine ruptures. The literature search also revealed five case reports of uterine rupture.[58, 59, 60 , 61, 62] Of these five cases, three occurred with combined mifepristone/misoprostol dosing. Four women had uterine scars, most commonly from at least one prior cesarean section, and one of them had had a prior uterine rupture in labor. Only one woman had no prior uterine scar (Willmott). In these case reports and studies, women received varying doses of misoprostol ranging from 400 mcg to 600 mcg to 800 mcg, and in two, the women received multiple doses of misoprostol (4 and 5 doses in the Wilmot and Bika reports respectively). The women required surgery to repair the uterus or hysterectomy and transfusion. See Table 15.

Source: NDA clinical reviewer table.

(b) (6) also conducted a review of FAERS cases from January 1,1965 through October 15, 2015 for reports of uterine rupture with mifepristone alone, misoprostol alone, or a combined regimen, with special interest in cases occurring in women ≤ 10 weeks pregnant (≤ 70 days). The FAERS search retrieved 80 cases of uterine rupture, with 77 citing misoprostol use alone and 3 citing both mifepristone and misoprostol use. No cases of uterine rupture were reported with mifepristone use alone. Vaginal administration of misoprostol was documented in the majority of the cases. The majority of the FAERS cases either occurred in the 3rd trimester of pregnancy, or did not report gestational age. In the cases where the gestational age was not reported, it is likely that most of these cases occurred during the 2nd or 3rd trimester, as many noted the induction of labor as the reason for misoprostol use. The majority of cases also noted at least one additional potential risk factor, with a history of at least one previous c-section, or the use of additional uterotonic drugs (e.g., oxytocin or dinoprostone) being the most commonly reported. The use of misoprostol during the 3rd trimester for the induction of labor, cervical ripening, or both, in women that had at least one previous c-section, was also documented in many cases.

There were only two cases (2.5% of all reports) that reported uterine rupture within the first 10 weeks of pregnancy. In both cases, misoprostol alone was utilized for termination of pregnancy. The first case provided minimal information other than documentation of a 5 week gestation, and an ultrasound noting “an important uterine separation” during an unspecified time after misoprostol (route not specified) administration. The remaining case was also a published case report in which uterine rupture was documented as occurring approximately 2.5 hours after 800 mcg of misoprostol was administered vaginally for cervical preparation prior to surgical termination of pregnancy. The patient was 8 weeks and 2 days pregnant, had a history of a prior c-section, and was of advanced maternal age. (b) (6) concluded that uterine

rupture associated with the use of mifepristone alone, misoprostol alone, or both, is likely a rare event in the 1st trimester.

Reviewer comment:

Based on the scarcity of reported cases in the first trimester of pregnancy, uterine rupture associated with early medical abortion using mifepristone with or without misoprostol is likely rare. There are a three reports of uterine rupture with mifepristone and misoprostol in the first trimester, most of which occurred in women with prior uterine surgery (e.g., a cesarean section).

7.4.1 Submission-Specific Primary Safety Concerns

Summary of requested dosing changes in the NDA Supplement that could affect safety:

1. **Proposing a new dosing regimen that uses mifepristone 200 mg oral and the buccal administration of 800 mcg misoprostol at 24-48 hours after Mifeprex and increasing the gestational age from 49 days to 70 days**

   The Applicant submitted several articles in support of the proposed dosing regimen as well as increasing the gestational age through 70 days using the proposed regimen, including the 24-48 hour interval. See Section 7.3 Major Safety Results for fatal and nonfatal serious adverse events reported with the proposed regimen and gestational age. The data submitted show these events to be exceedingly rare, indicating that the new dosing regimen and increasing the gestational age to 70 days is safe. Please see Section 7.3 Major Safety Results on Nonfatal Serious Adverse Events for a review of this information.

   In further support of changing the dosing interval for misoprostol to 24-48 hours after mifepristone is taken, the Applicant also provided a systematic review by Shaw et al.[63] In this study the authors searched Medline, ClinicalTrials.gov, Popline and the Cochrane Controlled Trials Register and included 20 randomized controlled trials and 9 observational studies. The majority of the studies used the proposed 200 mg dose of mifepristone, but three RCTs and two observational studies used 600 mg of mifepristone. The doses and route of misoprostol administration varied, including doses of 400 mcg, 600 mcg, and 800 mcg, some with repeat doses, and included vaginal, buccal, oral and sublingual routes. There was wide variation in time to administration of the misoprostol, ranging from <24 hours, 24-48 hours, 36-48 hours. Adverse events were not reported consistently. There was no statistically significant difference in nausea, vomiting or diarrhea.

[63] Shaw KA, Topp NJ, Shaw JG, Blumenthal PB. Mifepristone-misoprostol dosing interval and effect on induction abortion times. Obstet Gynecol 2013;121(6):1335-1347.

Reviewer comment:

Unlike the efficacy data, which is based on studies that look specifically at individual changes proposed by the Applicant, the adverse event data typically come from studies or reviews that include multiple changes (e.g., dose of each drug, dosing interval, gestational age) simultaneously. Therefore, it is not possible to provide safety data specific to each individual change.

The changing of the dosing interval to 24-48 hours does not appear to increase the risk of serious fatal or nonfatal adverse events or to increase the risk of common adverse events associated with medical abortion.

Reviewer's Final Recommendation:

Based on the available evidence, changing the dosing interval between mifepristone and misoprostol to 24-48 hours is safe to approve, including for use in gestations up through 70 days.

2. Home administration of misoprostol

Currently, the Dosage and Administration section of labeling for Mifeprex requires that patients return to the healthcare provider on Day 3 (two days after ingesting Mifeprex) for misoprostol. The Applicant proposes that the label be changed to allow for home administration of the misoprostol. The Applicant reasons that all published US trials after the initial trial by Spitz et al[26], as well as numerous international trials, included distribution of misoprostol for self-administration at home with evidence of safe and effective medical abortion. The Applicant also emphasizes that women usually start having bleeding within two hours of administration of the misoprostol and home administration gives the opportunity for more privacy in the process.

The Applicant submitted many articles to support this change. See Table 8 for US and foreign studies that enrolled over 30,000 women who administered misoprostol at home. None of the studies directly compare home versus clinic/office administration of misoprostol. Most of the studies include protocols where all of the subjects take misoprostol at home. Gatter[13] and Ireland[15] reported separately on large numbers of clients of Planned Parenthood Los Angeles (13,373 and 13,221 clients respectively, though likely with some overlap, in 2010-2011), while Winikoff (2012[19] and 2008[23]), Grossman[36], Creinin[25] and Middleton[24] reported on smaller numbers of US subjects. Internationally, Goldstone[20] reported on 13,345 medical abortions, while Kopp Kallner[64], Løkeland[65], Chong (2012)[40], Bracken[49], Pena[44],

[64] Kopp Kallner H, Fiala C, Stephansson O, Gemzell-Danielsson K. Home self-administration of vaginal misoprostol for medical abortion at 50-63 days compared with gestation of below 50 days. Human Reprod 2010;25(5):1153-1157.

[65] Løkeland M, Iversen OE, Engeland A, Økland I. Medical abortion with mifepristone and home administration of misoprostol up to 63 days' gestation. Acta Obstet Gynecol Scand 2014;93:647-653.

Ngoc[16], Louie[14], Sanhueza Smith[48], Boersma[22] and Lynd[66] report on smaller numbers of subjects. All of these studies have been reviewed above in Sections Deaths, Nonfatal Serious Adverse Events and Common Adverse Events. This information shows that home administration of misoprostol, as part of the proposed regimen, is associated with exceedingly low rates of serious adverse events, and with rates of common adverse events comparable to those in the original studies of clinic administration of misoprostol.

Swica et al[50] similarly conducted a non-randomized trial with 301 US women, 139 of whom chose home use of mifepristone and misoprostol and 162 of whom chose clinic administration of mifepristone followed by home use of misoprostol. The majority of women (74%) who chose home use took the mifepristone at the appointed 6-48 hour window; for those who took it at a different time than that planned with their provider, the median interval was 25 hours. Over 90% of women in both groups took the misoprostol at the scheduled time, and none waited past 72 hours to take the misoprostol. There were no significant differences in the mean number of days of work or school missed or dependent care needed. Most women made no additional calls (85% for home use group and 90% for office use group) or unscheduled visits to the doctor's office (96% for home use group and 99% for office use group).

The Applicant also submitted a commentary by Gold and Chong[67], in which they discuss benefits of home administration of Mifeprex and misoprostol. They cite the convenience of scheduling for women, the possibility of greater autonomy and privacy, the lack of burden on staff, and the safety.

Reviewer comment:

Home use of misoprostol has been evaluated as part of the proposed protocol in studies including well over 30,000 patients, as well as in dedicated studies of home use of mifepristone and misoprostol. The studies demonstrate that women take the misoprostol at the recommended time. The safety profile is acceptable, with rates of adverse events equal to or lower than those with the approved regimen requiring in-office dispensing of misoprostol. The studies, including those of home use of mifepristone and misoprostol, show increased convenience, autonomy and privacy for the woman, a smaller impact on their lifestyles, and no increased burden on the healthcare system. The safety data on the home use of misoprostol are adequate to support revision of labeling.

[67] Gold M, Chong E. If we can do it for misoprostol, why not for mifepristone? The case for taking mifepristone out of the office in medical abortion. Contraception 2015;92:194-196.

Reviewer's Final Recommendation:
Based on the available data, home use of misoprostol is safe to approve.

3. Repeat dose of misoprostol if needed.

The Applicant reasoned that studies include an option for a repeat dose of misoprostol to allow women to avoid a surgical procedure if possible and that this is a safe way to treat an incomplete medical abortion. The Applicant submitted two articles on the repeat use of misoprostol, one randomized trial and one systematic review, that were relevant to this safety review (other articles[12, 17, 22] did not present safety data stratified by number of misoprostol doses). Only one randomized trial reviewed the safety of repeat misoprostol. Coyaji et al[68] conducted a randomized controlled trial of 300 women seeking medical abortion in India. After taking mifepristone, women in one group took 400 mcg misoprostol followed by placebo 3 hours later, while women in the other group took two doses of 400 mcg misoprostol 3 hours apart. As discussed in the efficacy portion of this review, there was no significant difference in the complete abortion rate between the groups; however, the repeat misoprostol reduced need for surgical intervention. Before discharge home, there was no significant difference in the adverse effects observed—similar percentages of women experienced cramping (87% in the single dose group, 89% in the repeat dose group), nausea (both groups 1%), vomiting (both groups 0%), and diarrhea (0% in the single dose group versus 2% in the repeat dose group). More women in the repeat dose arm experienced moderate to severe cramping than women in the single dose arm on Day 4 (24% versus 15%, p=0.032) and on Day 7 (10% versus 4%, p=0.006).

Gallo[69] performed a systematic review of data relating to the safety and efficacy of more than one dose of misoprostol after mifepristone for medical abortion. The search yielded three randomized controlled trials that studied medical abortion ≤ 63 days. The studies included doses of mifepristone ranging from 200 mg to 600 mg followed by misoprostol 6 to 48 hours later, in doses ranging from 400 mcg to 800 mcg via the oral, sublingual or vaginal routes. In two trials, all subjects received repeat misoprostol—in one, three hours later, while in the other study subjects received misoprostol twice a day for days 4-10. In the third trial, subjects only received repeat misoprostol if there was still a gestational sac present. The only side effects discussed in the trials were diarrhea, which was more common in those groups receiving misoprostol orally than in those receiving it exclusively vaginally (26-27% versus 9%). Rash was reported <1%.

There is a good deal of literature on the use of misoprostol alone for medical abortion and in those regimens, doses of up to 800 mcg repeated in three hours have been

[68] Coyaji K, Krishna U, Ambardekar S, Bracken H, Raote V, Mandlekar A, Winikoff B. Are two doses of misoprostol after mifepristone for early abortion better than one? BJOG 2007;114:271-278.

[69] Gallo MF, Cahill S, Castelman L, Mitchell EMH. A systematic review of more than one dose of misoprostol after mifepristone for abortion up to 10 weeks gestation. Contraception 2006;74:36-41.

used. In a study by Blum et al[70], misoprostol only, given as two doses of 800 mcg three hours apart, was compared to mifepristone-misoprostol medical abortion where only one dose of 800 mcg misoprostol was administered. The two groups had similar rates of nausea, vomiting, fever and chills. Subjects in the repeat misoprostol group had more diarrhea than in the mifepristone-misoprostol group (83.9% vs. 61.2%, p<0.001). Please see Section 7.4 Significant Adverse Events for additional discussion on safety concerns with repeat doses of misoprostol.

Reviewer comment:

There are few articles concerning the safety of repeat misoprostol after mifepristone administration. Generally, the success of mifepristone-misoprostol medical abortion renders the need for a second dose of misoprostol to be relatively uncommon. In studies of misoprostol alone given using a single repeat dose, there is an increased risk of the common adverse event of diarrhea. There have been rare reports of uterine rupture in women with a prior uterine scar who receive repeated doses of misoprostol.

Reviewer's Final Recommendation:

Based on the available data, the option for repeat misoprostol in women whose pregnancy has been terminated, but who have not completely expelled the pregnancy is safe and should be approved. For women whose pregnancy is ongoing at follow-up, surgical intervention is recommended, rather than repeated misoprostol. The rare reports of uterine rupture in women with a prior uterine scar who receive repeated doses of misoprostol is discussed in labeling.

4. **Follow-up timing and method: follow-up is needed, but not necessarily in the clinic or licensed healthcare provider's office at 14 days after mifepristone administration**

The Dosage and Administration section of the current approved label for Mifeprex stipulates that patients will return for a follow-up visit approximately 14 days after the administration of Mifeprex to confirm by clinical examination or ultrasonographic scan that a complete termination of pregnancy has occurred. The Applicant acknowledges that follow-up is important to diagnose and treat complications, and to ensure complete abortion or identify ongoing pregnancies. However, the Applicant proposes to change the labeling to state that the provider should perform an assessment at 1-2 weeks, in order to broaden the timeframe and method used, to give patients and providers more flexibility and reduce loss to follow-up rates. Use of ultrasound, serum and urine pregnancy testing (semi-quantitative, and quantitative) and telephone calls have all been evaluated in the literature as options for follow-up of patients after medical

[70] Blum J, Raghavan S, Dabash R, Ngoc NTN, Chelli H, Hajri S, Conkling K, Winikoff B. comparison of misoprostol-only and combined mifepristone-misoprostol regimens for home-based early medical abortion in Tunisia and Vietnam. Int J Gynecol Obstet 2012;118:166-171.

abortion. Grossman and Grindlay[71] conducted a systematic review of the literature on alternatives to ultrasound for medical abortion follow-up. They identified eight studies, but found that outcomes of interest (ongoing pregnancy) were rare with medical abortion and not consistently defined across studies. Nonetheless, they found that serum hCG, a low sensitivity urine pregnancy test combined with a standardized assessment with multiple questions about women's symptoms, or standardized telephone follow-up, perhaps followed by high-sensitivity urine pregnancy test, all had sensitivities ≥90% and negative predictive values (NPVs) ≥99% and they resulted in a proportion of "screen positives (or women who had a self-assessment of ongoing pregnancy and had an unscheduled visit) ≤33%."

This reviewer analyzed relevant studies that were submitted by the Applicant and referenced in the Grossman and Grindlay assessment.[71] Perriera et al[21] conducted a prospective cohort study of 139 US women with ≤63 days gestation undergoing medical abortion at one center. Up to three attempts were made to phone subjects 7 days after taking mifepristone. The subjects were asked to confirm when they took misoprostol and generally to describe their experience. They were then asked a series of five standardized questions to assess for expulsion, including:

1 Did you have cramping and bleeding heavier than a period?
2 Did you pass clots or tissue?
3 What was the highest number of pads you soaked per hour?
4 Do you still feel pregnant now?
5 Do you think you passed the pregnancy?

If the clinician or the subject did not think the pregnancy had passed, the subject was asked to return to the center for an ultrasound within 7 days. If there was an ongoing pregnancy, women were offered additional misoprostol or a D&C. If the clinician and subject believed the pregnancy had passed, she was instructed to begin birth control or schedule a visit for injectable, implantable or intrauterine contraception. On Day 30, the subject was to perform a urine pregnancy test. Follow-up was obtained for 97.1% of subjects. Four subjects did not complete follow-up (2.9%)—one was never reached by phone, three were and two of them had positive pregnancy tests while one had an inconclusive test. These three never returned for an in-person visit and outcomes are not available on them. The sensitivity for correctly predicting an expelled pregnancy (completed abortion) was 95.9%, specificity was 50%, positive predictive value 97.5% and negative predictive value 37.5%. This study suggests that clinicians and subjects are almost always correct when they believe a pregnancy has passed. The loss to follow-up rate was not higher than for standard medical abortion follow-up.

Fiala et al[72] compared hCG with ultrasound for verification of completed abortion in 217 women ≤49 days with intrauterine pregnancy in Scotland. Successful expulsions were

[71] Grossman D, Grindlay K. Alternatives to ultrasound for follow-up after medication abortion: a systematic review. Contraception 2011;83:504-510.
[72] Fiala C, Safar P, Bygdeman M, Gemzell-Danielsson K. Verifying the effectiveness of medical abortion;

consistent with a marked decline in hCG values at follow-up. Using 20% of the initial value as cut-off at follow-up gave a high sensitivity. It allowed correct diagnosis in 98.5% of the patients with successful expulsion. When 20% of the initial hCG value was used as cut-off, a positive predictive value for successful expulsion was 99.5%. If the reduction of the hCG level was less than 80%, the negative predictive value was 50% and further evaluation was warranted. By contrast, the reliability of ultrasound examination in diagnosing successful expulsion was 89.8%.

Lynd et al[66] studied 300 women at ≤ 63 days gestation who underwent medical abortion in Vietnam. Women were given mifepristone and sent home with misoprostol and a semi-quantitative urine pregnancy test, a urine cup, instructions and a questionnaire. They were to take the urine test, record their impression of the results and complete the questionnaire on the morning of an in-person follow-up visit 2 weeks after mifepristone administration. Fifty-four women (18.5%) still felt pregnant at the follow-up visit, but only 11 of the semiquantitative urine tests indicated ongoing pregnancies. All 11 correctly identified ongoing pregnancies, with 100% sensitivity and 89.7% specificity. Ten of the 11 women with an ongoing pregnancy understood in-person follow-up was necessary.

Similarly, Cameron et al[73] reported on 1791 women undergoing medical abortion in Scotland, 1,726 (96%) of whom chose self-assessment with a low-sensitivity urine pregnancy test, instructions on how to interpret it, and signs/symptoms of ongoing pregnancy. The rest of the women chose in-clinic follow-up with an ultrasound or a phone call. Eight women in the self-assessment group had ongoing pregnancies, but only four of them had a positive low-sensitivity pregnancy test at the appointed time—within 4 weeks. Of the four who did not follow up in 4 weeks, two had a positive or invalid pregnancy test within two weeks after the medical abortion and should have presented for care, and two reported their pregnancy test was negative and did not present for care. All has successful termination either with repeat medical dosing or surgical aspiration. Most women presented within four weeks, but two women presented only after two missed menses. The delayed follow-up was not different from that for an in-person visit or an ultrasound.

Reviewer comments:

While the number of articles is not extensive, they include almost 2,400 subjects. The Applicant demonstrates that alternatives to in-clinic follow-up are effective and safe, detecting most of the ongoing pregnancies so that women can get needed treatment. It appears that, using standardized questionnaires or instructions or a telephone call along with a low or high sensitivity pregnancy test, ongoing pregnancies can be detected allowing for further treatment. There is some loss-to-follow-up, but the rates do not appear to exceed those associated

ultrasound versus hCG testing. Eur J Obstet Gynecol Reprod Biol 2003;109;190-195.
[73] Cameron ST, Glasier A, Johnstone A, Dewart H, Campbell A. Can women determine the success of early medical termination of pregnancy themselves? Contraception 2015;91:6-11.

with a planned in-clinic follow-up. Women should be allowed to have an in-person visit if desired, but also allowed the flexibility of other options if desired.

It is important to note that since 2005, Planned Parenthood Federation of America has waived the follow-up visit if it poses undue hardships owing to distances from abortion facilities or other reasons, and women manage their follow-up with serial hCG testing.[74] From the clinical reviewers' perspective, this is safe and acceptable. We further note that the NAF 2015 guidelines (page 23) state the following:

> **"Success of the medical abortion must be assessed by ultrasonography, hCG testing, or by clinical means in the office or by telephone. If the patient has failed to follow-up as planned, clinic staff must document attempts to reach the patient. All attempts to contact the patient (phone calls and letters) must be documented in the patient's medical record."**

The ACOG 2014 Practice Bulletin[1] on management of early MAB states "Follow-up after receiving mifepristone and misoprostol for medical abortion is important, although an in-clinic evaluation is not always necessary." Several options for follow up without an office/clinic visit are discussed and no specific method or algorithm is definitely recommended (i.e., it is left to the discretion of the provider and patient).

Reviewer's Final Recommendation:

Based on the available evidence, flexibility in the timing and method of follow-up is safe to approve.

7.5 Supportive Safety Results

7.5.1 Common Adverse Events

According to the currently approved Mifeprex label,[75] common adverse events include the following:

- Vaginal bleeding up to 16 days, with 8% of women experiencing bleeding up to 30 days. 4.8% of women in the original US trials and 4.3% in the original French trials required administration of uterotonic agents to control the bleeding. Only 1% of women required intravenous fluids and 1% required curettage. In the original French trials, 5.5% of women had a drop in hemoglobin of more than 2 g/dL.
- Abdominal pain in 96% of US women
- Uterine cramping in 83% of French women
- Nausea in 43-61%, vomiting in 18-26%

[74] Fjerstad M. Figuring out follow-up. Mife Matters. Planned Parenthood Federation of America/Coalition of Abortion Providers 2006;13:2–3.

[75] http://www.accessdata.fda.gov/drugsatfda_docs/label/2000/20687lbl.htm

- Diarrhea in 12-20%
- Headache in 2-31%
- Dizziness in 1-12%

A review of the literature submitted in the efficacy supplement, which includes Mifeprex at the proposed dose but also includes misoprostol administered buccally, vaginally or orally, reveals the following. Table 16 addresses bleeding that did not require transfusion (which is covered inTable 14: Transfusion by Gestational Age above), but was still significant in terms of requiring another intervention or in terms of a decrease in measured hemoglobin. Most of the studies include subjects up to 63 days' gestation, with the exception of Middleton 2005[24], which includes subject to 56 days, and Sanhueza Smith 2015[48] and Winikoff 2012[19], which include subjects through 70 days.

Table 16: Bleeding and Cramping in Literature

Study	N	Maximal Gestational Age	Route of misoprostol administration	Adverse Event Rate (%)		
				Bleeding requiring intervention*	Bleeding with drop in hemoglobin > 2g/dL	Cramping/pain

***Intervention includes aspiration or uterine evacuation, use of uterotonics, intravenous fluids**
***NR=not reported**

Source: NDA clinical reviewer table.

Reviewer Comments:

Given that Mifeprex and misoprostol are taken to terminate an intrauterine pregnancy, vaginal bleeding and cramping or abdominal pain are an expected

and necessary part of the process; therefore, these should only be considered adverse events if the amount of bleeding or pain exceeds what would be expected for such a process. The rate of bleeding requiring intervention is low and ranges from 0.5% to 4.2%, with the rates in the largest studies being around 1.8%. Two articles parsed the bleeding requiring intervention by gestational age. In Sanhueza Smith et al.[48] the rate was 1.1% (7/622) among women ≤ 56 days, 4.2% (8/190) in women 57-63 days and 1.4% (2/148) in women 64-70 days. In Gatter 2015[13], the rate was 0.65-1.43% up to 49 days, 2.04% in women 50-56 days, and 2.49% in women 57-63 days. These differing numbers from the two studies do not reveal a trend toward bleeding requiring intervention with increasing gestational age, specifically even through 70 days.

No articles submitted discussed a drop in hemoglobin of > 2 g/dL, most likely because routine laboratory studies are not obtained in medical abortion unless anemia or a medical illness is reported or suspected. Also not surprisingly, pain and cramping are an expected part of the medical abortion process, so most studies do not comment on the percentage of women who experience this.

GA = gestational age; *NR= not reported. † includes fever and chills, which were grouped together

Source: NDA clinical reviewer table.

Reviewer comment:

The range of reported percentages for each adverse event is wide, with some studies reporting virtually no patients experiencing nausea, vomiting or diarrhea, while others report at least half of subjects suffering these side effects. Only the Winikoff 2012[19] article parses out these side effects by gestational age (57-63 days versus 64-70 days). There is no statistically significant difference in the rates of any side effect between gestational age group except for vomiting, where 35.8% of women 57-63 days had vomiting and 45.7% of women 64-70 days did (p=0.008). It is hard to determine a value that could be used in labeling based on these wide variations, but the adverse events are common, expected and well-known with the medical abortion regimen and the ranges should be reported in labeling.

7.5.2 Laboratory Findings

Mifepristone with misoprostol is a well-established regimen for termination of pregnancy. Few laboratory tests are necessary before use of the regimen. Those that are commonly performed include confirmation of pregnancy (urine or serum pregnancy testing) as well as Rh testing (unless it has been previously documented), such that RhD immunoglobulin can be administered as indicated. Pre-medical abortion assessment of hemoglobin or hematocrit is indicated when anemia is suspected. Routine follow-up laboratory testing is also not indicated unless dictated by the patient's clinical condition, for example, heavy bleeding or signs of infection. Lab results are not typically reported in the literature, except for when studies look at decreases in hemoglobin related to bleeding.

7.5.3 Vital Signs

Vital signs are not typically reported in the literature on medical abortion.

7.5.4 Electrocardiograms (ECGs)

Mifepristone used with a prostaglandin analogue has been approved for medical termination of pregnancy since 1988 in France and subsequently in many countries around the globe. It has been well-established that doing an ECG prior to MAB is not standard procedure. It can be done if individual circumstances warrant its use. Literature does not typically report on ECGs.

7.5.5 Special Safety Studies/Clinical Trials

The pediatric studies are addressed in Section 7.6.3.

7.5.6 Immunogenicity

NA to this review

7.6 Other Safety Explorations

This section is not relevant to this application.

7.6.1 Additional Safety Evaluations

7.6.2 Human Carcinogenicity

The Applicant submitted no new data on human carcinogenicity.

7.6.3 Human Reproduction and Pregnancy Data

As noted in the efficacy portion of this review, some women who use Mifeprex do have ongoing pregnancies. Most of these are treated with an aspiration or a surgical evacuation of the uterus; there is little information on outcomes of ongoing pregnancies not terminated by another method. At the time of approval of the drug, the Applicant agreed to two postmarketing commitments, including one to conduct a surveillance study of the outcomes of ongoing pregnancies. On January 11, 2008, the Applicant was released from this commitment due to the lack of an adequate number of women enrolled. The Applicant explained that the small number was due, in part, to the requirement that the patients consent to participation *[in the surveillance study]* after seeking a pregnancy termination.

A review of all of the articles submitted by the Applicant for outcomes of ongoing pregnancies after mifepristone administration yielded minimal information. There is one article reporting a case of a fetus with sirenomelia, a cleft palate and lip, micrognathia, and hygroma; this infant was born to a woman who had received mifepristone as RU 486 at 18 weeks and was reported to Roussel-Uclef in France in 1989.[76] A prospective observational study[77] from fifteen French pharmacovigilance centers followed women exposed to mifepristone in the first trimester between1997 and 2010. The study included pregnant women who sought counseling on mifepristone exposure from a pharmacovigilance center or Paris Teratology Information Service (TIS). A total of 105 pregnancies were exposed to mifepristone in the first trimester; 46 to mifepristone alone, and 59 to mifepristone and misoprostol. The mean gestational age at exposure was 7.9 weeks; 81% were exposed between weeks 5 and 9 of gestation. About 40% of patients received 200 mg of mifepristone while about 50% received 600 mg. Of the patients who received both mifepristone and misoprostol, 48 received repeat misoprostol with four receiving 1200–2000 mcg of misoprostol, a significantly higher dose than recommended. Among all exposed women, there were 94 live births (90.4%),10 (9.6%) miscarriages (including one with a major malformation of major hydrocephalus associated with adductus thumb and a normal karyotype) and one patient had an elective termination of pregnancy for the subsequent diagnosis of trisomy 21. Eight of the ten miscarriages occurred in the mifepristone-only group; however, after potential confounding factors such as maternal age, gestational age at inclusion,

[76] Pons JC, Papiernik E. Mifepristone teratogenicity. Lancet 1991;338(8778):1332-3.

[77] Bernard N, Elefant E, Carlier P.Tebacher M, Barjhoux CE, Bos-Thompson MA, Amar E, Descotes J, Vial T. Continuation of pregnancy after first-trimester exposure to mifepristone: an observational prospective study. BJOG 2013;120:568–575.

drug exposure, and mifepristone dose were controlled for by logistic regression, the rate of miscarriage did not differ across mifepristone only versus mifepristone-misoprostol groups (p= 0.08). Among the live births, the mean gestational age at delivery was 39.5 weeks and there was no difference in birth weights between groups. The overall rate of major congenital malformations among the 95 examinable cases was 4.2% (95% CI 1.2–10.4%), with two cases among 38 patients exposed to mifepristone alone, and two cases among 57 patients exposed to both mifepristone and misoprostol. Three of the four major congenital malformations occurred with exposure to 600 mg of mifepristone, while one occurred in exposure to 400 mg of mifepristone. The malformations included:

- Claude Bernard–Horner syndrome with stridor
- Hydrocephalus with triventricular dilatation and adductus thumb (miscarriage patient noted above)
- Möbius syndrome
- Retrognathism, slight cleft palate, trismus, swallowing disorder, club foot with four toes, incomplete genital development and mild hypoplasia of the cerebellar vermis

The authors posit that the cases of major malformations in patients exposed to mifepristone alone could be explained by associated medical conditions, for example, the case of congenital Claude Bernard Horner syndrome could have been related to traumatic vaginal delivery of a high birth weight newborn, a well-recognized cause of this syndrome, while the spontaneously aborted hydrocephalic fetus may have been caused by streptococcus B chorioamnionitis, which was subsequently confirmed on pathological examination, or be an X-linked hydrocephalus. The authors also note that the two cases of major malformations in patients exposed to both mifepristone and misoprostol were consistent with malformations described after exposure to misoprostol alone. The authors concluded that major malformations after first-trimester exposure to mifepristone is only slightly higher than the expected 2–3% rate in the general population, which was reassuring regarding the risk evaluation for continuation of pregnancy after mifepristone exposure.

There are reports that misoprostol can result in congenital anomalies when used during the first trimester, including defects in the frontal or temporal bones, limb abnormalities with or without Mobius syndrome.[1] The Korlym label notes in Important Safety Issues with Consideration to Related Drugs: “In a report of thirteen live births after single dose mifepristone exposure, no fetal abnormalities were noted.”

Reviewer Comment:

There are anomalies associated with the use of misoprostol in the first trimester. The risk of teratogenic effects with a continued pregnancy after a failed pregnancy termination with Mifeprex in a regimen with misoprostol is unknown. Birth defects have been reported with a continued pregnancy after a failed pregnancy termination with Mifeprex in a regimen with misoprostol, but it is not clear if this just represents the usual background rate of birth defects.

As discussed above, FDA requested at the time of initial approval that the Applicant conduct a surveillance study of the outcomes of ongoing pregnancies. The Applicant was subsequently released from this commitment because it had been unable to enroll a sufficient number of women with ongoing pregnancies after an attempted medical abortion in the surveillance study.

7.6.4 Pediatrics and Assessment of Effects on Growth

The Applicant submitted no new data on assessment of effects on growth in pediatric patients. The Applicant did submit data on efficacy and safety of medical abortion in adolescents, using the proposed regimen of 200 mg oral Mifeprex followed by 800 mcg buccal misoprostol 24-48 hours later at home, in order to satisfy requirements for PREA. Gatter et al (2015)[13] included data on 322 adolescents. (b) (6), (b) (4) The adolescent efficacy was similar to that of all older women; this implies that compliance in taking the misoprostol dose properly at home was also acceptable. The study included adolescents aged 11-16 per Table 18 below:

Table 18: Age of Adolescents Undergoing Medical Abortion

Age	# Subjects
11	1
12	1
13	2
14	20
15	82
16	216

Source: (b) (6), (b) (4) **NDA 20687s20**

(b) (4), (b) (6) As is evident in the table, no adolescents had a hospitalization, severe infection or hemorrhage which required a transfusion.

Table 19: Serious Adverse Events in Adolescents vs. Adults

	Under 17	17+	All
Transfusion	0.00% (0/251)	0.03% (4/13,122)	0.03% (4/13,373)
Hospitalization	0.00% (0/251)	0.05% (7/13,122)	0.05% (7/13,373)
Infection	0.00% (0/251)	0.02% (2/13,122)	0.01% (2/13,373)

Source: (b) (6), (b) (4) **NDA 20687s20**

In 2011, Niinimäki et al[54] published a retrospective cohort study of the Finnish abortion registry from 2000-2006, in which they evaluated the rates of adverse events in 3,024

adolescents and 24,006 adult women undergoing medical abortion (regimen unspecified). The study population included women ≤ 20 week's gestation; 84.6% of the adolescents were ≤ 12 weeks, while 86.6% of the adults were ≤ 12 weeks. Adolescents ranged in age from 13-17, with a mean age of 16.1 years. The study showed that after adjustment for parity, previous abortion, marital status, types of residence, duration of gestation and year of abortion, in adolescents, the adjusted ORs were significantly lower for hemorrhage (0.87, 95% CI 0.77 to 0.99), incomplete abortion (0.69, 95% CI 0.59 to 0.82) and surgical evacuation (0.78, 95% CI 0.67 to 0.90) compared to adults. There was no significant difference in the OR for infection (0.97, 95% CI 0.73 to 1.30).

Phelps[53] had previously conducted a pilot study in 28 adolescents aged 14-17, at ≤ 56 days gestation, using Mifeprex 200 mg followed 48 hours later by misoprostol 800 mcg vaginally. As reported in Section Subpopulations, 100% of study subjects had a complete abortion, with five not requiring misoprostol. There were no serious adverse events. Subjects noted common expected adverse events including bleeding (100%), cramping (95%), nausea (62%), and vomiting (43%).

It is also important to consider adherence to the proposed regimen (including taking misoprostol at a location other than the clinic) and adherence to follow-up among adolescents versus adults.

There are no data specifically comparing adherence to the regimen among adolescents <17 with women ≥17 years old. The Gatter[13] study clearly demonstrates the efficacy and safety is the same for both age groups, suggesting that there is no clinically significant difference in adherence to the regimen between age groups. The Goldstone[20] article included 8 subjects aged 14 and 931 subjects aged 15-19. The efficacy and safety are not separated out by age; however, all subjects did take the proposed regimen and overall efficacy and safety is reassuring, indicating that adolescents and adults alike likely did adhere to the mifepristone and misoprostol regimen in a safe and effective way.

Regarding adherence to follow-up, four articles included 346 subjects <17 years old. Ngoc[16] is based in Vietnam and Cameron[73] is based in Scotland, while Gatter[13] and Horning[78], are US-based studies. (b) (4), (b) (6) . The difference in the follow-up rate for the combined data is 6.5%. The Gatter study accounts for 85% of all patients being compared. The difference in follow-up adherence is not clinically relevant as there is no difference in efficacy between the two age groups.

Table 20: Adherence to Follow-Up Among Adolescents vs. Adults

	<17 years old			≥17 years old		
	N	# Adherent	Adherence %	N	# Adherent	Adherence %
Gatter[13]	322	251	78.0%	15,517	13,122	84.6%
Cameron[71]	5	4	80.0%	607	516	85.0%
Ngoc[16]	1	1	100.0%	1,406	1,345	95.7%
Horning[78]	18	16	88.9%	846	648	76.6%
TOTAL	346	272	78.6%	18,376	15,631	85.1%

Reviewer Comment:

Medical abortion in adolescents appears to be at least as safe, if not safer, as in adult women. Adolescents appear able to comply with the regimen, including use of misoprostol outside of the clinic setting, as well as with alternative follow-up methods. These data support the safety of Mifeprex in adolescents and satisfy requirements for PREA. No information on safety and efficacy of use in premenarchal girls is required, as the medication is not indicated in that subset of the pediatric population.

Reviewer's Final Recommendation:

The available evidence supports that Mifeprex and the new proposed dosing regimen are safe to use in adolescents.

7.6.5 Overdose, Drug Abuse Potential, Withdrawal and Rebound

The Applicant submitted no new data on overdose, drug abuse potential withdrawal and rebound.

7.7 Additional Submissions / Issues

Summary of additional changes in labeling that may affect safety of Mifeprex

1. Change in labeled time for expulsion from 4-24 hours to 2-24 hours

The Applicant proposes to change the time to expulsion described in the labeling from 4-24 hours to 2-24 hours post misoprostol to more accurately reflect the data and real-life experiences with the drug. The Applicant reasons that in the large US trial upon

[78] Horning EL, Chen BA, Meyn LA, Creinin MD. Comparison of medical abortion follow-up with serum human chorionic gonadotropin testing and in-office assessment. Contraception 2012;85:402-407.

which labeling is based (Spitz, 1998[26]), the median time to expulsion was 4 hours. Indeed, in that study, women were observed for several hours after misoprostol administration, and during the four hours of observation, 49% of the women expelled the products of conception, and 60% had by the fifth hour. Several studies are provided to corroborate this. Only one uses buccal misoprostol; however, the misoprostol was administered within 5 minutes of the Mifeprex, not at the 24-48 hour interval as proposed in this supplement. Nonetheless, in this trial, Lohr[79] found the median time to onset of cramping to be 2 hours (range 10 minutes to 13 hours) and bleeding to be 3 hours (range 9 minutes to 11 hours). This shorter duration to expulsion is also seen in several other pilot studies submitted where subjects took vaginal misoprostol immediately or within 6-8 hours of mifepristone. If the focus is shifted to the randomized controlled studies that report times to onset of bleeding and cramping and include vaginal misoprostol, we find data confirming the timing of expulsion in the 2-24 hour window proposed by the Applicant. Creinin[25] noted a median time to onset of cramping of 1.7 hours and to onset of bleeding of 2 hours after misoprostol (administered 24 hours after Mifeprex). In a similar study[80] comparing misoprostol administered 24 vs. 6-8 hours after Mifeprex, the median time to onset of cramping was 1.5 hours and to bleeding was 2 hours in women with misoprostol given 24 hours after Mifeprex.

Reviewer comment:
The data from vaginal and buccal administration of misoprostol around 24 hours after mifepristone support the assertion that bleeding and cramping begin before the 4 hour mark that is currently labeled. Therefore the label should be revised to make this clearer. Median times seem to be around 1.5 to 2 hours. It is reasonable to label the time to expulsion 2-24 hours, but it could be labeled as beginning even earlier. A clearer label will help providers better counsel patients and patients can better select an appropriate time frame within the 24-48 hour window to take their misoprostol and can be prepared when the expulsion starts.

Reviewer's Final Recommendation:
Based on the available evidence, it is acceptable to revise the label so that it notes that the time to expulsion after misoprostol dosing is 2-24 hours.

2. Use of the term "(b) (4)

The Applicant proposes to use the term "(b) (4) in place of all other terms in labeling and in the REMS materials, for consistency and (b) (4) The Applicant

[79] Lohr PA, Reeves MF, Hayes JL, Harwood B, Creinin MD. Oral mifepristone and buccal misoprostol administered simultaneously for abortion: a pilot study. Contraception 2007;76:215-220.

[80] Creinin MD, Fox MC, Teal S, Chen A, Schaff EA, Meyn LA. MOD Study Trial Group: A randomized comparison of misoprostol 6-8 hours versus 24 hours after mifepristone for abortion. Obstet Gynecol 2004;103:851-859.

submitted an article demonstrating that nurse practitioners, certified nurse midwives and physician assistants can safely provide aspiration abortion.[81] The Division asked the Applicant to provide articles specifically addressing the provision of medical abortion services by non-physician practitioners, since that is the issue at hand.

The Applicant provided data on the efficacy of medical abortion provided by non-physician healthcare providers, including four studies with 3,200 women in randomized controlled clinical trials and 596 women in prospective cohorts. These studies took place in varying settings (urban, rural, international, low resource). The efficacy results are discussed in Section 6.1.10.

Regarding the safety of medical abortion provided by non-physician health care providers, a systematic review by Renner[82] identified five studies with a total of 8,908 subjects. A RCT in Nepal included 1,104 of those subjects, comparing medical abortions by nurses or auxiliary nurse midwives with those offered by physicians. Outcome data on 1,077 women showed no serious complications (hemorrhage requiring transfusion or condition necessitating hospitalization) and the rate of ongoing pregnancy or incomplete abortion did not vary by physician versus midlevel provider. Also in Nepal, Puri et al[83] described training female community health volunteers to provide education, and training auxiliary nurse midwives to provide medical abortion in intervention districts, and compared knowledge and medical abortion outcomes with those in neighboring districts where there were no interventions. Medical abortions were performed on 307 women in the intervention areas and 289 women in the comparison areas. There were five incomplete abortions (1.6%) in the intervention areas, treated with manual vacuum aspiration by the auxiliary nurse midwives, and 7 (2.4%) incomplete abortions in the comparison areas. The difference was not statistically significant. Kopp Kallner[84] conducted a randomized controlled equivalence trial of 1,068 women in Sweden who were randomized to receive medical abortion care from two nurse midwives experienced in medical terminations and trained in early pregnancy ultrasound versus a group of 34 physicians with varying training and experience. The trial showed fewer complications for the nurse midwife group, though this was not statistically significant (4.1% for nurse midwives, versus 6.1% for doctors, p=0.14).

[82] Renner R-M, Brahmi D, Kapp N. Who can provide effective and safe termination of pregnancy care: a systematic review. BJOG 2013;10:23-31.

[83] Puri M, Tamang A, Shrestha P, Joshi D. The role of auxiliary nurse-midwives and community health volunteers in expanding access to medical abortion in rural Nepal. Reproductive Health Matters 2015;Suppl(44):94-103.

[84] Kopp Kallner H, Gomperts R, Salomonsson E, Johansson M, Marions L, Gemzell-Danielsson K. The efficacy, safety and acceptability of medical termination of pregnancy provided by standard care by doctors or by nurse-midwives: a randomized controlled equivalence trial. BJOG 2015;122:510-517.

There were no serious complications and no blood transfusions in the study. There was no difference in unscheduled visits. Nurse midwives did call for more second opinions (26%) versus doctors (4%). Olavarrieta[85] conducted a randomized controlled non-inferiority trial in Mexico City abortion clinics. Eight physicians and seven nurses who had not previously independently provided medical abortion care received 1.5 weeks of training. A total of 1,088 women were randomized to two groups of providers. Nurses were not found to be inferior to physicians in the provision of abortion care. There was only one serious adverse event in the physician group, a woman requiring admission and surgical aspiration for heavy bleeding. Nurses requested consultation with an experienced obstetrician in 9 cases, whereas physicians requested consultation only twice.

Reviewer Comments:

The Applicant provided data from over 3,200 women in randomized controlled trials and data on 596 women in prospective cohorts comparing medical abortion care by physicians versus nurses or nurse midwives. The studies were conducted in varying settings (international, urban, rural, low-resource) and found no differences in efficacy, serious adverse events, ongoing pregnancy or incomplete abortion between the groups. Two studies did show that nurses or nurse midwives called for more second opinions than physicians, but these numbers were a small portion of the total subjects included.

Midlevel providers in the United States, such as nurse practitioners, nurse midwives and physician assistants currently provide family planning services and abortion care, including medical abortion care, under the supervision of physicians. The data here demonstrate that it would be safe to allow healthcare providers who are licensed to prescribe medications and who meet the criteria in the REMS to become certified to provide medical abortion care with Mifeprex and misoprostol. Midlevel providers are already practicing abortion care under the supervision of physicians, and the approved labeling and the REMS Prescriber's Agreement already stipulate that prescribers must be able to refer patients for additional care, including surgical management if needed. Therefore, facilities that employ midlevel prescribers already have an infrastructure in place for consultation and referral.

Reviewer's Final Recommendation:

Based on the available evidence, it is safe for midlevel providers to administer medical abortion. The term in the revised Prescriber Agreement Form will be "a healthcare provider who prescribes." Per the review by the (b) (6) ((b) (6) dated March 29, 2016, this term provides an accurate

[85] Olavarrieta CD, Ganatra B, Sorhaindo A, Karver TS, Seuc A, Villalobos A, Garcia SG, Pérez M, Bousieguez M, Sanhueza P. Nurse versus physician-provision of early medical abortion in Mexico: a randomized controlled non-inferiority trial. Bull World Health Organ 2015;93:249-258.

representation of the varied practitioners who are prescribers, while at the same time using language that is consistent with statute. We concur with the (b) (6) review.

3. Removal of references to "Under Federal Law" from the Prescriber's Agreement

The Applicant requests removal of the phrase "under Federal law" from the Prescriber's Agreement portion of the REMS materials. The phrase appears in two places:

- "Under Federal law, Mifeprex must be provided by or under the supervision of a licensed physician who meets the following qualifications:
  - Ability to assess the duration of pregnancy accurately.
  - Ability to diagnose ectopic pregnancies.
  - Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and are able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary."
- "Under Federal law, each patient must be provided with a Medication Guide. You must fully explain the procedure to each patient, provide her with a copy of the Medication Guide and Patient Agreement, give her an opportunity to read and discuss them, obtain her signature on the Patient Agreement, and sign it yourself."

The Applicant rationalizes that all of the conditions of Mifeprex approval, including the REMS, are under Federal law and that the statement is redundant and are no more subject to Federal law than the other conditions of approval.

Reviewer comment:
A rationale for the original inclusion of the phrase "Under Federal law" cannot be discerned from available historical documents, nor is it consistent with REMS materials for other products. All the conditions of approval, including the REMS materials, are under Federal law; therefore, the phrase is unnecessary and can be removed from the Prescriber's Agreement.

Reviewer's Final Recommendation:
The term "under Federal law" can be removed from the Prescriber's Agreement.

4. Addition of misoprostol to the indication statement

The Indication and Usage section of the currently approved labeling is as follows:

> "Mifeprex is indicated for the medical termination of intrauterine pregnancy through 49 days' pregnancy. For purposes of this treatment, pregnancy is dated from the first day of the last menstrual period in a presumed 28 day cycle with ovulation

occurring at mid-cycle. The duration of pregnancy may be determined from menstrual history and by clinical examination.

Ultrasonographic scan should be used if the duration of pregnancy is uncertain, or if ectopic pregnancy is suspected.

Any intrauterine device ("IUD") should be removed before treatment with Mifeprex begins.

Patients taking Mifeprex must take 400 mcg of misoprostol two days after taking mifepristone unless a complete abortion has already been confirmed before that time (see DOSAGE AND ADMINISTRATION).

Pregnancy termination by surgery is recommended in cases when Mifeprex and misoprostol fail to cause termination of intrauterine pregnancy (see PRECAUTIONS)."

The Applicant proposed two alternative indication statements, both of which include reference to misoprostol:

(b) (4)

Or

(b) (4)

The Applicant provides the rationale that:

- the two drugs are used in combination and placing misoprostol in the indication statement early on in labeling gives it greater prominence and highlights the importance of completing the full treatment regimen

- the mention of misoprostol enhances the goal of labeling, which is to give healthcare providers information necessary for safe and effective use of Mifeprex.

Subsequently on February 25, 2016, the Applicant proposed (b) (4) (b) (4) gestational age through 70 days, based on the literature already submitted.

Reviewer comment:

We recommend that the Indication Statement read:

> **"Mifeprex is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation."**

The rationale for this is that:

- **All supporting data are based on the combined regimen**
- **Inclusion of misoprostol in the Indication Statement would be consistent with the rest of Mifeprex labeling and with current medical practice**
- **It would be consistent with current FDA thinking (e.g., the internal Label Review Tool) which states that the indication and use statement should include "Information if drug is to be used only in conjunction with another therapy."**

Reviewer's Final Recommendation:

Misoprostol should be included in the Indication Statement for Mifeprex.

8 Postmarket Experience

A comprehensive review of the adverse events associated with Mifeprex from September 28, 2000 through November 17, 2015, performed by (b) (6) , (b) (6), yielded the following information on reported deaths. Regarding the US cases, there were 17 reported deaths. Deaths were associated with sepsis in eight of the 17 (seven cases tested positive for *Clostridium sordellii,* one case tested positive for *Clostridium perfringens).* Seven of the eight fatal sepsis cases reported vaginal misoprostol use; one case reported buccal misoprostol use. Seven of the nine remaining U.S. deaths involved two cases of ruptured ectopic pregnancy and one case each of the following: substance abuse/drug overdose; methadone overdose; suspected homicide; suicide; and a case of delayed onset toxic shock-like syndrome. In the eighth case, the cause of death could not be established despite performance of an autopsy; tissue samples were negative for *C. sordellii*. The autopsy report on the ninth death became available to the Agency and was reviewed on December 2, 2015. It showed the woman died of pulmonary emphysema.

There were 11 additional deaths in women in foreign countries who used mifepristone for medical termination of pregnancy. These fatal cases were associated with the

following: sepsis (*Clostridium sordellii* identified in tissue samples) in a foreign clinical trial; sepsis (Group A *Streptococcus pyogenes*); a ruptured gastric ulcer; severe hemorrhage; severe hemorrhage and possible sepsis; "multivisceral failure;" thrombotic thrombocytopenic purpura leading to intracranial hemorrhage; toxic shock syndrome (*Clostridium sordellii* was identified through uterine biopsy cultures); asthma attack with cardiac arrest; respiratory decompensation with secondary pulmonary infection 30 days after mifepristone in a patient on the lung transplant list with diabetes, a jejunostomy feeding tube, and severe cystic fibrosis; and a case of *Clostridium sordellii* sepsis (from a published literature report).

Reviewer Comments:

While an exact rate of death with use of mifepristone cannot be calculated from this information, given that there have been over 2.5 million uses of Mifeprex by US women since its marketing in 2000, the number of deaths is very low. Moreover, half of the deaths were associated with *C. sordellii* sepsis. Seven out of 8 of these cases occurred in women who used misoprostol via the vaginal route while one used buccal misoprostol. Since at least 2006, PPFA (comprising the majority of US medical abortion providers) switched its national guidelines to avoid vaginal administration of misoprostol (even though the data did not find a causal relationship).[23] Although the possibility that Mifeprex might increase the likelihood of infection by adversely affecting immune system function has been raised, the overall event rate of serious infections does not support this.

Since 2009, there have been no *C. sordellii* deaths associated with medical abortion in the US. This reviewer finds that the postmarketing data on deaths associated with medical abortion demonstrate low numbers and an improved safety profile with the buccal route of misoprostol administration as compared with the vaginal route.

The review by (b) (6) (b) (6) also yielded the following

Table 21 summarizing hospitalizations, blood loss requiring transfusions, and severe infections.

Table 21: US Postmarketing AEs- Mifepristone for Medical Abortion

Date ranges of reports received	09/28/00[†]-10/31/12	11/1/12 - 04/30/14[‡]
Cases with any adverse event	2740	504
Hospitalized, excluding deaths	768	110
*Experienced blood loss requiring transfusions[§]	416	66
Infections[‖] (*Severe infections[¶])	308 (57)	37 (5)

† U.S. approval date.
‡ FDA implemented FAERS on September 10, 2012, and migrated all of the data from the previous reporting system (AERS) to FAERS. Differences may exist when comparing case counts in AERS and FAERS. FDA validated and recoded product information as the AERS reports were migrated to FAERS. As a result of this change, it is not recommended to calculate a cumulative number when reviewing the data provided in Table 5.
* The majority of these women are included in the hospitalized category in Table 5.
§ As stated in the approved Mifeprex (mifepristone) labeling, bleeding or spotting can be expected for an average of 9-16 days, and may last for up to 30 days. Excessive vaginal bleeding usually requires treatment by uterotonics, vasoconstrictor drugs, curettage, administration of saline infusions, and/or blood transfusions.
‖ This category includes endometritis (inflammation resulting from an infection involving the lining of the womb), pelvic inflammatory disease (involving the nearby reproductive organs such as the fallopian tubes or ovaries), and pelvic infections with sepsis (a serious systemic infection that has spread beyond the reproductive organs). Not included are women with reported sexually transmitted infections such as chlamydia and gonorrhea, cystitis, and toxic shock syndrome not associated with a pelvic infection.
¶ This subset of infections includes cases that were determined to be severe based on medical review of the available case details. Severe infections generally result in death or hospitalization for at least 2-3 days, require intravenous antibiotics for at least 24 hours and total antibiotic usage for at least 3 days, or have other physical or clinical findings, laboratory data, or surgery that suggest a severe infection.

Source: Review by (b) (6) (b) (6) (b) (6) dated 08/27/2015.

The (b) (6) review also describes ectopic pregnancies:

Table 22: US Postmarketing Ectopic Cases- Mifepristone for Medical Abortion

Date Range of Cumulative Reports	9/28/2000-10/31/14*	11/1/14-4/30/2015
Ectopic Pregnancies†	79	10

* U.S. approval date

† Administration of mifepristone and misoprostol is contraindicated in patients with confirmed or suspected ectopic pregnancy (a pregnancy outside the uterus).

Source: (b) (6) (b) (6) (b) (6) Mifepristone U.S. Post-marketing Adverse Events 6 month Update Summary through 04/30/2015, dated 08/20/2015.

Reviewer comment:

While exact rates cannot be calculated, as these reports are spontaneously generated, a few conclusions can be drawn from the information provided:

- **Given that there have been over 2.5 million uses of Mifeprex by US women since its marketing in 2000, including the use of the proposed dosing regimen and extended gestational age at many clinic/office sites, the numbers of hospitalizations, severe infections, blood loss requiring transfusion and ectopic pregnancy will likely remain acceptably low.**
- **The numbers of each of these adverse events appears to have remained steady over time, with a possible decrease in severe infections.**

A discussion of a (b) (6) review of uterine rupture is found in the Section Significant Adverse Events.

(b) (6) identified another safety signal in a review dated January 27, 2016. A FAERS search retrieved one case of anaphylaxis and six cases of angioedema with mifepristone administration. A literature search did not reveal any case reports of either adverse event with mifepristone. Six of the seven cases were seen in women using mifepristone for termination of pregnancy. Six of the seven cases noted some type of medical intervention, such as treatment with an antihistamine, a histamine H2 antagonist, a corticosteroid, or a combination of the various medications. Hospitalization was noted in three of the seven total cases; all three hospitalization cases occurred in patients who experienced angioedema.

In the case of anaphylaxis, it was reported that the patient experienced an anaphylactic reaction three hours after mifepristone administration; however, co-administration of doxycycline was also documented. Because both mifepristone and doxycycline were discontinued simultaneously, the exact cause of the anaphylactic reaction cannot be determined.

Regarding angioedema, five of the six cases noted a time-to-onset within 24 hours of mifepristone administration for the termination of pregnancy, with no additional suspect medications reported. The remaining case of angioedema with mifepristone reported a time-to-onset of approximately one week in a Cushing's syndrome patient with a complex medical history and multiple concomitant medications; however, this case noted both a positive dechallenge and rechallenge upon sole re-introduction of mifepristone therapy. Evaluation of these FAERS cases provides supportive evidence of a drug-event association between angioedema and mifepristone. The (b) (6) reviewer recommends the inclusion of anaphylaxis and angioedema within the Mifeprex labeling, specifically to the Contraindications and Adverse Reactions Postmarketing Experience sections.

Reviewer Comment:

There does appear to be an association with angioedema and mifepristone administration. The reviewers agree with inclusion of anaphylaxis and angioedema in the labeling for Mifeprex and with continued pharmacovigilance for anaphylaxis.

9 Appendices

9.1 Literature Review/References

This NDA review obviously involved an extensive review of resources and the peer-reviewed medical literature that was pertinent to the requested changes of the Applicant. Such sources are noted throughout the review in footnotes. A detailed Reference List is found in Appendix 9.6.

9.2 Labeling Recommendations

The package insert (PI) for this product was submitted in the Physician Labeling Rule (PLR) format. Although not required for this supplement, Section 8 was revised in accord with the Pregnancy and Lactation Labeling Rule (PLLR). Section 17 Patient Counseling Information was also revised to be compatible with the new dosing regimen and follow-up. Major changes were made that updated the labeling with new safety and efficacy information, especially in two areas:

1) 6.1 Clinical Trials Experience in the section 6 Adverse Reactions
2) 14 Clinical Studies

Changes were also made in the patient package insert (PPI) and Medication Guide for the product. These format and content updates marked a significant improvement in the label. Agreement on the Final Approved label was reached with the Applicant on March 29, 2016.

Reviewer comment:

The new dosing regimen was based on the extensive number of articles submitted by the Applicant from the peer reviewed medical literature. The revised label used the new PLR format which is a complete change from the previous style. This meant that the newly approved label was extensively rewritten and much improved from the old format.

9.3 Advisory Committee Meeting

An Advisory Committee met in 1996 to discuss the approval of mifepristone plus misoprostol for medical termination of early pregnancy. There has been extensive US (15+ years with over 2.5 million uses) and global use (27+ years) of mifepristone and misoprostol for the medical termination of early pregnancy. No special external consultations were requested by the review Divisions. The FDA determined that the efficacy supplement did not raise complex scientific or other issues that would warrant holding an advisory committee meeting before approval of the supplement.

9.4 (b) (6) ((b) (6) Meeting

As noted in Product Regulatory Information, Mifeprex was originally approved under 21 CFR part 314, subpart H, “Accelerated Approval of New Drugs for Serious or Life-Threatening Illnesses” (subpart H). Specifically, in accordance with § 314.520 of subpart H, FDA restricted the distribution of Mifeprex and required that Mifeprex be provided by or under the supervision of a physician who met certain qualifications. Further, practitioners had to complete a Prescriber’s Agreement, provide patients with a Medication Guide and have patients sign a Patient Agreement. Mifeprex was included on the list of products deemed to have in effect an approved REMS[86] under section

86 Federal Register / Vol. 73, No. 60 | Issued: March 27, 2008

505-1 of the Federal Food, Drug, and Cosmetic Act with the passage of FDA Amendments Act (FDAAA) of 2007. A formal REMS proposal was submitted by Danco and approved on June 8, 2011, with the essential elements unchanged. The REMS included:

- Medication Guide
- Elements to Assure Safe Use (ETASU):
  - Prescribed only by certified prescribers (ETASU A; includes a Prescriber's Agreement)
  - Dispensed only in certain healthcare settings (ETASU C)
  - Dispensed with documentation of safe use conditions (ETASU D; includes a Patient Agreement)
- Implementation System
  - Distributed only by certified distributors

Following this approval, two REMS assessment reports were completed. The Year 1 assessment was completed on June 1, 2012 and the Years 2-4 assessment was completed on June 2, 2015. Agency review of these reports determined that the REMS goals were being met and that no modifications were required to the REMS at that time.

On July 16, 2015, the Applicant submitted a revised REMS as part of the efficacy supplement. The proposed modifications included:

- Prescriber's Agreement Form
  - Remove "Under Federal law"
  - Replace "physician" with "(b) (4)

The Agency determined that broader review of the REMS was warranted concurrently with the efficacy supplement because some proposed changes in labeling dovetail with proposed changes to the REMS, and the documents should remain consistent with each other. Further, extensive review of the postmarketing experience based on the literature submitted to support the efficacy supplement, and pharmacovigilance, suggested that certain components of the REMS may no longer be necessary to assure safe use of Mifeprex.

In light of the efficacy review, upon assessment of the proposed modifications, (b) (6) concurs with (b) (6) recommendations that:

- Removal of "under Federal law" from the Prescribers' Agreement was acceptable (see discussion in Additional Submissions / Issues)
- The term "healthcare providers who prescribe" is preferable to (b) (4) (see discussion in Additional Submissions / Issues)

(b) (6) and (b) (6) also proposed the following modifications:

- Removal of the Medication Guide from the REMS (will remain a part of labeling and must be distributed by the prescriber as required under 21 CFR part 208)
- Removal of the Patient Agreement form - Documentation of Safe Use (ETASU D)

- Revision of the Prescriber's Agreement form
- Revision of the REMS goal to reflect above changes

FDA considered the need for the current adverse event reporting requirements under the REMS, which are currently outlined in the Prescriber's Agreement to include "hospitalization, transfusion or other serious event." FDA has received such reports for 15 years; the safety profile of Mifeprex is well-characterized, no new safety concerns have arisen in recent years, and the known serious risks occur rarely. For this reason, the reviewers do not believe ongoing reporting of all of the specified adverse events is warranted. The Applicant will still be required by law, as is every NDA holder, to report serious, unexpected adverse events as 15-day safety reports, and to submit non-expedited individual case safety reports, and periodic adverse drug experience.

(b) (6) and (b) (6) met with the (b) (6) ((b) (6) on January 15, 2015, to discuss the proposed modifications. The (b) (6) concurred with the removal of the term "under Federal law" and with use of the term "healthcare providers who prescribe." The (b) (6) also concurred with the removal of the Medication Guide (MG) from the REMS, though the document would remain a part of labeling. FDA has been maintaining MGs as labeling but removing them from REMS when, as here, inclusion in REMS is not necessary to ensure that the benefits of a drug outweigh the risks, such as when the MG is redundant and not providing additional use or information to the patient about the risk(s) the REMS is intended to mitigate. This is consistent with ongoing efforts to streamline REMS by allowing for updates to the MG without need for a REMS modification. (b) (6) and the (b) (6) had subsequent interactions and on February 23, 2016, the (b) (6) concurred with the decision to remove the Patient Agreement (ETASU D) from the REMS. This decision was based on the following rationale:

- The safety profile of Mifeprex is well-characterized over 15 years of experience, with known risks occurring rarely; the safety profile has not changed over the period of surveillance
- Established clinical practice includes patient counseling and documentation of Informed Consent, and, more specifically with Mifeprex, includes counseling an all options for termination of pregnancy, access to pain management and emergency services if needed. The National Abortion Federation (NAF) provides clinical practice guidelines[Error! Bookmark not defined.] and evidence shows that practitioners are providing appropriate patient counseling and education; a survey published in 2009 demonstrated that 99% of facilities surveyed provided pre-abortion counseling with patient education.[87] This indicates that the Patient Agreement form is duplicative and no longer necessary to ensure that the benefits of the drug outweigh the risks.

- Medical abortion with Mifeprex is provided by a small group of organizations and their associated providers. Their documents and guidelines cover the safety information that is duplicated in the Patient Agreement.
- ETASUs A and C remain in place: The Prescriber's Agreement under ETASU A requires that providers "explain the procedure, follow-up, and risks to each patient and give her an opportunity to discuss them." The REMS will continue to require that Mifeprex be dispensed to patients only in certain healthcare settings, specifically, clinics, medical offices, and hospitals. This ensures that Mifeprex can only be dispensed under the supervision of a certified prescriber at the time the patient receives treatment with Mifeprex.
- Labeling mitigates risk: The Medication Guide, which will remain a part of labeling, contains the same risk information covered under the Patient Agreement.

CLINICAL FILING CHECKLIST FOR NDA/BLA or Supplement

NDA/BLA Number: 020687 **Applicant: Danco Labs** **Stamp Date: May 29, 2015**

Drug Name: Mifeprex (Mifepristone) **NDA/BLA Type: supplement #020**

On initial overview of the NDA/BLA application for filing:

	Content Parameter	Yes	No	NA	Comment
FORMAT/ORGANIZATION/LEGIBILITY					
1.	Identify the general format that has been used for this application, e.g. electronic CTD.	x			Paper submission.
2.	On its face, is the clinical section organized in a manner to allow substantive review to begin?	x			
3.	Is the clinical section indexed (using a table of contents) and paginated in a manner to allow substantive review to begin?	x			
4.	For an electronic submission, is it possible to navigate the application in order to allow a substantive review to begin (*e.g.*, are the bookmarks adequate)?			x	
5.	Are all documents submitted in English or are English translations provided when necessary?	x			
6.	Is the clinical section legible so that substantive review can begin?	x			
LABELING					
7.	Has the applicant submitted the design of the development package and draft labeling in electronic format consistent with current regulation, divisional, and Center policies?	x			
SUMMARIES					
8.	Has the applicant submitted all the required discipline summaries (*i.e.*, Module 2 summaries)?		x		The applicant has not provided module 2 summaries as this is an NDA based on published literature. The applicant has provided a justification summarizing the evidence of safety and efficacy for the proposed changes.
9.	Has the applicant submitted the integrated summary of safety (ISS)?		x		See comment for 8.
10.	Has the applicant submitted the integrated summary of efficacy (ISE)?		x		See comment for 8.
11.	Has the applicant submitted a benefit-risk analysis for the product?	x			Scientific justification-30 pg document
12.	Indicate if the Application is a 505(b)(1) or a 505(b)(2).	x			(b) (2)
505(b)(2) Applications					
13.	If appropriate, what is the reference drug?			X	
14.	Did the applicant provide a scientific bridge demonstrating the relationship between the proposed product and the referenced product(s)/published literature?	x			The sponsor provides a bridge from the approved product to the proposed changes, with literature based

File name: 5_Clinical Filing Checklist for NDA_BLA or Supplement 010908

CLINICAL FILING CHECKLIST FOR NDA/BLA or Supplement

	Content Parameter	Yes	No	NA	Comment
					on both the approved product and the proposed regimen.
15.	Describe the scientific bridge (e.g., BA/BE studies)	x			See #14.
DOSE					
16.	If needed, has the applicant made an appropriate attempt to determine the correct dosage and schedule for this product (*i.e.*, appropriately designed dose-ranging studies)? Study Number: Many articles from the published medical literature. Study Title: Sample Size: Arms: Location in submission:	x			
EFFICACY					
17.	Do there appear to be the requisite number of adequate and well-controlled studies in the application? Pivotal Study #1 Indication: Pivotal Study #2 Indication:	x			The applicant provides 54 articles total, with 32 specifically on efficacy of the proposed regimen. These include controlled trials, meta-analyses, observational and retrospective studies.
18.	Do all pivotal efficacy studies appear to be adequate and well-controlled within current divisional policies (or to the extent agreed to previously with the applicant by the Division) for approvability of this product based on proposed draft labeling?	x			
19.	Do the endpoints in the pivotal studies conform to previous Agency commitments/agreements? Indicate if there were not previous Agency agreements regarding primary/secondary endpoints.	x			
20.	Has the application submitted a rationale for assuming the applicability of foreign data to U.S. population/practice of medicine in the submission?			x	The applicant provides 54 articles total. 46 are studies (trials, retrospective, observational studies) and of these 17 are foreign. There are also 3 metanalyses which include foreign studies.
SAFETY					
21.	Has the applicant presented the safety data in a manner consistent with Center guidelines and/or in a manner previously requested by the Division?	x			The applicant provides 21 articles with information on safety, specifically on the serious adverse events of interest (hospitalization,

CLINICAL FILING CHECKLIST FOR NDA/BLA or Supplement

	Content Parameter	Yes	No	NA	Comment
					transfusion, infection requiring IV antibiotics, death). There are another 5 articles with limited safety information and 6 articles with safety information, but using different dosing regimens (e.g. not the approved or proposed new regimen).
22.	Has the applicant submitted adequate information to assess the arythmogenic potential of the product (*e.g.*, QT interval studies, if needed)?			x	
23.	Has the applicant presented a safety assessment based on all current worldwide knowledge regarding this product?	x			
24.	For chronically administered drugs, have an adequate number of patients (based on ICH guidelines for exposure[1]) been exposed at the dose (or dose range) believed to be efficacious?			x	
25.	For drugs not chronically administered (intermittent or short course), have the requisite number of patients been exposed as requested by the Division?	x			
26.	Has the applicant submitted the coding dictionary[2] used for mapping investigator verbatim terms to preferred terms?			x	There is no mapping of investigator terms to preferred terms. AE's were variably ascertained; 21 studies include data on SAE's of interest, 7 have limited safety information, 6 have safety information on the approved dosing regimen. Some 7 studies report no safety information.
27.	Has the applicant adequately evaluated the safety issues that are known to occur with the drugs in the class to which the new drug belongs?	x			
28.	Have narrative summaries been submitted for all deaths and adverse dropouts (and serious adverse events if requested by the Division)?			x	As of 7/16/15, there is one reported death; a complete report will be forthcoming. This

[1] For chronically administered drugs, the ICH guidelines recommend 1500 patients overall, 300-600 patients for six months, and 100 patients for one year. These exposures MUST occur at the dose or dose range believed to be efficacious.

[2] The "coding dictionary" consists of a list of all investigator verbatim terms and the preferred terms to which they were mapped. It is most helpful if this comes in as a SAS transport file so that it can be sorted as needed; however, if it is submitted as a PDF document, it should be submitted in both directions (verbatim -> preferred and preferred -> verbatim).

CLINICAL FILING CHECKLIST FOR NDA/BLA or Supplement

	Content Parameter	Yes	No	NA	Comment
					is not part of the presently submitted application.
OTHER STUDIES					
29.	Has the applicant submitted all special studies/data requested by the Division during pre-submission discussions?			x	
30.	For Rx-to-OTC switch and direct-to-OTC applications, are the necessary consumer behavioral studies included (*e.g.*, label comprehension, self selection and/or actual use)?			x	
PEDIATRIC USE					
31.	Has the applicant submitted the pediatric assessment, or provided documentation for a waiver and/or deferral?	x			The applicant requested a partial waiver for patients <12 and a waiver for patients 12-17, based on data from one study which included 322 subjects <17 years old.
ABUSE LIABILITY					
32.	If relevant, has the applicant submitted information to assess the abuse liability of the product?			x	
FOREIGN STUDIES					
33.	Has the applicant submitted a rationale for assuming the applicability of foreign data in the submission to the U.S. population?			X	29/46 studies are US data, 17 are based on foreign data.
DATASETS					
34.	Has the applicant submitted datasets in a format to allow reasonable review of the patient data?			x	NDA relies upon published studies; datasets were not provided.
35.	Has the applicant submitted datasets in the format agreed to previously by the Division?			x	
36.	Are all datasets for pivotal efficacy studies available and complete for all indications requested?			x	
37.	Are all datasets to support the critical safety analyses available and complete?			x	
38.	For the major derived or composite endpoints, are all of the raw data needed to derive these endpoints included?			x	
CASE REPORT FORMS					
39.	Has the applicant submitted all required Case Report Forms in a legible format (deaths, serious adverse events, and adverse dropouts)?			x	NDA relies upon published studies; CRFs were not provided.
40.	Has the applicant submitted all additional Case Report Forms (beyond deaths, serious adverse events, and adverse drop-outs) as previously requested by the Division?			x	
FINANCIAL DISCLOSURE					
41.	Has the applicant submitted the required Financial Disclosure information?			X	
GOOD CLINICAL PRACTICE					
42.	Is there a statement of Good Clinical Practice; that all clinical studies were conducted under the supervision of an			x

Mifepristone U.S. Post-Marketing Adverse Events Summary through 12/31/2024

The following information is from United States (U.S.) post-marketing reports received by FDA of adverse events that occurred among patients who had taken mifepristone for medical termination of pregnancy. Because FDA has eliminated duplicate reports, and in some cases, reclassified the adverse event terms for individual cases after reviewing the narrative details, the numbers provided here may differ from the numbers of the reports that may be obtained through Freedom of Information Act requests. These events cannot with certainty be causally attributed to mifepristone because of information gaps about patient health status, clinical management of the patient, concurrent drug use, and other possible medical or surgical treatments and conditions. The estimated number of women who have used mifepristone in the U.S. for medical termination of pregnancy through the end of December 2024 is approximately 7.5 million women.

For informational purposes, fatal foreign cases that were reported after U.S. approval of mifepristone for medical termination of pregnancy are also included in a footnote in Table 1.

Table 1. Cumulative Post-Marketing Fatal and Ectopic Pregnancy Reports in U.S. Women Who Used Mifepristone for Medical Termination of Pregnancy

Date range of cumulative reports	09/28/00[†] - 12/31/24
Died [‡]	36
*Ectopic pregnancies [||]	97

[†] U.S. approval date

[‡] The fatal cases are included regardless of causal attribution to mifepristone. Deaths were associated with sepsis in 13 of the 36 reported fatalities (9 cases tested positive for *Clostridium sordellii*, 1 case tested positive for *Clostridium perfringens*, 2 cases had negative blood cultures, and 1 case did not have blood culture data). Ten of the 13 fatal sepsis cases reported vaginal misoprostol use; 2 cases reported buccal misoprostol use; 1 case did not report the route of misoprostol use. Twenty-two of the 23 remaining U.S. deaths involved 2 cases of homicide, 2 cases of combined drug intoxication/overdose, 2 cases of ruptured ectopic pregnancy, 2 cases of drug intoxication, 2 cases of suicide, and 1 case each of the following: substance abuse/drug overdose; methadone overdose; suspected homicide; delayed onset toxic shock-like syndrome; hemorrhage; bilateral pulmonary thromboemboli; unintentional overdose resulting in liver failure; probable anaphylactic medication reaction; septic shock due to necrotizing fasciitis; sepsis with multiple complications possibly secondary to toxic shock syndrome 82 days after mifepristone; sudden death of undetermined etiology despite performance of an autopsy; and a case of natural death due to severe pulmonary emphysema. In the 23rd case, the cause of death could not be established despite performance of an autopsy; tissue samples were negative for *Clostridium sordellii*. There were 13 additional reported deaths in women in foreign countries who used mifepristone for medical termination of pregnancy. These fatal cases were associated with the following: sepsis (*Clostridium sordellii* identified in tissue samples) in a foreign clinical trial; sepsis (Group A *Streptococcus pyogenes*); a ruptured gastric ulcer; severe hemorrhage; severe hemorrhage and possible sepsis; "multivisceral failure;" thrombotic thrombocytopenic purpura leading to intracranial hemorrhage; toxic shock syndrome (*Clostridium sordellii* was identified through uterine biopsy cultures); sepsis (*Enterococcus faecalis* and *Escherichia coli* were identified in blood culture); asthma attack with cardiac arrest; thromboembolism; respiratory decompensation with secondary pulmonary infection 30 days after mifepristone in a patient on the lung transplant list with diabetes, a jejunostomy feeding tube, and severe cystic fibrosis; and a case of *Clostridium septicum* sepsis (from a published literature report).

* The majority of these women are included in the hospitalized category in Table 2.

[||] Administration of mifepristone and misoprostol is contraindicated in patients with confirmed or suspected ectopic pregnancy (a pregnancy outside the uterus).

Table 2. Post-Marketing Adverse Events in U.S. Women Who Used Mifepristone for Medical Termination of Pregnancy		
Date ranges of reports received	09/28/00[†] - 10/31/12	11/01/12 - 12/31/24[‡]
Cases with any adverse event	2740	1512
Hospitalized, excluding deaths	768	288
*Experienced blood loss requiring transfusions [§]	416	190
Infections [||] (*Severe infections [¶])	308 (57)	114 (22)

[†] U.S. approval date

[‡] FDA implemented the FDA Adverse Event Reporting System (FAERS) on September 10, 2012, and migrated all the data from the previous reporting system (AERS) to FAERS. Differences may exist when comparing case counts in AERS and FAERS. FDA validated and recoded product information as the AERS reports were migrated to FAERS. As a result of this change, it is not recommended to calculate a cumulative number when reviewing the data provided in Table 2.

* The majority of these women are included in the hospitalized category in Table 2.

[§] As stated in the approved labeling for Mifeprex (mifepristone) and its approved generic version, bleeding or spotting can be expected for an average of 9-16 days, and may last for up to 30 days. Excessive vaginal bleeding usually requires treatment by uterotonics, vasoconstrictor drugs, curettage, administration of saline infusions, and/or blood transfusions.

[||] This category includes endometritis (inflammation resulting from an infection involving the lining of the womb), pelvic inflammatory disease (involving the nearby reproductive organs such as the fallopian tubes or ovaries), and pelvic infections with sepsis (a serious systemic infection that has spread beyond the reproductive organs). Not included are women with reported sexually transmitted infections such as chlamydia and gonorrhea, cystitis, and toxic shock syndrome not associated with a pelvic infection.

[¶] This subset of infections includes cases that were determined to be severe based on medical review of the available case details. Severe infections generally result in death or hospitalization for at least 2-3 days, require intravenous antibiotics for at least 24 hours and total antibiotic usage for at least 3 days, or have other physical or clinical findings, laboratory data, or surgery that suggest a severe infection.

EXECUTIVE SUMMARY

This review provides the [redacted] rationale and conclusions regarding modifications to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (Mifepristone REMS Program) for new drug application (NDA) 20687 and abbreviated new drug application (ANDA) 91178.

ANDA 91178 was approved with the approval of the Mifepristone REMS Program on April 11, 2019 to mitigate the risk of serious complications associated with mifepristone 200 mg. The most recent REMS modification was approved on May 14, 2021. The REMS consists of elements to assure safe use (ETASU) under ETASU A, C and D, an implementation system, and a timetable for submission of assessments. To determine whether a modification to the REMS was warranted, FDA undertook a comprehensive review of the published literature; safety information collected during the COVID-19 public health emergency (PHE); the one-year REMS assessment report of the Mifepristone REMS Program; adverse event data; and information provided by advocacy groups, individuals and the Applicants. Our review also included an examination of literature references provided by plaintiffs in the *Chelius v. Becerra* litigation discussed below.

The modifications to the REMS will consist of:

- Removing the requirement under ETASU C that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (referred to here as the "in-person dispensing requirement" for brevity)
- Adding a requirement under ETASU B that pharmacies that dispense the drug be specially certified

A REMS Modification Notification letter will be sent to both Applicants in the Single Shared System.

1. Introduction

In connection with the *Chelius v. Becerra* litigation, FDA agreed to undertake a full review of the Mifepristone REMS Program, in accordance with the REMS assessment provisions of the Federal Food, Drug, and Cosmetic Act (FD&C Act).[a] This review provides the analysis of the (b) (6) ((b) (6) and the (b) (6) ((b) (6) regarding whether any changes are warranted to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone (hereafter referred to as the Mifepristone REMS Program) for new drug application (NDA) 20687 and abbreviated new drug application (ANDA) 91178. The Mifeprex REMS was initially approved in 2011; the single, shared system REMS for mifepristone 200 mg, known as the Mifepristone REMS Program, was approved in 2019.

The last time the existing REMS elements to assure safe use (under ETASU A, C and D) were reviewed was in the context of our review of supplement S-020 to NDA 20687; these ETASU were updated following review and approval of supplement S-020 on March 29, 2016. The key changes approved in 2016 are summarized below.

Changes to labeling included:

- Changing the dosing of Mifeprex to 200 mg orally x 1
- Extension of maximum gestational age through 70 days
- Inclusion of misoprostol in the indication statement
- Replacing the term “physician” with “licensed healthcare provider”
- Removal of the phrase “Under Federal Law”

The Mifeprex REMS and REMS materials were updated to reflect the changes above, and additional changes were made including:

- Removing the Medication Guide as part of the REMS but retaining it as part of labeling.

2. Background

2.1. PRODUCT AND REMS INFORMATION

[a] Section 505-1(g)(2) of the FD&C Act (21 U.S.C. § 355-1(g)(2)).

Mifepristone is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy (IUP) through 70 days gestation. Mifepristone is available as 200 mg tablets for oral use.

Mifeprex (mifepristone) was approved on September 28, 2000 with a restricted distribution program under 21 CFR 314.520 (subpart H)[b] to ensure that the benefits of the drug outweighed the risk of serious complications associated with mifepristone when used for medical abortion. Mifeprex was deemed to have a REMS under section 505-1 of the Federal Food, Drug, and Cosmetic Act with the passage of the Food and Drug Administration Amendments Act (FDAAA) of 2007, and the Mifeprex REMS was approved on June 8, 2011. On March 29, 2016, as noted above, a supplemental application and REMS modification was approved for Mifeprex. On April 11, 2019, ANDA 091178 was approved, and the Mifepristone REMS Program was approved. The Mifepristone REMS Program is a single, shared system REMS that includes NDA 020687 and ANDA 91178.

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a. Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program (under ETASU A).
b. Ensuring that mifepristone is only dispensed in certain healthcare settings, by or under the supervision of a certified prescriber (under ETASU C).
c. Informing patients about the risk of serious complications associated with mifepristone (under ETASU D).

Under ETASU A, to become specially certified to prescribe mifepristone, a healthcare provider must review the prescribing information, complete and sign the *Prescriber Agreement Form,* and follow the guidelines for use of mifepristone. Under ETASU C, mifepristone must be dispensed to patients only in certain healthcare settings, specifically clinics, medical offices, and hospitals, by or under the supervision of a certified prescriber. Under ETASU D, mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions (i.e., the patient must sign a *Patient Agreement Form*). The Mifepristone REMS Program also includes an implementation system, and a timetable for assessments (one year from the date of the initial approval of the REMS on April 11, 2019, and every three years thereafter).

[b] NDA approval letter Mifeprex (NDA 020687) dated September 28, 2000.

2.2. REGULATORY HISTORY AND EVENTS RELEVANT TO THIS REMS MODIFICATION RATIONALE REVIEW

The following is a summary of significant regulatory history since approval of the REMS modification on March 29, 2016:

- 03/29/2016: FDA approved an efficacy supplement (S-020) that, among other things, provided a new dosing regimen (200 mg mifepristone, followed in 24 to 48 hours by 800 mcg buccal misoprostol), increased the gestational age (GA) to which mifepristone may be used (through 70 days gestation), and modified the REMS.

- 03/29/2019: A Citizen Petition was received requesting that FDA revise the product labeling to reflect pre-2016 provisions (including limiting GA to 49 days and requiring patients to make 3 office visits) and that FDA maintain the REMS.

- 04/11/2019: ANDA 91178 was approved along with the Single Shared System REMS for Mifepristone 200 mg (Mifepristone REMS Program) for NDA 20687 and ANDA 91178.

- 01/31/2020: the COVID-19 public health emergency (PHE) was declared by the Secretary of Health and Human Services (HHS) as having existed since January 27, 2020.[c]

- 7/13/2020: The United States (US) District Court of Maryland granted a preliminary injunction in the *ACOG v. FDA* litigation to temporarily bar enforcement of the Mifepristone REMS Program in-person dispensing requirement during the COVID-19 PHE.

- 1/12/2021: US Supreme Court granted a stay of that injunction.

- 04/12/2021: FDA issued a General Advice Letter to both the NDA and ANDA Applicants, stating that provided that all other requirements of the Mifepristone REMS Program are met, and given that in-person dispensing of mifepristone for medical termination of early pregnancy may present additional COVID-related risks to patients and healthcare

[c] *See* Secretary of Health and Human Services, Determination that a Public Health Emergency Exists (originally issued January 31, 2020, and subsequently renewed), available at https://www.phe.gov/emergency/news/healthactions/phe/Pages/default.aspx

personnel because it may involve a clinical visit solely for this purpose, FDA intends to exercise enforcement discretion during the COVID-19 PHE with respect to the in-person dispensing requirement in the Mifepristone REMS Program, including any in-person requirements that may be related to the *Patient Agreement Form.* FDA further stated that to the extent all of the other requirements of the Mifepristone REMS Program are met, FDA intends to exercise enforcement discretion during the COVID-19 PHE with respect to the dispensing of mifepristone through the mail, either by or under the supervision of a certified prescriber, or through a mail-order pharmacy when such dispensing is done under the supervision of a certified prescriber.

- 05/07/2021: FDA stated that it would be reviewing the elements of the Mifepristone REMS Program in accordance with the REMS assessment provisions of section 505-1 of the FD&C Act.

- 05/14/2021: A modification was approved for the Mifepristone REMS Program. This modification was to revise the *Patient Agreement Form* to include gender-neutral language.

- 06/30/2021: An Information Request (IR) was sent to the Applicants for additional information on shipments and any program deviations, adverse events, or noncompliance with the REMS that occurred during the period from April 1, 2021 through September 30, 2021.

- 7/15/2021: An IR was sent to the Applicants to provide the total number of shipments during the period from April 1, 2021 to September 30, 2021 and details on whether any of those shipments were involved in any program deviation or non-compliance.

- 8/5/2021: An IR was sent to the Applicants for additional clinical and other information (e.g., adverse events and units of mifepristone shipped) for the period of March 29, 2016 through June 30, 2021, to be provided by August 31, 2021. This IR also requested information covering the period of July 1, 2021 through September 30, 2021 and an

aggregate summary (for the period of March 29, 2016 through September 30, 2021), to be provided by October 12, 2021.[d]

- 8/26/2021: The ANDA Applicant submitted a response to the IR issued on 8/5/2021.
- 08/27/2021: The NDA Applicant submitted a response to the IR issued on 8/5/2021.
- 10/08/2021: The NDA Applicant submitted a response to the June 30 and July 15, 2021 IRs as well as an aggregate summary for the period March 29, 2016 through September 30, 2021 in response to the August 5, 2021 IR. The NDA Applicant also included a follow-up to their initial response provided on August 27, 2021 to the August 5, 2021 IR.
- 10/12/2021: The ANDA Applicant submitted a response to the June 30 and July 15, 2021 IRs as well as an aggregate summary for the period March 29, 2016 through September 30, 2021 in response to the August 5, 2021 IR.
- 10/16/2021: The ANDA Applicant revised their Oct 12, 2012 response to provide a correction to the number of mifepristone tablets.
- (b) (4) .
- 11/02/2021: A (b) (6) ((b) (6) meeting was convened to obtain CDER concurrence on the removal of the in-person dispensing requirement and the addition of a certification requirement for pharmacies. The (b) (6) (b) (6) and senior CDER leadership concurred with removing the in-person dispensing and adding pharmacy certification.

3. Rationale for Proposed REMS Modification

[d] Multiple Information Requests were issued to obtain additional information on drug shipments, any program deviations or noncompliance, and use of alternative methods for drug distribution during the COVID-19 PHE. These IRs are referenced as appropriate in this document and the one-year REMS Assessment Review of the Mifepristone REMS Program, December 16, 2021.

3.1. CURRENT REQUIREMENTS FOR THE APPROVED REMS

The Mifepristone REMS Program includes elements to assure safe use (ETASU), an implementation system, and a timetable for submission of assessments. Elements to assure safe use in the current REMS include a prescriber certification requirement (ETASU A), a requirement that mifepristone be dispensed only in certain healthcare settings by or under the supervision of a certified prescriber (ETASU C), and a requirement that mifepristone be dispensed only with documentation of safe use conditions (ETASU D). Documentation of safe use conditions under ETASU D consists of a *Patient Agreement Form* between the prescriber and the patient indicating that the patient has received counseling from the prescriber regarding the risk of serious complications associated with mifepristone 200 mg for medical termination of early pregnancy.

3.2. EVALUATION OF THE EVIDENCE

We reviewed multiple different sources of information, including published literature, safety information submitted to the Agency during the COVID-19 PHE, FDA Adverse Event Reporting System (FAERS) reports, the first REMS assessment report for the Mifepristone REMS Program, and information provided by advocacy groups, individuals, and the Applicants. Our review also included an examination of literature references provided by plaintiffs in the *Chelius v. Becerra* litigation. Below is an overview of how information relevant to the current Mifepristone REMS Program was retrieved, analyzed, and applied to each of the individual ETASUs to determine if further changes should be considered.

Methods for the literature search

(b) (6) conducted a literature search in PubMed and Embase to retrieve publications relevant to this review. The time period used for this literature search was between March 29, 2016 (when the Mifeprex labeling and REMS were last substantially revised) through July 26, 2021. The search terms used were “medical abortion” and “mifepristone” and “pregnancy termination and mifepristone.”

The search retrieved 306 publications from PubMed and 613 from Embase, respectively; the search yielded 646 unique publications after eliminating duplications between the two databases. The result of our literature search was also supplemented by an examination of literature references provided by advocacy groups, individuals, plaintiffs in the *Chelius* litigation, and the Applicants, as well as letters from healthcare providers and researchers.

References included in these letters were considered for inclusion in this review using identical selection criteria to the (b) (6) literature search (outlined below).

For this review of the REMS, (b) (6) focused on publications containing safety data related to outcomes of medical abortion (objective safety data) obtained from our literature search and from the references provided to us relevant to the REMS ETASUs. We excluded systematic reviews and meta-analyses because these publications did not include original safety data related to the outcomes of medical abortion. The following are examples of materials that were excluded from our literature search:

- Information from survey studies or qualitative studies that evaluated perspectives on and/or satisfaction with medical abortion procedures from patients, pharmacists, clinic staff, or providers, even if the study assessed REMS ETASUs. These surveys or qualitative studies did not include objective safety data related to outcomes of medical abortion.

- Opinions, commentaries, or policy/advocacy statements. These publications did not include objective safety data related to outcomes of medical abortion.

- Safety data related to mifepristone use for second trimester medical abortion. These publications reported data not applicable to the approved indication for medical abortion up to 70 days gestation.

- Safety data related to mifepristone use for spontaneous first trimester abortion (i.e., miscarriages). These publications reported data not applicable to the approved indication for medical abortion up to 70 days gestation.

- Safety data that pertained only to surgical abortion or did not separate out medical abortion from surgical abortion.

- Other safety information unrelated to the REMS elements (e.g., articles limited to case reports or those discussing unrelated gynecologic or medical issues)

- Publications for which it was not possible to conduct a full review of the methods or results, i.e., the references were limited to an abstract of the study methods and results.

- Publications that provided only general statistics on abortion care in the United States.

- Information pertinent to molecular or other basic science aspects of mifepristone.

- Data on the logistics of accessing abortion care in general, such as time to appointment or the distance traveled to obtain care.

- Publications that provided data not related specifically to abortion care or the REMS (e.g., references focused on federal poverty guidelines, poverty data, or the financial impact of the COVID-19 pandemic).

One exception to the above literature search criteria was the inclusion in Section 3.2.2 of this review, which discusses the *Patient Agreement Form*, of publications that discussed changes in provider volume. The data discussed in relation to provider volume was obtained from surveys. This data was included because changes in provider volume could only be obtained from well-conducted survey studies.

Regarding medical/scientific references submitted with letters from the plaintiffs in the *Chelius* litigation, we applied the same criteria as for the literature search, as described above.

Letters from the plaintiffs in the *Chelius* litigation included several references that preceded our 2016 review of the REMS. Two of those pre-2016 studies were not captured in our 2016 literature search. These two studies were assessed as part of our current review; their results are consistent with the existing safety profile of the approved medical abortion regimen, and therefore, support our current conclusions regarding the REMS. See Appendix A.

3.2.1. Evaluation of the requirement for healthcare providers who prescribe the drug to be specially certified (ETASU A)

In order to become specially certified, prescribers must: 1) review the prescribing information for mifepristone and 2) complete the *Prescriber Agreement Form*. In signing the *Prescriber Agreement Form*, prescribers agree they meet the qualifications listed below:

- Ability to assess the duration of pregnancy accurately
- Ability to diagnose ectopic pregnancies
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or to have made plans to provide such care through others, and ability to

ensure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.

- Has read and understood the Prescribing Information of mifepristone (which the provider can access by phone or online).

In addition to meeting these qualifications, as a condition of certification the healthcare provider also agrees to follow the guidelines for use below:

- Review the *Patient Agreement Form* with the patient and fully explain the risks of the mifepristone treatment regimen. Answer any questions the patient may have prior to receiving mifepristone.
- Sign and obtain the patient's signature on the *Patient Agreement Form*.
- Provide the patient with a copy of the *Patient Agreement Form* and the Medication Guide.
- Place the signed *Patient Agreement Form* in the patient's medical record.
- Record the serial number from each package of mifepristone in each patient's record.
- Report deaths to the Applicant, identifying the patient by a non-identifiable patient reference and the serial number from each package of mifepristone.

The literature review was the primary source of information that contributed to our reassessment of ETASU A.

We continue to be concerned that absent these provider qualifications, serious and potentially fatal complications associated with medical abortion, including missed ectopic pregnancy and heavy bleeding from incomplete abortion, would not be detected or appropriately managed. Our review of the literature did not identify any studies comparing providers who met these qualifications with providers who did not. In the absence of such studies, there is no evidence to contradict our previous finding that prescribers' ability to accurately date pregnancies, diagnose ectopic pregnancies, and provide surgical intervention or arrange for such care through others if needed, is necessary to mitigate the serious risks associated with the use of mifepristone in a regimen with misoprostol. Therefore, our review continues to support the conclusion that a healthcare provider who prescribes mifepristone should meet the above qualifications. We conclude it is reasonable to maintain the requirement for a one-time prescriber certification where prescribers attest to having the ability to diagnose an intrauterine

pregnancy, to diagnose an ectopic pregnancy,[e] and to either manage serious complications themselves or arrange for other providers to provide the needed care in a timely manner.

In addition, in signing the *Prescriber Agreement Form* and placing it in the patient's medical record, the prescribers acknowledge the requirement to report patient deaths associated with mifepristone to the manufacturer. Such a requirement ensures that the manufacturer receives all reports of patient deaths and, in turn, fulfills its regulatory obligations to report those deaths to the FDA.

As discussed in Section 3.2.2 below, there is a potential for doubling of the number of prescribers of mifepristone if the in-person dispensing requirement in ETASU C is removed from the Mifepristone REMS Program. Given the potential addition of new prescribers, in addition to the considerations described above, we conclude that we should maintain the requirement for prescriber certification, to ensure that providers meet the necessary qualifications and adhere to the guidelines for use. Our literature review supports that these requirements are still necessary, and the potential increase in new prescribers under the REMS is a further reason to maintain prescriber certification. Healthcare provider certification continues to be a necessary component of the REMS to ensure the benefits of mifepristone for medical abortion outweigh the risks. The burden of prescriber certification has been minimized to the extent possible by requiring prescribers to certify only one time for each applicant.

3.2.2. Evaluation of the requirement for the drug to be dispensed with evidence or other documentation of safe-use conditions (ETASU D)

In order to receive mifepristone for medical termination of pregnancy through 70 days gestation, the patient must sign a *Patient Agreement Form* indicating that the patient has received, read, and been provided a copy of the *Patient Agreement Form* and received counseling from the prescriber regarding the risk of serious complications associated with mifepristone for this indication. The *Patient Agreement Form* ensures that patients are informed of the risks of serious complications associated with mifepristone for this indication.

[e] American College of Obstetricians and Gynecologists (ACOG) Practice Bulleting Number 191, February 2018. Tubal Ectopic Pregnancy. https://www.acog.org/clinical/clinical-guidance/practice-bulletin/articles/2018/03/tubal-ectopic-pregnancy. Mifepristone is not effective for terminating ectopic pregnancy. Some of the expected symptoms experienced with a medical abortion (abdominal pain, uterine bleeding) may be similar to those of a ruptured ectopic pregnancy. A missed ectopic pregnancy that ruptures is a medical emergency that requires immediate surgical intervention.

In a number of approved REMS, *Patient Agreement Forms* or *Patient Enrollment Forms* ensure that patients are counseled about the risks of the product and/or informed of appropriate safe use conditions.[f]

As a condition of certification under the Mifepristone REMS Program, healthcare providers must follow the guidelines for use of mifepristone, including reviewing the *Patient Agreement Form* with the patient, fully explaining the risks of the treatment regimen, and answering any questions the patient may have before receiving the medication. With this form, the patient acknowledges that they have received and read the form, and that they have received the counseling regarding when to take mifepristone, the risk of serious complications associated with mifepristone and what to do if they experience adverse events (e.g., fever, heavy bleeding). Both the healthcare provider and patient must sign the document and the patient must receive a copy of the signed form. In addition to the counseling described in the *Patient Agreement Form*, patients also receive a copy of the Medication Guide for mifepristone. Ultimately, the *Patient Agreement Form* serves as an important counseling component, and documentation that the safe use conditions of the Mifepristone REMS Program have been satisfied, as the prescriber is required to place the signed *Patient Agreement Form* in the patient's medical record.

Prior to the March 29, 2016 approval of the S-020 efficacy supplement for Mifeprex, FDA undertook a review of all elements of the REMS. At that time, the (b) (6) ((b) (6)), along with the (b) (6) ((b) (6)), recommended removal of the *Patient Agreement Form* (ETASU D). This recommendation received concurrence from the (b) (6) on February 23, 2016. The rationale for this recommendation in the 2016 review[g] is summarized here as follows:

- The safety profile of Mifeprex is well-characterized over 15 years of experience, with known risks occurring rarely; the safety profile has not changed over the period of surveillance.
- Established clinical practice includes patient counseling and documentation of informed consent and evidence shows that practitioners are providing appropriate patient

[f] REMS@FDA, https://www.accessdata fda.gov/scripts/cder/rems/index.cfm, Accessed November 15, 2021.
[g] (b) (6) Clinical Review, NDA 020687/S20, dated March 29, 2016. https://darrts fda.gov/darrts/faces/ViewDocument?documentId=090140af803dc7bd&_afrRedirect=386175573203745

counseling and education; the *Patient Agreement Form* is duplicative of these established practices.

- Medical abortion with Mifeprex is provided by a small group of organizations and their associated providers. Their documents and guidelines are duplicated in the *Patient Agreement Form*.
- ETASUs A and C remain in place: The *Prescriber Agreement Form* and the requirement that Mifeprex be dispensed to patients only in certain healthcare settings, specifically, clinics, medical offices, and hospitals under the supervision of a certified prescriber, remain in place.

In light of a memorandum from the Director of the Center for Drug Evaluation and Research, an addendum to the (b) (6) March 29, 2016 review and a memorandum from the signatory authority in (b) (6) indicated that the *Patient Agreement Form* would be retained in the REMS.[h,i]

The current review of literature from March 29, 2016 to July 26, 2021, is relevant to our assessment of the necessity of the *Patient Agreement Form* as part of the REMS. While our literature search yielded no publications which directly addressed this element of the REMS, we identified the following literature that focused on the informed consent process. These studies were reviewed for their potential relevance on this topic, though the articles do not directly assess the need for the *Patient Agreement Form* as a condition necessary to assure safe use of Mifepristone under ETASU D.

- Two studies[1,2] (both authored by Dr. Grossman in 2021) used the *Patient Agreement Form* and additional clinic-specific written informed consent forms as part of the study methodology. One study evaluated medical abortion with pharmacist dispensing of mifepristone and another evaluated mail-order pharmacy dispensing. Safety and efficacy outcomes were not assessed regarding the element of consent in isolation or the *Patient Agreement Form*.
- Several studies included use of electronic or verbal consent. Two studies were conducted using signed electronic consent (Chong[3], Kerestes[4]). Aiken[5] reported that patients had the option of providing consent verbally and the discussion had to be recorded in the notes. Rocca[6] described obtaining verbal informed consent from patients seeking medical abortion provided in pharmacies or government-certified

h (b) (6) Review of proposed REMS modifications to Mifeprex. March 29, 2106.
i (b) (6) Summary of Regulatory Action for Mifeprex. March 29, 2016.

public health facilities by auxiliary nurse midwives (ANMs) in Nepal. Outcomes were not assessed regarding the single element of consent and its role in the efficacy of medical abortion.

- A retrospective chart review (Wiebe[7]) was conducted in Canada. This study included telemedicine abortions between January 31, 2017 and January 31, 2019 and a similar group of controls seen in the clinic during the same time frame, matched by date of initial appointment. As part of the telemedicine process, patients read a consent form (not specified whether they could view an electronic version) and gave verbal consent "witnessed by the counselor". Again, outcomes were not assessed regarding the single element of consent and its role in the efficacy of medical abortion.

After review, we conclude that there are no outcome data from these studies that address the need for the *Patient Agreement Form* as a condition necessary to assure safe use of mifepristone. Nor do any of these studies provide evidence of whether the patient's informed consent has been adequately documented under the process set out in the study protocol. Therefore, these studies do not provide evidence that would support removing ETASU D.

Although (b) (6) agrees that informed consent in medicine is an established practice, the National Abortion Federation's 2020 Clinical Policy Guidelines for Abortion Care[8] continue to include a detailed section on patient education, counseling, and informed consent. The guidelines state that these steps are essential parts of the abortion process; that they should be conducted by appropriate personnel, with accurate information, including about alternatives and potential risks and benefits; and that the patients must have an opportunity to have any questions answered to their satisfaction prior to any intervention. Under these guidelines, documentation must show that the patient affirms that they understand all the information provided and that the decision to undergo an abortion is voluntary. The guidelines specifically list the risks that must be addressed at a minimum, including those pertinent to medical abortion: hemorrhage, infection, continuing pregnancy, and death. Additionally, Practice Bulletins from ACOG[9] and the Society of Family Planning also support detailed patient counseling.

In addition, trends in US clinical practice are developing which could negatively impact adequate patient counseling about the risks of medical abortion. One survey by Jones 2017[10] of abortion providers in the United States and Canada prior to the COVID-19 pandemic did reveal strong adherence to evidence-based guidelines. However, this same survey noted continued increasing uptake of medical abortion by US providers. Grossman[11] conducted a US survey in

2019 which suggested that the number of obstetrician/gynecologists providing medical abortion care may be increasing and that uptake might increase if mifepristone were dispensed by pharmacies instead of being dispensed in-person. A subsequent survey of US obstetricians/ gynecologists by Daniel in 2021[12] evaluated a subsample (n = 868) from a prior national survey of providers and found that 164 (19%) reported providing medical abortion in the previous year. Of those obstetrician/gynecologists not providing medical abortion, 171 (24%) said they would offer the method to their patients if the in-person dispensing requirement for mifepristone were removed. This indicates a potential doubling of providers (+ 104%, 95% confidence interval (CI): 97% −112%). There were geographical variations, with the largest potential increases being in the Midwest (+ 189%, 95% CI: 172% −207%) and the South (+ 118%, 95% CI: 103% −134%).

Based on the articles discussed above, removal of the in-person dispensing requirement from the Mifepristone REMS Program (as discussed below in section 3.2.3) could significantly increase the number of providers to a larger group of practitioners. The *Patient Agreement Form* is an important part of standardizing the medication information on the use of mifepristone that prescribers communicate to their patients, and also provides the information in a brief and understandable format for patients. The requirement to counsel the patient, to provide the patient with the *Patient Agreement Form*, and to have the healthcare provider and patient sign the *Patient Agreement Form*, ensures that each provider, including new providers, informs each patient of the appropriate use of mifepristone, risks associated with treatment, and what to do if the patient experiences symptoms that may require emergency care. The single-page *Patient Agreement Form* is in line with other elements of this REMS, in that it supports the requirement that certified prescribers be able to accurately assess a patient, counsel a patient appropriately and recognize and manage potential complications. The form is placed in the patient's medical record to document the patient's acknowledgment of receiving the information from the prescriber and a copy is provided to the patient. We determined, consistent with section 505-1(f)(2) of the FD&C Act, that this does not impose an unreasonable burden on providers or patients, and that the *Patient Agreement Form* remains necessary to assure the safe use of Mifepristone.

After considering potential burden on healthcare providers and patients and considering the available data discussed above, including the potential for increased prescribing of mifepristone if in-patient dispensing is removed from the REMS, we conclude that the *Patient Agreement Form* should remain a safe use condition in the REMS.

3.2.3. Evaluation of the requirement for drug to be dispensed only in certain healthcare settings (ETASU C)

Mifepristone applicants must ensure that mifepristone is available to be dispensed to patients only in clinics, medical offices, and hospitals by or under the supervision of a certified prescriber. This creates what we refer to in this document as an in-person dispensing requirement under the REMS; i.e., the patient must be present in person in the clinic, medical office or hospital when the drug is dispensed. The mifepristone REMS document states that mifepristone may not be distributed to or dispensed through retail pharmacies or settings other than these.

The following information contributed to our analysis of this requirement: Mifepristone REMS Program year-one assessment data, postmarketing safety information and literature review.

REMS Assessment Data

Reporting period for the Mifepristone REMS Program - April 11, 2019 through February 29, 2020

We evaluated information included in the one-year (1st)[j] REMS assessment reports for the Mifepristone REMS Program, which included healthcare provider certification data, program utilization data, compliance data, audit results and patient exposure data.[13] The assessment reports were submitted on April 10, 2020 by the NDA Applicant and April 15, 2020 by the ANDA Applicant and cover a reporting period from April 11, 2019 through February 29, 2020. During this reporting period, the NDA Applicant reported (b) (4) newly certified healthcare providers, and the ANDA Applicant reported (b) (4) newly certified healthcare providers in the Mifepristone REMS Program. The NDA Applicant reported a total of (b) (4) certified healthcare providers (includes new and previously certified) ordered mifepristone during the assessment reporting period, and the ANDA Applicant reported a total of (b) (4) certified healthcare providers ordered mifepristone during the assessment reporting period. The NDA Applicant estimated that a total of (b) (4) patients were exposed to mifepristone during the assessment reporting period. The ANDA Applicant reported an estimated total of (b) (4) patients were exposed to mifepristone during the reporting period.

During the reporting period, a small number of non-compliance events were reported. The authorized distributor for the NDA applicant reported to the NDA Applicant that they experienced deviations with scanning of the product serial numbers which were confirmed during the February 2020 audit. The authorized distributor conducted a root cause analysis and developed a corrective and preventive action (CAPA) on February 12, 2020. The CAPA was

[j] This REMS assessment report was the first to be submitted following the approval of the single, shared system REMS for mifepristone.

validated and deployed with monitoring of the system through April 10, 2020. The corrective action will prevent similar events from occurring in the future.

January 27, 2020 through September 30, 2021

During the timeframe from January 27, 2020 through September 30, 2021, there were periods when the in-person dispensing requirement was not being enforced.

- On July 13, 2020, the United States District Court for the District of Maryland granted a preliminary injunction in the *ACOG* case to temporarily bar enforcement of the in-person dispensing requirement during the COVID-19 PHE.
- On January 12, 2021, the United States Supreme Court issued a stay of the injunction.
- On April 12, 2021, the FDA issued a General Advice Letter informing the applicants of the Agency's intent to exercise enforcement discretion during the COVID-19 public health emergency regarding the in-person dispensing requirement in the Mifepristone REMS Program.[k,l]

To better understand whether there was any impact on safety or noncompliance during the periods when the in-person dispensing requirement was not being enforced, we requested additional information from the Applicants to provide for more comprehensive assessment of the REMS for the time period from January 27, 2020 (the effective date of the COVID-19 PHE) to September 30, 2021. We requested the Applicants provide a summary and analysis of any program deviation or noncompliance events from the REMS requirements and any adverse events that occurred during this time period that had not already been submitted to FDA. As part of an additional request for information for the REMS assessment report, the Applicants were also asked to submit the adverse events to FAERS and to notify FDA that the reports were submitted.

Between January 27, 2020 and September 30, 2021, the NDA Applicant distributed (b) (4) shipments representing (b) (4) tablets. The NDA Applicant reported that there were (b) (4) shipments representing a total of (b) (4) tablets sent to (b) (4) non-certified healthcare providers.[m,n] (b) (4) of these healthcare providers subsequently became certified while (b) (4) did not. Of the (b) (4) healthcare providers who were not subsequently certified, (b) (4) returned a total of (b) (4)

[k] FDA General Advice Letter for NDA 20687, April 12, 2021.
[l] FDA General Advice Letter for ANDA 091178, April 12, 2021.

[m] NDA 020687 September 9, 2021 response to the FDA's September 2, 2021 Information Request.
[n] NDA 020687 October 8, 2021 response to the FDA's June 30, 2021 Information Request.

Mifeprex tablets to the distributor. (b) (4) non-certified healthcare provider dispensed (b) (4) to a patient; no adverse events were reported. The NDA Applicant attributed the non-compliance observed to the authorized distributor's transition to a new platform. The NDA Applicant implemented a corrective and preventative action to address this issue, which we found to be acceptable.

The ANDA Applicant distributed (b) (4) shipments representing (b) (4) tablets of mifepristone from January 27, 2020 to September 30, 2021 and reported no instances of shipments to non-certified healthcare providers during this timeframe.

The NDA and the ANDA applicants reported a total of eight cases reporting adverse events between January 27, 2020 and September 30, 2021. These eight cases were also identified in the FAERS database and are described in the section below.

The number of adverse events reported to FDA during the COVID-19 PHE with mifepristone use for medical termination of pregnancy is small, and the data provide no indication that any program deviation or noncompliance with the Mifepristone REMS Program contributed to these reported adverse events. Further analysis of the adverse events is included below in the section on Pharmacovigilance Data.

Pharmacovigilance Data

The (b) (6) ((b) (6) conducted a search of the FAERS database and the published medical literature to identify U.S. postmarketing adverse events that reportedly occurred from January 27, 2020 through September 30, 2021 with mifepristone use for medical termination of pregnancy.[o,p]

The data for this time period were then further divided into date ranges when the in-person dispensing requirement was being enforced per the REMS (January 27, 2020 - July 12, 2020 & January 13, 2021 - April 12, 2021) versus when the in-person dispensing requirement was not being enforced (July 13, 2020 - January 12, 2021 (in-person dispensing requirement was temporarily enjoined) & April 13, 2021 - September 30, 2021 (in-person dispensing requirement was not being enforced because of the COVID-19 PHE)).

---

[o] (b) (6). Pharmacovigilance Memorandum: Mifepristone and All Adverse Events. NDA 020687 and ANDA 091178. (b) (6) # 2007-525. Finalized April 12, 2021.

[p] (b) (6) Pharmacovigilance Memorandum: Mifepristone and All Adverse Events. NDA 020687 and ANDA 091178. (b) (6) # 2007-525. Finalized December 16, 2021.

A total of eight cases that met the search criteria were identified in FAERS and no additional case reports were identified in the medical literature. Two of the eight cases reported adverse events that occurred when the in-person dispensing requirement in the REMS was being enforced (i.e., January 27, 2020 - July 12, 2020 & January 13, 2021 - April 12, 2021). These two cases reported the occurrence of uterine/vaginal bleeding (case 1) and uterine/vaginal bleeding and sepsis (case 2). Of note, uterine/vaginal bleeding and sepsis are labeled adverse events. Five of the eight cases reported adverse events that occurred when the in-person dispensing requirement was not being enforced (i.e., July 13, 2020 - January 12, 2021 & April 13, 2021 - September 30, 2021). These five cases reported the occurrence of ongoing pregnancy (case 3), drug intoxication and death approximately 5 months after ingestion of mifepristone (case 4), death [cause of death is currently unknown] (case 5), sepsis and death (case 6), and pulmonary embolism (case 7). Although these adverse events occurred during the period when the in-person dispensing requirement was not being enforced, the narratives provided in the FAERS reports for cases 5, 6, and 7 explicitly stated that mifepristone was dispensed in-person. Of note, ongoing pregnancy, and sepsis, including the possibility of fatal septic shock, are labeled adverse events. The remaining case from July 2021 reported the occurrence of oral pain/soreness (case 8) but did not provide sufficient information to determine the exact date of the adverse event. Based upon the U.S. postmarketing data reviewed, no new safety concerns were identified by (b) (6)

In addition to the FAERS data provided above, (b) (6) routinely monitors adverse events reported to FAERS and published in the medical literature for mifepristone for medical termination of pregnancy. (b) (6) has not identified any new safety concerns with the use of mifepristone for medical termination of pregnancy.

To enable additional review of adverse events, the Applicants were requested[q] to provide a summary and analysis of adverse events reported with incomplete medical abortion requiring surgical intervention to complete abortion, blood transfusion following heavy bleeding or hemorrhage, ectopic pregnancies, sepsis, infection without sepsis, hospitalization related to medical abortion, and emergency department (ED)/urgent care encounter related to medical abortion. The Applicant for Mifeprex provided a summary of postmarketing safety information from March 29, 2016, when S-020 was approved, through September 30, 2021, on August 27 and October 8, 2021. During the time period in question, (b) (4) tablets were shipped, and

[q] On August 5, 2021, an IR was sent to the Applicants requesting a summary and analysis of adverse events from March 29, 2016 through June 30, 2021 and from July 1, 2021 through September 30, 2021.

48 adverse events were received. The 48 adverse events included 4 deaths (one of which occurred in 2010 but was reported in 2017), 25 incomplete abortions requiring surgical intervention, 17 blood transfusions following heavy vaginal bleeding, 2 ectopic pregnancies, 7 infections (1 sepsis and 6 infection without sepsis), 13 hospitalizations, and 43 ED or urgent care visits related to medical abortion. For the period between January 27, 2020 and September 30, 2021, a time frame that includes the entire period when the COVID-19 public health emergency (PHE) has been in effect, there were three adverse events reported corresponding to the above cases from FAERS identified by (b) (6) case 1 (uterine/vaginal bleeding), case 2 (uterine/vaginal bleeding and sepsis), and case 4 (drug intoxication and death).

The ANDA Applicant provided a summary of postmarketing safety information from April 11, 2019 (date of ANDA approval) through September 30, 2021. On August 26, 2021, the Applicant provided distribution and adverse event information from April 11, 2019 through June 30, 2021. During this time period, a total of (b) (4) tablets were shipped. There were 7 adverse events including 3 deaths (1 from sepsis, 1 from bilateral pulmonary artery thromboemboli, 1 in a patient who complained of not being able to breathe), 1 ongoing pregnancy treated with uterine aspiration, 2 blood transfusions, 1 sepsis (with death), 1 hospitalization, and 3 ED or urgent care visits related to medical abortion. On October 12, 2021 the Applicant provided information from July 1, 2021 to September 30, 2021; there were no additional adverse events. For the period between January 27, 2020 and September 30, 2021, there were four adverse events reported corresponding to the above cases from FAERS identified by (b) (6) case 3 (ongoing pregnancy), case 5 (death unknown cause), case 6 (sepsis and death), and case 7 (pulmonary embolism).[r]

The postmarketing data from FAERS were analyzed by (b) (6) to determine if there was a difference in adverse events between periods when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced. Based on this review, we conclude that there does not appear to be a difference in adverse events between periods when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced. This suggests that mifepristone may be safely used without an in-person dispensing requirement.

[r] The eighth FAERS case, oral pain/soreness, was not within the scope of the August 5, 2021 IR and was not considered for this review of postmarketing safety information submitted by the Applicants in response to the IRs.

(b) (6) review of the Applicants' IR responses, which included the same cases identified by (b) (6) from FAERS, did not change our conclusion.[s]

Literature Review

Published studies have described alternatives in location and method for dispensing mifepristone by a certified prescriber (or an equivalent healthcare provider in countries other than the US). Some studies have examined replacing in-person dispensing in certain health care settings with dispensing at retail pharmacies (Grossman[2], Wiebe[7], Rocca[6]) and dispensing mifepristone from pharmacies by mail (Grossman[1], Upadhyay[14], Hyland[15]). Other studies have evaluated two modes of dispensing by prescribers: (1) prescribers mailing the medications to women (Gynuity study [Raymond[16], Chong[3], Anger[17]], Kerestes[4], Aiken[5] (2021)) and (2) prescribers using couriered delivery of medications (Reynolds-Wright[18]). Other studies have evaluated dispensing mifepristone by mail by an entity described as "a partner organization" (Aiken[19] (2017), Norton[20], Endler[21]). For ease of review, in the sections below that describe these studies, we have separated relevant references by the methodology used to dispense mifepristone.

Retail pharmacy dispensing

Three studies report medical abortion outcomes for retail pharmacy dispensing of mifepristone after clinical evaluation. Grossman[2] conducted a US-based study in which mifepristone and misoprostol were dispensed from a pharmacy partnered with the clinic where the participant had an evaluation by ultrasound and counseling. Of the 266 participants enrolled, 260 had known abortion outcomes. Complete abortion without additional procedure occurred in 243 participants (93.5% of those with known outcomes). Seventeen participants (6.5% of those with known outcomes) were diagnosed with incomplete abortion and underwent uterine aspiration. The reported proportion of complete abortion is within the range described in the approved mifepristone labeling. However, the finding represents a lower-than-expected efficacy based on the cohort's GA (84% of participants were at ≤ 56 days GA, a cohort for which the labeled success rate is 96.8%). No participants experienced a serious adverse event, were hospitalized, or required transfusion. Three participants had ED visits with treatment (intravenous hydration, pain medication, pelvic infection after uterine aspiration for incomplete abortion). The study's

[s] The reporting period of (b) (6) assessment of the adverse events in FAERS is not identical to the time period for summaries of adverse events in the IRs to the Applicants. Therefore, the numbers of cases and adverse events summarized in (b) (6) assessment may differ from the numbers of cases and adverse events summarized by the Applicants in their responses to IRs (note that each case report may include more than one adverse event).

safety and efficacy outcomes are consistent with labeled frequencies. The majority of participants (65%) were very satisfied with the experience. There were some complaints from participants about not receiving all prescribed medications at the initial pharmacy visit, privacy not being adequately maintained, and perceived negative pharmacist attitude.

Overall, we conclude that this study has limited generalizability because it was conducted in two US states and involved partnered pharmacies, some of which were in the same building as the clinic. Additionally, all participating pharmacies in this study were required to have a pharmacist on duty during clinic hours who had been trained in the study protocol and was willing to dispense mifepristone. The study conditions may not be generalizable to US retail pharmacies; there is insufficient information to assess this. Rocca[6] conducted an observational study evaluating 605 participants at ≤63 days GA who obtained medical abortions in Nepal by comparing the provision of medical abortion service by newly trained nurse midwives in pharmacies to medical abortion provided in government-certified clinics. Participants who presented to pharmacy study sites underwent clinical screening including a pelvic exam by trained nurse midwives at the pharmacy (which was equipped with an examination room) and if eligible for medical abortion, were dispensed mifepristone and misoprostol in the pharmacy at the time of their visit. Participants who presented to public health facilities underwent clinical screening including pelvic examination by abortion providers including trained nurse midwives and if eligible for medical abortion were dispensed mifepristone and misoprostol in the clinic at the time of their visit. The authors reported that, with respect to complete abortion (>97%) and complications (no hospitalizations or transfusions), evaluation and dispensing in pharmacy was non-inferior to in-clinic evaluation and dispensing.

Wiebe,[7] in a retrospective, chart review study conducted in Canada, compared abortion outcomes of 182 women at ≤ 70 days GA who underwent medical abortion with telemedicine consult, and either received medications by courier or picked them up at a local pharmacy, with outcomes of a matched control cohort of 199 women who received the medications at a pharmacy after an in-clinic visit. The groups had similar documented complete medical abortion outcomes (90%, calculated maintaining subjects with unknown outcomes in the denominator; ≥ 95% calculated with known outcomes only). The telemedicine group had one case of hemorrhage (0.5%) and one case of infection requiring antibiotics (0.5%) compared with no cases of hemorrhage or infection requiring antibiotics in the in-clinic cohort. The telemedicine group had more ED visits (3.3% compared to 1.5% in-clinic cohort). Both models of dispensing mifepristone resulted in efficacy and safety outcomes within labeled frequency.

None of the three studies described above allow a determination regarding differences in safety between in-person dispensing by a certified prescriber in a health care setting and dispensing through a retail pharmacy, due to limitations on the generalizability of the studies to the current retail pharmacy environment in the US. The outcome findings from the one US study (Grossman[2]), in which the pharmacies were partnered with prescribers, may not be generalizable to much of the US as they do not reflect typical prescription medication availability with use of retail pharmacy dispensing. Although retail pharmacy dispensing of mifepristone and misoprostol in Canada has been described in the literature, there are important differences in healthcare systems between Canada and the US that render the findings from studies in Canada (Wiebe[7]) not generalizable to the US. In the Wiebe study, timely provision of medication from the retail pharmacy was accomplished by either courier to the woman or faxed prescription to the woman's pharmacy. It is unknown whether conditions that allow timely access to medications for medical abortion would occur in retail pharmacies throughout the US. Canada's federal government has reaffirmed that abortion is an essential health service[t] which may have implications affecting access to medical abortion from retail pharmacies in Canada. The Rocca[6] study evaluated medical abortion provided in Nepali pharmacies and essentially moved the abortion provider and clinical examination into the pharmacy, a scenario that is not, at this time, applicable to the US retail setting.

Mail order pharmacy

Grossman[1] published an interim analysis of an ongoing prospective cohort study evaluating medical abortion with mifepristone and misoprostol dispensed by mail-order pharmacy after in-person clinical assessment. All participants were evaluated for eligibility during a clinic visit with GA up to 63 days confirmed with either an ultrasound or examination; instead of receiving medication at the clinic visit, participants received medications from a mail-order pharmacy. A total of 240 participants have been enrolled; three participants did not take either medication. A total of 227 (94.6%) provided some outcome information, of whom 224 provided abortion outcome information. Complete abortion without additional procedures occurred in 217 participants (96.9% of those with known outcomes). Two (0.9%) participants experienced serious adverse events (SAE); one received a blood transfusion, and one was hospitalized overnight. Nine (4%) participants attended 10 ED visits. In this interim analysis, the outcomes are consistent with labeled frequencies. With respect to the time interval between a

[t] As noted in Mark[23] and Martin[24], most provincial and federal health insurance programs in Canada cover medical abortion, and covered services are free at the point of care.

participant's clinic visit and receipt of medications, of the 224 participants with known abortion outcomes, 184 (82.1%) received medication within 3 days. However, 17% received between 4-7 days and one participant waited over 7 days for receipt. Seven of 216 (3.2%) participants who completed the day-3 survey reported compromised confidentiality (e.g., someone found their medication, privacy concerns).

Upadhyay[14] reports findings from a retrospective cohort study of 141 women undergoing medical abortion in the US without a consultation or visit. Eligibility was assessed based on a participant-completed online form collecting pregnancy and medical history. Participants who were considered eligible received medication delivered by a mail-order pharmacy. Three interactions via text, messaging or telephone occurred to confirm medication administration, assessment of expulsion and pregnancy symptoms, and results of a 4-week home pregnancy test. Abortion outcome was determined by either the day 3 assessment or the 4-week pregnancy test. The investigators reported a complete abortion rate without additional procedures of 95% (105 participants out of 110 for whom outcomes were known) and stated that no participants had any major adverse events. The proportion of abortion outcomes assessed at 3 days versus 4 weeks is not reported. Regardless, determining outcomes at 3 days is insufficient to determine outcome rates or safety findings because a 3-day follow-up period is too short. Additionally, a substantial number of participants (31) provided no outcomes information. Among the 141 participants enrolled, 128 had any follow-up contact with the study staff, and 110 provided outcomes information. Excluding outcomes of 22% of the cohort is a limitation of this study. This study used a model with numerous deviations from standard provision of medical abortion in the US, such as no synchronous interaction with the prescriber during informed consent or prior to prescribing medication, no confirmation of self-reported medical, surgical, and menstrual history. Further, follow-up information based on a 3-day period is insufficient to determine outcome rates or safety findings. These deviations, limited follow-up information, and small sample size limit the usefulness of this study.

Hyland[15] describes findings from a cohort study in Australia evaluating medical abortion outcomes utilizing telemedicine and a central mail order pharmacy. All participants obtained screening tests including ultrasound confirmation of GA. A total of 1010 participants completed the screening process and were provided mifepristone and misoprostol. Abortion outcomes were determined for 754 (75%) of the 1010. Outcomes for the remaining 256 participants (25%) were not included because 31 provided no relevant information after shipment, 14 reported not taking misoprostol, and 211 did not have "full follow up" (i.e., known outcome of either complete medical abortion, uterine evacuation, or ongoing pregnancy with plan to continue).

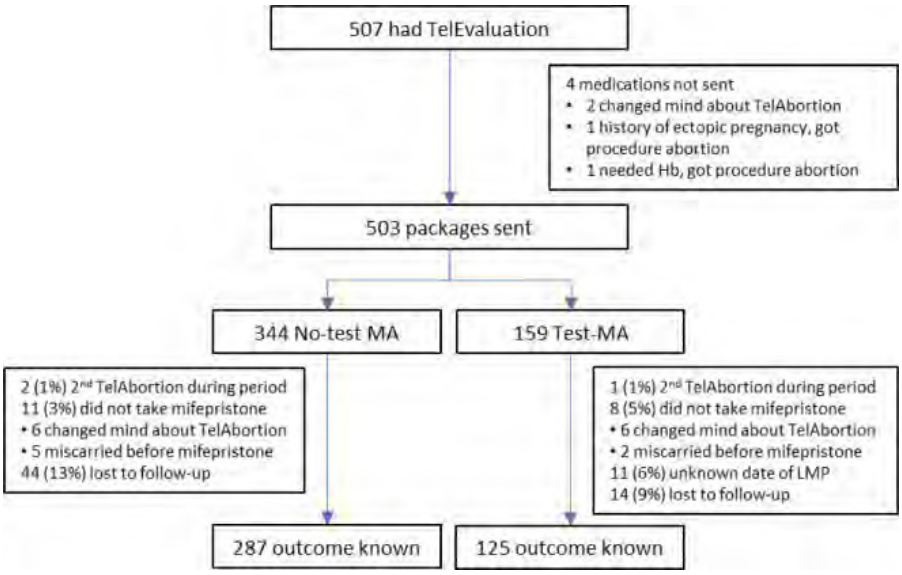
Complete abortions without additional procedures occurred in 727 participants (96% of those with definitively documented outcomes) and is consistent with labeled efficacy. Of the 754 participants included in the analysis 717 (95%) had no face-to-face clinical encounters after medications were mailed while 21 (3%) were admitted to the hospital and 16 (2%) had an outpatient encounter. One participant who was hospitalized and underwent a surgical uterine evacuation received a transfusion. Not included in the findings are 7 hospitalizations occurring in 7 participants who did not have "full follow up". The authors do not report any other adverse events and conclude use of the telemedicine medical abortion service is safe. The reasons for hospitalization are not discussed by the authors; therefore, it is unknown why the patients were hospitalized. Although the reported number of hospitalizations (3%) is higher than the less than 1% in the FDA-approved mifepristone labeling, conclusions regarding the safety findings in this study cannot be made in the absence of information about the reasons for hospitalization. Other limitations of this study include incomplete information about outcomes with face-to-face encounters, and not reporting outcomes of 25% of the enrolled cohort.

Overall, the three studies evaluating mail order pharmacy dispensing suggest that the efficacy of medical abortion is maintained with mail order pharmacy dispensing. In the Grossman[1] study, the interim analysis, although small, does not raise serious safety concerns. We note that 18% of participants did not receive medications within 3 days; the potential for delay in receiving medication by mail could limit the GA eligible for medical abortion through mail order pharmacy dispensing, because women at GA closer to 70 days might not receive medication in time. A small proportion (3%) of participants raised concerns regarding the issues of confidentiality and privacy. Safety findings from the Hyland[15] study are difficult to interpret. Although only one transfusion is reported, and the authors state the findings demonstrate safety, the higher hospitalization rates, and lack of information on the reasons for hospitalization do not allow any conclusions about safety findings. Lastly, the Upadhyay[14] study had no reported adverse events, but the findings are less useful because of the limited follow-up, and because medical abortions were provided using a model with numerous deviations from standard provision of medical abortion in the US.

Clinic dispensing by mail

A total of five studies evaluated clinic dispensing by mail.[3,4,5,16,17] Gynuity Health Projects conducted a prospective cohort study (the "TelAbortion" study) evaluating use of telemedicine for remote visits and mifepristone being dispensed from clinics via overnight or regular tracked mail. Three publications reviewed have reported outcomes for the Gynuity population

exclusively: Raymond[16] from May 2016 to December 2018, Chong[3] from May 2016 to September 2020 and Anger[17] from March 2020 to September 2020. Due to the pandemic, the Gynuity study deviated from the protocol requirement of confirmation of GA by examination or ultrasound for many participants treated from March 2020 onward (although none of the three publications reported on the single element of dispensing mifepristone from the healthcare setting by mail). A fourth study, Kerestes,[4] reports outcomes of medical abortion at the University of Hawai'i from April 2020 to November 2020: seventy-five (of whom 71 were enrolled in the Gynuity study) of the 334 participants in Kerestes were dispensed mifepristone by mail after a telemedicine consult. The section below discusses these four studies from the US as well as a large UK study by Aiken[5] (2021).



Raymond [16] (2019) reported outcomes from the Gynuity study prior to the pandemic. In the TelAbortion study, participants were not required to have an in-person clinic visit; rather, they obtained screening tests at laboratories and radiology offices and then communicated with the abortion provider by videoconference. If the participant was eligible for treatment, the provider dispensed the medications by mail. Of 433 women screened, 165 (38%) either declined to schedule the videoconference or did not keep the videoconference appointment. Among the 268 participants evaluated via videoconference, medication packages were sent to 248. Abortion outcomes were determined for 190 (77%) of the 248; outcomes for 58 (23%) participants were unknown. Complete abortion without additional procedures occurred in 177 participants (93% of those with known outcomes). The investigators obtained follow-up information from 217 participants after package shipment; there were two hospitalizations (one received a transfusion for severe anemia despite having had a complete abortion), and 16 other participants (7%) had clinical encounters in ED and urgent care centers. The reported outcomes in Raymond[16] (2019) are similar to outcomes described in approved labeling except the combined ED/urgent care center encounters (7%) exceeded the ED visits in approved labeling (2.9-4.6%). The authors note that half of the ED/urgent care visits did not entail any medical treatment and opine that the increased number of visits may have been due to the study participants living farther from the abortion providers.[16] All participants received medications within 8 days.

Chong[3] updated the findings from the Gynuity study described in Raymond[16] and reported on 1157 medical abortion outcomes, of which approximately 50% occurred during the period of the COVID-19 PHE. Although a screening ultrasound was required per the protocol, sites determined in 52% (346/669) of abortions that occurred during the period of the COVID-19 PHE that, in order to avoid potential exposure to COVID-19 at a health care facility, those

participants were not required to obtain a screening ultrasound. Use of urine pregnancy test to confirm abortion completion also increased from 67% (144/214) in the 6 months prior to the pandemic to 90% (602/669) in the 6 months during the pandemic. Of the 1390 participants to whom medicine packages (containing both mifepristone and misoprostol) were mailed, 1157 (83.2%) had known abortion outcomes. Complete abortion without a procedure occurred in 1103 participants (95% of the those with a known outcome). Ten women experienced an SAE (5 transfusions (0.4%) and 7 hospitalizations (0.7%)) and 70 (6%) participants had unplanned clinical encounters in ED/urgent care. Surgical interventions were required in 47 participants (4.1% of 1390) to complete abortion. The reported outcomes in this study are similar to outcomes described in approved labeling, except that the combined ED/urgent care center encounters (6%) exceeded the ED visits in approved labeling (2.9-4.6%).

Anger[17] compared outcomes among participants enrolled in the Gynuity study who did versus did not have confirmation of GA/intrauterine location with an examination or ultrasound from 10 jurisdictions across the US. These participants were screened for enrollment from March 25 through September 15, 2020. All participants had a telemedicine consultation and received mifepristone and misoprostol by mail from the healthcare facility. Determination of which participants did not require confirmation of GA by examination or ultrasound to be eligible depended on the study clinician's assessment of eligibility for "no-test medication abortion"[u] based on a sample protocol published by Raymond[22] (2020). There were two key differences between the two groups. Participants for whom the study clinician determined a pre-abortion ultrasound was required were more likely than the participants who had no ultrasound or examination to live further than 150 miles from the clinic (51.2% vs. 31.7%) and were more likely to have a GA above 63 days (12.0% vs. 1.7%). The study sites shipped 503 medication packages during the analysis period; 344 packages went to the "no test" group while 159 went to the "test" medical abortion cohort (see figure below). However, because the two cohorts were not randomized in this study, they had different baseline characteristics. Consequently, findings based on the comparisons between the two cohorts should be interpreted carefully.

[u] "No-test medication abortion" refers to medical abortion provided without a pretreatment ultrasound, pelvic examination, or laboratory tests when, in the judgment of the provider, doing so is medically appropriate (appropriateness based on history and symptoms); "no-test medication abortion" does include post-abortion follow up. A sample protocol is described by Raymond et al.[22]

Source: Figure 1 in this publication. MA= medical abortion.

The investigators' analyses excluded 91 (18% of 503; 57 in the no-test group and 34 in the test group) participants because they did not provide a date of the last menstrual period (LMP), did not take mifepristone, or did not have a recorded abortion outcome. Overall, 410 participants (81.5% of 503) provided outcomes data. There were no reported ectopic pregnancies in either group. The number of ED/urgent care visits and the proportion of unplanned clinical encounters that led to medical treatment were not reported. In the no-test group, complete medical abortion was confirmed in 271 participants who took medications (94% among those with known outcome). In the no-test cohort, two participants were "hospitalized and/or blood transfusion," and 36 (12.5%) had an unplanned clinical encounter (participant sought in-person medical care related to abortion and the visit was not planned prior to abortion).

In the test medical abortion group, complete abortion was confirmed in 123 participants (of 125 with known outcomes); the completion rate was 98% among those with known outcomes. In the test medical abortion group, one participant was "hospitalized and/or blood transfusion," and 10 (8.0%) had an unplanned clinical encounter. The authors concluded that, compared to participants who had an ultrasound prior to medical abortion, those without an examination prior to medical abortion were more likely to require procedural interventions and had more unplanned clinical encounters.

Kerestes[4] was the only publication that linked outcomes of medical abortion with different delivery models. Participants included in the report had GA up to 77 days and received

medications in Hawaii between April 2020 and January 2020. A total of 334 medication packages (to 330 unique participants) were dispensed containing mifepristone and misoprostol; three different delivery models were used concurrently: 110 (32.9%) had traditional in-person visits, 149 (44.6%) had telemedicine consultation with in-person pick-up of medications, and 75 (22.5%) were sent medications by mail (71 of these were enrolled through Gynuity's TelAbortion study). Seven participants of the 330 participants who received 334 medication packages reported that they did not take them and were excluded from analysis of the outcomes. Among participants with follow-up data, the rates of successful medical abortion without surgery were 93.6%, 96.8%, and 97.1% in the in-clinic group, telemedicine + in-person pickup group, and telemedicine + mail group, respectively; these were consistent with outcomes in approved labeling. Blood transfusion was given to two participants (both in the telemedicine + in-person pickup group). Eleven participants went to an ED. Although ED visits occurred the most frequently in the telemedicine + mail group (four participants or 5.8%) and the least in the in-person group (two participants or 2.1%), the study reported no increases in other serious adverse events.

Taken together, the three Gynuity study reports[3,16,17] and Kerestes[4] support dispensing mifepristone and misoprostol by mail after a telemedicine visit. Efficacy was maintained in all four studies. All of the studies reported SAEs frequencies comparable to labeled rates, except two of the Gynuity study reports (Raymond[16], Chong[3]) and Kerestes[4] report a higher frequency of ED/urgent care visits than the labeled frequency of ED visits. We do not know whether the reporting of combined ED and urgent care visits represents an increased rate of ED visits compared to the labeled rate of ED visits (2.9-4.6%). Other labeled SAEs (e.g., transfusion) occur infrequently (< 1%).

Aiken[5] (2021) reports outcomes of medical abortion up to 70 days GA in the UK before and during the pandemic in a retrospective cohort study. In the UK, prior to the COVID-19 pandemic, all patients attended an in-clinic visit where they received an ultrasound, were administered mifepristone in the clinic, and given misoprostol in-clinic for use at home (traditional model). During the pandemic, medical abortion consultations were performed remotely by telephone or video. Based on the consultation and questionnaire (including date of last menstrual period; menstrual, contraceptive and medical history; symptoms; risk for ectopic pregnancy), an assessment of eligibility for treatment via telemedicine was made. If eligible, medications were delivered to participants via mail or were made available for collection from the clinic for use at home. If the participant was assessed to be ineligible for treatment via

telemedicine, an in-person assessment with ultrasound was performed and medications were provided from the clinic for home use (hybrid model).

The study compared the two cohorts: 22,158 obtained medical abortion before the pandemic and had in-person visits and dispensing (traditional model) and 29,984 obtained medical abortion during the pandemic with either in-person visit and in-person dispensing, or a telemedicine visit and dispensing by mail or picked up from the clinic (hybrid model). Outcomes were obtained from electronic records and incident databases. Outcomes of all hospitalizations related to abortion, ED visits, infection without sepsis, and hemorrhage without transfusion were not reported. The investigators' analysis for non-inferiority determined the efficacy and safety were comparable between both cohorts. Complete abortion occurred in > 98% in both cohorts. Hemorrhage requiring transfusion was reported in 0.04% and 0.02% of the traditional and hybrid cohorts, respectively; this is lower than the labeled 0.5% transfusion rate. There were no severe infections requiring hospitalization, major surgery or deaths reported.

A secondary analysis of the hybrid cohort was reported. Within the 29,984-person hybrid model cohort, 11,549 (39%) abortions were conducted in-person (in-person assessment with ultrasound was performed and medications provided from the clinic for home use) and 18,435 (61%) abortions were provided by telemedicine visit, without tests or confirmation of GA/intrauterine position by ultrasound, and medications either mailed or picked up from the clinic. Outcomes stratified by type of mifepristone dispensing were not reported. The rate of complete abortion was slightly higher in the telemedicine group (99.2%) than that in the in-person group (98.1%). There were no significant differences in the rates of reported SAEs. Adjustments for clinical and demographic characteristics were made because the two groups differed in baseline characteristics, including a higher proportion of pregnancies with GA over 6 weeks in the in-person group (68.2% compared with 55.1%). The authors conclude a hybrid model for medical abortion that includes no-test medical abortion[u] (no ultrasound, no pelvic exam, no pregnancy test) is effective and safe.

We conclude that although the Aiken[5] (2021) study has a large sample size and includes 85% of all medical abortions performed in England and Wales during the study period, the study has limitations. The authors acknowledge the main limitation of their study was that analysis was based on deidentified information in the NHS database and the investigators were unable to verify the outcomes extracted. Other limitations included that their search only captured

outcomes in electronic records and incident databases that met the authors' defined threshold for SAE reporting, and that the labeled abortion outcomes considered serious, such as hospitalizations related to abortion, infection without sepsis, hemorrhage without transfusion, or ED/urgent care visits, were not all included in the authors' definition of serious adverse event.

Data from the mail order dispensing studies with telemedicine visits from Gynuity (Raymond, Chong and Anger),[3,16,17] Kerestes[4], and Aiken[5] (2021) support that efficacy of medical abortion was maintained. The Aiken[5] study appears to be of sufficient sample size to determine whether safety outcomes with mail dispensing differ from in-person dispensing; however, the study's design did not capture all serious safety outcomes, thus limiting the certainty of the findings. Study reports of Raymond[16] Chong[3], and Kerestes[4] all suggest there may be an increase in ED/urgent care visits with telemedicine visits and dispensing by mail without increases in other adverse events. Anger's[17] comparative analysis suggests a pre-abortion examination may decrease the occurrence of procedural intervention and decrease the number of unplanned visits for postabortion care. Overall, despite the limitations noted, these studies support that dispensing by mail is safe and effective. Although the literature suggests there may be more frequent ED/urgent care visits related to the use of mifepristone when dispensed by mail from the clinic, there are no apparent increases in other SAEs related to mifepristone use. One reason for the increase in frequent ED/urgent care visits in the Raymond[16] publication, according to its authors, may have been that a substantial proportion of participants lived significant distances from their providers and increased distances have been associated with higher use of ED following treatment. Raymond[16] reported that half of the participants who had an ED/urgent care visit did not require medical treatment.

Clinic dispensing by courier

Reynolds-Wright[18] reported findings from a prospective cohort study of 663 women at less than 12 weeks' GA in Scotland undergoing medical abortion at home with use of telemedicine during the pandemic (from April 1 to July 9, 2020). The majority of medical abortions (78.7%) used telemedicine visits, eliminated pre-abortion ultrasound, and provided mifepristone for pick up at the service or by couriered delivery to woman's home. The number of couriered deliveries was not reported; thus, this study does not provide abortion outcomes separately for couriered delivery of mifepristone and misoprostol. With access to NHS regional hospital databases, the investigators were able to verify pregnancy outcomes and complications. Of the 663 participants, 642 (98.2%) were under 10 weeks GA, 21 (1.8%) were between 10 and 12 weeks

GA, and one participant was never pregnant. A total of 650 participants had complete abortion without requiring surgical intervention (98%), 5 (0.8%) an ongoing pregnancy and 4 (0.6%) an incomplete abortion. The outcomes from this study in Scotland are consistent with labeled mifepristone outcomes. The study shares the same limitations as the Aiken[5] (2021) study.

Partner organization dispensing by mail

Women on Web (WoW), an internet group, connects patients and providers outside of the US and provides medical abortion globally, dispensing mifepristone through "a partner organization" by mail.[v] Medical abortion eligibility is determined using an online questionnaire with asynchronous physician review. If eligible, medications are mailed to the women. WoW provides help and support by email or instant messaging.

Aiken[19] (2017) conducted a population-based study analyzing findings from 1,636 women in the Republic of Ireland and Northern Ireland who were sent medications between 2010 and 2012. Receipt of medications was confirmed for 1,181 women, among whom 1,023 confirmed use of mifepristone and misoprostol; outcome information was available for 1,000 (61% of women sent medications). Of the 1,000 women, the majority (781, 78%) were less than 7 weeks GA and 219 (22%) were at 7-9 weeks. Complete abortion without surgical intervention occurred in 947 (94.7% of 1,000 with known outcome); 7 (0.7%) women received a blood transfusion, 26 (2.6%) received antibiotics (route of administration undetermined) and 87 (8.7%) sought medical care at a hospital or clinic for symptoms related to medical abortion. Hospitalizations related to abortion were not reported. The reported proportion of complete abortion is within the range labeled for medical abortion up to 70 days (92.7-98.1%). However, the finding of 94.7% complete abortion represents a lower-than-expected efficacy based on the cohort's GA (almost 80% less than 7 weeks, labeled success for medical abortion ≤ 49 days is 98.1%). This study has limitations, including outcomes based on self-report without validation of completed abortion by examination or laboratory testing, and no known outcomes for 39% of study cohort. Additionally, the authors noted medical abortion was provided in a legally-restrictive setting, where the law provided a maximum penalty of life imprisonment for the woman undergoing the abortion, which may affect participants' self-reporting.

[v] In March 2019, FDA sent a WL to Aidaccess.org, a group affiliated with WoW. Aidaccess.org received this WL because it was introducing misbranded and unapproved new drugs into the U.S. In the context of this REMS review, studies involving WoW are included solely for purposes of evaluating of data regarding the methods of dispensing mifepristone.

Endler[21] and Norten[20] have reported outcomes from WoW cohorts but do not provide relevant information on mifepristone dispensing by mail, because neither provide meaningful outcomes data for consideration. Endler[21] compared the outcomes of self-reported heavy bleeding and clinical visits occurring during the "first or second day of abortion" that occurred in women undergoing medical abortion at 9 weeks GA or less, with outcomes from women at more than 9 weeks GA. Outcome data from day 1 or 2 is of limited usefulness. Norten[20] describes findings from a survey of women who were sent medical abortion medication through WoW and provided self-reported outcomes. Results were based on surveys returned from only 37% of participants, a return rate that is too low for the study to be considered valid.

WoW uses a model with numerous deviations from the standard provision of medical abortion in the US. For example, this model has no synchronous interaction with the prescriber during informed consent or prior to prescribing medication and no confirmation of self-reported medical, surgical, and menstrual history or confirmed pregnancy testing. Further, although Aiken[19] (2017) is a large cohort study, the outcomes are self-reported with no verification of complete abortion by laboratory or clinical evaluation and 39% of outcomes are unaccounted for. These limitations in the Aiken study result in the data being insufficient to determine the safety of dispensing mifepristone by mail through a partner organization.

4. Discussion

After review of the published literature, safety information collected during the COVID-19 PHE, postmarketing data, information from the first Mifepristone REMS Program assessment report, responses to information requests to the Applicants, and information provided by advocacy groups, individuals and the plaintiffs in the *Chelius v. Becerra* litigation, we conclude that the REMS can be modified to reduce burden without compromising patient safety.

Prescriber Certification

None of the publications we reviewed would support a conclusion that a healthcare provider who prescribes mifepristone does not need to meet the qualifications included in the Mifepristone REMS Program as described above in section 3.2.1. Absent these provider qualifications, serious complications associated with medical abortion, including missed ectopic pregnancy and heavy bleeding from incomplete abortion, would not be detected or appropriately managed.

We conclude that prescriber certification (ETASU A) should be maintained. The current process requires the prescriber to agree to the requirements of the Mifepristone REMS Program and to attest that they meet the qualifications described in section 3.2.1 above. The REMS has been structured to minimize burden to prescribers by requiring only a one-time certification by the prescriber for each Applicant. We have determined that healthcare provider certification continues to be necessary to ensure the benefits outweigh the risks, especially considering that, if the in-person dispensing requirement is removed from the Mifepristone REMS Program, the number of new providers may increase (see discussion in section 3.2.2 above).

Drug to be dispensed with evidence or other documentation of safe use conditions

The requirement to counsel the patient and provide them with the *Patient Agreement Form* ensures that each patient is informed of the appropriate use of mifepristone, the risks associated with treatment, and what to do if they experience symptoms that may require emergency care.

In 2016, we initially recommended eliminating the *Patient Agreement Form* (see section 3.2.2), though the form was ultimately maintained as part of the REMS. As discussed above, our current literature review has indicated that there is no basis to remove the *Patient Agreement Form* from the REMS. In addition, surveys we reviewed suggest that if the in-person dispensing requirement for mifepristone is removed, there could be a potential doubling of medical abortion providers. This potential doubling of medical abortion providers supports the continued need to ensure that patients are consistently provided patient education under the Mifepristone REMS Program regarding the use and risks of mifepristone. The *Patient Agreement Form* is an important part of standardizing the medication information that prescribers communicate to their patients, including new prescribers, and also provides the information in a brief and understandable format to patients. We determined, in accordance with section 505-1(f)(2) of the FD&C Act, that this does not impose an unreasonable burden on providers or patients.[w]

Given the likelihood of a potential increase in new prescribers if the in-person dispensing requirement is removed from the Mifepristone REMS Program, we conclude that maintaining the *Patient Agreement Form* remains necessary to assure safe use at this time.

[w] *The Patient Agreement Form* can be signed in person or through other means.

Drug to be dispensed only in certain healthcare settings

As discussed above in section 3.2.3, our evaluation of information submitted by the applicants in the one-year (1st) REMS assessment report for the Mifepristone REMS Program and in response to follow-up requests from the Agency indicates that the number of adverse events reported to FDA during the COVID-19 PHE with mifepristone use is small, and the data provide no indication that any program deviation or noncompliance with the Mifepristone REMS Program contributed to these adverse events. We further conclude, based our review of the postmarketing safety data from FAERS during the COVID-19 PHE and information submitted by the applicants for the timeframe of January 27, 2020 through September 30, 2021, that there does not appear to be a difference in adverse events between periods during the COVID-19 PHE when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced; nor have we identified any new safety concerns with the use of mifepristone for medical termination of early pregnancy.

Alternatives to in-person dispensing of mifepristone have been investigated in several studies and countries. The literature review identified 15 publications[x] that assessed safety outcomes from various medication delivery models (US, UK, Canada, Ireland, Australia, Nepal), including dispensing by retail and mail order pharmacies, prescribers mailing medications or using couriered service to deliver medications, and dispensing by "partner organizations". The ability to generalize the results of these studies to the US population is hampered by differences in pre-abortion care (e.g., telemedicine versus in-person, testing), and the usefulness of the studies is limited in some instances by small sample sizes and lack of follow-up information on outcomes with regard to both safety and efficacy.

In addition, there are factors which complicate the analysis of the dispensing element alone. Some of these factors are: (1) only a few studies have evaluated alternatives for in-person dispensing of mifepristone in isolation; for example, most studies on mail dispensing of mifepristone also include telemedicine consultation, and (2) because most SAEs with medical abortion are infrequent, though they can be life threatening, further evaluation of changes in dispensing would require studies with larger numbers of participants. We did not find any large clinical studies that were designed to collect safety outcomes in healthcare systems similar to the US.

[x] The 15 publications correspond to endnote numbers: 1-7, 14-21.

Based on the literature identified by our review, dispensing mifepristone by mail from the clinic or from a mail order pharmacy does not appear to jeopardize the efficacy of medical abortion. The studies we reviewed are not adequate on their own to establish the safety of the model of dispensing mifepristone by mail, although the safety and efficacy outcomes reported in these studies remain within the ranges described in mifepristone labeling except for increased numbers of ED/urgent care visits and hospitalizations.

Four publications (Raymond[16], Chong[3], Anger[17] and Kerestes[4]), describe a relevant US cohort where dispensing mifepristone from the clinic by mail was paired with telemedicine visits. These studies showed that efficacy was maintained and there was no increased frequency of SAEs except for higher ED/urgent care visits. The increased ED/urgent care visits were not associated with increases of other SAEs, and in the view of one study's authors (Raymond[16]), may be associated with participants being located significant distances from their providers. The Aiken[5] (2021) study of a large UK cohort where the clinics mailed mifepristone report small (lower than labeled) occurrences of transfusion and no significant infections requiring hospitalization. In Grossman[1] and Hyland[15], where the pharmacies mailed mifepristone after prescribers confirmed GA, efficacy is maintained. Grossman's[1] interim analysis found no increases in SAEs. Hyland[15] reported higher numbers of hospitalizations but did not report increases of other SAEs. Overall, while the studies assessing mifepristone dispensing by mail suggest more frequent encounters with healthcare providers, they generally support a conclusion that dispensing by mail is safe. Despite the limitations of the studies we reviewed, we conclude that overall, the outcomes of these studies are not inconsistent with our conclusion that, based on the 1st year REMS assessment report and postmarketing safety data, mifepristone will remain safe, and efficacy will be maintained if the in-person dispensing requirement is removed from the Mifepristone REMS Program.

Based on the REMS assessment data, FAERS data from the time period when the in-person dispensing requirement was not being enforced, our review of the literature, and information provided by advocacy groups, individuals, the Applicants, and the plaintiffs in the *Chelius v. Becerra* litigation, we conclude that mifepristone will remain safe and effective for medical abortion if the in-person dispensing requirement is removed, provided all the other requirements of the REMS are met, and pharmacy certification is added as described below.

Removing the in-person dispensing requirement will render the REMS less burdensome to healthcare providers and patients and provided all other requirements of the REMS are met, including the additional requirement for pharmacy certification, the REMS will continue to

ensure that the benefits of mifepristone for medical abortion outweigh the risks. Therefore, to reduce the burden imposed by the REMS, the Mifepristone REMS Program should be modified to remove the in-person dispensing requirement, which would allow, for example, dispensing of mifepristone by mail via certified prescribers or pharmacies, in addition to in-person dispensing in clinics, medical offices and hospitals as currently outlined in ETASU C.

New requirement to be added for pharmacy certification

The current distribution model requires the certified prescriber to dispense mifepristone directly to the patient in a clinic, medical office, or hospital. During the periods when the in-person dispensing requirement was not being enforced, both applicants used mail order pharmacies to receive and hold mifepristone on behalf of the certified healthcare providers who had purchased the product.[j,y,z] Pursuant to a prescription for mifepristone, the mail order pharmacy would ship the product to a named patient.

The Mifepristone REMS Program continues to require that mifepristone be prescribed only by certified prescribers. With the removal of the in-person dispensing requirement, however, the drug is no longer required to be dispensed only in a clinic, medical office or hospital. Under the REMS as modified, mifepristone can be dispensed through a pharmacy, provided the product is prescribed by a certified prescriber and all other requirements of the REMS are met. Given this modification to the dispensing requirements in the REMS, it is necessary to add a requirement for certification of pharmacies under ETASU B. Adding the pharmacy certification requirement incorporates pharmacies into the REMS, ensures that pharmacies are aware of and agree to follow applicable REMS requirements, and ensures that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers. Without pharmacy certification, a pharmacy might dispense product that was not prescribed by a certified prescriber. Adding pharmacy certification ensures that ETASU A is met prior to dispensing the product to a patient; certified prescribers, in turn, have agreed to meet all the conditions of the REMS, including ensuring that the *Patient Agreement Form* (ETASU D) is completed. In addition, wholesalers and distributors can only ship to certified pharmacies. Based on our review of the safety data and our consideration of the distribution model implemented by the Applicants during the periods

---

y ANDA 091178: September 23, 2021 response to the September 15, 2021 information request; October 11 and 16, 2021 responses to the June 30, 2021 and July 15, 2021 information requests; October 26, 2021 response to the October 22, 2021 information request; October 29, 2021 response to the October 27 information request.
z NDA 020687: September 20, 2021 response to the September 15, 2021 information request; October 26, 2021 response to the October 22 information request.

when the in-person dispensing requirement was not being enforced, as well as REMS assessment data and published literature, we conclude that provided all other requirements of the REMS are met, the REMS program, with the removal of the in-person dispensing requirement and the addition of a requirement for pharmacy certification, will continue to ensure the benefits of mifepristone for medical abortion outweigh the risks while minimizing the burden imposed by the REMS on healthcare providers and patients. As modified, the REMS would allow, for example, dispensing by mail order or specialty pharmacies, similar to the distribution model used by applicants during the periods when the in-person dispensing requirement was not being enforced.[aa]

The above recommendations were discussed with the (b) (6) ((b) (6) and senior leadership from CDER on November 2, 2021. The (b) (6) (b) (4) along with senior CDER leadership, concurred with removing the in-person dispensing requirement provided that all of the remaining REMS requirements are met, including but not limited to prescriber certification where prescribers need to attest to having certain qualifications, and maintaining the *Patient Agreement Form*. The (b) (6) (b) (4) and senior leadership from CDER were also in favor of adding pharmacy certification to assure the safe use of mifepristone.

5. Conclusions and Recommendations

Based on the results of REMS assessments; our review of safety data collected during the PHE as well as data from FAERS; our literature search; and information provided by advocacy groups, individuals, the Applicants, and the plaintiffs in the *Chelius v. Becerra* litigation, (b) (6) and (b) (6) have concluded that a REMS modification is necessary and should include the following changes:

- Removing the requirement under ETASU C that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals.
- Adding a requirement under ETASU B that pharmacies that dispense the drug be specially certified.

[aa] Our current conclusion that the REMS would allow dispensing by mail order or specialty pharmacies is based on data received from Applicants relating to the periods when the in-person dispensing requirement was not enforced and mail-order pharmacies were used to dispense the product, as well as our analysis of postmarketing safety data and available literature. At this time we do not have data (from the Applicants or from other sources) to assess the certification of retail pharmacies under the REMS. We have not yet determined the details of pharmacy certification requirements, including whether any limitations on the types of pharmacies that may dispense the product are necessary.

(b) (6) and (b) (6) recommend the Applicants be issued a REMS Modification Notification Letter that requests submission within 120 days from the date of the letter.

Questions and Answers on Mifepristone for Medical Termination of Pregnancy Through Ten Weeks Gestation

On this page:

- General Information
- The Mifepristone REMS Program
- Additional Information
- The January 2023 REMS Modification
- Litigation and Other Legal Issues

General Information

1. **What is mifepristone and how does it work?**

   Mifepristone is a drug that blocks a hormone called progesterone that is needed for a pregnancy to continue. Mifepristone, when used together with another medicine called misoprostol, is used to end an intrauterine pregnancy through ten weeks gestation (70 days or less since the first day of the last menstrual period). The approved mifepristone dosing regimen is:

   - On day one: 200 mg of mifepristone taken by mouth
   - 24 to 48 hours after taking mifepristone: 800 mcg of misoprostol taken buccally (in the cheek pouch), at a location appropriate for the patient
   - About seven to fourteen days after taking mifepristone: follow-up with the health care provider

2. **When did the FDA approve mifepristone for medical termination of pregnancy?**

   The FDA first approved Mifeprex (mifepristone) in September 2000 for medical termination of pregnancy through seven weeks gestation, and this was extended to ten weeks gestation in 2016. FDA approved a generic version of Mifeprex, Mifepristone Tablets, 200 mg, in April 2019. The agency's approval of this generic reflects the FDA's determination that Mifepristone Tablets, 200 mg, is therapeutically equivalent to Mifeprex and can be safely

GBP-PET01409

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 339 of 352 PageID #: 4357

substituted for Mifeprex. Like Mifeprex, the approved generic product is indicated for the medical termination of an intrauterine pregnancy through 70 days gestation. The labeling for the approved generic version of Mifeprex is consistent with the labeling for Mifeprex.

3. **Who should not take mifepristone, in a regimen with misoprostol, for medical termination of pregnancy?**

   An individual should not take mifepristone, in a regimen with misoprostol, for medical termination of pregnancy if it has been more than 70 days since the first day of their last menstrual period, or if they:

   - have an ectopic pregnancy (a pregnancy outside of the uterus)
   - have problems with the adrenal glands (the glands near the kidneys)
   - are currently being treated with long-term corticosteroid therapy
   - have had an allergic reaction to mifepristone, misoprostol or similar drugs
   - have bleeding problems or are taking anticoagulant (blood thinning) drug products
   - have inherited porphyria (a rare disorder that can affect the liver and other organs)
   - have an intrauterine device (IUD) in place (it must be removed before taking mifepristone)

4. **Is it safe to use mifepristone?**

   Yes. Mifepristone is safe when used as indicated and directed and consistent with the Mifepristone Risk Evaluation and Mitigation Strategy (REMS) Program. The FDA approved Mifeprex more than 20 years ago based on a thorough and comprehensive review of the scientific evidence presented and determined that it was safe and effective for its indicated use. As of 2016, it is approved for use for medical termination of pregnancy up to 70 days of gestation. The FDA's periodic reviews of the postmarketing data for Mifeprex and its approved generic have not identified any new safety concerns with the use of mifepristone for medical termination of pregnancy through 70 days gestation. As with all drugs, the FDA continues to closely monitor the postmarketing safety data on mifepristone for the medical termination of pregnancy.

5. **What are the possible side effects of using mifepristone for medical termination of pregnancy through ten weeks gestation?**

   The possible side effects are described in the labeling (https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s025Lbl.pdf) and in the Medication Guide (https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s025Lbl.pdf#page=16) for mifepristone.

GBP-PET01410

6. **What serious adverse events have been reported after the use of mifepristone for medical termination of pregnancy through ten weeks gestation?**

   As with all approved drugs, when the FDA receives new information regarding adverse events, the agency reviews the new information and, as appropriate, takes necessary action. This could include, for example, providing updates to health care providers and their patients so that they have information on how to use a drug safely.

   It is common for the FDA to receive reports of serious adverse events for prescription drugs after they are approved. Many drugs are associated with serious adverse events that are known at the time of approval and considered when the FDA makes its approval decision. The FDA continuously reviews reports of adverse events to, among other things, determine whether they are known risks or whether they are signals of emerging safety concerns.

   The FDA has received reports of serious adverse events in patients who took mifepristone. As of December 31, 2024, there were 36 reports of deaths in patients associated with mifepristone since the product was approved in September 2000, including two cases of ectopic pregnancy (a pregnancy located outside the womb, such as in the fallopian tubes) resulting in death, and several fatal cases of severe systemic infection (also called sepsis). The adverse events cannot with certainty be causally attributed to mifepristone because of concurrent use of other drugs, other medical or surgical treatments, co-existing medical conditions, and information gaps about patient health status and clinical management of the patient. A summary report of adverse events that reflects data through December 31, 2024, is here (/media/185245/download?attachment). The FDA has reviewed this information and did not identify any new safety signals. The FDA intends to update this summary report as appropriate.

7. **What should health care providers watch for in patients who have taken mifepristone for medical termination of pregnancy through ten weeks gestation?**

   Health care providers should review the approved labeling for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg. The signs and symptoms they should watch for are included in the labeling, available here (https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s025Lbl.pdf).

8. **What is an ectopic pregnancy?**

   An ectopic pregnancy is a non-viable pregnancy that develops outside of the womb. It occurs in approximately two percent of all pregnancies. An ectopic pregnancy is usually located in one of the fallopian tubes. As the fetus grows, the tube cannot hold it, causing the tube to rupture (burst) and bleed. Unless they are discovered and treated early, almost 40 percent of ectopic pregnancies rupture suddenly, causing pain and bleeding in the abdominal cavity. The other 60 percent usually cause slow bleeding in the abdomen.

GBP-PET01411

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 241 of 352 PageID #: 4359

Ruptured ectopic pregnancies can be fatal. The approved labeling for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg, states that the use of mifepristone, in a regimen with misoprostol, for the medical termination of pregnancy through ten weeks gestation is contraindicated in patients with a confirmed or suspected ectopic pregnancy.

9. **Does the FDA endorse this drug product?**

   The FDA does not endorse any drug product. The agency evaluates all drug applications submitted by applicants to determine whether the data and information in an application support the approval of the application. The same standards are applied to the drug applications for Mifeprex and the approved generic Mifepristone Tablets, 200 mg, as are applied to all drug applications.

The Mifepristone REMS Program

10. **Why is there a REMS for this product?**

    The FDA's determination as to whether a REMS is necessary for a particular drug is a drug-specific evaluation. The agency considers whether (based on premarketing or postmarketing risk assessments) there is a particular risk or risks associated with the use of the drug that, on balance, outweigh its benefits and whether additional risk mitigation measures beyond the FDA-approved labeling are necessary to ensure that the drug's benefits outweigh its risks.

    The Mifepristone REMS Program is intended to mitigate the risk of serious complications associated with mifepristone when used for medical termination of pregnancy through ten weeks gestation by, among other things, requiring that prescribers have the necessary qualifications to assess whether patients are appropriate candidates for the drug and to provide necessary intervention in case of complications (or have made plans to provide such care through others), ensuring that mifepristone is only dispensed by certified pharmacies or by or under the supervision of certified prescribers, and requiring that patients be informed of the risks of the treatment regimen.

11. **What are the restrictions on prescribing and dispensing mifepristone for medical termination of pregnancy through ten weeks gestation?**

    When the agency reviewed and approved the original new drug application for Mifeprex (mifepristone) in 2000, it concluded that certain restrictions were necessary to ensure the safe use of the drug. These restrictions were approved as a risk evaluation and mitigation strategy (REMS) in 2011 and have been modified since then.

    These REMS requirements also apply to the approved generic version of Mifeprex. Mifeprex and the approved generic version of Mifeprex are subject to a single, shared system REMS, known as the Mifepristone REMS Program. This program sets the requirements that must be

GBP-PET01412

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 242 of 352 PageID #: 4360

followed to ensure safe use of both Mifeprex and the approved generic version of Mifeprex.

Under the Mifepristone REMS Program, these requirements include, among others:

- Mifepristone must be prescribed by a health care provider that meets certain qualifications and is certified under the Mifepristone REMS Program.
- In order to become certified to prescribe mifepristone, health care providers must complete a Prescriber Agreement Form.
- The Patient Agreement Form must be reviewed with and signed by the patient and the health care provider, and the risks of the mifepristone treatment regimen must be fully explained to the patient before prescribing mifepristone.
- The patient must be provided with a copy of the Patient Agreement Form and the mifepristone Medication Guide (FDA-approved information for patients).
- Mifepristone may only be dispensed by or under the supervision of a certified prescriber, or by a certified pharmacy on a prescription issued by a certified prescriber.
- To become certified to dispense mifepristone, pharmacies must complete a Pharmacy Agreement Form.
- Certified pharmacies must be able to ship mifepristone using a shipping service that provides tracking information.
- Certified pharmacies must ensure mifepristone is dispensed to the patient in a timely manner.

Each REMS is required to have a plan for periodic assessments by the applicants, which are reviewed by the agency to determine whether the REMS is meeting its goals or whether certain goals or elements of the REMS must be modified. The FDA may require applicants to modify a REMS if the agency determines that an element is no longer necessary to ensure that the benefits of the drug outweigh the risks or to minimize the burden on the health care delivery system.

12. **How does the Mifepristone REMS Program ensure safe use of the drug?**

    The Mifepristone REMS Program requires that in order for patients to receive mifepristone, it must be prescribed by a certified prescriber who has certain qualifications and agrees to follow certain guidelines for use. Under the Mifepristone REMS Program, mifepristone must be dispensed by or under the supervision of a certified prescriber or by a certified pharmacy on a prescription issued by a certified prescriber. The Mifepristone REMS Program is a closed system, meaning prescribers, pharmacies, and distributors are certified or authorized

GBP-PET01413

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 243 of 352 PageID #: 4361

and verified under the REMS prior to distribution or dispensing of the drug. The Mifepristone REMS Program ensures that mifepristone is only distributed to health care providers and pharmacies that have agreed to the REMS requirements.

13. **How does the Mifepristone REMS Program as modified in January 2023 differ from the previous REMS requirements?**

    Prior to the modifications to the Mifepristone REMS Program approved in January 2023, the Mifepristone REMS Program required mifepristone to be dispensed in person in a clinic, medical office, or hospital. The requirement to dispense in person in one of these settings was referred to as the "in-person dispensing requirement." There were periods when the in-person dispensing requirement was not being enforced. First, from July 13, 2020, until January 12, 2021, the FDA was enjoined from enforcing the in-person dispensing requirement by an injunction issued in the ACOG v. FDA litigation, which was filed in the U.S. District Court for the District of Maryland. On April 12, 2021, the agency stated its intent to exercise enforcement discretion with respect to the in-person dispensing requirement during the COVID-19 public health emergency.

    In 2021, after conducting a comprehensive review of the Mifepristone REMS Program, the FDA determined, based on the available data and information, that the REMS must be modified to reduce burden on the health care delivery system and to ensure the benefits of the product outweigh the risks. On December 16, 2021, the FDA announced that the modifications to the Mifepristone REMS Program would consist of:

    - Removing the "in-person dispensing requirement"
    - Adding a requirement that pharmacies that dispense the drug be certified

    Consistent with the typical process for REMS modifications, the FDA sent REMS Modification Notification letters to the applicants for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg. Following receipt of these letters, the applicants prepared a proposed REMS modification and submitted it to their respective applications. After reviewing the applicants' submissions, the FDA approved the REMS modification on January 3, 2023. The REMS document and materials are available at:

    - Find information on Mifeprex (mifepristone) here (https://www.earlyoptionpill.com/for-health-professionals/ordering-mifeprex/) (http://www.fda.gov/about-fda/website-policies/website-disclaimer)
    - Find information on generic mifepristone here (https://genbiopro.com/) (http://www.fda.gov/about-fda/website-policies/website-disclaimer)

Where can patients get mifepristone for medical termination of pregnancy through ten weeks gestation?

GBP-PET01414

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 244 of 352 PageID #: 4362

Mifepristone must be prescribed by a certified prescriber who meets certain qualifications and agrees to follow certain guidelines for use. Under the Mifepristone REMS Program, mifepristone can be dispensed by or under the supervision of a certified prescriber or by a certified pharmacy on a prescription issued by a certified prescriber.

14. **What qualifications must health care providers have to become certified to prescribe mifepristone for medical termination of pregnancy through ten weeks gestation?**

    Health care providers who would like to become certified to prescribe mifepristone must review the Prescribing Information for mifepristone and must have the ability to date pregnancies accurately and the ability to diagnose ectopic pregnancies. Health care providers must also be able to provide any necessary surgical intervention or have made arrangements for others to provide for such care. Health care providers must be able to ensure that patients have access to medical facilities for emergency care, and must agree to other responsibilities, including reviewing and signing the Patient Agreement Form with the patient and providing each patient with a copy of the signed Patient Agreement Form.

    Some states allow health care providers other than physicians to prescribe medications. Health care providers should check their individual state laws.

15. **Under the Mifepristone REMS Program, are patients required to see a health care provider in person before obtaining mifepristone for medical termination of pregnancy through ten weeks gestation?**

    The Mifepristone REMS Program does not require patients to see a health care provider in person before obtaining mifepristone for medical termination of pregnancy through ten weeks gestation. Mifeprex and the approved generic, Mifepristone Tablets, 200 mg, are indicated, in a regimen with misoprostol, for the medical termination of an intrauterine pregnancy through 70 days gestation and are contraindicated for certain patients, including those with an ectopic pregnancy. The FDA has determined that it is not necessary for the REMS to mandate how providers clinically assess patients for duration of pregnancy and for ectopic pregnancy. The prescription labeling for Mifeprex and the approved generic provide guidance to prescribers regarding how they can confirm the gestational age of the pregnancy and confirm that the pregnancy is located in the uterus. Aspects of a patient's medical history that may constitute contraindications to medical termination of pregnancy may be elicited without direct physical contact with the certified prescriber and can be done in different types of health care settings, thus certified prescribers are not necessarily required to be physically present with the patient when they prescribe mifepristone. As explained above (Question 15), health care providers certified under the Mifepristone REMS Program must also be able to provide any necessary surgical intervention or have made arrangements for others to provide for such care and must be able to ensure that patients have access to medical facilities for emergency care.

GBP-PET01415

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 345 of 352 PageID #: 4363

16. **What information did the FDA consider when it reviewed the Mifepristone REMS Program in 2021?**

    To determine whether a modification to the Mifepristone REMS Program was warranted, the FDA conducted a comprehensive review of the published literature, other relevant safety and adverse event data, and information provided by advocacy groups, individuals, and the applicants related to the modifications that were under consideration. Our review also included an examination of literature references provided by plaintiffs in the *Purcell v. Becerra* (previously *Chelius v. Becerra*) litigation.

17. **Prior to the FDA's action in January 2023, how was mifepristone dispensed to patients?**

    Prior to the FDA's action on the REMS modification applications submitted by the applicants for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg, in 2022, the Mifepristone REMS Program required that mifepristone be dispensed in person in a clinic, medical office, or hospital. The requirement to dispense in person in one of these settings was referred to as the "in-person dispensing requirement."

    There were periods when the in-person dispensing requirement was not being enforced. First, from July 13, 2020, until January 12, 2021, the FDA was enjoined from enforcing the in-person dispensing requirement by an injunction issued in a lawsuit, *ACOG v. FDA* filed in the U.S. District Court for the District of Maryland. On April 12, 2021, the agency stated its intent to exercise enforcement discretion with respect to the in-person dispensing requirement during the COVID-19 public health emergency.

    During the periods when the in-person dispensing requirement was not being enforced, the applicants for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg, used mail order pharmacies to receive and hold mifepristone on behalf of the certified prescribers who purchased the product. Pursuant to a prescription for Mifeprex or its approved generic, the mail order pharmacy would ship the product to a named patient.

18. **What is the FDA's role in overseeing the Mifepristone REMS Program?**

    As with all REMS, the FDA monitors the applicants' compliance with the Mifepristone REMS Program, including by reviewing periodic assessment information from the applicants and conducting on-site inspections, and takes action as appropriate.

19. **What is pharmacy certification and why is it a requirement of the Mifepristone REMS Program?**

    The Mifepristone REMS Program requires all pharmacies that dispense mifepristone to be specially certified. The pharmacy certification requirement incorporates pharmacies into the REMS, ensures that pharmacies are aware of and agree to follow applicable REMS

GBP-PET01416

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 246 of 352 PageID #: 4364

requirements, and ensures that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers. Any pharmacy that meets the requirements of the Mifepristone REMS Program is eligible to be certified.

20. **What steps are required for pharmacy certification?**

    The pharmacy certification requirement ensures that pharmacies are aware of and agree to follow applicable REMS requirements and ensures that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers.

    To become certified to dispense mifepristone, pharmacies must: (1) be able to receive Prescriber Agreement Forms by email and fax; (2) be able to ship mifepristone using a shipping service that provides tracking information; (3) designate an authorized representative to carry out the certification process on behalf of the pharmacy; and (4) ensure the authorized representative oversees implementation and compliance with the Mifepristone REMS Program, which includes, among other requirements, the completion of a Pharmacy Agreement Form.

21. **Is mifepristone available at retail pharmacies?**

    The January 2023 modification to the Mifepristone REMS Program removed the restriction that did not allow mifepristone to be dispensed by retail pharmacies. While pharmacy certification is required, any pharmacy that meets the requirements of the Mifepristone REMS Program is eligible for certification.

22. **Is mifepristone available for over-the-counter use?**

    No. Mifepristone for medical termination of a pregnancy through ten weeks gestation is only available by prescription. An applicant seeking to switch mifepristone for medical termination of pregnancy through ten weeks gestation from prescription to nonprescription (also referred to as over-the-counter) status would need to submit this information to the FDA for evaluation. In order for a drug product to be approved for nonprescription use (including switching a prescription drug product to nonprescription marketing), the applicant must provide sufficient information demonstrating that the drug can be used safely and effectively by consumers without the supervision of a health care provider.

23. **What would be required to remove the REMS?**

    The FDA may release a REMS or remove certain components of a REMS if, after review of REMS assessments or other information, the agency determines that the REMS or certain components of the REMS are no longer necessary to ensure a medication's benefits outweigh its risks.

GBP-PET01417

Additional Information

25. **Is it possible for an individual to become pregnant again after taking mifepristone for medical termination of pregnancy through ten weeks gestation?**

    It is possible for an individual to become pregnant again soon after a pregnancy ends. A patient should consult with their health care provider regarding any specific questions they may have.

26. **Is mifepristone approved in any other countries for medical termination of pregnancy?**

    Mifepristone for medical termination of pregnancy has been approved in France since 1988, and also is approved in the United Kingdom, Sweden, and approximately 100 other countries.

27. **Does the FDA set the price of mifepristone and is the drug reimbursed by health insurance providers?**

    The FDA does not have the authority to regulate the prices of drug products in the United States. Manufacturers, distributors, and retailers establish the prices. Additionally, the FDA does not have input into or legal control over whether an insurance company does or does not cover the cost of a drug. Insurance coverage is a decision made by an insurance provider. Individuals should contact their insurance provider if they have questions about whether a particular insurance provider will cover the cost of the drug.

28. **Has FDA ever taken action regarding the sale of mifepristone online?**

    The FDA has sent warning letters to websites selling unapproved and misbranded mifepristone and misoprostol over the internet, including AidAccess (/inspections-compliance-enforcement-and-criminal-investigations/warning-letters/aidaccessorg-575658-03082019) and Rablon (/inspections-compliance-enforcement-and-criminal-investigations/warning-letters/rablon-1111111-03082019).

    There have also been several criminal cases related to the online sale of mifepristone for medical termination of pregnancy. We are aware of three cases about which the Agency can speak publicly. The first is *United States v. O'Neil*, in the U.S. District Court for the District of Maryland. Information about two more individual prosecutions are available here: March 28, 2017: Former Atlantic County, New Jersey, Man Charged with Smuggling and Dispensing Misbranded Drugs | FDA (/inspections-compliance-enforcement-and-criminal-investigations/press-releases/march-28-2017-former-atlantic-county-new-jersey-man-charged-smuggling-and-dispensing-misbranded) and here: New York Woman Sentenced for Selling Abortion-Inducing Pills Illegally Smuggled Into US | USAO-WDWI | Department of Justice (https://www.justice.gov/usao-wdwi/pr/new-york-woman-sentenced-selling-abortion-

GBP-PET01418

inducing-pills-illegally-smuggled-us). The FDA also issued a Final Debarment Order for Ursula Wing (https://www.federalregister.gov/documents/2021/03/26/2021-06258/ursula-wing-final-debarment-order), debarring her for a period of five years from importing or offering for import any drug into the United States. This debarment was based on her felony conviction (https://www.justice.gov/usao-wdwi/pr/new-york-woman-sentenced-selling-abortion-inducing-pills-illegally-smuggled-us) related to her importation and distribution of unapproved and misbranded mifepristone and misoprostol over the internet.

The January 2023 REMS Modification

29. **What action did the FDA take on the Mifepristone REMS Program in January 2023?**

    In response to the REMS Modification Notification letters sent on December 16, 2021, to the applicants for Mifeprex and the approved generic Mifepristone Tablets, 200 mg, the applicants submitted supplemental applications to modify the Mifepristone REMS Program to remove the in-person dispensing requirement and add pharmacy certification. The FDA reviewed the applicants' supplemental applications and approved a modification to the Mifepristone REMS Program. Under the Mifepristone REMS Program, as modified, Mifeprex and its approved generic can be dispensed by or under the supervision of a certified prescriber or by a certified pharmacy on a prescription issued by a certified prescriber.

    The Mifepristone REMS Program continues to require the Patient Agreement Form and certification of health care providers who prescribe mifepristone.

30. **What was the process for approving the current REMS modification?**

    In 2021, in order to determine whether a modification to the Mifepristone REMS Program was warranted, the FDA conducted a comprehensive review of the published literature, other relevant safety and adverse event data, and information provided by advocacy groups, individuals, and the applicants related to the modifications that were under consideration. After conducting this review, the FDA determined that the REMS must be modified to remove the in-person dispensing requirement and add pharmacy certification. In accordance with the typical process for REMS modifications, the FDA sent REMS Modification Notification letters to the applicants for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg. Following receipt of these letters, the applicants prepared a proposed REMS modification and submitted it to their respective applications.

31. **Why did the FDA conduct a review of the Mifepristone REMS Program in 2021?**

    The agency's comprehensive review of the Mifepristone REMS Program, which led to the agency's December 16, 2021, decision that a modification was required, was related to the litigation in *Purcell v. Becerra* (previously *Chelius v. Becerra*). On May 7, 2021, the FDA and the plaintiffs in *Purcell* filed a joint motion to stay that litigation, which involves the single,

GBP-PET01419

Case 6:25-cv-01491-DCJ-DJA Document 54-14 Filed 02/03/26 Page 349 of 352 PageID #: 4367

shared system REMS for Mifeprex and its approved generic, Mifepristone Tablets, 200 mg. The court granted the stay on May 7, 2021. The *Purcell* case was reopened on February 28, 2023, and the plaintiffs now challenge the modified Mifepristone REMS Program. The agency generally does not comment on pending litigation.

32. **Was there a change in the reported adverse events during the pandemic when the in-person dispensing requirement was not enforced?**

    No. There were periods when the in-person dispensing requirement was not being enforced. First, from July 13, 2020, until January 12, 2021, the FDA was enjoined from enforcing the in-person dispensing requirement by an injunction issued in the *ACOG v. FDA* litigation, which was filed in the U.S. District Court for the District of Maryland. On April 12, 2021, the agency stated its intent to exercise enforcement discretion with respect to the in-person dispensing requirement during the COVID-19 public health emergency. The FDA analyzed postmarketing data to determine if there was a difference in adverse events between periods when in-person dispensing was and was not enforced. Based on this review, the agency concluded that there did not appear to be a difference in adverse events between periods when in-person dispensing was and was not enforced

Litigation and Other Legal Issues

33. **Was the Mifepristone REMS Program modified in 2023 in response to the Supreme Court's 2022 decision in *Dobbs v. Jackson Women's Health Organization*?**

    No. The agency's comprehensive review of the Mifepristone REMS Program, which led to the 2021 decision that a modification was required, is related to the litigation in *Purcell v. Becerra* (previously *Chelius v. Becerra)*. In accordance with the typical process for REMS modifications, the FDA sent REMS Modification Notification letters to the applicants for Mifeprex and the approved generic, Mifepristone Tablets, 200 mg. Following receipt of these letters, the applicants prepared a proposed REMS modification and submitted it to their respective applications. The FDA reviewed the REMS modification supplements submitted by the applicants in the Mifepristone REMS Program and approved a REMS modification that removes the in-person dispensing requirement and adds pharmacy certification.

34. **Was the Mifepristone REMS Program modified in 2023 in response to state abortion laws?**

    No. See response to Question 33.

35. **What happens if a state refuses to allow mifepristone to be prescribed for medical termination of pregnancy?**

    Any questions regarding the application of state law should be directed to the Department of Justice.

GBP-PET01420

36. **What is the status of the *Alliance for Hippocratic Medicine* lawsuit about the approval of mifepristone?**

On November 18, 2022, the FDA and HHS were sued in the U.S. District Court for the Northern District of Texas by the Alliance for Hippocratic Medicine and other plaintiffs. In June 2024, the Supreme Court held that the original plaintiffs lack standing to challenge FDA's actions, and the original plaintiffs voluntarily dismissed their claims in November 2024. Several states (Missouri, Idaho, and Kansas) intervened in the case before the Supreme Court's ruling. The agency generally does not comment on pending litigation.

GBP-PET01421

What is a Serious Adverse Event?

Reporting Serious Problems to FDA

What is a Serious Adverse Event?

Product Problems

Reporte problemas serios a la FDA

¿Qué es una reacción adversa grave?

Problemas con los productos

Español

Content current as of: 05/18/2023

An adverse event is any undesirable experience associated with the use of a medical product in a patient. The event is serious and should be reported to FDA when the patient outcome is:

Death

Report if you suspect that the death was an outcome of the adverse event, and include the date if known.

Life-threatening

Report if suspected that the patient was at substantial risk of dying at the time of the adverse event, or use or continued use of the device or other medical product might have resulted in the death of the patient.

Hospitalization (initial or prolonged)

Report if admission to the hospital or prolongation of hospitalization was a result of the adverse event.

Emergency room visits that do not result in admission to the hospital should be evaluated for one of the other serious outcomes (e.g., life-threatening; required intervention to prevent permanent impairment or damage; other serious medically important event).

Disability or Permanent Damage

Report if the adverse event resulted in a substantial disruption of a person's ability to conduct normal life functions, i.e., the adverse event resulted in a significant, persistent or permanent change, impairment, damage or disruption in the patient's

body function/structure, physical activities and/or quality of life.

Congenital Anomaly/Birth Defect

Report if you suspect that exposure to a medical product prior to conception or during pregnancy may have resulted in an adverse outcome in the child.

Required Intervention to Prevent Permanent Impairment or Damage (Devices)

Report if you believe that medical or surgical intervention was necessary to preclude permanent impairment of a body function, or prevent permanent damage to a body structure, either situation suspected to be due to the use of a medical product.

Other Serious (Important Medical Events)

Report when the event does not fit the other outcomes, but the event may jeopardize the patient and may require medical or surgical intervention (treatment) to prevent one of the other outcomes. Examples include allergic brochospasm (a serious problem with breathing) requiring treatment in an emergency room, serious blood dyscrasias (blood disorders) or seizures/convulsions that do not result in hospitalization. The development of drug dependence or drug abuse would also be examples of important medical events.

FOOD AND DRUG ADMINISTRATION

Approval and Oversight of the Drug Mifeprex

Why GAO Did This Study

In September 2000, the Food and Drug Administration (FDA), part of the Department of Health and Human Services (HHS), approved the drug Mifeprex for use in terminating early term pregnancy. FDA approved the drug under a provision of its Subpart H regulations, allowing it to restrict the drug's distribution to assure its safe use. Critics have questioned aspects of the Mifeprex approval process, including the reliance on historically-controlled clinical trials that compare a drug's effects on a condition to the known course of the condition rather than to another drug or placebo. Critics argued that Mifeprex does not fit within the scope of Subpart H, which applies to drugs that treat serious or life-threatening illnesses. Concerns have also been raised about FDA's oversight of the drug since approval, including the agency's response to deaths in U.S. women who had taken the drug.

In this report GAO (1) describes FDA's approval of Mifeprex, including the evidence considered and the restrictions placed on its distribution; (2) compares the Mifeprex approval process to the approval processes for other Subpart H restricted drugs; and (3) compares FDA's postmarket oversight of Mifeprex to its oversight of other Subpart H restricted drugs. GAO reviewed FDA regulations, policies, and records pertaining to its approval and oversight of Mifeprex and the eight other Subpart H restricted drugs. In addition, GAO interviewed FDA officials and external stakeholders.

What GAO Found

FDA approved Mifeprex after evaluating the sponsor's initial and revised new drug application through three review cycles. In the first cycle, FDA concluded that the available data supported the safety and efficacy of Mifeprex and that, because the course of pregnancy was well-documented and the effects of the drug were self-evident, the use of historical controls was consistent with FDA regulations. FDA also concluded that before the drug could be approved, the sponsor needed to provide final data from an ongoing U.S. trial, and more detail on restricting the drug's distribution. In the second cycle, FDA concluded that while the U.S. trial data confirmed the drug's safety and efficacy, the sponsor needed to revise its distribution plan and address labeling and manufacturing deficiencies. In the final review, FDA concluded that termination of unwanted pregnancy is a serious condition and imposing restrictions under Subpart H was necessary. FDA approved Mifeprex, but required that the sponsor commit to conduct two postmarketing studies, imposed several distribution restrictions intended to ensure that only qualified physicians prescribe the drug, and required that patients attest to understanding the treatment's potential complications.

The approval process for Mifeprex was consistent with the processes for the other Subpart H restricted drugs, although the details of FDA's approval depended on the unique risks and benefits of each drug. Common elements of the approval processes included that FDA needed to evaluate potential limitations in key clinical data (Mifeprex and six of the other drugs), did not approve the drugs in the first review cycle (Mifeprex and five others), and imposed similar types of distribution restrictions on Mifeprex and the other drugs, though the specific details of the restrictions varied across the drugs.

FDA's postmarket oversight of Mifeprex has been consistent with its oversight of other Subpart H restricted drugs. To oversee compliance with distribution restrictions, FDA has reviewed data from all sponsors and conducted inspections for Mifeprex and two other drugs. To oversee compliance with postmarketing study commitments, FDA has relied on required updates from sponsors and found unfulfilled commitments for most drugs, including Mifeprex. To oversee compliance with adverse event reporting requirements, FDA has evaluated data in sponsors' reports and, for Mifeprex and seven other drugs, has conducted inspections that revealed deficiencies for most of these drugs, including Mifeprex. Lastly, FDA has taken similar steps to oversee postmarket safety across the drugs, such as analyzing adverse events. For Mifeprex, FDA investigated the deaths of six U.S. women who developed a severe infection after taking the drug and concluded that the evidence did not establish a causal relationship between Mifeprex and the infections. Finally, FDA has taken similar actions to address emerging safety concerns across the drugs, such as changing labeling.

HHS reviewed a draft of this report and informed GAO that it did not have comments.

Ranking Member
Committee on Health, Education, Labor, and Pensions
United States Senate

The Honorable Jim DeMint
United States Senate

The Honorable Roscoe G. Bartlett
House of Representatives

In September 2000, the Department of Health and Human Services' (HHS) Food and Drug Administration (FDA) granted marketing approval to the prescription drug Mifeprex (mifepristone) for the medical termination of early term pregnancy.[1] It remains the only drug approved in the United States for this purpose. FDA approved the drug under a provision of the agency's Subpart H regulations that allows FDA to restrict the distribution or use of a drug in order to assure its safe use.[2] Under this provision FDA can require, as it did for Mifeprex, that distribution be restricted to certain health care providers with specific training or experience. Since the drug's approval, more than 900,000 women are estimated to have taken Mifeprex in the United States.

[1]Mifeprex is the trade name for the mifepristone product marketed in the United States. Mifepristone is the name of the underlying drug substance. Mifepristone is also sometimes called "RU-486," a reference to the name the drug had during laboratory testing.

[2]Subpart H of FDA's drug approval regulations—titled "Accelerated Approval of New Drugs for Serious or Life-Threatening Illnesses"—applies to drugs that are intended to treat serious or life-threatening illnesses and provide a meaningful therapeutic benefit to patients over existing treatments. The regulations contain two approval provisions. One provides a process through which FDA may restrict the distribution or use of a drug to assure its safe use. The other provides FDA with flexibilities that allow the agency to accelerate the approval process for certain drugs on the basis of clinical trial endpoints that are considered reasonably likely to predict clinical benefit. See 21 C.F.R. §§ 314.500-560 (2007).

Before a drug can be marketed in the United States, the drug sponsor must submit a new drug application (NDA) to FDA containing data demonstrating the safety and efficacy of the drug.[3] FDA reviews the NDA to determine whether the drug's benefits outweigh its risks.[4] Once FDA completes its review, the agency issues an action letter in which it either approves the drug as safe and effective for its intended use (approval letter), informs the sponsor that the drug is likely to be approved once the deficiencies FDA has identified are resolved (approvable letter), or indicates that approval cannot be obtained without substantial additional information (not approvable letter).[5] If FDA issues an approvable or not approvable letter, a subsequent review cycle can begin once the sponsor has addressed the issues FDA identified. FDA may require, as a condition of approval, that a sponsor agree to restrict the drug's distribution under the agency's Subpart H regulations.[6]

Critics have raised concerns and questions regarding several aspects of FDA's approval process for Mifeprex. For example, questions have been raised about the reliance on data from historically controlled clinical trials—trials that compare a drug's effects on a condition within the study population to the known course of that same condition in patients or

[3]A drug sponsor is the person or entity who assumes responsibility for the marketing of a new drug, including responsibility for complying with applicable laws and regulations.

[4]FDA also reviews supplemental NDAs, which sponsors submit to support proposed changes to a drug's label, a new dosage or strength of the drug, a new patient population or intended use, or changes to the way the drug is manufactured after a drug has an approved NDA.

[5]FDA issued a final rule on July 10, 2008, amending its drug approval regulations. The final rule, among other things, discontinues FDA's use of approvable letters and not approvable letters. Instead, in the event that FDA determines it will not approve an application in its current form, the agency will send applicants a "complete response letter" to indicate that the review cycle for an application is complete and to describe the specific deficiencies the agency identified in the application. The amended regulations are effective on August 11, 2008. See 73 Fed. Reg. 39588-89 (July 10, 2008).

[6]21 C.F.R. § 314.520 (2007). From 1992—the year that the regulations were promulgated—through February 2007, nine drugs, including Mifeprex, had either an NDA or supplemental NDA approved under this restricted distribution provision. Under the Food and Drug Administration Amendments Act of 2007 (FDAAA), FDA may determine that a risk evaluation and mitigation strategy (REMS) is necessary to ensure that the benefits of a drug outweigh its risks. The REMS provisions of FDAAA went into effect on March 25, 2008. As part of a REMS, FDA can require "elements to assure safe use," which include restrictions similar to those that can be required under Subpart H regulations. 21 U.S.C. § 355-1(a), (e), (f); Pub. L. No. 110-85, §§ 901, 909(a), 121 Stat. 823, 922, 926-38, 950.

GBP-PET01429

populations that were not part of the trial—to support the safety and efficacy of Mifeprex.[7] FDA regulations allow for the use of such historical controls when the course of the condition in question is well-documented within a comparable population and the effect of the drug is apparent. Questions have also been raised about whether Mifeprex fit within the scope of Subpart H regulations, which apply to drugs that are intended to treat a serious or life-threatening illness. Critics have argued that unwanted pregnancy should not be considered a serious or life-threatening illness. They have also questioned whether FDA's use of Subpart H regulations was consistent with its use of the regulations to approve other drugs.

Additionally, concerns have been raised about FDA's postmarket oversight of Mifeprex, including its efforts to ensure the sponsor's compliance with conditions of approval as well as the actions the agency has taken in response to reported adverse events.[8] For approved drugs, FDA oversees sponsors' compliance with applicable reporting requirements, distribution restrictions, and other conditions of approval.[9] FDA also monitors the drugs' postmarket safety and efficacy. In the case of Mifeprex, six U.S. women have died from severe bacterial infection after taking the drug, raising questions about its safety. Some have questioned FDA's conclusion—which it discussed at a May 2006 congressional hearing—that the available evidence had not established a causal relationship between Mifeprex and the infections.

You asked us to review FDA's approval of Mifeprex and its oversight of the drug since approval. In this report we (1) examine FDA's approach to approving Mifeprex, including the types of evidence considered and the

[7]21 C.F.R. § 314.126(b)(2)(v) (2007). In contrast, clinical trials that use concurrent controls demonstrate the safety and efficacy of a drug by comparing its effects on patients in a treatment group to the effects of a different treatment—such as another drug or a placebo—on patients in a control group within the same study population.

[8]The term postmarket refers to activities occurring after a drug has been approved for marketing. FDA uses the term adverse drug event to refer to any untoward medical event associated with the use of a drug in humans.

[9]FDA regulations require sponsors of approved drugs to submit various postmarket safety reports. See 21 C.F.R. §§ 314.80, 314.81 (2007). Additionally, sponsors of approved drugs must report to FDA annually on the progress of any postmarket studies required by FDA or agreed to by the sponsor. 21 U.S.C. § 356b; 21 C.F.R. § 314.81(b)(2)(vii) (2007). FDA uses such postmarket studies to gather additional information about a drug's safety, efficacy, or use once it is marketed.

GBP-PET01430

restrictions placed on its distribution and use; (2) compare the approval process for Mifeprex to the approval processes for other drugs approved under the restricted distribution provision of Subpart H; and (3) compare FDA's oversight of the use of Mifeprex since its approval to the agency's oversight of the other drugs approved under the restricted distribution provision of Subpart H.

To examine FDA's approval of Mifeprex, we reviewed relevant laws, regulations, policies, and guidance. We reviewed FDA records including an archive of documents pertaining to the approval of Mifeprex.[10] We also reviewed documentation from an FDA advisory committee meeting,[11] testimony statements and the related transcript, FDA responses to congressional requests, an August 2002 citizen's petition and responses from outside organizations, and other documentation pertaining to FDA's approval of Mifeprex. We interviewed FDA officials and external stakeholders who had access to technical information or had conducted analyses pertaining to Mifeprex that were not available through FDA. These included a representative of the sponsor of the Mifeprex application and its licensee,[12] the American College of Obstetricians and Gynecologists and the American Association of Pro Life Obstetricians and Gynecologists.

To compare the approval process for Mifeprex to those of other drugs, we reviewed FDA documentation pertaining to FDA's approval of the other eight drugs that the agency had approved under the restricted distribution

[10]In response to a Freedom of Information Act request, FDA posted certain documents pertaining to its approval of Mifeprex on the agency's Web site (see http://www.fda.gov/cder/archives/mifepristone/default.htm). The documents, which total over 9,000 pages, include a range of sometimes redacted material such as handwritten notes or email communications, communications between the drug sponsor and FDA, meeting minutes, copies of international labeling, and study protocols.

[11]FDA may convene an advisory committee to obtain advice from scientific experts and representatives of the public regarding a drug. FDA requests advice from advisory committees on a variety of matters, including aspects of drug applications and postmarket safety concerns for drug products. The primary role of an advisory committee is to provide independent advice that will contribute to the quality of the agency's regulatory decision-making. Although the committees provide recommendations to the agency, final decisions are made by FDA.

[12]The Population Council, a non-profit organization involved in reproductive health and population issues, sponsored the Mifeprex application. During the NDA review process, the Population Council contracted with Danco Laboratories, L.L.C. to serve as its licensee with responsibility for commercial manufacturing and marketing of the drug. Following the drug's approval, the Population Council transferred ownership of the Mifeprex NDA to Danco.

GBP-PET01431

provision of Subpart H as of February 2007.[13] Specifically, we examined key documents related to FDA's internal review and approval processes as well as documentation from advisory committee meetings in order to identify commonalities and differences in FDA's process across the nine Subpart H restricted drugs, including Mifeprex. In our examination we focused on issues that had arisen during FDA's review of Mifeprex to determine whether similar issues had arisen in FDA's review of the other drugs, and how FDA had addressed those issues for the other drugs.

To compare FDA's oversight of the use of Mifeprex since approval to the agency's oversight of the other Subpart H restricted drugs, we reviewed relevant regulations and FDA guidance. We also examined FDA documentation on the agency's oversight of sponsors' compliance with distribution restrictions, postmarketing study commitments, and adverse event reporting requirements for the nine Subpart H restricted drugs. In addition, we reviewed FDA's process for evaluating and responding to postmarket data on adverse events for each drug. Lastly, we interviewed FDA officials and staff who are responsible for postmarket oversight of these drugs. We conducted our work from February 2007 through August 2008 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Results in Brief

On September 28, 2000, FDA approved Mifeprex under the restricted distribution provision of its Subpart H regulations after examining the NDA through three review cycles. In its first review, FDA concluded that the available evidence supported the safety and efficacy of Mifeprex. This conclusion was based in part on FDA's determination that because the course of pregnancy was well-documented and the effects of the treatment were self-evident, the reliance on historical controls in three key clinical trials—two conducted in France and one ongoing in the United States—was appropriate and consistent with FDA regulations. FDA issued an approvable letter in September 1996 concluding that the sponsor needed

[13]We initiated our work in February 2007. In June 2007, FDA approved one additional drug—Letairis—under the restricted distribution provision of Subpart H. This drug was not included in our review.

GBP-PET01432

to provide additional information, such as the final data from the U.S. trial and a detailed plan to restrict the drug's distribution, before an approval decision could be made. The second review cycle began when the sponsor submitted a complete response to this letter. FDA issued a second approvable letter in February 2000 after concluding that the new data confirmed the safety and efficacy of Mifeprex for the U.S. market but also that the sponsor needed to revise its distribution plan and address labeling and manufacturing deficiencies. In its final review, FDA deliberated about the distribution restrictions and conditions of use needed to assure the safe use of the drug. FDA concluded that termination of an unwanted pregnancy is a serious condition and that the drug can allow patients to avoid a surgical procedure and therefore Mifeprex fit within the scope of Subpart H. FDA further concluded that the drug could only be used safely if distribution was limited to qualified physicians. The sponsor argued that the drug did not treat a serious condition and that because they had voluntarily agreed to the restrictions FDA had requested, it was neither appropriate nor necessary to impose the restrictions under Subpart H. However, the sponsor eventually acquiesced to FDA's requirement that approval be under Subpart H. After FDA concluded that the sponsor had adequately revised its distribution plan and addressed the remaining issues identified in FDA's reviews, it approved the Mifeprex NDA under Subpart H with several restrictions. These included requiring that prescribing physicians attest to possessing specific skills, agree to fully discuss the treatment with patients, and agree to report certain adverse events to the sponsor; that the drug be distributed directly to physicians by an authorized distributor; and that patients attest to fully understanding the treatment and its potential complications. The drug was also approved subject to the sponsor's commitment to conduct two postmarket studies related to patient outcomes.

The approval process for Mifeprex was generally consistent with the approval processes for the other eight Subpart H restricted drugs, but the details of FDA's approval process for each drug depended on the drug's unique risks and benefits. One common element across the approval processes for seven of the drugs, including Mifeprex, was that FDA needed to evaluate potential limitations—such as lack of concurrent controls or small sample sizes—in key clinical trials supporting the NDA. For some of these drugs other than Mifeprex, FDA concluded that there were weaknesses in the data submitted in the NDA that needed to be addressed. Another common element for six of the drugs, including Mifeprex, was that FDA issued at least one prior action letter before ultimately approving the drug for marketing under Subpart H. Additionally, the types of distribution restrictions that FDA imposed on Mifeprex were similar to

GBP-PET01433

those the agency imposed on the other drugs, though the details of the restrictions varied depending on the drug. Lastly, eight of the drugs, including Mifeprex, were approved with two or more postmarketing study commitments, each with one or more commitments related to adverse events or patient outcomes of interest.

FDA's postmarket oversight of Mifeprex has been consistent with the agency's postmarket oversight of the other Subpart H restricted drugs. To oversee the drug sponsors' compliance with distribution restrictions, FDA has relied on data submitted by sponsors for all of the drugs. For three of the drugs, one of them Mifeprex, FDA has also completed inspections of the sponsor or its distributors. To oversee compliance with postmarketing study commitments, FDA has relied on updates in required reports from sponsors. Most of the drugs, including Mifeprex, have at least one study commitment that remains unfulfilled. To oversee compliance with adverse event reporting requirements, FDA has relied on sponsors' reports for all of the drugs and has also conducted inspections of the sponsor or its manufacturers for eight of them. FDA has cited the sponsors of seven of the drugs, including Mifeprex, for adverse event reporting deficiencies. To oversee the postmarket safety of all of the Subpart H restricted drugs, FDA has routinely conducted reviews of adverse event reports to monitor for safety concerns. In the case of Mifeprex, FDA investigated the deaths of six U.S. women who developed a fatal infection following treatment with Mifeprex for medical abortion. FDA has determined that in all six of the deaths, the women used a Mifeprex treatment regimen that has not been approved by FDA. Based on its investigations, FDA has concluded that a causal relationship between the use of Mifeprex and the fatal infections has not been established. FDA has also monitored other kinds of adverse events and has concluded that, with the exception of the cases of fatal infection, reported serious adverse events associated with Mifeprex have been within or below the ranges it expected. Additionally, for Mifeprex and the other drugs, FDA has taken similar actions—such as issuing warnings and requesting changes to the product labeling—to communicate safety information to consumers and health care providers.

HHS reviewed a draft of this report and informed us that it did not have general comments. In addition, HHS provided technical comments which we incorporated as appropriate.

GBP-PET01434

Background

The Mifeprex NDA provided for the use of Mifeprex, in combination with another drug, for the medical termination of pregnancy. The treatment regimen described in the NDA involved taking Mifeprex orally, and then taking the drug misoprostol orally 2 days later unless termination of the pregnancy had already occurred.[14] Patients return for a follow-up visit with their prescribing physician 2 weeks later to ensure that the termination of the pregnancy has been completed. The treatment regimen works by both interrupting the hormones that the body needs to maintain a pregnancy and inducing the uterine cramping necessary to cause a medical abortion.

At the time that the drug sponsor submitted the Mifeprex NDA, in March 1996, mifepristone had already been approved in multiple countries. The drug was first approved for the medical termination of pregnancy in France and China in 1988.[15] It was approved subsequently in the United Kingdom in 1991, in Sweden in 1992, and various other European countries throughout the 1990s. In general, the treatment regimens approved in these countries were similar to those studied in the Mifeprex NDA, though in some cases the specific drug used in combination with mifepristone was different.

FDA Application Review Process

FDA reviews drug applications to determine whether they provide sufficient evidence to demonstrate that a drug is safe and effective for the proposed use, including whether the benefits of the drug outweigh its risks. FDA's formal process for new drug approval begins after a drug sponsor submits an application, typically following a long period of research and development. During a preliminary review, FDA determines whether the application is sufficiently complete to be reviewed and if so, designates it for either standard or priority review, depending on the

[14]Misoprostol is one of several drugs that had been studied in combination with mifepristone for the medical termination of pregnancy because they have been shown to induce uterine contractions. However, it is approved for marketing in the United States for a different indicated use.

[15]The company that discovered mifepristone and manufactured it for marketing in France—Roussel Uclaf—did not want to produce the drug for the U.S. market. Instead, the U.S. sponsor retained a contract manufacturer. For a more detailed discussion of the history of the development of mifepristone for the U.S. market, see: Congressional Research Service, *Abortion: Termination of Early Pregnancy with RU-486 (Mifepristone)*, (Washington, D.C.: 2001).

GBP-PET01435

therapeutic potential of the drug.[16] The agency then assigns a team of reviewers—including medical officers, chemists, statisticians, microbiologists, pharmacologists, and other experts—within the relevant FDA review division. This review team, which is usually led by a medical officer, conducts a comprehensive evaluation of the clinical and non-clinical information in the application including the safety and efficacy data for the drug, the design and quality of the studies used to support the application, and the proposed labeling for the drug and also reviews the results of inspections of the facilities where the drug is manufactured.[17] The review team compiles the results of its analyses and recommends either an approval, approvable, or not approvable action.

FDA managers, usually including the review team's supervisor and senior management within the applicable review division, determine what action to take on an application, based on the recommendations of the review team. These managers examine the review team's analysis and individually decide whether to concur with the recommendation. The final decision on the action the agency should take is usually, but not always, made by the director of the applicable review division. In some cases, actions must be reviewed and agreed to by the relevant FDA office.

This review process may span several cycles. For those applications not approved during the first review cycle—both approvable and not approvable—the second FDA review cycle begins once the sponsor submits an amendment to the application providing responses to the deficiencies FDA identified in its previous review. These amendments often contain additional studies, analyses, data, or clarifying information to address FDA's concerns. The responsible review team reviews the information provided by the sponsor, conducts any additional analyses that are required, reviews the results of any additional inspections that have been conducted, and again recommends either an approval, approvable, or not approvable action. As with the first review cycle, the process ends once FDA management reviews the recommendations of the

[16]FDA may grant priority review status when it determines that a drug may provide significant benefits in the treatment, diagnosis, or prevention of a disease as compared to marketed drugs or non-drug therapies, such as surgery, or provide a treatment where no adequate therapy exists.

[17]The non-clinical data in an NDA pertains to, for example a drug's chemistry, manufacturing, and controls as well as its toxicology and pharmacology.

GBP-PET01436

review team and makes its decision on the action to take on the application.

Restricting Drug Distribution and Subpart H Regulations

To address concerns FDA identifies regarding the safe use of a drug, the agency may condition approval by requiring that the sponsor agree to restrict the drug's distribution. FDA has established restricted distribution programs for approved drugs primarily by requiring that a drug's approval be under the restricted distribution provision of Subpart H regulations. According to the scope of the regulations, Subpart H applies to new drugs that "have been studied for their safety and effectiveness in treating serious or life-threatening illnesses and that provide meaningful therapeutic benefit to patients over existing treatments" for the condition.[18] FDA may approve a drug under the restricted distribution provision of these regulations if it meets these criteria and the agency concludes that the drug is effective but can be safely used only if distribution or use is restricted. For example, FDA may require that distribution of a drug be limited to certain facilities or physicians with special training.

As of February 2007, nine drugs—Actiq, Accutane, Lotronex, Mifeprex, Plenaxis, Revlimid, Thalomid, Tracleer, and Xyrem—had either an NDA or supplemental NDA approved under the restricted distribution provision of Subpart H.[19] For each of the drugs, either during the application review process or based on postmarket data, FDA identified concerns about the safe use of the drug that led the agency to apply Subpart H. The drugs were approved to treat a range of conditions, such as breakthrough cancer pain, specific symptoms of narcolepsy, and severe acne.

FDA has also required that drug sponsors agree to restrict the distribution of drugs without imposing Subpart H. Clozaril, Tikosyn, and Trovan are three examples of drugs that have restricted distribution programs that were imposed outside of Subpart H. (See app. I for a table describing drugs FDA has approved with restricted distribution programs and the conditions they are intended to treat). While Clozaril was first approved in

[18]21 C.F.R. § 314.500 (2007).

[19]21 C.F.R. § 314.520 (2007). The sponsor for Plenaxis—approved in 2003 for the palliative care of certain patients with advanced prostate cancer—withdrew the product from the market in 2006. Additionally, three generic versions of Accutane have been approved for marketing under this restricted distribution provision.

GBP-PET01437

1989, FDA imposed distribution restrictions on both Tikosyn and Trovan after Subpart H regulations had been promulgated.

A second approval provision of Subpart H provides FDA with flexibilities that allow the agency to accelerate the approval process for drugs that provide meaningful therapeutic benefits over alternatives for serious or life-threatening illnesses.[20] Specifically, under the provision, FDA may approve a drug on the basis of clinical trials establishing that the drug has an effect on a surrogate endpoint—such as weight gain or reduced occurrence of infections in patients with HIV—that is reasonably likely to predict a clinical benefit or on the basis of an effect on a clinical endpoint other than survival or irreversible morbidity.[21] This allows FDA to approve a drug before measures of effectiveness that would usually be required for approval are available. However, under this approval provision, drug sponsors are ordinarily required to conduct postmarket studies to confirm and further describe the drug's clinical benefit. As of February 2007, FDA had used this provision to approve 52 drugs, most of which are intended to treat HIV/AIDS or various cancers.

FDA's Role in Postmarket Oversight

Because some risks may not become known until after a drug's approval and use in a wider segment of the population, FDA has a range of postmarket oversight responsibilities once a drug is approved for marketing in the United States. FDA's postmarket oversight responsibilities include assessing sponsors' compliance with requirements for a given drug, such as postmarketing study commitments, adverse event reporting, and restricted distribution requirements. In addition, FDA monitors reported adverse events to assess the postmarket safety of approved drugs and may take action if it develops a concern about a drug's safety.

With regard to postmarketing study commitments, FDA oversees sponsors' compliance with regulations that require sponsors of all approved drugs to report to FDA annually on their progress in meeting the

[20]See 21 C.F.R. § 314.510 (2007).

[21]According to FDA, although some surrogate endpoints are recognized as well-established and have long been a basis for approval (such as change in blood pressure or cholesterol), accelerated approval regulations allow reliance on a "surrogate endpoint that, while 'reasonably likely' to predict clinical benefit, is not so well-established as the surrogates ordinarily used as bases of approval in the past." 57 Fed. Reg. 58942, 58944 (Dec. 11, 1992).

GBP-PET01438

commitments. FDA requires that sponsors report on the status of these studies in an annual report that also includes updates on the distribution of the drug, labeling changes, clinical literature published on the drug, and the drug's marketing.[22] FDA designates unfulfilled study commitments as submitted, pending, ongoing, delayed, released, or terminated.

FDA also oversees sponsors' compliance with regulations that require sponsors of all approved drugs to report periodically to FDA on safety information and specific types of adverse events that occur in association with an approved drug.[23] Sponsors must provide in periodic reports (quarterly for the first 3 years after approval and annually thereafter) a narrative summary and analysis of adverse event information. For adverse events that are considered both serious and unexpected,[24] sponsors are required to submit a report—known as a "Postmarketing 15-day Alert Report"—to FDA within 15 calendar days from the time the sponsor was informed of the event. To assess sponsors' compliance with these adverse event reporting requirements, FDA reviews sponsors' reports and conducts inspections of the sponsors' reporting policies and procedures.

For drugs approved under the restricted distribution provision of Subpart H, FDA oversees sponsors' compliance with the restrictions placed on the drugs' distribution or use. To assess compliance with restrictions, FDA reviews information such as summaries of sponsors' distribution programs in annual reports and in some cases separate reports required by the agency to provide details and updates on distribution programs. In addition, FDA may conduct inspections of a sponsor's corporate headquarters, manufacturing sites, or contractors, such as specialty distributors, to evaluate whether distribution policies and procedures comply with the approved restrictions for a given drug. If FDA identifies deficiencies during an inspection, it may issue a formal citation—known as a Form FDA 483. In addition, FDA may communicate less serious findings as written or oral "observations" or "recommendations."[25]

[22]See 21 C.F.R. § 314.81 (2007).

[23]See 21 C.F.R. § 314.80 (2007).

[24]Unexpected events are those that are not included in the current labeling for a drug.

[25]FDA uses the same reporting scheme—noting citations, observations, or recommendations— for its inspections to assess sponsor compliance with adverse event reporting.

GBP-PET01439

To monitor postmarket safety of approved drugs, FDA reviews clinical literature, routinely evaluates the available data on reported adverse events, and conducts investigations of the nature and patterns of these events. FDA compiles data from sponsor's reports on adverse events, along with data from voluntary reports submitted to the MedWatch program, in its Adverse Event Reporting System (AERS) database.[26] FDA safety evaluators analyze data from AERS and in the clinical literature to detect signs of potential safety concerns. These evaluations may reveal the need for further studies of a drug or may result in FDA action to ensure the safety of the drug.[27]

If FDA identifies problems with a sponsor's compliance with agency requirements or identifies postmarket safety concerns, the agency can take a range of actions to address the concern and communicate safety information to healthcare providers and the public. For example, FDA may revise the restrictions on a drug's distribution, request changes to a drug's labeling, issue patient advisories or public health alerts, or request that a sponsor issue letters to health care providers or pharmacists to alert them to safety concerns. FDA may also issue a regulatory letter citing violations of laws or regulations. Typically, FDA issues a Warning letter for violations that may lead FDA to pursue further enforcement action if not corrected or issues an untitled letter for violations that do not meet this threshold. FDA also has the authority to withdraw a drug's marketing approval for safety-related and other reasons,[28] although it rarely does so. Additionally,

[26]MedWatch is a voluntary reporting program through which health professionals and consumers can report adverse reactions, product problems, and use errors related to drugs and other products approved by FDA.

[27]GAO has previously reported on and made recommendations regarding FDA's postmarket oversight of approved drugs. See GAO, *Drug Safety: Improvements Needed in FDA's Postmarket Decision-making and Oversight Process*. GAO-06-402. (Washington, D.C.: Mar. 31, 2006).

[28]21 U.S.C. § 355(e).

GBP-PET01440

Subpart H regulations establish an expedited process for withdrawing a drug's marketing approval, in certain circumstances.[29]

FDA Approved Mifeprex under the Subpart H Restricted Distribution Provision After Concluding That Clinical Evidence Supported Its Safety and Efficacy

FDA approved Mifeprex after three review cycles. In its initial review, FDA concluded that reliance on historical controls in three key clinical trials was appropriate and consistent with FDA regulations and that the available data supported the safety and efficacy of the drug. In an approvable letter, FDA notified the sponsor that it needed to provide additional data and more detail on its proposal to restrict the drug's distribution before an approval decision could be made. A second review cycle began when the sponsor submitted data responding to this letter. The agency issued a second approvable letter after finding that new data confirmed Mifeprex's safety and efficacy but also that the sponsor needed to revise its distribution plan and address labeling and manufacturing deficiencies. FDA further concluded that the drug was a candidate for approval under Subpart H. In the final review cycle, FDA concluded that the sponsor's revised distribution plan and other revisions were sufficient to address FDA's comments. FDA also concluded that Mifeprex met the scope of Subpart H and that approval under the restricted distribution provision of Subpart H was necessary to ensure that only qualified physicians prescribed the drug. On September 28, 2000, FDA approved Mifeprex under the restricted distribution provision of Subpart H with several restrictions and two postmarketing study commitments. (See table 1 for a timeline of key events in the Mifeprex approval process.)

[29]Under Subpart H regulations, FDA may withdraw a drug's marketing approval after providing for a hearing, in the following circumstances; (1) a postmarketing clinical study fails to verify clinical benefit; (2) the sponsor fails to perform the required postmarketing study with due diligence; (3) use after marketing demonstrates that postmarketing restrictions are inadequate to assure safe use of the drug product; (4) the sponsor fails to adhere to the postmarketing restrictions agreed upon; (5) the promotional materials are false or misleading; or (6) other evidence demonstrates that the drug product is not shown to be safe or effective under its conditions of use. 21 C.F.R. § 314.530 (2007).

GBP-PET01441

Table 1: Timeline of Key Events in FDA's Approval of Mifeprex

Date	Event
First review cycle	
March 1996	The sponsor submitted a new drug application (NDA) for the use of Mifeprex in combination with the drug misoprostol for the medical termination of intrauterine pregnancy.
July 1996	FDA Reproductive Health Drugs Advisory Committee meeting.
September 1996	FDA issued an approvable letter listing issues that the sponsor needed to address before the application could be approved.
Second review cycle	
August 1999	After delays securing a manufacturer, the sponsor completed its responses to FDA's 1996 approvable letter.
February 2000	FDA issued a second approvable letter, listing issues that the sponsor needed to address prior to approval.
Third review cycle	
March 2000	The sponsor completes its responses to FDA's second approvable letter.
September 2000	FDA approved Mifeprex under the restricted distribution provision of Subpart H.
November 2000	Distribution of Mifeprex began in the United States.

Source: GAO analysis of FDA and drug sponsor data.

FDA's Initial Review Cycle and Approvable Action (March to September 1996)

FDA's initial review began when the drug sponsor submitted the Mifeprex NDA in March 1996. After conducting a preliminary review of the NDA, FDA designated the application for priority review, establishing a goal that the agency would issue an action letter within 6 months. FDA's rationale for the designation was that as the first drug that would be approved for its particular indication, Mifeprex was a therapeutic advance because women using the drug could potentially avoid the risks of surgery and anesthesia involved in a surgical termination of a pregnancy.

FDA assigned a team of reviewers within the Division of Reproductive and Urologic Drug Products to review the evidence in the Mifeprex NDA. The key safety and efficacy data in the NDA consisted of three historically controlled clinical trials, two conducted in France and one conducted in the United States. These trials studied the Mifeprex treatment regimen—mifepristone in combination with misoprostol—in a total of more than 4,000 women. At the time the NDA was submitted, the French trials were complete and the U.S. trial was ongoing. As a result, during the first review cycle, the review team analyzed the complete safety and efficacy data from the French clinical trials, but only summary data on serious adverse events

GBP-PET01442

from the U.S. clinical trial. FDA reviewers also considered results from other trials conducted in Europe from 1983 through 1996 in which mifepristone was studied either alone or in combination with misoprostol or similar drugs. In addition, the review team considered safety information from extensive postmarketing experience in Europe, including a postmarket safety database containing information on women who had used mifepristone. Lastly, the review team considered the non-clinical data in the application, including data on the drug's chemistry and manufacturing.

In its review of the Mifeprex data, FDA reviewers determined that the reliance on historical controls in the key clinical trials was appropriate and consistent with FDA regulation. According to FDA, historical control designs can make it more difficult to evaluate which effects can be attributed to the drug being studied.[30] However, FDA regulations list historical controls as an acceptable type of control when the natural history of the condition being treated is well-documented and when the effects of the drug are self-evident.[31] In the case of the Mifeprex NDA, FDA determined that the historically controlled trials provided substantial evidence of safety and efficacy because the outcomes of women taking the Mifeprex regimen were compared with the well-documented data on the natural course of pregnancy, including rates of miscarriage, and the effect of the drug—termination of a pregnancy—was obvious.[32]

To assist the review team in its assessment of Mifeprex, FDA convened the Reproductive Health Drugs Advisory Committee in July 1996 and asked the members to examine the data and vote on their conclusions regarding the drug's safety and efficacy. Six of the eight voting members voted, with

[30]See FDA, *Guidance for Industry: E 10 Choice of Control Group and Related Issues in Clinical Tials* (Rockville, Md.: May 2001).

[31]21 C.F.R. § 314.126(b)(2)(v) (2007). The regulation also states that studies that are "adequate and well-controlled" provide the primary basis for determining whether there is "substantial evidence" in support of the claims of effectiveness for new drugs. Among other things, an adequate and well-controlled study provides sufficient details of study design, conduct, and analysis to allow critical evaluation, and the design must permit a valid comparison with a control to provide a quantitative assessment of the drug's effect.

[32]FDA has cited examples of other drugs that have relied upon historical controls. According to FDA, for contraceptives the effect of the drug can be compared to the well-documented rate of pregnancy in sexually active women between the ages of 15 and 35 in the absence of contraception. For example, FDA approved the contraceptive drug products Lybrel, Implanon, Yaz, and NuvaRing on the basis of historically controlled clinical trials.

GBP-PET01443

two abstentions, that the available evidence demonstrated that the benefits of the regimen outweighed its risks for the proposed indication in the United States. However, the members agreed unanimously that FDA should provide the final safety and efficacy data from the U.S. clinical trial for their review. The advisory committee also discussed the basic elements of a voluntary restricted distribution system proposed by the drug's sponsor, which would require that Mifeprex be distributed directly to physicians, that prescribing physicians meet certain training requirements, and that patients meet certain conditions before receiving the drug. The advisory committee voted unanimously that they agreed with the concept of restricting distribution of the drug but had reservations about how the proposed system would assure that physicians had adequate credentials. The members recommended that the sponsor conduct postmarket studies to address six unanswered questions about the treatment regimen and the distribution system. The members also provided extensive comments on the draft labeling proposed by the sponsor.

The FDA review team concluded that the NDA was approvable, based on its assessment of the clinical and non-clinical data and the input from the advisory committee. The medical officer leading the review team concluded that the available clinical data indicated "that medical abortion can be safely delivered in a wide variety of United States settings." The data from the French trials showed the treatment to be roughly 95 percent effective at terminating pregnancy through 49 days gestation. The data from the French clinical trials also showed that almost all patients experienced some side effects—such as uterine cramping and bleeding—most of which were expected based on the way the drug works. Though serious adverse events were considered rare, some women experienced bleeding that required medical intervention, and approximately 0.2 percent of patients required transfusion. The medical officer concluded that the preliminary U.S. data on adverse events did not appear to differ significantly from the French trials.[33]

[33]The medical officer noted that it was only possible to make general comparisons across these events because definitions and reporting requirements were different in the two countries. Additionally, while the sponsor had not yet completed its analysis of the safety and efficacy data from the U.S. clinical trial, information from the studies was forwarded to the sponsor weekly. The medical officer concluded, based on preliminary examination of this information, that the final results of the U.S. trials were likely to be similar to the results of the French trials.

GBP-PET01444

In September 1996, FDA issued an approvable letter for the use of Mifeprex in combination with the drug misoprostol for the termination of intrauterine pregnancy up to 49 days gestation. In memos documenting concurrence with the review team, and in the approvable letter itself, FDA management outlined the clinical and non-clinical issues the sponsor needed to address prior to approval. First, the full data from the U.S. clinical trial were needed to establish safety and efficacy of the Mifeprex regimen in the U.S. health care setting. Second, FDA agreed with the sponsor's proposal to limit the drug's distribution, but the sponsor had not yet submitted sufficient detail on how it would be implemented to allow for the plan to be fully evaluated.[34] Third, the drug labeling proposed by the sponsor needed to be revised to provide more information on the treatment and to address comments from the advisory committee. Fourth, the sponsor would need to commit to pursue the postmarket studies suggested by the advisory committee. Finally, the sponsor would need to address certain deficiencies in chemistry and manufacturing data identified in FDA's review.

FDA's Second Review Cycle and Approvable Action (August 1999 to February 2000)

FDA's second review cycle for the Mifeprex NDA officially began once the sponsor had completed its responses to the first approvable letter. However, these responses were delayed because of difficulties the sponsor encountered in securing a manufacturer for the drug product. In the interim, the sponsor submitted a range of data to FDA, including the final safety and efficacy results from the U.S. clinical trial, updated safety data from other trials of mifepristone and international postmarketing experience with the drug, formal revisions of the product labeling, and outstanding chemistry and manufacturing data. In August 1999, the sponsor completed its responses to the approvable letter by submitting an overview of the key principles of the restricted distribution system as well as responses to the postmarketing study commitments. At the time of this submission, the sponsor was still working with its planned distributor on the details of the restricted distribution system.

Based on the updated data, the review team recommended approval for the Mifeprex NDA once the sponsor had clarified the details of the drug's distribution, revised the drug labeling, and addressed deficiencies in the

[34]FDA management's concurrence memos noted that because the sponsor had voluntarily proposed a restricted distribution system, imposing restrictions through Subpart H regulations did not appear warranted.

GBP-PET01445

chemistry and manufacturing data. The medical officer concluded that the final results from the U.S. clinical trial were acceptable and confirmed the results of the French trials that the regimen was safe and effective.[35] The medical officer concluded that the comments from the July 1996 advisory committee meeting were fully considered and, to the extent possible, implemented.[36] The medical officer also concluded that additional detail was needed to determine whether the sponsor's proposed distribution plan was sufficient. The non-clinical reviews during this review cycle—which included inspections of manufacturing facilities[37]—identified deficiencies in the drug's chemistry data and manufacturing processes that needed to be addressed, as well as sections of the drug's labeling that needed to be revised.

In January 2000, the sponsor submitted a more detailed plan describing how the proposed distribution restrictions would be implemented. The plan had three key elements. First, the Mifeprex regimen would only be administered under the supervision of qualified physicians who had agreed to provide the treatment according to several guidelines. Specifically, prescribing physicians would be required to attest to being able to accurately assess the duration of a pregnancy, diagnose an ectopic pregnancy,[38] and assure that patients have access to appropriate follow up care if needed to manage complications. The physicians would also need to agree to fully explain the procedure to each patient and obtain her

[35]The U.S. clinical trial data showed the treatment to be 92 percent effective for terminating pregnancy through 49 days gestation, which was slightly lower than the 95 percent from the French trials. Adverse event rates were also slightly higher in the U.S. trials. The medical officer attributed these differences to the relative inexperience of U.S. clinicians with the treatment. In addition, the medical officer concluded that the updated information from international studies, postmarket experience, and the published literature was consistent with the results from the U.S. and French trials.

[36]In November 1999, FDA provided advisory committee members the final results from the U.S. clinical trial for their review and comment. FDA did not receive any comments from the members on these results.

[37]The drug substance (mifepristone) in the Mifeprex product was manufactured by the Shanghai Haulian Pharmaceutical Co., Ltd., with the manufacturing facilities located in China. Initial FDA inspections found the manufacturer not in compliance with FDA's good manufacturing practice standards.

[38]Ectopic pregnancy—which occurs when a fertilized egg improperly implants outside of the uterus—is a contraindication for receiving the Mifeprex regimen. Accurate screening to ensure that patients with an ectopic pregnancy do not receive the treatment was a concern because a ruptured ectopic pregnancy is a life-threatening condition and its symptoms are similar to the side effects of the Mifeprex regimen.

GBP-PET01446

signed consent, record the unique product serial number for tracking purposes, and report any serious adverse event or on-going pregnancy to the sponsor. Second, the drug would only be distributed directly to physicians after an authorized distributor had verified that the physician had registered with it and had a signed attestation on file. Third, patients would be required to meet certain conditions before receiving the drug, such as signing a patient agreement attesting to her understanding of the potential complications of the treatment.

FDA management concluded that the proposed distribution plan did not provide for adequate training and certification of prescribing physicians and needed to be revised before the NDA could be approved. In February 2000, FDA issued a second approvable letter for Mifeprex, notifying the sponsor that it needed to revise its proposed distribution plan, address deficiencies in the drug's chemistry data and manufacturing, and revise the drug's labeling. The letter also stated that FDA had considered the application under the restricted distribution provision of Subpart H and that distribution restrictions would be necessary in order to assure the safe use of the drug. The approvable letter further reminded the sponsor of its commitment to pursue postmarketing study commitments to address questions that were raised at the time of the advisory committee meeting.

FDA's Final Review Cycle and Marketing Approval for Mifeprex (March to September 2000)

In March 2000, the sponsor submitted its complete response to FDA's February 2000 approvable letter. This submission included updated safety data from ongoing trials and international postmarket experience, international product labeling, and revisions to the distribution plan. The sponsor also provided additional data and revisions—including updated chemistry and manufacturing data, a revision to the distribution plan, and revised labeling—to address comments from FDA that arose during the review cycle. The agency's review of these submissions included multiple meetings and teleconferences with the sponsor and input from a consultant who was a special government employee (SGE) and a member of the Reproductive Health Drugs Advisory Committee.[39]

[39]According to FDA, it is not uncommon for the agency to consult with members of its advisory committees who have special expertise in a particular drug under review. Generally, an SGE is defined as an officer or employee who is retained, designated, appointed, or employed by the government to perform temporary duties, with or without compensation, for not more than 130 days during any period of 365 consecutive days. 18 U.S.C. § 202(a).

GBP-PET01447

During the final review cycle, FDA's deliberations—which involved a wide range of agency staff and management, including at times the Commissioner—focused on four key issues: whether prescribing physicians should be required to participate in a formal training and certification program, whether to require that approval be under Subpart H, what conditions of use should be specified, and what postmarketing study commitments would be needed to assure the safe use of the drug.

- Physician Training: In its deliberations, FDA considered requiring that physicians participate in specific training and have their qualifications certified before being allowed to prescribe Mifeprex, as opposed to relying on the sponsor's proposed system of self-attestation. However, FDA concluded that such a requirement was not necessary. FDA officials told us that the agency determined that its concern about ensuring that prescribers were adequately qualified could be addressed by requiring that the sponsor make educational materials and training programs readily available and requiring that prescribing physicians sign an agreement attesting to their qualifications. The SGE consultant agreed with this conclusion. FDA officials also told us that the agency wanted to minimize the burden that the restricted distribution program would place on providers and patients by requiring only what was necessary to address safety concerns.[40]

  In July 2000, the sponsor submitted its revised distribution plan. This plan addressed FDA's comments by providing increased emphasis in the product labeling on the educational materials and trainings available to physicians and the importance of participating in the training. The other key elements of the plan—including the specific qualifications that physicians were required to meet and agreements regarding discussing the treatment and adverse event reporting—were essentially unchanged from those the sponsor proposed in its January 2000 plan.

- Approval under Subpart H Regulations: FDA had maintained through the first two review cycles that distribution restrictions would be required for Mifeprex. However, minutes from meetings between FDA and the sponsor indicate that the agency was still considering whether it was necessary to impose those restrictions under Subpart H during the final review cycle. During the second review cycle, FDA had concluded that the restricted

[40]Subpart H regulations state that any restrictions imposed will be commensurate with the specific safety concerns presented by the drug product. 21 C.F.R. § 314.520(b) (2007).

GBP-PET01448

distribution provision could be applied to Mifeprex.[41] FDA eventually concluded that it would be necessary to do so. In its documented rationale for this conclusion, FDA stated that the drug met the scope of the regulations because the termination of an unwanted pregnancy is a serious condition, and that the drug provided a meaningful therapeutic benefit over existing therapies by allowing patients to avoid the procedure required with surgical termination of pregnancy. FDA officials told us that the agency has broad discretion to determine which conditions or illnesses may be considered serious or life threatening, and that in the case of Mifeprex it considered the potential in any pregnancy for serious or life-threatening complications—such as hemorrhage—in its determination.[42] Additionally, FDA concluded that Mifeprex could only be used safely if distribution was limited to physicians who could assess the duration of a pregnancy, diagnose an ectopic pregnancy, and provide patients with access to surgical intervention if necessary.

Throughout the approval process, the sponsor was opposed to approval under Subpart H. Specifically, the sponsor argued that the drug did not fit within the scope of Subpart H because pregnancy itself is not a serious or life threatening illness. The sponsor also argued that the intent of the restricted distribution provision was to allow for restricted distribution of highly toxic or risky drugs, and that Mifeprex did not fit this description.[43] The sponsor also expressed concern that approving the drug under Subpart H could unfairly mark Mifeprex as risky and deter women from using the drug. Lastly, the sponsor held that imposing Subpart H was unnecessary because it had voluntarily committed to the distribution

[41]FDA had also noted that approving the drug under Subpart H would allow the agency to impose similar restrictions on any future generic mifepristone products approved for the same indication. The patent for Mifeprex expired in October 2004, but as of May 2008, no generic versions of mifepristone have been approved for marketing.

[42]The terms "serious" and "life-threatening" are not defined in Subpart H regulations, but were discussed in the preambles to the proposed and final rules. In its proposed rule, FDA stated that the seriousness of a disease is a matter of judgment, but generally is based on its impact on survival, day-to-day functioning, or other factors, and provided examples of conditions that could be within the scope of the regulation. FDA noted that many diseases or conditions can be serious for some populations in some or all of their phases and explicitly reserved the discretion to determine whether the regulations were applicable to a given product. See 57 Fed. Reg. 13234-5 (Apr. 15, 1992), 57 Fed. Reg. 58942, 58946 (Dec. 11, 1992); See also 21 C.F.R. §§ 312.34, 312.81 (2007), and FDA, *Guidance for Industry: Fast Track Drug Development Programs—Designation, Development, and Application Review* (Rockville, Md.: Jan. 2006).

[43]In support of its arguments about the intent of the regulations, the sponsor cited the pertinent language from preambles to the proposed and final rules. See footnote 42.

GBP-PET01449

restrictions requested by FDA. However, in a September 2000 letter to FDA, the sponsor agreed to FDA's requirement that approval be under Subpart H, while noting that it still believed that applying these regulations to Mifeprex was not appropriate.

- Conditions of Use: FDA reviewed data and held multiple meetings with the sponsor regarding the specific conditions of use that should be required for Mifeprex. For example, FDA deliberated about whether it was necessary to require that prescribing physicians possess the ability to perform follow-up surgical interventions in the event that it was necessary to manage complications. The sponsor maintained that such a requirement was inconsistent with the practice of medicine, because management of incomplete miscarriages was routinely handled by referring patients to outside providers with specialized surgical or emergency care training. On this issue, FDA concluded that access to follow-up care could be ensured by requiring adequate information in the labeling and requiring that physicians attest to having made arrangements for their patients to have access to any needed surgical or emergency care. The SGE consultant agreed with FDA's conclusion. FDA disagreed with the sponsor on other suggested conditions of use. For example, the sponsor provided data to support allowing patients to self-administer the misoprostol dose at home, instead of requiring them to return to their prescribing physicians. FDA concluded that the available data did not support the safety of home use of misoprostol and that such use should not be included in the final product label. As a part of its deliberations about the conditions of use, FDA also concluded that approved labeling should include a medication guide to provide patients with information about the risks and benefits of the drug and the approved conditions of use and treatment regimen.[44]

- Postmarketing Study Commitments: In both the September 1996 and February 2000 approvable letters, FDA had reminded the sponsor of its commitment to conduct a series of six postmarket studies to address comments raised in the 1996 advisory committee meeting. FDA reviewed data and met with the sponsor during the final stages of its review to revisit these commitments in light of experience gained with the treatment regimen since the advisory committee meeting, concerns about potential infringement on the privacy of patients, and the potential resources needed to fulfill all six commitments. FDA concluded that the originally proposed commitments could be sufficiently addressed in two redesigned

[44]FDA may require that a drug be distributed with a medication guide that provides patients with information about the safe and effective use of the drug. See 21 C.F.R. pt. 208 (2007).

GBP-PET01450

studies. The first was a study on the safety outcomes of a group of patients receiving the treatment under the care of physicians with surgical intervention skills compared to physicians who refer their patients for surgical intervention when necessary. The second was a surveillance study to determine the outcomes of ongoing pregnancies that were not surgically terminated after a failure of the Mifeprex regimen, including the health of any children born. FDA also concluded that the outstanding questions could be incorporated into the two postmarket studies and an audit of signed patient agreement forms.

Once the sponsor had addressed the issues that FDA raised during the third review cycle, both the review team responsible for the Mifeprex NDA and FDA management concluded that the drug should be approved. The medical officer concluded that the updated safety data did not reveal any new issues that would change the ratio of benefit-to-risk for the drug. The medical officer also reviewed revised product labeling related to the distribution of the drug. Based on these reviews, the medical officer recommended approval of the application. The non-clinical reviews during this review cycle included additional inspections of manufacturing facilities. After the sponsor had addressed several issues, including deficiencies identified in a second inspection of the drug manufacturing facilities, the non-clinical reviewers also recommended approval of the application. FDA management concurred with the recommendations of the review team that the Mifeprex NDA should be approved.

On September 28, 2000, FDA approved Mifeprex under the restricted distribution provision of Subpart H. The sponsor began distribution of Mifeprex in November 2000. FDA approved the drug with the two postmarketing study commitments discussed above and with several key restrictions on distribution. First, prescribing physicians must sign a prescriber's agreement attesting to possessing the training and skills needed to administer the treatment regimen, and also agreeing to provide patients with the approved medication guide. They must also attest that they will fully discuss the treatment with patients and report to the sponsor any serious adverse events or ongoing pregnancies that are not terminated after a failure of the Mifeprex regimen. Second, the drug must be distributed directly to prescribing physicians by an authorized distributor only after the distributor has verified that the physician has a signed agreement on file. Third, patients must sign a patient agreement attesting to having read, discussed, and understood the risks and potential complications of the treatment. For a more detailed list of the individual components of the restricted distribution program for Mifeprex, see

GBP-PET01451

appendix II. For a copy of the approved prescriber's agreement, see appendix III.

Approval Process for Mifeprex Was Generally Consistent with That of the Other Eight Subpart H Restricted Drugs

Although each drug had unique risks and benefits, the approval process for Mifeprex was generally consistent with the approval processes for the other eight Subpart H restricted drugs. Each of the drugs had unique risks and benefits that were specific to their indication and target populations. For some of the drugs, the safety issues that prompted FDA to apply Subpart H were similar, with the potential for causing birth defects, the potential for liver or other serious toxicities, and appropriate patient selection being the most common issues. However, there were also safe use concerns that were unique to particular drugs. For example, for Mifeprex, ensuring patient access to follow-up care was a key safety concern, while for Actiq a key concern was ensuring that children did not accidentally ingest the drug.[45] Each of the drugs represented potential advances in the treatment of their targeted condition and in two cases—Mifeprex and Xyrem—the drug was the first approved to treat that condition. (See app. I for a table including each of the Subpart H restricted drugs and their approved indications.)

One common element across the approval processes for the Subpart H restricted drugs was that for seven of the drugs, including Mifeprex, FDA needed to evaluate potential limitations in key clinical data supporting the NDA. Specifically, with the exception of Accutane and Lotronex, the drugs were approved on the basis of studies without concurrent controls or data that were limited by relatively small sample sizes or data collection issues.[46] FDA approved the Mifeprex NDA on the basis of historically controlled clinical trials that studied the drug in several thousand patients. FDA concluded that the use of historical controls was not a limitation

[45]Actiq contains the controlled substance fentanyl in a lozenge formulation intended to allow for more rapid delivery of the medication for pain management in patients who have developed a tolerance. Because of the formulation there are concerns that Actiq may be perceived by children as a lollipop.

[46]Both Accutane and Lotronex were approved under Subpart H after they had first been marketed in the United States. In the case of Lotronex, the sponsor withdrew the drug from the market in 2000 because of safety concerns. In 2002, FDA approved a supplemental NDA under Subpart H, allowing the drug to be marketed with a restricted distribution program and substantially more limited indication. For Accutane, which was originally approved for marketing in 1982, FDA approved a supplemental NDA under the restricted distribution provision of Subpart H in 2005 in order to require a more formal restricted distribution program that linked Accutane prescribing and dispensing to pregnancy testing results.

GBP-PET01452

because the course of pregnancy was well-documented and the effect of the treatment was self-evident. Revlimid, Thalomid, Plenaxis, and Xyrem were also each approved on the basis of data that included at least one key clinical study that lacked a concurrent control.[47] In contrast to the Mifeprex data, FDA concluded that the lack of concurrent controls in these studies was a weakness because data on the course of the disease in a comparable population was not available to be used as a reliable historical control. For example, Thalomid was approved on the basis of clinical trial data from the published literature as well as a series of retrospective case studies for several dozen patients.[48] Additionally, five of the drugs—Actiq, Revlimid, Thalomid, Tracleer, and Xyrem—were approved on the basis of key clinical studies with relatively small sample sizes of several hundred patients or less. Finally, for Actiq, Plenaxis, Thalomid, and Xyrem, FDA identified data collection issues, such as incomplete documentation, in some of the key data sources.

Another common element was that for six of the drugs, including Mifeprex, FDA issued at least one prior action letter before ultimately approving the drug for marketing. FDA issued one approvable letter before ultimately approving Thalomid and Tracleer. Both Mifeprex and Xyrem received two approvable letters. In some cases the types of issues FDA cited—such as insufficient safety or efficacy data, the need for additional information on the restricted distribution system, or chemistry and manufacturing issues—were similar. For all four of these drugs, the adequacy of proposed distribution restrictions was a significant issue. For Xyrem, FDA's initial approvable action was also linked to the sufficiency of the data provided in the application. FDA issued not approvable letters for both Actiq and Plenaxis prior to their eventual approval. In the case of Actiq, FDA cited multiple deficiencies, such as reliance on a key clinical study with flaws and an inadequate plan for risk management. For Plenaxis, FDA initially concluded that the risks of the drug exceeded its

[47]FDA approved Plenaxis on the basis of one uncontrolled clinical trial in the indicated population—men with advanced symptomatic prostate cancer—and three concurrently-controlled clinical trials in men with less advanced prostate cancer. FDA approved Xyrem on the basis of one uncontrolled key safety trial, and two concurrently-controlled clinical trials.

[48]FDA considers such case studies to be historically controlled. In this case, the reviewing division concluded that the data were not sufficient to demonstrate the safety and efficacy of Thalomid. However, that decision was overridden by both the Director of the relevant FDA office and the Director of FDA's Center for Drug Evaluation and Research, based on their individual analyses of the available data.

GBP-PET01453

benefits because of the potential for severe, systemic allergic reactions in patients.

As a result of these complexities, the approval process for the Subpart H restricted drugs was typically longer than the process for other drugs. Across the seven drugs with NDAs approved under Subpart H, an average of almost 25 months elapsed from the time that the sponsor submitted its NDA to the time FDA approved the NDA. The length of time to approval ranged from almost 9 months for Revlimid to more than 54 months for Mifeprex. In comparison, in analyses conducted for our 2006 report on new drug development, we found that it took FDA on average almost 18 months to approve NDAs submitted from 1996 through 2002.[49]

We also found that the types of distribution restrictions FDA imposed on Mifeprex were similar to those imposed on the other Subpart H restricted drugs, though the specifics of the restrictions depended on FDA's safe use concern for the drug.[50] (See table 2.) For all of the drugs except Actiq, FDA required some form of program enrollment or registration process. For example, for Mifeprex and three other drugs, FDA required that patients sign written agreements and that physicians enroll in a prescribing program and attest to their qualifications. For five of the drugs, FDA required formal registries of all prescribing physicians and patients.[51] Additionally, for seven of the drugs, FDA required that distribution be limited to authorized distributors or pharmacies.[52] And for eight of the

[49]See, GAO, *New Drug Development: Science, Business, Regulatory, and Intellectual Property Issues Cited as Hampering Drug Development Efforts*, GAO-07-49. (Washington, D.C.: Nov. 17, 2006). In contrast, the drugs approved under the surrogate endpoint provision of Subpart H have generally been approved more rapidly than drugs approved under the restricted distribution provision of Subpart H and than drugs approved outside of Subpart H.

[50]Additionally, except for Plenaxis, FDA convened a meeting of the relevant advisory committee prior to each drug's approval under Subpart H to obtain expert input regarding the appropriate actions to address the agency's safe use concerns, including the distribution restrictions that should be required. The advisory committee meetings that FDA has held for the drugs Accutane and Lotronex occurred after each drug was first marketed in the United States, but prior to their approvals under Subpart H.

[51]FDA has used various types of registries as a mechanism to collect data on patients, providers, and others as a tool for monitoring outcomes of interest.

[52]Two of the drugs—Actiq and Xyrem—were approved as controlled substances and therefore subject to the restrictions imposed by the Controlled Substances Act. Requirements imposed under this act are enforced by the Drug Enforcement Administration and are distinct from the distribution restrictions imposed on these drugs by FDA under Subpart H. See, e.g., 21 U.S.C. § 822; 21 C.F.R. § 1301.11 (2007).

GBP-PET01454

drugs, FDA required that the sponsor establish a process to ensure that dispensing or distribution of the drug was contingent on verification that physicians and others had enrolled or registered in the distribution program, or that patients had complied with certain safety measures. FDA also required that all of the sponsors implement some form of educational program for patients, prescribers, or pharmacists, though FDA did not require that prescribing physicians participate in formal training for any of the drugs. For six of the nine drugs, FDA required that the sponsor report periodically to the agency specifically on implementation of their restricted distribution programs. For seven of the drugs, FDA required that sponsors report to the agency on specific adverse events—such as fetal exposures or liver toxicity—more frequently than is required for other drugs. In the case of Mifeprex and Xyrem, at the time the drugs were approved, FDA did not require that the sponsors submit additional adverse event reports beyond those required for all approved drugs, but did require that physicians agree to report specific types of adverse events to the sponsor.

Table 2: Selected Features of Restricted Distribution Programs Imposed by FDA at Time of Approval under Subpart H

Features Required at Approval	Mifeprex (mifepristone)	Lotronex (alosetron hydrochloride)	Actiq (oral transmucosal fentanyl citrate)	Thalomid (thalidomide)	Tracleer (bosentan)	Xyrem (sodium oxybate)	Plenaxis (abarelix for injectable suspension)	Revlimid (lenalidomide)	Accutane (isotretinoin)

Additional adverse event reporting by the sponsor[e]		✓	✓	✓	✓		✓	✓	✓

Source: GAO analysis of FDA data.

GBP-PET01455

[a]Program enrollment or registration requirements varied across the drugs. For Accutane, Lotronex, Mifeprex, and Plenaxis, FDA required that physicians enroll in a prescribing program and attest to their qualifications. For Accutane, Revlimid, Thalomid, Tracleer, and Xyrem, FDA required formal registries of all prescribing physicians and patients. FDA also required registration of pharmacies, wholesalers, or distributors for Thalomid, Revlimid, and Accutane.

[b]The specific limitations imposed on distribution channels varied across the drugs, and in some cases more than one limitation was required. These limitations included, for example, requiring that a drug only be distributed directly to prescribing physicians, allowing only authorized distributors or wholesalers to ship a drug, and allowing only registered or centralized pharmacies to dispense a drug.

[c]The verification mechanisms varied across the drugs. For example, for Mifeprex, an authorized distributor must verify that a physician has a signed prescriber agreement on file before distributing the drug. For Lotronex, before dispensing and drug, pharmacists must verify that prescriptions include a sticker that is only available to physicians enrolled in the prescribing program. For Accutane, Revlimid, and Thalomid, a registered pharmacy is required to confirm prescription authorizations and that patients have complied with requirements to use one or more methods of contraception before dispensing the drug.

[d]In general, sponsors were required to develop educational materials (such as patient information videos) for patients, and make educational materials and training programs readily available to prescribing physicians, pharmacists, and other groups involved in the restricted distribution program. For some of the drugs, dispensing pharmacists were required to participate in formal training. At the time of Subpart H approval, FDA required medication guides for all of the drugs except Actiq, Plenaxis, and Thalomid.

[e]Sponsors for seven of the drugs were required to submit 15-day alert reports on specific adverse events. Sponsors of four of the drugs were required to provide updates more frequently than typically required for events related to FDA's safe use concern for the drug. For Mifeprex, as part of their prescriber agreement, physicians agreed to report ongoing pregnancies, hospitalizations, transfusions, and other serious events to the sponsor. For Xyrem, FDA required that physicians agree to collect and report to the sponsor information on specific adverse events and inappropriate use of the drug.

Finally, eight of the nine Subpart H restricted drugs were approved with two or more postmarketing study commitments.[53] Each of these had at least one commitment that involved developing a postmarket study to monitor adverse events or patient outcomes of interest for that drug. The number of study commitments FDA required ranged from 2 to 10, depending on the drug. Additionally, for most of the drugs, including Mifeprex, the study protocols for the various commitments had not been finalized at the time of approval.

[53]FDA's approval of Accutane under Subpart H through a supplemental NDA did not include any postmarket study commitments.

GBP-PET01456

FDA's Postmarket Oversight of Mifeprex Has Been Consistent with the Agency's Oversight of the Other Subpart H Restricted Drugs

The actions FDA has taken to oversee Mifeprex have been consistent with the actions it has taken to oversee the other Subpart H restricted drugs. FDA has relied primarily on information submitted by the sponsors of all the Subpart H restricted drugs and inspections for three of the drugs to oversee compliance with restricted distribution requirements. FDA has also relied on updates submitted by these sponsors to oversee compliance with postmarketing study commitments and has found that most have unfulfilled commitments. To oversee compliance with adverse event reporting requirements, FDA has reviewed a variety of safety information including reports submitted by the sponsors of all nine of the drugs restricted under Subpart H and has conducted inspections to evaluate compliance with reporting of adverse events for eight of the drugs. As a result, for most of the drugs, FDA has identified deficiencies in compliance with adverse event reporting requirements. To oversee reported adverse events FDA has used similar methods—such as monitoring, investigating, and addressing safety concerns—for Mifeprex and the other eight Subpart H restricted drugs. As a result of its oversight of safety data, FDA has identified postmarket safety concerns for most of the drugs and has used a variety of methods to communicate safety information to health care providers and the public. (See table 3 for an overview of FDA's postmarket oversight of these drugs.)

GBP-PET01457

Table 3: Selected Features of FDA's Oversight of Postmarket Safety for Drugs Approved under Subpart H, as of May 2008

Oversight Activities and Findings	Mifeprex (mife-pristone)	Lotronex (alosetron hydro-chloride)	Actiq (oral transmucosal fentanyl citrate)	Thalomid (thalidomide)	Tracleer (bosentan)	Xyrem (sodium oxybate)	Plenaxis (abarelix for injectable suspension)	Revlimid (lenali-domide)	Accutane (isotretinoin)

Source: GAO analysis of FDA data.

Note: FDA provided or confirmed data on these selected features of oversight through May 2008.

[a]In May 2008, FDA officials told us that they had conducted such inspections for three additional drugs. However, the reports from those inspections were not yet available. Inspections were in addition to report review.

[b]FDA classifies unfulfilled postmarketing study commitments as ongoing, pending, delayed, released, or terminated; FDA has documented that the sponsor for Xyrem has fulfilled two of its postmarketing study commitments and has submitted the final report for the third and final commitment.

[c]Inspections were in addition to report review conducted for all of the drugs. In the case of Revlimid, FDA inspected Celgene—the sponsor of both Revlimid and Thalomid—before Revlimid was approved in December 2005.

GBP-PET01458

[d]Communication of new safety information includes activities such as changing product labeling, issuing Public Health Advisories and Safety Alerts, and distributing letters to health care providers.

To Oversee Compliance with Distribution Restrictions, FDA Relied on Information Submitted by All Drug Sponsors and Its Own Inspections for Some of the Drugs, Including Mifeprex

For all nine of the drugs that have been approved under the restricted distribution provision of Subpart H, FDA has relied mainly on information submitted by sponsors in required reports to oversee the sponsors' compliance with distribution restrictions. For six of the drugs—not including Mifeprex—FDA relied on reports specific to the drugs' restricted distribution programs.[54] The type of information provided by the sponsors in these documents included data on the operation of the restricted distribution program, such as requirements for distributors, pharmacies, prescribers, and patients participating in the program. In addition, to oversee compliance with the restricted distribution programs for most of the drugs—including Mifeprex—FDA has relied on annual reports, supplemental applications, or periodic reports for required updates on the postmarket use of the drugs, including summaries of updates to the restricted distribution program.[55]

Through the end of 2007, FDA had conducted inspections specifically to oversee sponsors' compliance with distribution restrictions for three of the drugs—Mifeprex, Tracleer, and Xyrem. In the case of Mifeprex, in 2002 FDA conducted routine inspections of two of the drug's distributors to oversee their compliance with distribution restrictions. FDA inspectors reviewed standard operating procedures and other information in order to oversee adherence to the requirements of the restricted distribution program such as procedures for maintaining signed provider agreements, distributing medication guides with shipments of the drug, and maintaining the physical security of the drug. For one of the inspections of Mifeprex distributors, FDA did not issue a citation. For the other inspection, FDA issued a citation in which the agency cited four

[54]FDA approved six of the nine Subpart H restricted drugs with a requirement that the sponsor report periodically to FDA specifically on implementation of the respective restricted distribution program. Under FDAAA, sponsors of all drugs with an approved REMS will be required to submit periodically to FDA an assessment of their REMS. Pub. L. No. 110-85, § 901(b), 823 Stat. 929, 932, *codified at* 21 U.S.C. § 355-1.

[55]Though FDA's Subpart H regulations provide an expedited process for withdrawing marketing approval for a drug if FDA determines that promotional materials are false or misleading, the agency has not done so for a Subpart H drug. See 21 C.F.R. § 314.530(a)(5) (2007). However, it has issued warning letters citing the sponsors for two of the drugs—Thalomid and Tracleer—for promoting unapproved use of the drug in violation of FDA regulations.

GBP-PET01459

inconsistencies between the approved distribution plan and the distributor's standard operating procedures. For example, FDA cited the distributor for the absence of certain written procedures pertaining to the distribution of the drug. The sponsor responded to this citation, noting that at the time of approval the distribution plan did not require that distributors prepare such written procedures. Other examples of the inconsistencies FDA noted were serial numbers that had not been properly recorded on a shipping label as required for tracking purposes and the requirement that a medication guide be provided with each dose of the drug was not reflected in the written procedures for processing orders. As a result of its 2006 inspection of the Tracleer restricted distribution program, FDA did not issue a formal citation, but provided recommendations to the sponsor. In its 2007 inspection of the Xyrem restricted distribution program, FDA did not identify any specific deficiencies.[56] However, many of the responsibilities for the program are contracted out to a pharmacy, which was not inspected. The inspection report notes that, for that reason, FDA could not verify whether the sponsor had fulfilled the requirements for the drug's restricted distribution program.

Although FDA's inspections for Mifeprex and Tracleer led to recommendations for improving the respective restricted distribution programs, through the end of 2007, FDA had not conducted inspections of compliance with restricted distribution requirements for six Subpart H restricted drugs. FDA officials told us that the agency has conducted

[56]FDA's inspection report notes that the sponsor refused to provide FDA access to full reports from audits that the sponsor had conducted to evaluate its contractors' compliance with agreed upon responsibilities under the restricted distribution program.

GBP-PET01460

inspections of compliance with distribution restrictions for three additional drugs since the beginning of 2008.[57, 58]

To Oversee Compliance with Postmarketing Study Commitments, FDA Relied on Sponsors' Data That Found That Most Have Unfulfilled Commitments

For the eight Subpart H restricted drugs approved with postmarketing study commitments, FDA has relied on sponsors' annual reports for updates on the status of each commitment. FDA's reviews of these reports are the basis for its determination of the status of each commitment as fulfilled, submitted, pending, ongoing, delayed, released, or terminated. FDA officials told us that the status of postmarketing study commitments for Subpart H drugs is monitored the same way as those commitments for other drugs.

Seven of the eight Subpart H restricted drugs approved with postmarketing study commitments had at least one commitment that was not fulfilled as of September 2007.[59] Of these seven drugs, most have study commitments that FDA has classified as ongoing, pending, or delayed.[60] In the case of Mifeprex, FDA had categorized both of the drug's postmarketing study commitments—to which the sponsor agreed at time of the drug's approval in 2000—as ongoing until December 2007 when the agency changed the status of one of the commitments to released. For the first commitment—a study to compare outcomes for patients whose

[57]In 2008, FDA conducted initial inspections specific to the restricted distribution programs for Accutane, Actiq, and Revlimid. In addition, FDA conducted a second such inspection for the Tracleer program. As of May 13, 2008, the results from these inspections were not available.

[58]In February 2007, agency officials told us that they were working to establish a process to conduct regular inspections to oversee sponsors' compliance with distribution restrictions for Subpart H restricted drugs. Since that time, agency officials told us that FDA had decided to combine the inspection of restricted distribution programs with inspections examining compliance with adverse event reporting requirements. However, agency officials noted in May 2008 that FDA is reevaluating its process for conducting inspections in light of recent legislative changes. Under FDAAA, FDA is required to evaluate, at least annually, for one or more drugs that have elements to assure safe use as part of their REMS, whether those elements assure the safe use of the drug, are not unduly burdensome on patient access, and to the extent practicable minimize the burden on the health care delivery system. 21 U.S.C. § 355-1(f)(5)(B).

[59]FDA has documented that the sponsor for Xyrem has fulfilled two of its postmarket study commitments and has submitted the final report for the third and final commitment.

[60]In its June 2006 report on FDA's management of postmarket studies, the Department of Health and Human Services Office of the Inspector General found that it is common across all drugs approved by FDA with postmarket study commitments for sponsors to have unfulfilled commitments.

GBP-PET01461

health care providers perform a surgical abortion with outcomes for patients who are referred to another facility for follow-up care in the event of treatment failure—the sponsor has reported difficulty in enrolling participants into the study. FDA told us that according to the sponsor, the "vast majority of prescribers" can provide surgical abortion services on site. FDA has opted not to terminate the study, and has categorized it as ongoing. FDA officials told us that this gives the agency additional flexibility in the event that provider or practice patterns change over time, making enrollment of study participants more feasible. The sponsor also has reported enrollment challenges in the case of the second study commitment for Mifeprex—to conduct surveillance of ongoing pregnancies following failure of treatment. FDA officials told us that postmarket experience with the drug has shown that most patients opt to have a surgical abortion in the event that the Mifeprex regimen is not successful in terminating the pregnancy. In December 2007, FDA released the sponsor from this commitment because it determined that the study will no longer provide helpful information because of low enrollment.

FDA has worked with some of the sponsors of the Subpart H restricted drugs to make adjustments to agreed upon commitments that have not been completed.[61] FDA officials told us that the agency has in some cases made changes to a sponsor's postmarketing study commitments or requested new commitments in addition to those specified at approval. For example, FDA recommended several additional postmarketing study commitments for Thalomid following the agency's approval of an expanded indication for the drug. In the case of Tracleer, FDA recommended changes to some of the drug's study commitments. FDA had not requested additions or changes to the postmarketing study commitments for Mifeprex until the agency released the sponsor from its commitment to conduct surveillance of ongoing pregnancies following failure of treatment.

[61]FDA may withdraw approval of a drug approved under Subpart H if a sponsor does not carry out its required postmarketing studies with due diligence. 21 C.F.R. § 314.530(a)(2) (2007). According to FDA, the regulations only require postmarketing study commitments for drugs approved under the surrogate endpoint provision (21 C.F.R. § 314.510) and not for drugs approved under the restricted distribution provision (21 C.F.R. § 314.520). FDAAA provides FDA with additional authority with regard to requiring postmarketing studies and/or trials. See 21 U.S.C. § 355(o)(3).

GBP-PET01462

To Oversee Compliance with Adverse Event Reporting Requirements, FDA Reviewed Sponsors' Data, Conducted Inspections and Identified Deficiencies for Most of the Drugs

To oversee compliance with adverse event reporting requirements, FDA has both reviewed data submitted by sponsors in required reports and conducted inspections. Sponsor reporting for the drugs has included annual reports in which the sponsor provided a summary of the adverse events reported in the previous year; periodic update reports which inform FDA of adverse events monthly, quarterly, or at some other interval established by FDA; and 15-day alert reports for events that are both serious and unexpected. In addition, in some cases sponsors have agreed or FDA has required them to provide 15-day alert reports for other types of serious adverse events. For example, the sponsor of Mifeprex agreed to provide 15-day alert reports for cases of serious infection and ruptured ectopic pregnancy in women who used the drug, and FDA required the sponsor of Thalomid to report suspected or confirmed pregnancy in women taking that drug.[62] In some cases, including for Mifeprex, FDA specifically documented its assessments of adverse event reporting contained in annual, periodic update, or 15-day alert reports or reports submitted to the AERS database. FDA officials told us that staff review all submitted reports, but do not always document their reviews.

In addition to relying on reports submitted by the sponsors, FDA has conducted inspections specifically to oversee the sponsors' compliance with adverse event reporting requirements for eight of the nine drugs, including Mifeprex.[63] Between 2001 and May 2008, FDA had conducted 19 such inspections with a range of none to four inspections conducted for each drug.[64] In the case of Mifeprex, FDA has conducted three inspections—in 2002, 2004, and 2006—related to adverse event reporting. In these inspections, FDA reviewed a variety of documents pertaining to adverse event reporting for Mifeprex, including standard operating procedures, product labeling, MedWatch reporting forms, 15-day alert

[62]Mifeprex labeling specifically cautions against the use of the drug in women with ectopic pregnancy. The sponsor has noted that the condition is not an adverse drug experience as FDA defines the term.

[63]As of May 2008 FDA had not conducted an adverse event reporting inspection for the sponsor of Revlimid since this drug was approved under Subpart H. The agency inspected Celgene—the sponsor of Revlimid and Thalomid—in 2001, 2002, 2004, and 2005, but these inspections occurred before Revlimid was approved in December 2005. FDA officials told us they did not have specific goals for how frequently sponsors are inspected to monitor compliance with adverse event reporting requirements.

[64]These inspections include two inspections of the sponsor of Accutane (isotretinoin). FDA conducted an additional four adverse event reporting inspections of sponsors or the manufacturer of generic isotretinoin products.

GBP-PET01463

reports, complaint file, periodic update reports on adverse events, and annual NDA reports. In addition, FDA documented reviews of samples of the sponsor's adverse event reports for completeness, accuracy, and timeliness.

As a result of the Mifeprex inspections, FDA issued citations for deficiencies related to the accuracy, completeness, or timeliness of some reports as well as for the sponsor's failure to follow certain procedures for handling some adverse event follow-up activities. In each of the Mifeprex inspections, FDA identified some examples of misclassified reports—events which FDA said should have been submitted as 15-day alert reports rather than in periodic reports. For example, FDA cited the sponsor for not classifying some events resulting in hospitalization as serious events and thus not reporting those events as 15-day alert reports. In another inspection, FDA found that some of the sponsor's procedures for reporting and following up on adverse events were inadequate or had not been developed. These deficiencies were similar to those FDA found for other drugs, and FDA identified fewer problematic reports for Mifeprex than for some of the other Subpart H restricted drugs. Following each of the inspections for Mifeprex, the sponsor provided a written response to FDA in which it either agreed to address FDA's findings or noted its disagreement with the deficiencies FDA cited. For example, following the first inspection, the sponsor agreed to address the examples of misclassified or incomplete reporting FDA cited and to reinforce procedures for handling adverse event-related correspondence with its staff. In some cases the sponsor disagreed with FDA's characterization of a deficiency or presented evidence to refute a claim that it had not complied with a reporting requirement or procedure.

As a result of FDA's inspections for the other seven drugs, the agency issued written citations to six of the sponsors for deficiencies. In addition, FDA noted only "oral observations" for the other sponsor. Similar to the Mifeprex inspections, FDA staff reviewed information such as sponsor documentation and standard operating procedures related to adverse event reporting for the other seven drugs for which it conducted inspections. As it did for the Mifeprex inspections, FDA reviewed samples of adverse event reports for completeness, accuracy, or timeliness for most of the other drugs. As it did with Mifeprex, FDA cited some sponsors for deficiencies such as incomplete or late reporting of adverse events or failure to adhere to certain procedures for reporting. For example, FDA cited the sponsor of Thalomid for failure to submit several reports of serious and unexpected adverse events as a 15-day alert report and for late reporting of some other adverse events that included deaths and

GBP-PET01464

hospitalizations. In addition, FDA issued an untitled letter to the sponsor citing its failure to review and submit 82 reports of serious and unexpected adverse events within the required time frame.

FDA was not always consistent in how it documented deficiencies in adverse event reporting. In some of its inspections FDA documented the same type of deficiency as a citation while in others it noted them as oral observations or discussion points. For example, FDA did not issue a citation for the sponsor of Tracleer after inspectors noted 52 late 15-day reports—instead discussing the late reports with the sponsor at the close of the inspection. However, in its first inspection of the sponsor for Mifeprex, FDA issued a citation for failure to file a single 15-day report within the required 15 days. FDA also cited the sponsor for 6 late 15-day reports in each of its two subsequent inspections, although the sponsor refuted this finding in written responses following each inspection. As in the case of Mifeprex, sponsors responded to FDA in writing to describe actions they had taken to address deficiencies or to disagree with FDA's conclusions following an inspection.

To Oversee Postmarket Safety, FDA Used Similar Methods to Review Reported Adverse Events and Took a Variety of Actions in Response to Emerging Concerns

FDA has used similar methods to oversee postmarket safety—monitoring, investigating, and taking action on emerging safety concerns—for Mifeprex and the other eight Subpart H restricted drugs. For Mifeprex, FDA has routinely reviewed the available information on reported adverse events from sources such as annual reports, periodic update reports, 15-day alerts, and data from its AERS database. Since the time Mifeprex was approved, FDA has documented regular reviews and summarized the available data on adverse event reports to monitor the drug's safety. FDA believes that, because the distribution system for Mifeprex requires that prescribing physicians agree to report hospitalizations and other serious adverse events, it is unlikely there are significant numbers of these events that are not reported to FDA. However, FDA acknowledges that because the reporting system is voluntary, the agency cannot be certain that they have reports of all serious adverse events.

FDA officials have concluded that, with the exception of the cases of fatal infection, the reported serious adverse events associated with Mifeprex have been within or below the ranges expected based upon the medical literature on adverse events following medical abortion. In its May 2006

GBP-PET01465

response to congressional inquiries regarding Mifeprex,[65] FDA stated that the most commonly reported serious adverse events had been blood loss requiring a transfusion, infection, and ectopic pregnancy. FDA estimated that 0.023 percent of U.S. women who had taken Mifeprex have required transfusion, compared to a transfusion rate of 0.15 percent observed in international studies of the drug. FDA also noted that the rate of ectopic pregnancy among U.S. women who had used Mifeprex was 0.005 percent, compared to the overall rate of 1.3 to 2 percent in all U.S. pregnancies. Based on the medical literature, FDA estimated that fewer than 1 percent of patients will develop an infection of any kind following medical abortion with Mifeprex.

According to FDA, as of May 2008, among the estimated 915,000 U.S. women who had taken Mifeprex for termination of pregnancy since its approval, the agency was aware of seven deaths that may be related to the use of the drug.[66] Six of the deaths were due to severe infection, and one death involved an undiagnosed ectopic pregnancy. Of the cases involving infection, five of the women were infected with a rare bacterium, *Clostridium sordellii*, while one woman was infected with the bacterium *Clostridium perfringens*. With assistance from the Centers for Disease Control and Prevention (CDC) and other outside experts, FDA has investigated all reported infection-related deaths in U.S. women who have taken the Mifeprex regimen for termination of pregnancy. These investigations included requesting the medical records and autopsy reports for each case; evaluating available adverse event data from the United States, the United Kingdom, and the World Health Organization; consulting with scientific experts and health care providers from inside and outside FDA; and microbiological testing to identify the bacterium involved. In addition, FDA evaluated samples from the drug lots of Mifeprex and misoprostol associated with some of the deaths to test for contamination with the bacteria.[67] FDA found that in the six cases of death

[65]FDA statement to the Subcommittee on Criminal Justice, Drug Policy, and Human Resources, Committee on Government Reform, May 17, 2006.

[66]In her testimony to Congress on May 17, 2006, Dr. Janet Woodcock stated FDA was aware of five infection-related deaths in U.S. women. In the course of GAO's research for this study, FDA reported that an additional infection-related death occurred in 2007. In her testimony, Dr. Woodcock also discussed three other cases of deaths in U.S. women who had taken Mifeprex that, following investigation, were determined unlikely to be related to the use of the drug. In addition, she discussed three women in other countries whose deaths were related to the use of mifepristone and misoprostol for medical abortion.

[67]The product tracking provision of the restricted distribution program for Mifeprex enabled FDA to locate the lot numbers for the drugs administered in each of the cases.

GBP-PET01466

due to infection, the women used a regimen of Mifeprex and misoprostol that has not been approved by FDA.[68] FDA has stated that it is aware that many health care providers use modified regimens, and while some of the regimens have been described in the medical literature, FDA has not evaluated the safety and effectiveness of any other regimen than the one described in the drug's approved labeling.

To further explore the nature of the infections, FDA initiated an interagency scientific workshop in May 2006 with CDC and the National Institutes of Health entitled "Emerging Clostridial Disease." These agencies had observed a general increase in the United States in reports of serious clostridial infections including infections in women who had used Mifeprex, that raised questions about *Clostridium's* relationship to fatal illness and pregnancy. According to the meeting minutes, participants discussed recent cases of clostridial infection—including those occurring among women who had taken Mifeprex and misoprostol for termination of pregnancy and those who had not—reviewed what was currently known about these infections, and discussed how to conduct surveillance to ensure that cases and trends of clostridial infections are monitored. At the workshop, a CDC official reported on the history of clostridial infections, including a cluster of ten fatal cases reported in the literature between 1977 and 2001 among previously healthy women. Of the ten cases, eight of the women became infected following childbirth, one became infected following a medical abortion, and the other case was unrelated to pregnancy.

As a result of its investigative efforts, FDA has concluded that the evidence does not indicate that Mifeprex caused the fatal infections. In response to congressional inquiry, FDA stated that "the nature of the relationship between taking a single dose of the drug and the reported cases of serious infection with a rare bacterium is highly uncertain."[69] Laboratory testing of samples from the drug lots of Mifeprex and misoprostol associated with some of the deaths due to infection has

[68]In the case of five of the deaths in the U.S. due to infection, the women used an oral dose of Mifeprex, followed by a dose of misoprostol taken intravaginally. In the other case of death due to infection, the woman used an oral dose of Mifeprex followed by a dose of misoprostol taken by inserting it in the pouch of the cheek. The regimen approved by FDA calls for swallowing doses of both Mifeprex and misoprostol.

[69]See FDA letter to Representative Mark E. Souder, then-Chairman of the Subcommittee on Criminal Justice, Drug Policy, and Human Resources, Committee on Government Reform, U.S. House of Representatives, July 31, 2006.

GBP-PET01467

shown no evidence of contamination with the bacteria.[70] FDA officials have said that the relationship between the infections and the use of unapproved regimens of Mifeprex and misoprostol remains unknown. Some research has suggested that the use of Mifeprex may suppress the immune system which could lead to infection. However, FDA has noted that if this were the case, the agency would expect to see a higher rate of other types of serious infections in patients who had used the drug, which has not been the case. FDA has noted that findings by the CDC and in the medical literature suggest that pregnancy itself—rather than the medication—may be the critical risk factor for women who have become infected with *Clostridium sordellii*.

FDA, working with the drug's sponsor, has taken a variety of steps—such as issuing warnings and making changes to the product labeling—to address safety concerns for Mifeprex that were identified through postmarket monitoring and investigation. For example, in response to reports of ruptured ectopic pregnancy, FDA developed a questions and answers document about the condition and worked with the drug's sponsor to alert health care providers and to highlight the importance of careful screening for the condition. In addition, FDA approved a labeling change to provide information about the importance of evaluating patients for ectopic pregnancy. In response to concerns about serious infections and associated deaths—all of which involved an off-label use of the drug—FDA issued Public Health Advisories to notify healthcare providers about patient deaths and the treatment regimens used in those cases, and to remind them of the regimen FDA has approved, and that FDA has not established the safety of alternative regimens. In addition, FDA issued a news release, reviewed letters from the sponsor to health care providers and emergency room directors to alert them to the safety concerns regarding serious infection, and approved changes to product labeling including revisions to the warning to include information about the deaths due to serious infection.[71] FDA also has established a Web site with information about Mifeprex, questions and answers about the drug, and

[70]FDA officials told us that the agency did not test for bacterial contamination of the specific lot associated with the most recent death because examination of the prior lots revealed no contamination.

[71]FDA officials told us that the sponsor distributed a letter to all health care providers who had signed the prescriber's agreement as of the time of the distribution of the letter and distributed a letter to all emergency room directors in the United States.

GBP-PET01468

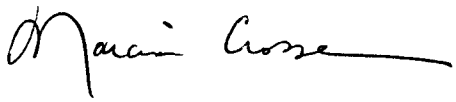
links to other safety-related information.[72] FDA used labeling changes—including updating the medication guide that prescribers agree to discuss with their patients—and information posted on its Web site to remind consumers and health care providers that FDA has not assessed the safety and efficacy of any regimen other than the one approved for the drug and indicated in its labeling.

FDA has similarly monitored adverse events for the other Subpart H restricted drugs. As FDA has done with Mifeprex, the agency has documented periodic safety reviews of the available information it had on reported adverse events for all of the other drugs. FDA's reviews analyzed data on reported adverse events from sources such as annual NDA reporting, periodic update reports, 15-day alerts, and data from the AERS database. Some FDA reviews summarized the available data on a specific type of adverse event—like liver toxicity, or severe bleeding—or adverse events in general, in order to determine whether the data suggest an emerging safety concern for the drug. In addition, in some cases, as it did with Mifeprex, FDA has sought the advice and assistance of other federal agencies and outside experts to investigate serious adverse events.

As a result of its monitoring activities, FDA has identified postmarket safety concerns for most of the Subpart H restricted drugs and has taken similar actions to address them. When FDA has found safety concerns related to a Subpart H restricted drug, it has worked with the drug's sponsor to employ a variety of measures to ensure the drug's safe use. These have included adding or strengthening a warning on the label, issuing a Public Health Advisory, and sending letters to health care providers to alert them to a safety risk. FDA has approved safety-related labeling changes, such as boxed warnings, for eight of the nine drugs. In the case of four of the drugs, including Mifeprex, the agency issued a Public Health Advisory or Safety Alert. The sponsors of five of the drugs including Mifeprex sent a letter to health care providers who prescribe (or may prescribe) the drug to alert them of safety concerns or to communicate new information regarding the drug. For example, in the case of Tracleer, adverse event reports revealed an increased risk of liver damage in patients who were treated with the drug. As a result, FDA and the sponsor notified health care providers of the risk by issuing a Safety Alert, highlighting the need for continued monitoring of liver function in

[72]FDA's Web site for Mifeprex safety information is located at: http://www.fda.gov/cder/drug/infopage/mifepristone/default.htm

GBP-PET01469



patients using the drug. The sponsor added a boxed warning about potential liver injury to the labeling and issued a letter to health care providers to alert them to the potential risk. In general, the actions FDA took in response to safety concerns were similar across all of the drugs.

Agency Comments

We provided HHS with a draft of this report for review. HHS informed us that it did not have general comments on the draft report. In addition, HHS provided technical comments, which we incorporated as appropriate.

As we agreed with your offices, unless you publicly announce the contents of this report earlier, we plan no further distribution of it until 30 days from the date of this letter. We will then send copies to others who are interested and make copies available to others who request them. In addition, the report will be available at no charge on GAO's Web site at http://www.gao.gov.

If you or your staffs have any questions about this report, please contact me at (202) 512-7114 or crossem@gao.gov. Contact points for our Offices of Congressional Relations and Public Affairs may be found on the last page of this report. GAO staff who made major contributions to this report are listed in appendix IV.

Appendix I: Select Drugs Approved by FDA with Restricted Distribution

Drugs approved under the restricted distribution provision of Subpart H	Condition treated	Application type (year first approved under Subpart H)
Accutane (isotretinoin)	Severe recalcitrant nodular acne.	Supplemental NDA (2005)
Actiq (oral transmucosal fentanyl citrate)	Management of breakthrough cancer pain in patients with malignancies who are already receiving and who are tolerant to opioid therapy.	NDA (1998)
Lotronex (alosetron hydrochloride)	Severe diarrhea predominant irritable bowel syndrome (IBS) in women who have: chronic IBS symptoms (generally lasting 6 months or longer), had anatomic or biochemical abnormalities of the gastrointestinal tract excluded, and failed to respond to conventional therapy.	Supplemental NDA (2002)
Mifeprex (mifepristone)	Medical termination of intrauterine pregnancy through 49 days' pregnancy.	NDA (2000)
Plenaxis (abarelix for injectable suspension)	Palliative treatment of men with advanced symptomatic prostate cancer, with specified risks or symptoms.	NDA (2003)
Revlimid (lenalidomide)	Treatment of a limited subset of patients with transfusion dependent anemia.	NDA (2005)
	Treatment of multiple myeloma patients who have received at least one prior therapy.	Supplemental NDA
Thalomid (thalidomide)	Acute treatment of cutaneous manifestations of moderate to severe erythema nodosum leprosum (ENL) and as maintenance therapy for prevention and suppression of the cutaneous manifestations of ENL recurrences.	NDA (1998)
	Newly diagnosed multiple myeloma.	Two Supplemental NDAs[a]
Tracleer (bosentan)	Pulmonary arterial hypertension.	NDA (2001)
Xyrem (sodium oxybate)	Cataplexy associated with narcolepsy.	NDA (2002)
Select Drugs with restricted distribution imposed outside of Subpart H		**Application type (year first approved)**
Clozaril (clozapine)	Management of severely ill schizophrenic patients who fail to respond adequately to standard drug treatment for schizophrenia.	NDA (1989)
Tikosyn (dofetilide)	Irregular heartbeats (atrial fibrillation and atrial flutter).	NDA (1999)
Trovan (trovafloxacin/ alatrofloxacin)	Serious, life- or limb-threatening infections in an inpatient healthcare setting.	n/a[b] (1997)

Source: GAO analysis of FDA data.

Note: We list each drug by its trade name with its chemical name in parentheses.

[a]These supplemental NDAs were approved under both the restricted distribution and surrogate endpoint provisions of Subpart H.

[b]Trovan was not originally approved with distribution restrictions. Based on postmarket evidence of serious liver injury in some patients, the sponsor agreed to FDA's requests to limit the distribution of Trovan to patients with specific symptoms only in inpatient settings. However, these restrictions were not associated with a supplemental application.

GBP-PET01471

Appendix II: Detailed Description of Distribution Restrictions for Mifeprex

FDA approved Mifeprex with the following specific restrictions on distribution:

- Mifeprex must be provided by or under the supervision of a physician who possesses adequate qualifications and agrees to provide the treatment according to several guidelines. To accomplish this, the system required that prescribing physicians register with an authorized distributor by providing a signed Prescriber's Agreement attesting to the following:
  - Possesses the ability to assess the duration of pregnancy accurately.
  - Possesses the ability to diagnose ectopic pregnancies.
  - Possesses the ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or has made plans to provide such care through other qualified physicians, and are able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
  - Has read and understood the prescribing information about Mifeprex.
  - Will provide each patient with a medication guide and fully explain the procedure to each patient, provide her with a copy of the medication guide and Patient Agreement, give her an opportunity to read and discuss both the medication guide and the Patient Agreement, obtain her signature on the Patient Agreement and sign it as well.
  - Will notify the sponsor or its designate in writing as discussed in the Package Insert under the heading DOSAGE AND ADMINISTRATION in the event of an ongoing pregnancy, which is not terminated subsequent to the conclusion of the treatment procedure.
  - Will report any hospitalization, transfusion or other serious events to the sponsor or its designate.
  - Will record the Mifeprex package serial number in each patient's record.
- Provisions for the physical security of the drug during distribution such as
  - Direct distribution of the drug through select authorized distributors to physicians who have signed the Prescriber's Agreement, which includes providing their medical license number. Distributors are

GBP-PET01472

required to ensure that the physician is registered before distributing the drug.

- Secure manufacturing, receiving, distribution, shipping, and return procedures, including unique serial numbers on packaging and tamper-proof seals.

Appendix III: Prescriber's Agreement for Mifeprex Distribution

The following is the prescriber's agreement at the time of the Mifeprex approval. Under the restricted distribution program for Mifeprex, the agreement is provided—by the sponsor's licensee Danco Laboratories, Inc.—to all providers to be signed and returned before the prescriber can receive any shipments of Mifeprex.

GBP-PET01474

MIFEPREX™
(Mifepristone) Tablets, 200 mg

PRESCRIBER'S AGREEMENT

We are pleased that you wish to become a provider of Mifeprex* (Mifepristone) Tablets, 200 mg, which is indicated for the medical termination of intrauterine pregnancy through 49 days from the first day of the patient's last menstrual period (see full prescribing information). Prescribing Information, Mifeprex Medication Guides and PATIENT AGREEMENT forms will be provided together with your order of Mifeprex.

Prior to establishing your account and receiving your first order, you must sign and return this letter to the distributor, indicating that you have met the qualifications outlined below and will observe the guidelines outlined below. If you oversee more than one office facility, you will need to list each facility on your order form prior to shipping the first order.

By signing the reverse side, you acknowledge receipt of the PRESCRIBER'S AGREEMENT and agree that you meet these qualifications and that you will follow these guidelines for use. You also understand that if you do not follow these guidelines, the distributor may discontinue distribution of the drug to you.

Under Federal law, Mifeprex must be provided by or under the supervision of a physician who meets the following qualifications:

- Ability to assess the duration of pregnancy accurately.
- Ability to diagnose ectopic pregnancies.
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and are able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the prescribing information of Mifeprex. The prescribing information is attached to this letter, and is also available by calling our toll free number, 1-877-4 Early Option (1-877-432-7596), or logging on to our website, www.earlyoptionpill.com.

In addition to these qualifications, you must provide Mifeprex in a manner consistent with the following guidelines.

- Under Federal law, each patient must be provided with a Medication Guide. You must fully explain the procedure to each patient, provide her with a copy of the Medication Guide and PATIENT AGREEMENT, give her an opportunity to read and discuss them, obtain her signature on the PATIENT AGREEMENT, and sign it yourself.
- The patient's follow-up visit at approximately 14 days is very important to confirm that a complete termination of pregnancy has occurred and that there have been no complications. You must notify Danco Laboratories in writing as discussed in the Package Insert under the heading DOSAGE AND ADMINISTRATION in the

event of an on-going pregnancy which is not terminated subsequent to the conclusion of the treatment procedure.

- While serious adverse events associated with the use of Mifeprex are rare, you must report any hospitalization, transfusion or other serious event to Danco Laboratories, identifying the patient solely by package serial number to ensure patient confidentiality.
- Each package of Mifeprex has a serial number. As part of maintaining complete records for each patient, you must record this serial number in each patient's record.

GAO Contact

Marcia Crosse, (202) 512-7114 or crossem@gao.gov.

Acknowledgments

In addition to the contact named above, Martin T. Gahart, Assistant Director; Jill Center; Chad Davenport; and Cathy Hamann made key contributions to this report. Julian Klazkin also contributed.

GAO's Mission

The Government Accountability Office, the audit, evaluation, and investigative arm of Congress, exists to support Congress in meeting its constitutional responsibilities and to help improve the performance and accountability of the federal government for the American people. GAO examines the use of public funds; evaluates federal programs and policies; and provides analyses, recommendations, and other assistance to help Congress make informed oversight, policy, and funding decisions. GAO's commitment to good government is reflected in its core values of accountability, integrity, and reliability.

Obtaining Copies of GAO Reports and Testimony

The fastest and easiest way to obtain copies of GAO documents at no cost is through GAO's Web site (www.gao.gov). Each weekday, GAO posts newly released reports, testimony, and correspondence on its Web site. To have GAO e-mail you a list of newly posted products every afternoon, go to www.gao.gov and select "E-mail Updates."

Order by Mail or Phone

The first copy of each printed report is free. Additional copies are $2 each. A check or money order should be made out to the Superintendent of Documents. GAO also accepts VISA and Mastercard. Orders for 100 or more copies mailed to a single address are discounted 25 percent. Orders should be sent to:

U.S. Government Accountability Office
441 G Street NW, Room LM
Washington, DC 20548

To order by Phone: Voice: (202) 512-6000

Information on Mifeprex Labeling Changes and Ongoing Monitoring Efforts

GAO-18-292

March 2018

FOOD AND DRUG ADMINISTRATION

Information on Mifeprex Labeling Changes and Ongoing Monitoring Efforts

GAO Highlights

Highlights of GAO-18-292, a report to congressional requesters

Why GAO Did This Study

FDA initially approved Mifeprex in 2000 and restricted the drug's distribution to assure its safe use. In 2011, the agency approved a REMS for the drug. In March 2016, FDA approved an application for changes to the indication and dosing regimen for Mifeprex, which were reflected in revised labeling. Other changes included omitting the requirement that the prescriber be a physician. At that time, FDA also made modifications to the REMS. Some have questioned the safety implications of these changes for women using the drug.

GAO was asked to review FDA's relabeling of Mifeprex. GAO describes (1) the information FDA used to make its decisions regarding the relabeling of Mifeprex; and (2) what FDA's monitoring of Mifeprex has revealed, and stakeholders' views of FDA's monitoring and the safety of the drug.

GAO reviewed documents related to Mifeprex's relabeling, including FDA policies and regulations. GAO analyzed adverse event reports related to Mifeprex and reviewed FDA inspection reports of Mifeprex's sponsor. GAO also examined studies and data related to the safety and use of Mifeprex, and obtained information from FDA officials; Mifeprex's sponsor; and 13 stakeholder organizations, including medical associations and advocacy groups selected on the basis of their medical or scientific expertise, relevant publications, or familiarity with the drug's safety.

The Department of Health and Human Services provided technical comments on a draft of this report, which we incorporated as appropriate.

View GAO-18-292. For more information, contact Marcia Crosse at (202) 512-7114 or crossem@gao.gov.

What GAO Found

The Food and Drug Administration (FDA) followed its standard review process when it approved the application and revised labeling reflecting certain changes, including the indication and dosing regimen, for the drug Mifeprex, which is used for the medical termination of early pregnancy. It based its approval on reviews of peer-reviewed published studies, articles, and other information submitted by Mifeprex's sponsor. These studies focused on topics related to the proposed labeling changes, including revision of the dosing regimen, increased gestational age, method of follow-up care, and type of health care provider authorized to prescribe Mifeprex. FDA also received three letters from advocacy groups requesting that FDA revise the Mifeprex labeling in a manner that would reflect clinical practice. In addition, FDA reviewed the Risk Evaluation and Mitigation Strategy (REMS)—a set of restrictions beyond the label that FDA may impose—associated with Mifeprex, and determined it continued to be necessary. FDA also reviewed adverse events—which the agency refers to as any untoward medical event associated with the use of a drug in humans, whether or not the event is considered to be drug related—associated with Mifeprex. It determined that the rates of certain adverse events remained stable and acceptably low. In addition, FDA reviewed information regarding potential risks of specific conditions associated with the use of Mifeprex and revised the labeling accordingly. FDA determined that the information it reviewed supported the changes to the Mifeprex labeling.

FDA has conducted a variety of monitoring activities and these have not identified significant concerns with the safety and use of Mifeprex, in accordance with its approved REMS.

- FDA has conducted three inspections of Mifeprex's sponsor since 2008 regarding adverse event reporting associated with Mifeprex—in 2010, 2014, and 2016—and identified minor deficiencies, such as the use of an outdated reporting form.
- FDA conducted a REMS compliance inspection in 2014 and did not identify any deficiencies.
- FDA identified approximately 4,200 instances of adverse events associated with Mifeprex from September 28, 2000, through June 30, 2017, among the approximately 3.2 million women who have used the drug. FDA identified 20 deaths in this period—a rate much lower than for women who proceeded to live birth. FDA learned of 2 additional deaths associated with Mifeprex since June 30, 2017.

GAO found that the views of stakeholder organizations were mixed regarding FDA's monitoring of Mifeprex. Positive comments included that the agency has a comprehensive monitoring program and a robust adverse event reporting system. Criticisms included that adverse events may be underreported and that FDA may only be aware of a fraction of them. Similarly, stakeholder organizations shared mixed views on the drug's safety. Positive comments included that the mortality rate associated with Mifeprex is extremely low. Safety concerns included that the revised labeling no longer requires patients to have a second visit with a health care provider, and that certain safety issues may be exacerbated by the increased gestational age limit approved by FDA.

U.S. GOVERNMENT ACCOUNTABILITY OFFICE
441 G St. N.W.
Washington, DC 20548

March 28, 2018

Congressional Requesters

The prescription drug Mifeprex, in combination with the prescription drug misoprostol, is used for the medical termination of early pregnancy. The Food and Drug Administration (FDA), an agency within the Department of Health and Human Services (HHS), initially granted marketing approval of Mifeprex in September 2000. As a condition of the drug's approval, FDA imposed restrictions on the distribution of Mifeprex under its general authority to help assure the safety and effectiveness of new drugs.[1] More than 3 million women in the United States are estimated to have used this drug.

We have previously reported on FDA's approval of Mifeprex and its oversight of the drug's safety, including the restrictions the agency placed on the drug's distribution.[2] Since that time, in 2011, FDA approved a Risk Evaluation and Mitigation Strategy (REMS) for Mifeprex, with the goal of informing patients about the benefits and risks of Mifeprex, and to minimize the risk of serious complications associated with the drug.[3] In May 2015, Mifeprex's sponsor proposed several changes to the administration of the drug.[4] It submitted a supplemental new drug application to FDA to obtain approval to revise the drug's labeling.[5]

[1]See 21 C.F.R. § 314.520 (2000).

[2]GAO, *Food and Drug Administration: Approval and Oversight of the Drug Mifeprex*, GAO-08-751, (Washington, D.C.: Aug. 7, 2008).

[3]A REMS is a set of restrictions specifically authorized by statute that FDA may impose to ensure that a drug's benefits outweigh its risks. See 21 U.S.C. § 355-1.

[4]A drug sponsor is the person or entity who assumes responsibility for the marketing of a new drug, including responsibility for complying with applicable provisions of laws, such as the Federal Food, Drug, and Cosmetic Act and related regulations. Danco Laboratories, L.L.C., the sponsor of Mifeprex, is responsible for the marketing and manufacturing of Mifeprex, and submitted the supplemental application to FDA.

[5]Supplemental new drug applications are submitted to make certain changes to already approved new drug applications, including adding or modifying an indication or claim, or revising the dose or dosing regimen. FDA review and approval of most types of supplemental new drug applications is required before the drug may be marketed with these changes. FDA characterized the supplemental application submitted for Mifeprex as an efficacy supplement that, among other things, revised its dosing regimen. See 21 C.F.R. § 314.3 (2017). Throughout this report, references to the Mifeprex application pertain to this supplemental new drug application, submitted as an efficacy supplement.

Among other things, the sponsor proposed changing the dosing regimen, increasing the gestational age limit up to which Mifeprex can be taken, and eliminating the requirement that the dose of misoprostol be administered in a medical facility. FDA approved the labeling change in March 2016 and determined that the REMS continued to be necessary, with some modifications.

You and others have questioned whether the revised Mifeprex labeling has safety implications for the women who use the drug. For example, some stakeholder organizations, such as medical associations and research organizations, have raised concerns regarding FDA's postmarketing monitoring of Mifeprex and the drug's safety.[6] You asked us to report on FDA's relabeling of Mifeprex and its monitoring activities. This report describes

1. the information FDA used to make its decisions regarding the relabeling of Mifeprex; and
2. what FDA's monitoring of Mifeprex has revealed, and stakeholders' views of FDA's monitoring and the safety of the drug.

To describe the information FDA used to make its decisions regarding the relabeling of Mifeprex, we obtained information regarding the agency's review and subsequent approval of the revised Mifeprex labeling. Specifically, we reviewed documents in FDA's approval package for the Mifeprex supplemental new drug application. The approval package included FDA's assessments of the published literature submitted by Mifeprex's sponsor to support the safety and efficacy of the proposed changes.[7] Additionally, we reviewed other documents in the approval package, including communications between FDA and Mifeprex's sponsor during the application process, and the revised Mifeprex labeling and REMS. In addition, we studied FDA's assessments of adverse events associated with Mifeprex.[8] Finally, we examined federal regulations and FDA's policies and guidance documents, and interviewed FDA officials.

[6]The term postmarketing refers to activities occurring after a drug has been approved for marketing.

[7]FDA has posted documents pertaining to its review and approval on the agency's website (see https://www.accessdata.fda.gov/drugsatfda_docs/nda/2016/020687Orig1s020TOC.cfm).

[8]FDA uses the term adverse event to refer to any untoward medical event associated with the use of a drug in humans, whether or not the event is considered to be drug related.

To describe how FDA monitors the safety and use of Mifeprex, we analyzed FDA's postmarketing adverse event summary reports associated with the use of Mifeprex from September 28, 2000, (when the drug was approved) through June 30, 2017, and obtained information from FDA officials regarding the agency's monitoring activities.[9] We also reviewed quarterly adverse event summary reports submitted to FDA by Mifeprex's sponsor for fiscal year 2017. To further describe FDA's monitoring, we reviewed documentation from inspections the agency conducted to determine the sponsor's compliance with relevant regulations and the Federal Food, Drug, and Cosmetic Act. Specifically, we reviewed FDA's reports from inspections of Mifeprex's sponsor for compliance with adverse event reporting requirements and the Mifeprex REMS that were performed since our 2008 report was issued.[10] We obtained information from FDA on the number and results of inspections that FDA has conducted since 2008 for compliance with current good manufacturing practices.[11] We also reviewed studies and data related to the safety and use of Mifeprex from FDA, stakeholders, and other entities. We discussed FDA's data collection processes and any limitations with agency officials and determined that the data we used were sufficiently reliable for the purposes of this report. We also obtained information from Mifeprex's sponsor on its perspectives of FDA's monitoring. Finally, to describe stakeholders' views of FDA's monitoring and the safety of the drug, we obtained information from 13 organizations, including medical associations and advocacy groups with a variety of perspectives for their

[9]FDA officials said that the adverse events associated with Mifeprex in its summary reports do not necessarily reflect a conclusion by the company or FDA that the drug caused or contributed to an adverse event. See 21 C.F.R. § 314.80(l) (2017).

[10]See GAO-08-751.

[11]Current good manufacturing practices provide a framework for a manufacturer to follow to produce safe, pure, and high-quality drugs. See 21 C.F.R. pts. 210-21 (2017).

views on FDA's monitoring of Mifeprex, including any safety-related concerns they may have about the drug.[12]

We conducted this performance audit from April 2017 to March 2018 in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Background

The treatment regimen of taking Mifeprex, in combination with misoprostol, works by both interrupting the hormones that the body needs to maintain a pregnancy and inducing the uterine cramping necessary to cause a medical abortion.[13] Mifepristone, the active ingredient in Mifeprex, was first approved in France and China in 1988, and is now approved in approximately 60 other countries, including the United States.

FDA's Review of New Drug Applications and Supplemental Applications

FDA must approve an application for a new drug before it can be marketed in the United States. FDA reviews scientific and clinical data contained in these applications as part of its process in considering them for approval to be marketed. FDA initially approved Mifeprex for use in the

[12]We obtained information from the following 13 organizations: the American Association of Pro-Life Obstetricians and Gynecologists; American College of Pediatricians; American Congress of Obstetricians and Gynecologists; Association of Reproductive Health Professionals; Bixby Center for Global Reproductive Health, University of California San Francisco; Charlotte Lozier Institute; Family Research Council; Guttmacher Institute; Gynuity Health Projects and the lead author of the Mifeprex REMS Study Group; Institute for Safe Medication Practices; National Right to Life Committee; Office of Population Research, Princeton University; and Planned Parenthood Federation of America. We selected these organizations on the basis of their medical or scientific expertise, their publication of relevant articles and web-based materials, or their familiarity with the safety and use of Mifeprex.

[13]Mifeprex is the trade name for one of the two mifepristone products approved and marketed in the United States (the trade name for the other product is Korlym, which has a different, unrelated indication). Mifepristone is the underlying drug substance and is also sometimes called RU-486, a reference to the name the drug had during laboratory testing. Medical abortion terminates a pregnancy using medications, rather than through a surgical procedure.

GBP-PET01486

United States on September 28, 2000.[14] FDA approved the drug subject to restrictions that it considered necessary to ensure safe usage.

In addition to reviewing applications to market new drugs, FDA reviews supplemental new drug applications that drug sponsors submit to propose changes to an approved drug, such as adding or modifying an indication, revising the dose or dosing regimen, providing for a new route of administration, or changing the marketing status from prescription to over-the-counter use. As with original new drug applications, the agency assembles an internal team of reviewers—including medical officers, chemists, statisticians, pharmacologists, and other experts—to evaluate the information submitted in a supplemental application. During the review process, FDA may communicate with sponsors about issues that arise that may affect the approvability of the supplemental application. In response, sponsors can submit additional information to FDA in the form of amendments to the pending supplemental application. The review team compiles the results of its analyses and recommends to FDA management whether the supplemental application should be approved. Once the review is completed, the agency issues an action letter to the sponsor. FDA may approve the supplemental application (approval letter) or, if it determines it will not approve the supplemental application in its present form, it describes the specific deficiencies it identified in the supplemental application (complete response letter).

The review process for a drug application, including a supplemental application, may span several cycles before the agency approves the application.[15] For those applications that receive a complete response letter during a review cycle, the next FDA review cycle begins once the sponsor resubmits its application, providing responses to the deficiencies FDA identified in its previous review. These resubmissions often contain additional studies, analyses, data, or clarifying information to address FDA's concerns. The agency's review team examines the additional information provided by the sponsor, conducts any additional analyses

[14]In general, the mifepristone treatment regimens approved in other countries were similar to the regimen approved in the United States, although in some cases the specific drug used in combination with mifepristone was different than misoprostol.

[15]The first review cycle begins when FDA receives an application from a sponsor and ends when FDA issues an action letter. If FDA does not approve the application during the first review cycle, a new review cycle begins if the sponsor resubmits the application to provide responses to the deficiencies identified by FDA in the previous review cycle. See 21 CFR § 314.110(b)(1) (2017).

that are required, studies the results of any additional inspections that have been conducted, and again recommends either an approval or complete response action. As with the first review cycle, the process ends once FDA management reviews the recommendations of the review team and makes its decision on the action to take on the application.

Mifeprex's Supplemental Application

Prior to submitting its supplemental application, Mifeprex's sponsor met with FDA officials on January 29, 2015, to discuss the proposed labeling and Mifeprex REMS changes. At this meeting, both parties agreed that the sponsor should submit a supplemental new drug application covered by section 505(b)(2) of the Federal Food, Drug, and Cosmetic Act.[16] On May 29, 2015, Mifeprex's sponsor submitted a supplemental application to FDA to revise the dosing regimen, amend the Mifeprex labeling, and modify the Mifeprex REMS. FDA's review for this supplemental application was classified as a standard review—as opposed to a priority review—with the performance goal of completing the application review and issuing an action letter to Mifeprex's sponsor within 10 months.[17] FDA approved the supplemental application on March 29, 2016, after one review cycle, meeting the agency's performance goal for the timely review of supplemental applications.[18] Table 1 shows key components of the original Mifeprex regimen and the revised regimen.

[16]This pertains to new drug applications that rely, at least in part, on investigations that "were not conducted by or for the applicant and for which the applicant has not obtained a right of reference or use from the person by or for whom the investigations were conducted . . . ." See 21 U.S.C. § 355(b)(2). For example, such an application may rely on the finding of safety or effectiveness for an approved product or on published literature in addition to studies conducted by the sponsor.

[17]FDA generally grants priority review to applications for drugs that treat serious conditions and that, if approved, would provide significant improvements in safety or effectiveness of the treatment, diagnosis, or prevention of serious conditions compared to available therapies. FDA has a performance goal for completing priority reviews of supplemental applications in 6 months. FDA assigns a standard review designation to applications for drugs that do not meet the priority review designation criteria. FDA's goal is to generally complete review of these applications in 10 months.

[18]Food and Drug Administration, Mifeprex label, March 2016, accessed January 25, 2018, https://www.accessdata.fda.gov/drugsatfda_docs/label/2016/020687s020lbl.pdf.

GBP-PET01488

Table 1: Key Components of the Original Mifeprex Regimen and Prescriber Requirements, Approved in 2000, and the Revised Mifeprex Regimen and Prescriber Requirements, Approved in 2016

Regimen component	Original regimen	Revised regimen
Dosage	600 mg Mifeprex (mifepristone); 400 mcg misoprostol	200 mg Mifeprex (mifepristone); 800 mcg misoprostol
Dosing regimen	Day 1: 600 mg Mifeprex in a single oral dose. Day 3: 400 mcg misoprostol in a single oral dose if termination of pregnancy is not complete.	Day 1: 200 mg Mifeprex in a single oral dose. Day 2 or 3: 800 mcg misoprostol by buccal route (i.e., in the cheek pouch), 24 to 48 hours after taking Mifeprex.
Maximum gestational age (since first day of last menstrual period)	49 days	70 days
Prescriber requirements	To become certified, a licensed physician must sign and return the Prescriber Agreement Form to Mifeprex's sponsor.[a]	To become certified, a healthcare provider who prescribes must sign and return the Prescriber Agreement Form to Mifeprex's sponsor.[a]
Office visits and follow-up visits with prescriber, and location of dosing administration	Required three office visits by the patient: (1) 600 mg of Mifeprex administered to the patient by the physician or under the supervision of the physician in a clinic, medical office, or hospital. (2) Patient returns on day three for examination with physician; if termination of pregnancy is not complete, physician administers 400 mcg of misoprostol for patient to take orally. (3) Patient returns to physician for follow-up visit approximately 14 days after administration of Mifeprex to confirm complete termination of the pregnancy occurred.	Requires one office visit by the patient: (1) 200 mg of Mifeprex administered to the patient by the healthcare provider who prescribes, or under the supervision of a healthcare provider who prescribes, in a clinic, medical office, or hospital. (2) Patient takes 800 mcg of misoprostol by buccal route 24 to 48 hours after Mifeprex administration; the healthcare provider who prescribes discusses with the patient an appropriate location for her to be when she takes the misoprostol. (3) Patient should follow up with healthcare provider who prescribes approximately 7 to 14 days after Mifeprex administration to confirm complete termination of pregnancy has occurred and to evaluate the degree of bleeding.
Repeat misoprostol dose, if necessary	N/A	If the pregnancy has ended, but complete expulsion did not occur after the initial dose of misoprostol, the patient may be prescribed an additional 800 mcg of misoprostol to take buccally; women who choose to take a repeat dose of misoprostol should have a follow-up visit with their healthcare provider who prescribes in approximately 7 days to assess for complete expulsion.

Source: GAO analysis of information from the Food and Drug Administration. | GAO-18-292

[a]By signing the Prescriber Agreement Form, the prescriber certifies that he or she agrees with all specified requirements, including that the sponsor's Medication Guide will be supplied to all patients.

Mifeprex REMS

FDA initially approved a REMS for Mifeprex in June 2011.[19] When FDA approved the revised Mifeprex labeling in March 2016, the agency determined the REMS continued to be necessary, with some modifications.[20] Modifications from the original REMS to the revised REMS included

- changing the requirement that Mifeprex be provided "by or under the supervision of a physician" meeting specified qualifications to "by or under the supervision of a healthcare provider who prescribes" and meets such qualifications;
- changing the requirement for prescribers to agree to report to Mifeprex's sponsor any serious adverse event associated with Mifeprex, including hospitalizations and blood transfusions, to requiring prescribers to agree to report deaths associated with Mifeprex to the sponsor;[21]
- requiring Mifeprex's sponsor to report to FDA any death associated with Mifeprex, whether or not the death was considered drug-related, no later than 15 calendar days from the initial receipt of the information);[22] and
- removing the Medication Guide (which contained specific patient information, such as how to take Mifeprex and potential side effects) as an element of the REMS, although the Medication Guide remains part of the approved Mifeprex labeling, and the revised REMS requires the healthcare provider to provide a copy of the Medication Guide to the patient.[23]

[19]As part of a REMS, FDA can require "elements to assure safe use," 21 U.S.C. § 355-1(f)(1). This may include restrictions similar to those required to assure safe use under which Mifeprex was originally approved. 21 C.F.R. § 314.520 (2000).

[20]Food and Drug Administration, Mifeprex Risk Evaluation and Mitigation Strategy, March 2016, accessed January 25, 2018, https://www.accessdata.fda.gov/drugsatfda_docs/rems/Mifeprex_2016-03-29_REMS_full.pdf.

[21]This requirement does not affect the sponsor's other reporting requirements under federal regulations.

[22]This requirement does not affect the sponsor's other reporting requirements under federal regulations.

[23]See 21 C.F.R. 208.24 (2017).

GBP-PET01490

As part of the REMS, Mifeprex's sponsor is required to submit REMS assessments to FDA. The first REMS assessment was due one year from the date of initial approval of the REMS. Subsequent assessments are due every three years thereafter.[24] The REMS assessments include data on the cumulative number of health care providers enrolled in the Mifeprex REMS program; the number of providers ordering Mifeprex during the assessment reporting period; and the number of women exposed to Mifeprex, both cumulative and during the reporting period. In addition, they include copies of reports for certain adverse events, including hospitalizations due to complications, blood transfusions, serious infections, and deaths, as well as the cumulative numbers of these adverse events since the approval of Mifeprex and the number during the reporting period.

FDA's Postmarketing Oversight Activities

Federal regulations require sponsors of approved drugs to report periodically to FDA on safety information and specific types of adverse events that occur in association with their use.[25] Sponsors must provide in periodic reports—quarterly for the first three years after approval and annually thereafter—a narrative summary and analysis of adverse event information to FDA. For adverse events that are considered both serious and unexpected, sponsors are required to submit a Postmarketing 15-day Alert Report to FDA within 15 calendar days of initial receipt of the information.[26]

In some instances, FDA may request sponsors to study matters that it has determined worthy of further examination. Such requests are known as postmarketing study commitments and include studies or clinical trials that FDA has requested—and sponsors have agreed to conduct—to

[24]Mifeprex's sponsor submitted its first REMS assessment to FDA in June 2012, and the second one in June 2015.

[25]See 21 C.F. R. § 314.80 (2017).

[26]Serious adverse events are those that result in any of the following outcomes: death, a life-threatening adverse event, inpatient hospitalization or prolongation of an existing hospitalization, a significant or persistent disability or incapacity, or a congenital anomaly or birth defect. Unexpected adverse events are those that are not included in the current labeling for a drug. Adverse events associated with a drug do not necessarily imply the drug caused the event.

GBP-PET01491

address such issues.[27] FDA requires sponsors to report on the status of these studies in an annual report that also includes other information such as updates on the distribution of the drug, labeling changes, clinical literature published on the drug, and the drug's marketing.[28] FDA designates unfulfilled study commitments as submitted, pending, ongoing, delayed, released, or terminated.

FDA conducts postmarketing adverse drug experience inspections of sponsors to assess compliance with adverse event reporting requirements. FDA also conducts inspections of sponsors' compliance with the REMS, as applicable.[29] In addition, FDA inspects manufacturers for compliance with current good manufacturing practices. FDA classifies the results of each type of inspection in one of three ways:

- A classification of "official action indicated" means that objectionable conditions were found that may warrant regulatory action by the agency.
- A classification of "voluntary action indicated" means that objectionable conditions that do not meet the threshold for regulatory action were identified, and any corrective actions are left to the establishment to take voluntarily.
- A classification of "no action indicated" means that no objectionable conditions or practices were found during the inspection, or that the significance of the documented objectionable conditions found does not justify further FDA action.

To monitor and analyze adverse events associated with an approved drug, FDA compiles data from sponsors' reports on adverse events, as well as data from voluntary reports submitted to the MedWatch program, all of which are entered into FDA's Adverse Event Reporting System

[27]See Pub. L. No. 105-115, § 130, 111 Stat. 2296, 2331-2 (codified at 21 U.S.C. § 356b). Sponsors may also be required to conduct additional postmarketing studies or clinical trials (i.e., in connection with accelerated approval of drugs for serious conditions or approval based on animal efficacy data, or where determined necessary to identify or assess a serious risk related to use of a drug). See 21 U.S.C. §§ 355(o) (serious risk), 356(c)(2)(A) (accelerated approval); 21 C.F.R. § 314.610(b)(1) (2017) (animal efficacy data).

[28]See 21 C.F. R. § 314.81(b)(2) (2017).

[29]In 2008, we reported that FDA conducted three postmarketing adverse drug experience inspections of Mifeprex's sponsor in 2002, 2004, and 2006. The REMS for Mifeprex was not in place at that time. See GAO-08-751.

(FAERS).[30] FDA also established the Sentinel System, which may be used to monitor drugs using electronic health care data. This system complements FDA's existing monitoring capabilities, such as FAERS, by providing administrative and claims data that can be queried to monitor the use of FDA-regulated medical products and potential outcomes of treatment. The Sentinel System currently includes reimbursement data related to diagnoses, procedures, and drugs dispensed to over 223 million patients derived from 17 different data partnerships, including national health insurers and managed care organizations. While reimbursed health care encounters, procedures, and medications are included in the Sentinel System, those that are not reimbursable—such as visits to free health care clinics, drug samples given in physicians' offices, use of low-cost generic medications that do not incur an insurance copayment, or over-the-counter medications—generally are not captured.

FDA Reviewed Published Studies that Supported the Efficacy of the Proposed Mifeprex Labeling Changes, and Evaluated Safety Information and Adverse Event Data

In considering the supplemental application to revise the Mifeprex labeling, FDA reviewed 62 studies and articles that were submitted by the drug's sponsor related to different aspects of the efficacy and safety of the proposed changes. Over the course of FDA's application review, the agency also requested and received more detailed information from the authors of select publications through communication with Mifeprex's sponsor. Additionally, FDA evaluated adverse event data associated with Mifeprex.

[30]MedWatch is a voluntary reporting system through which health professionals and consumers can report adverse reactions, product problems, and errors in use related to drugs and other products approved by FDA.

FDA Reviewed Numerous Studies in Considering the Efficacy of the Proposed Changes to the Mifeprex Labeling

To determine the efficacy of the proposed changes to the Mifeprex labeling, FDA reviewed numerous published studies submitted by Mifeprex's sponsor, which included both U.S. and international studies.[31] Some of these studies assessed the efficacy of one component of the proposed Mifeprex labeling changes, such as the dosing regimen. Other studies assessed more than one component, such as home administration of misoprostol and the gestational age limit for Mifeprex. FDA also requested and received more detailed information from the authors of select publications through communication with Mifeprex's sponsor. In their review of the application, FDA reviewers identified what they considered major proposed changes. Some of the published studies submitted by Mifeprex's sponsor that FDA reviewed to support each of these proposed changes included the following:

- **Changes to the proposed dose and dosing regimen.** FDA reviewed 30 studies that evaluated changes to the dose and dosing regimen. For example, 22 of these studies, collectively, evaluated over 35,000 women who took the proposed dosing regimen—200 milligrams of Mifeprex orally and 800 micrograms of misoprostol buccally (i.e., in the cheek pouch) 24 to 48 hours after Mifeprex administration. The efficacy rates, defined as complete termination of the pregnancy without need for surgical intervention for any reason, ranged from 91 percent to 98 percent. One of these publications summarized the results of 20 studies, all but one of which used the proposed Mifeprex regimen in gestations through 70 days.[32] The overall efficacy rates in these 20 studies ranged from 97 percent to 98 percent for those studies that provided this information.
- **Extending the gestational age to 70 days.** FDA reviewed 19 studies that evaluated increasing the gestational age limit for taking Mifeprex. In addition to the publication discussed above that summarized the

[31]FDA accepts the use of peer-reviewed literature as primary or supportive data for an application under the framework of a 505(b)(2) application. See U.S.C. 21 § 355(b)(2). As part of its submission to FDA, Mifeprex's sponsor noted that it did not provide financial support or sponsor any of the studies submitted in its supplemental application. FDA's webpage pertaining to its review and approval of the Mifeprex supplemental application includes review documents (e.g., Cross Discipline Team Leader Review and Medical Review(s) documents) that contain lists and tables of references citing the publications FDA reviewed in the supplemental application (see https://www.accessdata.fda.gov/drugsatfda_docs/nda/2016/020687Orig1s020TOC.cfm).

[32]M.J. Chen and M.D. Creinin, "Mifepristone with Buccal Misoprostol for Medical Abortion: A Systematic Review," *Obstetrics & Gynecology,* vol. 126, no.1 (2015): 12-21.

results of 20 studies, 4 of the studies that FDA reviewed evaluated the proposed dosing regimen through 70 days gestation.[33] Three of these studies evaluated the efficacy rates for gestational ages of 64 to 70 days, which ranged from 91 percent to 96 percent. The fourth study evaluated the efficacy rates through 70 days gestation when the drug was administered by physician providers (98 percent) and by nurse providers (98 percent). An additional publication submitted by the sponsor was a systematic review of studies that covered various dosing regimens, including the proposed regimen from 64 to 70 days gestation, which had a 93 percent efficacy rate.[34] Two other studies evaluated the efficacy rates from 64 to 70 days gestation, but used different dosing regimens than the proposed regimen, with efficacy rates of 92 percent for one study and 95 percent for the other study.[35] The remaining 11 studies evaluated efficacy rates for gestation greater than the then-approved 49 days gestation, but less than 64 days, with efficacy rates ranging from 87 percent to 100 percent.

- **Home administration of misoprostol.** FDA reviewed 15 studies that evaluated home administration of misoprostol, although FDA reported that none of these studies evaluated treatment outcomes with the use of misoprostol at home compared to a clinic setting. However, one study was a large literature review of 87 studies that included over

[33]The four studies were: (1) B. Winikoff, I.G. Dzuba, E. Chong, et al., "Extending Outpatient Medical Abortion Services through 70 Days of Gestational Age," *Obstetrics & Gynecology,* vol. 120 (2012): 1070-1076; (2) A.A. Boersma, B. Meyboom-de Jong, and G. Kleiverda, "Mifepristone Followed by Home Administration of Buccal Misoprostol for Medical Abortion up to 70 days of Amenorrhoea in a General Practice in Curacao," *The European Journal of Contraception & Reproductive Health Care,* vol. 16 (2011): 61-66; (3) P. Sanhueza Smith, M. Pena, I.G. Dzuba, et al., "Safety, Efficacy and Acceptability of Outpatient Mifepristone-Misoprostol Medical Abortion through 70 days Since Last Menstrual Period in Public Sector Facilities in Mexico City," *Reproductive Health Matters,* vol. 22 (2015): 75-82; and (4) C.D. Olavarrieta, B. Ganatra, A. Sorhaindo, T.S. Karver, A. Seuc, A. Villalobos, S.G. Garcia, M. Pérez, M. Bousieguez, and P. Sanhueza, "Nurse Versus Physician-Provision of Early Medical Abortion in Mexico: A Randomized Controlled Non-Inferiority Trial," *Bulletin of the World Health Organization*, vol. 93 (2015): 249-258.

[34]D. Abbas, E. Chong, and E.G. Raymond, "Outpatient Medical Abortion is Safe and Effective through 70 Days Gestation," *Contraception,* vol. 92 (2015):197-199.

[35]The two studies were: (1) H. Bracken, R. Dabash, G. Tsertsvadze, et al., "A Two-Pill Sublingual Misoprostol Outpatient Regimen following Mifepristone for Medical Abortion through 70 Days' LMP: A Prospective Comparative Open-Label Trial," *Contraception*, vol. 89(3) (2014): 181-186; and (2) E.V. Gouk, et al., "Medical Termination of Pregnancy at 63-83 Days Gestation," *BJOG: An International Journal of Obstetrics and Gynaecology*, vol. 106 (1999): 535-539. FDA noted that these two studies were relevant because the dosage levels and routes of administration were expected to have similar or lower effectiveness than the proposed dosing regimen.

45,000 women evaluated using a variety of mifepristone treatment regimens with different misoprostol doses, routes of administration, and dosing intervals in gestations through 63 days.[36] Half of the studies in this review did not require women to take misoprostol in a clinic. The results showed that the rates of treatment failure and ongoing pregnancy were very similar regardless of whether misoprostol was taken in a clinic or at another location. A further analysis of factors leading to increased failure found no evidence that home use of misoprostol increased rates of treatment failure or serious complications.

- **Use of a repeat misoprostol dose.** FDA reviewed 10 studies to support the use of a repeat dose of misoprostol. This repeat dose would be taken in instances when complete expulsion did not occur after the initial misoprostol dose and Mifeprex dose. For example, one study evaluated 68 women who did not have complete expulsion after taking Mifeprex and were given a second vaginal dose of misoprostol, with an efficacy rate of 62 percent.[37] In another study that evaluated the proposed regimen through 70 days gestation, 5 of 330 women took a second dose of misoprostol, because of the absence of bleeding after the first dose of misoprostol. The study found that one of the five women who took the second dose did not achieve the desired result.[38] In one other study that evaluated women using the proposed regimen through 63 days gestation, 16 of 863 women received a second dose of misoprostol, with an efficacy rate of 100 percent.[39] The other 7 studies had efficacy rates for an additional dose of misoprostol ranging from 67 percent to 100 percent.[40]

[36]E.G. Raymond and D.A. Grimes, "The Comparative Safety of Legal Induced Abortion and Childbirth in the United States," *Obstetrics & Gynecology,* vol. 119 (2012): 215-219.

[40]Mifeprex's sponsor noted to FDA that approximately 1 percent to 5 percent of women will need a second dose of misoprostol following the initial Mifeprex dosing regimen.

GBP-PET01496

- **Follow-up care requirements.** FDA reviewed 11 studies that evaluated different methods for follow-up care after Mifeprex administration. One of these studies, which FDA considered a key publication on this topic, was a review of studies that assessed the impact of the timing of follow-up care.[41] This study found no differences in the failure rates between women who received follow-up care within one week of taking mifepristone compared to those who received follow-up care a week or more after taking mifepristone. The other 10 studies included a variety of study designs and dosing regimens through 63 days gestation, and FDA determined that the various methods of follow up, including home pregnancy testing and phone contact with the patient to inquire about symptoms, were acceptable alternatives to an in-clinic follow up.
- **Change in provider qualifications.** FDA reviewed four studies that addressed the efficacy of medical abortion performed by nonphysician health care providers; three of which used the proposed dosing regimen and one evaluated vaginal administration of misoprostol.[42] In these studies, almost 1,500 women had gestations through 70 days or more, and over 700 of these women had nonphysician care. In addition, almost 2,300 women had gestations up to 63 days, and over 1,000 of these women had nonphysician care. The efficacy rates were greater than or equal to 96 percent across all of the studies, regardless of gestational age or provider type.

FDA also received three letters from representatives of advocacy organizations and professional associations—some of which were signed by more than one entity—requesting that FDA revise the Mifeprex labeling in a manner that would reflect then-current clinical practice,

[41]E.G. Raymond, et al., "First-Trimester Medical Abortion with Mifepristone 200 mg and Misoprostol: A Systematic Review," *Contraception,* vol. 87 (2013): 26-37.

[42]The three studies that used the proposed regimen were (1) H. Kopp Kallner, R. Gomperts, E. Salomonsson, M. Johansson, L. Marions, and K. Gemzell-Danielsson, "The Efficacy, Safety and Acceptability of Medical Termination of Pregnancy Provided by Standard Care by Doctors or by Nurse-Midwives: A Randomized Controlled Equivalence Trial," *BJOG: An International Journal of Obstetrics and Gynaecology*, vol. 122 (2015): 510-517; (2) Olavarrieta, Ganatra, Sorhaindo, Karver, Seuc, Villalobos, Garcia, Pérez, Bousieguez, and Sanhueza, "Nurse Versus Physician-Provision of Early Medical Abortion," 249-258; and (3) M. Puri, A. Tamang, P. Shrestha, D. Joshi, "The Role of Auxiliary Nurse-Midwives and Community Health Volunteers in Expanding Access to Medical Abortion in Rural Nepal," *Reproductive Health Matters,* vol. 44 Supplement (2015): 94-103. The study that addressed vaginal misoprostol was: I.K. Warriner, D. Wang, N.T.M. Huong, K. Thapa, A. Tamang, I. Shah, et al., "Can Midlevel Health-Care Providers Administer Early Medical Abortion as Safely and Effectively as Doctors? A Randomized Controlled Equivalence Trial in Nepal," *Lancet,* vol. 377 (2011): 1155-1161.

including the new dosing regimen and extending the gestational age limit through 70 days.[43] Among others, the signers of these letters included the American Congress of Obstetricians and Gynecologists, American Public Health Association, Gynuity Health Projects, Ibis Reproductive Health, and National Abortion Federation. FDA officials told us that the peer-reviewed studies the agency received from external entities (i.e., entities other than Mifeprex's sponsor) were also submitted by Mifeprex's sponsor in the supplemental application, which FDA reviewed.[44] In addition, FDA officials told us that they received letters from organizations that were based on other than scientific perspectives, and FDA officials noted that they only considered scientific information in their review of the Mifeprex supplemental application.

FDA Evaluated Safety Information and Adverse Event Data as Part of Its Assessment of the Proposed Changes to the Mifeprex Labeling

FDA also reviewed published studies submitted by the drug's sponsor to assess the safety profile of the proposed dosing regimen, including both U.S. and international studies. Of the seven U.S. studies submitted with the Mifeprex supplemental application that examined safety issues, one specifically addressed deaths associated with Mifeprex.[45] This study noted that there were no deaths among 578 patients who received the proposed Mifeprex dosing regimen through 63 days gestation. According to FDA, because only one of these studies addressed deaths associated with Mifeprex, this may reflect the fact that it is a rare outcome and, therefore, the absence of reported deaths might not be noted by the authors of a study. In addition, FDA reviewed an observational study from Australia that was also submitted as part of the application. It identified one death from sepsis—a life-threatening complication of an infection—

[43]According to FDA, once the agency approves a drug, health care providers generally may prescribe the drug for an unapproved use when they judge that it is medically appropriate for their patient, a practice known as off-label use. FDA also indicated that the proposed changes approved in the Mifeprex supplemental application were consistent with current medical practice.

[44]According to FDA officials, the agency received one study from an external entity that was superseded by a more current publication on the same topic by one of the same authors. In this instance, FDA officials reviewed the more current publication provided by Mifeprex's sponsor.

[45]D. Grossman, K. Grindlay, T. Buchacker, K. Lane, and K. Blanchard, "Effectiveness and Acceptability of Medical Abortion Provided through Telemedicine," *Obstetrics & Gynecology,* vol. 118 (2011): 296-303.

among 13,345 pregnancy terminations using the proposed dosing regimen through 63 days gestation.[46]

In addition to reviewing published studies submitted by Mifeprex's sponsor, FDA reviewed adverse event reports from the drug's approval on September 28, 2000, through November 17, 2015. During this time, there were 17 reported deaths in the United States associated with Mifeprex, and 8 of those were associated with sepsis. Seven of the 8 sepsis cases were associated with vaginal use of misoprostol, which was, but no longer is, a common practice, according to FDA. The agency found that the adverse event data that it reviewed demonstrated that the rates of hospitalizations, severe infections, blood loss requiring transfusion, and complications related to ectopic pregnancy remained stable and acceptably low.

FDA also reviewed common adverse events, such as nausea, vomiting, diarrhea, and fever/chills, reported in U.S. and international studies submitted by Mifeprex's sponsor, and found the reporting of the frequencies of these events was higher in the U.S. studies. However, FDA determined that these differences likely reflected lower reporting of adverse events in international studies. These common adverse events are included in the Mifeprex labeling. The labeling also cites bleeding and cramping, which are expected effects of the drug regimen, according to FDA. Overall, FDA found the rate of deaths and nonfatal serious adverse events associated with Mifeprex to be acceptably low, and data for the proposed regimen did not suggest a safety profile that deviated from that of the originally approved Mifeprex regimen, which was approved as part of an application with restrictions to assure safe use. In addition, no association between adverse outcomes and increasing gestational age was identified.

In January 2016, FDA completed a review of adverse event data associated with Mifeprex in its FAERS database, as well as the published medical literature, on a potential safety concern regarding anaphylaxis and angioedema associated with mifepristone.[47] FDA's review of FAERS data found one case of anaphylaxis and six cases of angioedema with

[46]P. Goldstone, J. Michelson, and E. Williamson, "Early Medical Abortion Using Low-Dose Mifepristone Followed by Buccal Misoprostol: A Large Australian Observational Study," *Medical Journal of Australia,* vol. 197 (2012): 282-286.

[47]Anaphylaxis is a severe, potentially life-threatening allergic reaction. Angioedema is a form of severe swelling beneath the skin's surface.

mifepristone administration, with six of the seven cases seen in women using mifepristone for pregnancy termination, as opposed to using mifepristone for Cushing's syndrome.[48] The sole case of anaphylaxis could not be directly attributed to mifepristone because an oral antibiotic (doxycycline) was concomitantly administered, according to FDA. FDA did not find any additional cases of anaphylaxis or angioedema with mifepristone administration in its review of the literature. FDA noted that anaphylaxis was included in the current labeling for misoprostol. Because the approved Mifeprex regimen includes misoprostol, FDA determined that the Mifeprex labeling should also be updated to include anaphylaxis, despite the lack of anaphylaxis cases with mifepristone alone. The addition of angioedema was supported by the FAERS data documented in FDA's review. As a result, anaphylaxis and angioedema were added to the areas of the Mifeprex labeling that address allergic reactions.

The potential risk of uterine rupture was also considered in FDA's review of the Mifeprex supplemental application. FDA reviewers conducted a literature search on this topic, and identified five reports of uterine rupture in studies published from 2000 through 2014; three of which occurred with the combined mifepristone/misoprostol dosing regimen. FDA also completed a review of FAERS from January 1, 1965, through October 15, 2015, for reports of uterine rupture.[49] Of the 80 reports found in FAERS, 77 cited use of misoprostol alone, and 3 cited use of both mifepristone and misoprostol. Two reports of uterine rupture in the first trimester were identified in the FAERS review, both using misoprostol alone. One report entailed an unspecified dose and route of misoprostol at 5 weeks gestation. The other report involved vaginal administration of 800 micrograms of misoprostol at 8 weeks gestation for cervical preparation prior to a surgical abortion in a woman with a prior uterine scar. Information regarding this safety concern was added to the Mifeprex labeling when the supplemental application was approved on March 29, 2016. The agency concluded, however, that no restriction of use was needed, because this was an extremely rare adverse event.

FDA concluded that the evidence it reviewed and evaluated, including the revisions to the REMS, demonstrated acceptable safety for the proposed

[48]Cushing's syndrome is a hormonal disorder affecting both men and women caused by prolonged exposure of the body's tissues to high levels of the hormone cortisol. Mifepristone is also approved for this indication, under the brand name Korlym.

[49]According to FDA, January 1, 1965, is the date that the FAERS predecessor system was initiated.

GBP-PET01500

changes to the Mifeprex regimen, and that the dosing regimen had a similar safety profile as the original regimen approved in 2000. The agency further concluded that adverse events of interest—such as deaths, serious infection, transfusions, ectopic pregnancies, and uterine rupture—remained rare, and were not necessarily attributable to Mifeprex use.[50]

FDA's Monitoring Activities Have Not Identified Significant Safety Concerns with Mifeprex; Stakeholders' Views on FDA's Monitoring and the Drug's Safety Were Mixed

FDA's monitoring of Mifeprex—primarily through inspections, and review and analysis of adverse event data—has not identified any significant concerns with the safety and use of Mifeprex. The views of the stakeholder organizations that we contacted regarding FDA's monitoring of the safety of Mifeprex and the safety of the drug itself were mixed.

FDA's Monitoring Has Not Identified Any Significant Concerns Regarding the Safety and Use of Mifeprex as Marketed with the Approved REMS

Since our prior report was issued in 2008, FDA conducted three postmarketing adverse drug experience inspections of Mifeprex's sponsor—in 2010, 2014, and 2016.[51] It identified minor deficiencies, but no significant safety concerns. These inspections each contained between two and four inspection observations—that is, the investigator observed conditions that, in his or her judgment, constituted violations of applicable federal requirements. In each of these inspections, FDA's final classification was "voluntary action indicated," meaning that objectionable conditions or practices were found, but they did not meet the threshold of regulatory significance. According to agency officials, FDA's practice for

[50]Similarly, a recently issued study by the National Academies of Sciences, Engineering, and Medicine reported that complications—such as hemorrhage, hospitalization, persistent pain, infection, or prolonged heavy bleeding—are rare after a medical abortion. This study cited some of the same studies FDA relied on and noted that complications occur in no more than a fraction of a percent of patients. National Academies of Sciences, Engineering, and Medicine, *The Safety and Quality of Abortion Care in the United States* (Washington, D.C.: prepublication copy).

[51]See GAO-08-751.

inspections resulting in this classification is to review the corrective actions taken by the establishment related to the objectionable conditions or practices during the course of the next regularly scheduled inspection. FDA officials told us that they have not yet scheduled the next postmarketing adverse drug experience inspection.

According to FDA, violations associated with postmarketing adverse drug experience inspections classified as voluntary action indicated are typically technical in nature. Examples of some of the observations from inspections of Mifeprex's sponsor include the following:

- In 2010, the sponsor was found to have used an older version of the form used for mandatory reporting of adverse events (FDA Form 3500A), rather than the more recent version.
- In 2014, two serious adverse events were not reported to FDA within the required 15-day period, and instead were included in the sponsor's subsequent quarterly adverse event report to FDA.
- In 2016, the sponsor's quarterly adverse event reports did not include the required analysis of the Postmarketing 15-day Alert Reports that occurred over the period.

In addition to postmarketing adverse drug experience inspections, Mifeprex's sponsor was subject to a REMS compliance inspection, which the agency conducted in 2014. According to FDA officials, the agency did not identify any compliance issues and determined that the final classification was no action indicated.

FDA also conducted three inspections since 2008 of the facility where Mifeprex is manufactured to ensure compliance with current good manufacturing practices. FDA did not find any deficiencies during two of these inspections; however, in the other inspection, FDA's findings resulted in a final classification of voluntary action indicated. According to the inspection report, FDA officials found an improperly performed test on a raw material used in another product produced at the same facility, not related to Mifeprex. A subsequent inspection determined that corrective action was taken by the manufacturer.

In addition to inspection data, FDA conducted ongoing monitoring of adverse event data. These data are collected through required reporting, including periodic reports on adverse events provided by the sponsor and reports by the prescriber to the sponsor, which, depending on the event, may be required under the REMS. In addition, voluntary reports may be made by the public. FDA compiled this information into periodic

postmarketing adverse event summary reports, the interval of which ranged from 2 to 18 months. These reports show that between September 28, 2000, and June 30, 2017, there were approximately 4,200 reports of adverse events associated with Mifeprex, including approximately 1,000 hospitalizations and 20 deaths.[52] These deaths represented a reporting rate of 0.0006 percent for the approximately 3.2 million women who have used Mifeprex since 2000. For context, a study of mortality among women who did not have an abortion and proceeded to a live birth estimated a mortality rate of 0.009 percent. Nonfatal adverse events, including blood loss requiring transfusion and infections, were more common among women who took Mifeprex, but still relatively low compared to the number of users. (See table 2.)

[52]Mifeprex's sponsor reported two additional deaths to FDA that had not yet been included in FDA's periodic adverse event report—one reported in September 2017 and one reported in December 2017. FDA gathers and reports data on adverse events associated with Mifeprex, which are not necessarily caused by Mifeprex. For example, an unrelated health condition observed near the time that a woman took Mifeprex may be included in FDA's adverse event summary data.

GBP-PET01503

Table 2: Adverse Events Associated with Mifeprex Reported to FDA from September 28, 2000, through June 30, 2017

	September 28, 2000 to October 31, 2012[a]	November 1, 2012 to June 30, 2017[a]
Adverse event category	**Number of cases**	**Number of cases**
Any adverse event[b]	2,740	1,439
Specific types of adverse events[c]		
Deaths[d]	14	6
Hospitalization	768	273
Blood loss with transfusion	416	182
Infections	308	103
Ectopic pregnancies	66	31
Severe infections	57	12

Source: GAO analysis of Food and Drug Administration (FDA) data. | GAO-18-292

Notes: (1) Approximately 3.2 million women have taken Mifeprex since its initial approval in 2000. (2) An adverse event associated with Mifeprex does not necessarily indicate that Mifeprex caused the event.

[a]FDA implemented the FDA Adverse Event Reporting System (FAERS) in 2012, and migrated all the data from the previous reporting system to FAERS. Adverse event summary reports beginning on November 1, 2012, are based on FAERS data. Differences may exist when comparing case counts in FAERS with FDA's previous reporting system. Therefore, FDA does not recommend calculating a cumulative number for the data in table 2, with the exception of the case counts for deaths and ectopic pregnancies. These data were harmonized by FDA and may be added.

[b]Any adverse event includes all the categorized adverse events listed below it (i.e., deaths, hospitalization, blood loss with transfusion, infections and severe infections, and ectopic pregnancies), as well as other noncategorized events.

[c]Of the six types of categorized adverse events, only deaths are solely recorded as such—that is, they are not reflected in the tally for other categorized adverse events. The remaining categories are overlapping, meaning that a single case could be counted within multiple categories. Also, the hospitalization category includes both categorized and noncategorized adverse events. According to FDA, the most common adverse events among those that are not categorized (accounting for approximately 94 percent) are vaginal bleeding not requiring transfusion, retained products of conception, ongoing pregnancy, cramping, dizziness, and nausea. Among noncategorized adverse events resulting in hospitalization, the most common is dilation and curettage (accounting for approximately 81 percent).

[d]In addition to the 20 deaths included in FDA's periodic adverse event reports, the sponsor reported two additional deaths to FDA—one reported in September 2017 and one reported in December 2017—which the agency said will be included in its next periodic adverse event report.

Although postmarketing study commitments or requirements are another method for obtaining additional information about drug safety and use, in the case of Mifeprex the planned studies were deemed by FDA to be infeasible. As we previously reported, FDA originally approved Mifeprex subject to the sponsor's commitment to conduct two postmarketing studies.[53] For the first study, the sponsor agreed to assess whether

[53]See GAO-08-751.

clinical outcomes were similar for patients under the care of providers who possessed the surgical intervention skills to perform a surgical abortion compared with patients of providers who did not have such skills and referred patients for surgical abortions. FDA said the sponsor reported that the number of physicians who prescribed Mifeprex and did not possess the surgical intervention skills to perform a surgical abortion was so small that such a study was not feasible. FDA agreed and released them from that commitment in September 2008. For the second study, the sponsor was required to examine, through a surveillance and reporting system, the outcomes of pregnancies where the drug regimen failed to result in their termination. According to FDA officials, Mifeprex's sponsor reported to FDA that over nearly 2 years of monitoring (January 2006 through November 2007) there were one or two instances per year of the drug not resulting in termination. The sponsor told FDA that this was, in part, because patients had to consent to being monitored, resulting in a very small number of participants. Given these low numbers, FDA agreed that this study was also not feasible.

We also found that FDA's Sentinel System, which was developed to enhance the agency's ability to monitor postmarketing safety, is not a viable option for monitoring the use of Mifeprex. Although it contains millions of records, the Sentinel System is based on administrative and claims data, and only reimbursed health care encounters, procedures, and medications are captured in the system. Because of the REMS restrictions placed on the drug's distribution, Mifeprex is not dispensed in pharmacies. Instead, it is only available under certain conditions and from certain clinics, medical offices, and hospitals. Therefore, according to FDA officials, the Sentinel System does not include a sufficient number of Mifeprex dispensings to generate valid results. Nonetheless, we asked FDA to query the Sentinel System for mifepristone (the active pharmaceutical ingredient for Mifeprex) beginning in 2000, when the drug was first approved. The results of this query showed that, until 2012, mifepristone registered a small number of drug dispensings. Specifically, between 2000 and 2011, only 12 individuals were identified as potentially exposed to mifepristone. However, from 2012 through 2016, 243 individuals were identified, including both men and women. FDA officials explained that another drug—Korlym, which treats Cushing's syndrome and contains the same active pharmaceutical ingredient as Mifeprex—

became available in 2012.[54] Even with additional dispensings beginning in 2012, FDA officials said there were still insufficient data captured to enable a robust safety assessment.

Stakeholder Organizations Had Mixed Views on FDA's Monitoring of Mifeprex and of Mifeprex's Safety

The views of the stakeholder organizations that provided us with information on FDA's monitoring of the safety and use of Mifeprex, and the safety of the drug itself, were mixed. Stakeholders provided positive comments regarding FDA's monitoring of Mifeprex and also made suggestions to improve what they considered to be weaknesses. Positive comments included that

- FDA had a very comprehensive monitoring program that mandated the reporting of serious adverse events associated with Mifeprex up through 2016. In light of the low rates of nonfatal adverse events and the good safety profile of Mifeprex, FDA no longer requires providers to report nonfatal adverse events.
- FDA is properly monitoring the safety and use of Mifeprex through a robust adverse event reporting system, and FDA is doing its due diligence, based on the agency's mission, to identify any safety issues with the drug.
- FDA's requirement that Mifeprex be subject to a REMS has made it more likely that adverse events would be reported. Specifically, additional contacts with health care providers, as is required by the Mifeprex REMS in the form of prescriber certification and patient education, generally lead to higher adverse event reporting rates than drugs without such requirements.

Stakeholders that either commented that FDA's monitoring efforts could be improved or that expressed concern about the agency's ability to know the extent of potential safety issues said, for example, that

- FDA may only be aware of a fraction of adverse events associated with Mifeprex. There are anecdotal examples of adverse events, such as severe bleeding, that may not be reported as such or that may be interpreted by emergency health care providers as a natural

[54]The analysis that was conducted in the Sentinel System only recognizes the active pharmaceutical ingredient and does not distinguish between the drugs dispensed, according to FDA officials. The data show both men and women receiving mifepristone since 2012. Korlym's dose of mifepristone is significantly higher than that of Mifeprex and, unlike Mifeprex, the drug is taken by patients on an ongoing basis.

GBP-PET01506

miscarriage. Underreporting may get worse under the revised Mifeprex label, which eliminates the follow-up visit and does not require prescribers to report nonfatal adverse events.

- FDA may not have reliable data on the number of women who have used Mifeprex, which would affect the denominator for tracking adverse events. With an unclear denominator, FDA may not have an accurate measure of adverse event rates associated with Mifeprex.

Regarding the safety of Mifeprex, stakeholders we contacted provided a mix of favorable comments about the drug, as well as certain safety concerns. Positive comments included the following

- The mortality rate associated with Mifeprex is extremely low—about one fourteenth the mortality rate associated with live birth.
- Nonfatal serious adverse events following Mifeprex use, such as hospital admission, blood transfusion, or serious infection, are also rare, occurring at rates ranging from 0.01 percent to 0.7 percent, and are almost always treatable without permanent effects. Side effects, such as bleeding, cramping, fever, and chills, are typically minor and transient.
- In the years since mifepristone's approval, multiple clinical trials, dozens of studies, and extensive experience across the globe have confirmed FDA's finding that mifepristone is a safe and reliable method of abortion. Thus, any significant concern about the safety of Mifeprex would be unwarranted.

Stakeholders also expressed some concerns about Mifeprex's safety. For example, they reported that

- Mifeprex may be linked to hemorrhaging and serious infections. A study was cited that showed adverse events were more likely to be associated with a medical abortion rather than a surgical abortion.[55] Two other studies were cited that examined the effect mifepristone may have on the body's ability to control hemorrhaging and prevent

[55]M. Niinimäki, et al., "Immediate Complications after Medical Compared with Surgical Termination of Pregnancy," *Obstetrics & Gynecology,* vol. 114, no. 4 (October 2009): 795-804. This study of over 42,000 women in Finland who had abortions from 2000 to 2006 found that, overall, medical abortion had roughly four times the rate of adverse events than surgical abortion, and hemorrhaging was experienced by 16 percent of medical abortion patients compared with 2 percent of surgical abortion patients.

GBP-PET01507

serious infections.[56] For example, one of the studies found that serious bacterial infection and sepsis may occur without the usual signs of infection with the use of mifepristone for medical abortion.

- Safety issues may be exacerbated by the Mifeprex labeling changes. For example, a study was cited that found that the rates of pregnancy termination with Mifeprex dropped from 92 percent up to the 7th week of gestation to 77 percent at the 9th week.[57]
- Women in the later weeks of pregnancy who live far from a health care provider may be at increased risk of serious hemorrhaging under the revised labeling, which does not require a second visit with a health care provider.

In addition, another comment we heard was that the agency was being too restrictive by continuing to require a REMS for the drug. Specifically, we were told that Mifeprex should not continue to be restricted to being dispensed at a clinic, medical office, or hospital—as it is under the Mifeprex REMS—because ample research shows Mifeprex to be safe and adverse events to be rare. Stakeholders also noted that women in rural areas may have less access to the drug, and Mifeprex's sponsor commented that the distribution restrictions likely result in the drug being less accessible than it otherwise would be.[58]

In response to the concerns regarding Mifeprex that we heard from stakeholder organizations, FDA officials said that the agency approved the supplemental application for Mifeprex under the same approval standards that it applies to all new drug applications and supplemental applications, and found that the data and information submitted in the supplemental application demonstrated that Mifeprex is safe and effective

[56]R.P. Miech, "Pathopharmacology of Excessive Hemorrhage in Mifepristone Abortions," *Annals of Pharmacotherapy,* vol. 41, no. 12 (December 2007): 2002-2007. See also, R.P. Miech, "Pathophysiology of Mifepristone-induced Septic Shock due to *Clostridium sordellii*," *Annals of Pharmacotherapy,* vol. 39, no. 9 (September 2005): 1483-1488.

[57]I. M. Spitz, C. W. Bardin, L. Benton, and A. Robbins, "Early Pregnancy Termination with Mifepristone and Misoprostol in the United States," *New England Journal of Medicine,* vol. 338, no. 18 (Apr. 30, 1998): 1241-1247.

[58]In October 2017, a doctor and several professional health associations filed a lawsuit in the U.S. District Court for the District of Hawaii to challenge the distribution restrictions imposed by FDA under the Mifeprex REMS. Chelius, et al. v. Wright, No. 17-cv- 00493 (D. Hawaii, filed Oct. 3, 2017). Plaintiffs argued that REMS requirements may be imposed only when necessary to ensure that a drug's benefits outweigh its risks, and that restrictions requiring Mifeprex to be distributed through clinics or hospitals do not meet the criteria.

for its intended use. FDA officials noted that Mifeprex also has a REMS in place to ensure safety. They also stressed that, as with all FDA-approved drugs, Mifeprex is subject to adverse event reporting requirements and continued postmarketing safety monitoring by the agency.

Agency Comments

We provided a draft of this report for comment to HHS. HHS provided technical comments, which we incorporated as appropriate.

We are sending copies of this report to the Secretary of Health and Human Services, appropriate congressional committees, and other interested parties. In addition, the report will be available at no charge on the GAO Web site at http://www.gao.gov.

If you or your staff have any questions about this report, please contact me at (202) 512-7114 or crossem@gao.gov. Contact points for our Offices of Congressional Relations and Public Affairs are on the last page of this report. GAO staff who made major contributions to this report are listed in appendix I.

Abortion-related emergency department visits in the United States: An analysis of a national emergency department sample

Ushma D. Upadhyay[1*], Nicole E. Johns[1], Rebecca Barron[2], Alice F. Cartwright[1], Chantal Tapé[2], Alyssa Mierjeski[2] and Alyson J. McGregor[2]

Abstract

Background: Media depictions and laws passed in state legislatures regulating abortion suggest abortion-related medical emergencies are common. An accurate understanding of abortion-related emergencies is important for informing policy and practice. We assessed the incidence of abortion-related emergency department (ED) visits in the United States (U.S.).

Methods: We used a retrospective observational study design using 2009–2013 data from the Nationwide Emergency Department Sample, a nationally representative sample of U.S. ED visits from 947 to 964 hospitals across the U.S. per year. All ED visits among women of reproductive age (15–49) were included. We categorized ED visits by abortion relatedness and treatments received, and assessed whether the visit was for a major incident (defined as requiring blood transfusion, surgery, or overnight inpatient stay). We estimated the proportion of visits that were abortion-related and described the characteristics of patients making these visits, the diagnoses and subsequent treatments received by these patients, the sociodemographic and hospital characteristics associated with the incidents and observation care only (defined as receiving no treatments), and the rate of major incidents for all abortion patients in the U.S.

Results: Among all ED visits by women aged 15–49 (189,480,685), 0.01% ($n = 27,941$) were abortion-related. Of these visits, 51% (95% confidence interval, 95% CI 49.3–51.9%) of the women received observation care only. A total of 20% (95% CI 19.3–21.3%) of abortion-related ED visits were for major incidents. One-fifth (22%, 95% CI 20.9–23.0%) of abortion-related visits resulted in admission to the same hospital for abortion-related reasons. Of the visits, 1.4% ($n = 390$, 95% CI 1.1–1.7%) were potentially due to attempts at self-induced abortion. In multivariable models, women using Medicaid (adjusted odds ratio, AOR 1.28, 95% CI 1.08–1.52) and women with a comorbid condition (AORs 2.47–4.63) had higher odds of having a major incident than women using private insurance and those without comorbid conditions. During the study period, 0.11% of all abortions in the U.S. resulted in major incidents as seen in EDs.

Conclusions: Abortion-related ED visits comprise a small proportion of women's ED visits. Many abortion-related ED visits may not be indicated or could have been managed at a less costly level of care. Given the low rate of major incidents, perceptions that abortion is unsafe are not based on evidence.

Background

Emergency departments (EDs) are key sites of health-care delivery in the United States (U.S.), with 141.4 million visits in 2014 alone [1], and 55% of these visits are made by women. Although abortion-related complications are rare [2], the surge in legislation aimed at regulating abortion access [3] suggests that complications are common and that abortion is generally unsafe.

Since 2011, state legislatures across the U.S. have passed numerous laws that regulate abortion provision, many requiring abortion providers to obtain local hospital admitting privileges and have transfer agreements with nearby hospitals [3]. These laws are passed under a presumption that they are needed to protect women's health and safety [4, 5] and that hospitalization as a result of abortion is an occurrence frequent enough to necessitate legislation formalizing the relationship between hospitals, abortion providers, and clinics.

National-level estimates of abortion-related ED visits do not exist. However, data from one state suggests that abortion-related ED visits are rare. In a study using data from California's Medicaid program, Upadhyay et al. found that 0.03% of abortions were followed by an immediate ambulance transfer to an ED and 2.6% of abortions were followed by an abortion-related ED visit within 6 weeks of the abortion [2]. Another study that examined all medication abortions done by Planned Parenthood in 2009 and 2010 found an ED treatment rate of 0.10%, although medication abortions represented only about 23% of abortions at the time, and this study included only those ED visits that involved treatment [6]. In a study of outcomes of abortion procedures by family physicians in New York and Philadelphia, 0.3% of first-trimester medication and aspiration abortion patients were referred or went to an ED for assessment [7].

There is a paucity of published national data on the incidence and outcomes of ED visits after abortion. In this study, we examine the frequency of abortion-related ED visits, the frequency of major abortion-related incidents, and the characteristics of abortion-related ED visits in the U.S. using a nationally representative sample of ED visits.

Methods

Study design and data source

We conducted a retrospective observational study of abortion-related ED visits using data from the Nationwide Emergency Department Sample (NEDS), a nationally representative sample of ED visits. NEDS is a database of ED visits from 947 to 964 hospitals across the U.S. per year. Annually it includes more than 30 million unweighted visits, which represent more than 135 million weighted visits. NEDS was developed for the Healthcare Cost and Utilization Project (HCUP) and is maintained by the Agency for Healthcare Research and Quality. Data are available from 2006 onward. For this study, we utilized the five most recent years of data available (2009–2013). The study was certified exempt by the institutional review board of the University of California, San Francisco.

Unweighted visits are data collected on actual visits, which are then weighted proportionately to the total number of ED visits in the country based on the sampling strategy. The NEDS is a stratified single-stage cluster sample of state-level ED data reported to HCUP. Using the American Hospital Association Annual Survey of Hospitals as the target universe, the available data are selected to approximate a 20% stratified sample of all U.S. hospital-based EDs. More details of the sampling of hospitals can be found on the HCUP website [8, 9]. The characteristics used for sample stratification in the NEDS are U.S. region, urban or rural location, teaching status, ownership, and trauma level (see Fig. 1 for region definitions and states contributing data).

The NEDS includes patient-level and hospital-level information. Each ED visit has patient-level demographic characteristics including age, sex, primary and secondary payment source, and zip code-based urbanicity and income quartile. Each ED visit also has clinical characteristics, including up to 15 diagnoses (International Classification of Diseases, 9th Revision [ICD-9] codes), up to 15 procedures or treatments (Healthcare Common Procedure Coding System [HCPCS] and Current Procedural Terminology [CPT] codes), injury codes, admission and discharge status, diagnosis and treatment codes for inpatient care if admitted to the same hospital, and total charges. Each visit also has the corresponding hospital code, and hospital characteristics such as region, trauma level, urban-rural location, and teaching status. In this dataset, 5 of 13 states in the West, 11 of 12 states in the Midwest, 8 of 16 states in the South, and 8 of 9 states in the Northeast were represented in the data. Midwest hospitals were represented the most. The trauma level of a hospital refers to how well equipped it is to provide care to patients with traumatic injuries. Trauma level influences patient composition and was key to sample stratification in the dataset. Hospital ownership was categorized by the data distributor according to information reported in the American Hospital Association Annual Survey Database. Ownership could be governmental, private non-profit, or private for-profit. Hospitals with religious affiliations, including Catholic hospitals, are included, but are not distinguished as such and may fall into private for-profit or private non-profit categories. Federal hospitals (Veterans Affairs and Department of Defense) were not included in the sample. Patient-level and hospital-level weights were also provided to generate nationally representative estimates. HCUP provided weights for the NEDS data and these

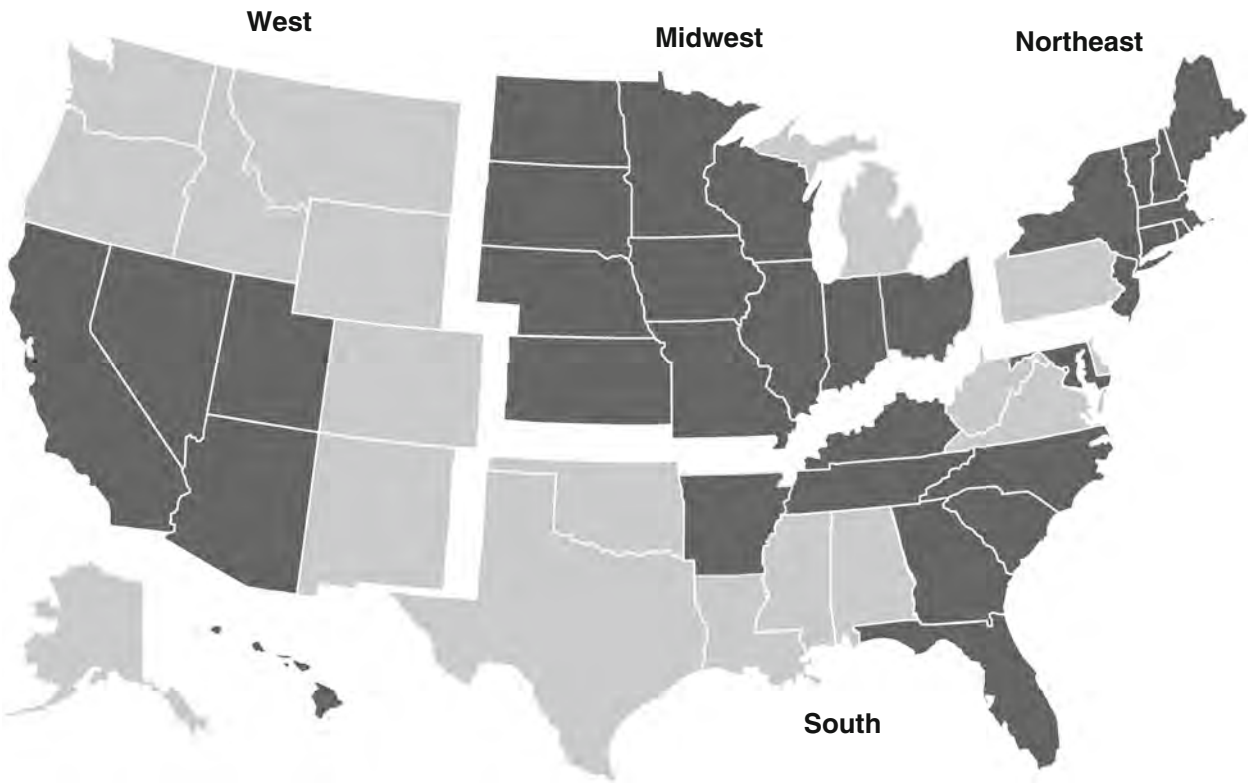

Fig. 1 U.S. regions in the National Emergency Department Sample. States in darker shades contributed data to the National Emergency Department Sample during the study period, 2009–2013

were calculated at the hospital level after sampling by hospital strata. Patient weights were calculated first by stratifying the data by hospital characteristics (region, urbanicity, trauma level, teaching status, and ownership). Within each of these strata, a weight was generated by dividing the total number of ED visits in the U.S. in that year for that stratum (from American Hospital Association data) by the number of ED visits for that stratum in the NEDS data. Weighted data thus represent all ED visits in the U.S. for a year.

Data preparation

We identified all ED visits that had an ICD-9 diagnosis code for abortion (ICD-9 diagnosis codes 635, 636, 637, and 638). We categorized ED visits by abortion relatedness and treatments received, and assessed whether the visit was for a major or minor incident. Visit categorization was based on the previously developed Procedural Abortion Incident Reporting and Surveillance (PAIRS) Framework [10]. Based on procedure codes, visits that were for observation care, repeat procedures (codes present in the dataset were CPT/HCPCS procedure codes 59812, 59820, 59821, 59840, 59841, 59851, 59855, and 59856; and ICD-9 procedure codes 6901, 6902, 6909, 6951, 6952, 6959, 734, and 750), blood transfusions (CPT/HCPCS procedure codes 36430 and P9021; and ICD-9 procedure codes 9903–9905), and abortion-related surgeries (CPT/HCPCS procedure codes 49320, 58662, 58999, 59300, and 59898; and ICD-9 procedure codes 680, 6831, 6839, 6849, 6851, 6859, 6869, and 7491) were systematically coded without individual visit review. Where procedure and diagnosis codes for a visit did not fall into one of these categories, several authors who are emergency medicine physicians or students with physician supervision provided an individual review of each visit following a modified version of the PAIRS framework (see Fig. 2). After a joint review of 100 visits with refinement of the decision rules, the physicians reviewed the remaining uncategorized visits, resulting in 1642 reviewed ED visits in total.

For each reviewed visit, the emergency medicine physicians assigned the reason for the patient's ED visit to one of five categories: abortion-related, concurrent condition, pre-existing condition, not abortion-related, or cannot determine. They classified an ED visit as abortion-related based on the constellation of diagnosis and procedure codes for that visit. Abortion-related visits included adverse events, such as hemorrhage or infection, and symptoms directly related to the procedure, such as abdominal pain and vomiting. Concurrent conditions were defined as

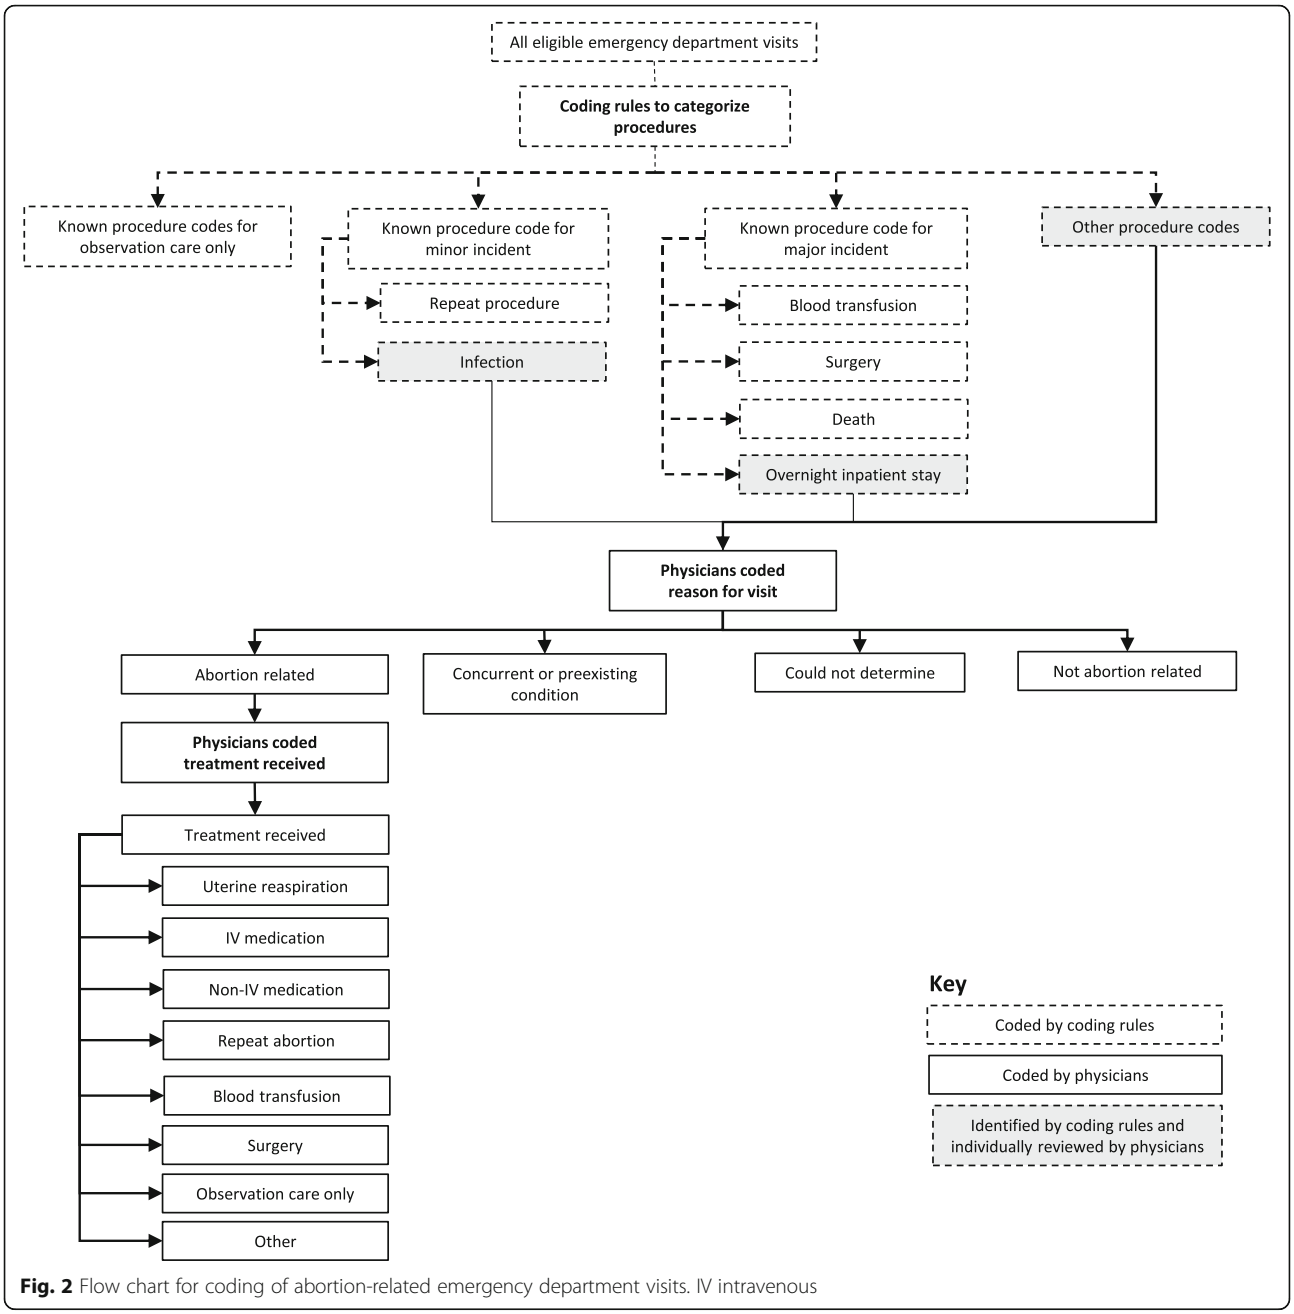

Fig. 2 Flow chart for coding of abortion-related emergency department visits. IV intravenous

conditions that may have been noticed during or exacerbated by abortion, but were not directly caused by the abortion, such as ovarian cysts, vaginitis, urinary tract infection, or anxiety/depression. Pre-existing conditions were defined as chronic conditions such as hypertension or diabetes. The data were also categorized with regards to treatments received for abortion-related complaints. Categories of treatment included uterine reaspiration (which involves suction, not an incision, and does not meet the criteria for surgery), intravenous (IV) and non-IV medication, repeat abortion, blood transfusion, surgery, observation care, or other. The medication category excluded codes for injections or infusion of a therapeutic substance if no accompanying medication was listed. The observation care category included women who had routine testing for their symptoms but did not receive any medications or other treatments. This included women who had IV fluids, blood work, testing for sexually transmitted infections, and diagnostic imaging studies, but no treatments. The NEDS dataset also included information on whether patients were admitted as an inpatient to the same hospital, discharged home, transferred to another facility, or left against medical advice. Among women who were admitted, the reason for visit

and treatment information in their chart was used to determine if the admission was likely abortion-related.

Major and minor incidents were systematically coded, with major incidents defined as those requiring an overnight inpatient stay, blood transfusion, or surgery. Minor incidents were defined as all other incidents that involved an abortion-related diagnosis or treatment. All overnight stays were further reviewed by physicians, and a group of treatments for an abortion-related diagnosis that together required the patient to stay overnight qualified as a major incident. Visits that involved concurrent conditions, pre-existing conditions, or visits that were not abortion-related were categorized as no incident. We identified the prevalence of comorbid conditions based on diagnosis codes. These included three key conditions hypothesized to be associated with abortion-related adverse events: diabetes, hypertension, and having an overweight/obese body mass index (BMI) [11–14].

ED visits were additionally categorized as being potentially indicative of a self-induced abortion. The physician team individually reviewed all abortion-related visits that had diagnosis codes of illegal abortion, failed attempted abortion, and certain injury codes (including poisonings and indications of self-harm). They looked at all of the diagnosis codes for that case and made a clinical judgement based on the group of codes together and their ED experience. Visits that were coded as illegal abortions, particularly those that included injury codes, were more often considered potentially self-induced. In addition, visits that included injury codes consistent with self-induction were categorized as such. Cases which were unlikely to have been abortion-related were removed.

Statistical analysis

We estimated the number of abortion-related ED visits annually in the U.S. and the proportion of ED visits among women of reproductive age (15–49) that were for abortion-related care. We examined the characteristics of the sample and compared these to published estimates of the characteristics of abortion patients [15]. We also described outcomes including treatments received and discharge status. Based on treatments received, ED visits were categorized as being for a major incident, a minor incident, no incident, or that the incident type could not be determined. We then built multivariable logistic regression models to examine the factors associated with major incidents and observation care, controlling for sociodemographic characteristics, comorbidities, and hospital characteristics with the ED visit as the unit of analysis. Per the recommendation of the HCUP, the organization which oversees the NEDS database, sample weights were not used in the multivariable models [16]. We also estimated the proportion of ED visits that were potentially due to attempted self-induced abortion. Because the weighted estimates are nationally representative, we were also able to use published national estimates of abortion incidence [17] to estimate the major incident rate for abortion in the U.S. during the study period. This assumes that the vast majority of major incidents go through an ED evaluation (although we acknowledge that a small percentage do not). For all analyses, we report weighted results unless otherwise specified. Where data were missing, a missing category was retained for all analyses. Statistical significance was set at $P < 0.05$ for all chi-squared tests and adjusted odds ratios (AORs). We used STATA 14 for all analyses.

Results

Among 42,493,214 unweighted visits among women of reproductive age (15–49) during the study period, 6342 visits had an abortion diagnosis. Among these, 70 visits were determined to be unrelated to abortion based on clinician review and 33 visits were duplicates (all variables were identical other than ID number); these 103 visits were excluded, leaving an analytical sample of 6239 unweighted abortion-related ED visits. We did not include an additional 101 visits with abortion diagnoses for women outside the age range of interest (younger than 15 or older than 49).

The final analytical sample corresponded to 27,941 weighted ED visits for abortion-related reasons among 189,480,685 weighted ED visits among women of reproductive age. Thus abortion-related ED visits represented 0.01% of all ED visits among women of reproductive age during the study period. All subsequent results are weighted.

The average age of the population seeking abortion-related ED care was 26, and 12.9% of visits were by women under 20 (Table 1). Women using Medicaid were most common (45.2% of visits), followed by those using private insurance (31.4%), and those who self-paid (17.1%). The population seeking abortion-related ED care was overwhelmingly of urban residence (91.0%). Low-income zip code residences were overrepresented in the sample; 27.5% of women lived in a zip code with the lowest national income quartile, while 20.5% lived in the highest income quartile. Comorbid conditions including diabetes (1.5%), hypertension (3.2%), and overweight/obese BMI (1.8%) were noted in abortion-related ED visits. Hospitals in the South (35.5%) and West (31.7%) had the largest number of abortion-related ED visits. Most visits were to non-trauma or trauma level III hospitals (62.8%) and most were to hospitals in urban locations (92.3%). Visit numbers remained approximately constant throughout the study period. Average ED costs were $4719, with 8.6% of ED visits costing $10,000 or more.

ED emergency department, *IV* intravenous
[A]Minor incident includes all other incidents that involved an abortion-related diagnosis or treatment, such as those requiring medication or repeat procedure
[B]Major incident includes those requiring overnight inpatient stay, blood transfusion, or surgery
[C]Other treatments include suture of laceration to the cervix, laminaria insertion, and abscess drainage

5.6%), abortion-related surgery (1.0%, 95% CI 0.7–1.2%), or other treatments (0.3%, 95% CI 0.2–0.5%), and 19.4% (95% CI 18.5–20.5%) of all abortion-related visits resulted in an overnight inpatient stay at the same hospital. Major incidents, treated with blood transfusion, surgery, or overnight inpatient stay, accounted for 20.3% (95% CI 19.3–21.3%) of all visits. Minor incidents accounted for 36.1% (95% CI 34.9–37.4%) of visits.

Three-quarters (75.1%) of abortion-related ED visits resulted in discharge from the ED. Another 21.2% were admitted to the same hospital for abortion-related reasons and 0.8% were admitted for non-abortion-related reasons. For the remaining 3%, the disposition was unknown or they were transferred to another medical facility or left against medical advice. Among all abortion-related ED visits over the 5 years of data ($n = 27,941$), 15 ended in the patient's death.

Several demographic and hospital factors were significantly associated with major incidents in a multivariable model (Table 3). Women over 30 were more likely than women aged 20–24 to have major incidents ($P < 0.001$), and women using Medicaid ($P = 0.004$) were more likely than women with private insurance to have a major incident. Women who paid out of pocket for the ED visit were less likely to have a major incident than women with private insurance ($P = 0.001$). The presence of any of the three examined comorbid conditions was associated with more than double the odds of a major incident compared to women without those comorbid conditions ($P < 0.01$). ED visits at trauma hospitals were more likely to be for major incidents than those at non-trauma hospitals ($P < 0.001$). ED visits in all regions were significantly more likely to be for a major incident than those in the Midwest ($P < 0.001$). There was a decreasing trend in major incidents over time. Similar significant relationships were found for factors associated with receipt of observation care only, but factors associated with increased likelihood of major incidents were associated with a lower likelihood of requiring observation care only. Two notable exceptions are a significantly higher likelihood of observation care only in the West compared to the Midwest ($P < 0.001$) and the absence of a trend over time for receipt of observation care only.

We used published rates of the total number of abortions to calculate the percentage of all abortions seen in an ED that resulted in a major incident. During the 5-year study period, there were an estimated 5,282,500 total abortions in the U.S. [17]. Using this number as the denominator, we estimate the rate of major incidents seen in EDs for abortion in the U.S. is 0.11%, or 108 per 100,000 abortions.

We identified 390 ED visits that represented potential self-induced abortion and accounted for 1.4% of abortion-related ED visits during the study period (95% CI 1.1–1.7%). There were slightly higher rates of potential self-induced abortion in the South (2.0%) than in the Midwest (1.0%), West (1.1%), and Northeast (1.3%) ($P = 0.05$) (Table 4). There were no time trends or other factors associated with self-induced abortion.

Discussion

We found that abortion-related ED visits comprised 0.01% of ED visits among women aged 15–49. In other

words, 14 of every 100,000 ED visits among women aged 15–49 were for abortion-related reasons. The majority (51%) of these were visits involving observation care only.

These data also allowed us to estimate the national major incident rate after an abortion. The rate of 0.11% (108 per 100,000) abortion patients is slightly higher than the rate of 0.05% found in a study of first trimester abortion patients in California [18], and slightly lower than the rate of 0.23% found in a study of all abortions covered by California's Medicaid program [2]. While not all abortion-related incidents lead to an ED visit and thus, are not reflected in this estimate, we believe that the vast majority of major incidents (those involving a blood transfusion, surgery, or hospital admission) are reflected here. Those that would be missed from this analysis are cases that skip the ED and are directly admitted to a hospital or an outpatient surgicenter (usually for scheduled hospitalization) and complications arising from the small proportion (4%) of abortions done in hospitals [17] and are then directly admitted. Thus, the major incident rate may be slightly underestimated.

The major incident rate for abortion (0.1%) is lower than the published rates for pregnancy (1.4%) [19], as well as other common procedures such as colonoscopy (0.2%) [20], wisdom tooth removal (1.0%) [21], and tonsillectomy (1.4%) [22]. Abortion care is, thus, safer than many other unregulated outpatient procedures. Additionally, we found 15 deaths between 2009 and 2013, which is slightly lower than the total number of abortion-related deaths reported in 2009–2012, the most recent years available ($n = 24$) [23].

Notably, the majority of visits involved observation care only, which is consistent with a previous study [2].

Table 4 Potential self-induced abortion, by region

	Weighted *N*	Weighted percentage of all abortion-related emergency department visits	Weighted percentage 95% confidence interval	Chi-squared test *P* value

South	195	2.0	1.5–2.6	
West	94	1.1	0.7–1.6	

Patients experience a range of post-abortion symptoms, including ongoing uterine cramping and bleeding for up to 3 weeks after the abortion. Patients may not realize that this is normal. Some women do not start to bleed until several days after the abortion, while some stop bleeding and then start again. Increased cramping and bleeding could start several days after the abortion. Patients may not be given ample information about what to expect or they may have trouble differentiating normal post-abortion symptoms from signs of a complication. Patient visits to EDs for non-urgent care have the potential to be costly to the health system. Such visits could be due to several reasons and little research has been done on factors that contribute to patients' decisions to visit an ED after abortion. EDs offer 24-h access to care compared to abortion facilities, which have relatively limited hours and may require an appointment [24]. The long distances that many women across the U.S. must travel to reach an abortion provider may make return visits for follow-up too arduous [25, 26]. Indeed, research found that patients who travel longer distances to reach an abortion provider are more likely to visit an ED for follow-up care or to manage subsequent symptoms and less likely to return to the original abortion provider [27]. We note that patients presenting to the ED were disproportionately of urban residence (91% in the sample compared to 81% of the U.S. population) [28]. This is likely explained in that 91% of abortion patients live in urban areas [29] and 92% of EDs in the sample were in urban areas, attracting mainly local residents who may find them convenient geographically.

Post-abortion visits to the ED may also be driven by stigma, worry, or distrust of abortion providers. A perception that abortion is unsafe [30–32] may lead women to worry about mild symptoms, such as cramping and bleeding, even though they are an expected result of abortion. Such perceptions may stem from abortion portrayals in the media and popular culture. A study of abortion-related storylines in fictional American television shows found a major incident rate of 34% [33], over 34,000% greater than the real-life major incident rate of 0.1% found here. The long-term consequences of these fictional abortions were much more likely to be severe, including frequent depictions of negative mental health sequelae, infertility, and even death.

Women using Medicaid had higher odds of major incidents than those not using Medicaid and lower odds of observation care. In this context, insurance type may be a proxy for socioeconomic status, as women requiring Medicaid are low income and as a result, face a multitude of barriers to accessing health care and are known to have poorer health status, including multiple chronic conditions, than women with private insurance. Women who were self-pay were less likely to have major incidents and more likely to receive observation care only, suggesting that patients without healthcare coverage may not have been given treatments to reduce patient costs.

We found that the pre-existing chronic conditions that have previously been suspected to be associated with major abortion-related incidents were indeed associated with a significantly higher rate of those incidents in this sample. While there is limited previous research on the impact of chronic health conditions on the risk of abortion complications, it is well established that women with chronic conditions are more likely to have pregnancy-related complications [34]. Our findings are consistent with provider guidance that suggests women with multiple chronic medical conditions may be at increased risk [35], but conflicting with previous studies that find that obesity and chronic health conditions confer no increased risk among women having abortions [11–14]. This increased risk might be explained in that women who had overnight inpatient stays (one of the categories of a major incident) were more likely to have their obesity or other chronic diseases documented in their charts than those who did not have an overnight stay.

We found some cases of potential self-induced abortions using such means as poisoning or other methods of self-harm. While self-induced abortions are safe when appropriate dosages of mifepristone and misoprostol or misoprostol alone are used, other methods are hazardous, as evidenced by ED visits. Rates were highest in the South, which is known to have the most barriers to abortion access, including the fewest providers [17, 26],

and the most state-level restrictions. States that are hostile to abortion may see more ED visits due to self-induced abortion than non-hostile states, potentially due to stigma, protesters, and other barriers to in-clinic abortion.

This study included a large, nationally representative sample of ED visits, allowing us to draw national- and regional-level conclusions about abortion safety. However, using billing codes to understand the nature of the ED visit can be imprecise and incomplete. The estimates produced here may be conservative if patients did not report having had an abortion due to fear of stigmatization or if relevant diagnosis and procedure codes were not reported or were systematically misreported. The lack of full clinical data to determine abortion relatedness could cause errors. For example, the visits in this study could include cases of miscarriage. Likewise, this study may miss abortion-related incidents that were inaccurately coded as a miscarriage.

Conclusions

These new findings can inform policy debates regarding abortion regulation in the U.S. Regulations on abortion provider or facility relationships to hospitals or EDs should be considered in light of their relative impact on improving women's health. Because abortion-related ED visits comprise a very small proportion of women's ED visits, and the rate of major incidents is very low, regulations on abortion are unlikely to have any impact on women's health outcomes. Many abortion-related ED visits are for observation only and may not be indicated or could be managed at a less costly level of care. Perceptions that abortion is unsafe are not based on evidence.

Telehealth abortion has become critical to addressing surges in demand in states where abortion remains legal but evidence on its effectiveness and safety is limited. California Home Abortion by Telehealth (CHAT) is a prospective study that follows pregnant people who obtained medication abortion via telehealth from three virtual clinics operating in 20 states and Washington, DC between April 2021 and January 2022. Individuals were screened using a standardized no-test protocol, primarily relying on their medical history to assess medical eligibility. We assessed effectiveness, defined as complete abortion after 200 mg mifepristone and 1,600 µg misoprostol (or lower) without additional intervention; safety was measured by the absence of serious adverse events. We estimated rates using multivariable logistic regression and multiple imputation to account for missing data. Among 6,034 abortions, 97.7% (95% confidence interval (CI) = 97.2–98.1%) were complete without subsequent known intervention or ongoing pregnancy after the initial treatment. Overall, 99.8% (99.6–99.9%) of abortions were not followed by serious adverse events. In total, 0.25% of patients experienced a serious abortion-related adverse event, 0.16% were treated for an ectopic pregnancy and 1.3% abortions were followed by emergency department visits. There were no differences in effectiveness or safety between synchronous and asynchronous models of care. Telehealth medication abortion is effective, safe and comparable to published rates of in-person medication abortion care.

In 2021, the US Food and Drug Administration (FDA) removed the in-person dispensing requirement on mifepristone, the first drug used in a medication abortion. This ruling allowed clinicians to begin offering a 'no-test' telehealth model of medication abortion care. Clinicians could now offer entirely remote consultations, using the patient's self-reported medical history instead of ultrasonography or other tests to screen for medical eligibility.

Moving abortion out of the clinic reduced travel, cost and stigma-related barriers and increased convenience for patients[1,2]. While telehealth abortion is usually conducted through synchronous communication, with a real-time scheduled videoconference appointment with the patient, some virtual clinics rely on entirely asynchronous communication, using secure text messaging without a scheduled interaction. Follow-up for both models is usually asynchronous, through secure text messaging.

This expansion of services became critical after the June 2022 Supreme Court Dobbs v. Jackson Women's Health Organization decision allowed states to ban abortion. In states such as Illinois, Kansas and Colorado, where abortion remained legal but neighboring states banned abortion, clinics experienced large increases in patient

[1]Department of Obstetrics, Gynecology, and Reproductive Sciences, University of California, San Francisco, San Francisco, CA, USA. volume[3]. Telehealth became vital to meeting increased demand by reducing appointment waiting times and serving patients from states with abortion bans[4]. Some individuals from US states with an abortion ban use methods such as mail forwarding and mailing medications to a friend or Post Office box close to the border in states where abortion is permitted, minimizing the travel required[5]. Additionally, some clinicians have begun to use the legal protections of their state's "shield laws" to provide medication abortion via telehealth to patients in banned states[6].

However, access to mifepristone for medication abortion has been under threat, with a federal court ruling to reverse FDA regulatory approvals of mifepristone, including the 2021 decision that allowed telehealth for abortion to continue even after the pandemic. This ruling was issued despite multiple FDA reviews and abundant evidence demonstrating the effectiveness and safety of mifepristone[7]. According to the mifepristone label, 97.4% of 16,794 patients in US clinical trials of in-person medication abortion had a complete abortion and less than 0.5% had a serious adverse event[8].

While decades of evidence support the effectiveness and safety of mifepristone provided in person, the evidence supporting no-test direct-to-patient telehealth abortion is more limited. Before 2021, US research on the effectiveness and safety of telehealth abortion was limited to clinic-to-clinic[9–11] or direct-to-patient models that required pre-abortion ultrasonography or other tests[12]. To date, only five US studies have examined the outcomes of no-test direct-to-patient telehealth abortion models; four of these had small (fewer than 350) samples of patients receiving such care; thus, they were underpowered to examine outcomes as rare as serious adverse events[13–16]. The fifth study was a retrospective examination of no-test medication abortion provided either in-person or by telehealth and mail. Among 3,779 medication abortions, 95% were complete without procedural intervention and 0.5% experienced a serious adverse event. Effectiveness and safety were similar whether medications were dispensed in-person or by mail[17,18]. However, this study did not report the effectiveness and safety outcomes of asynchronous telehealth abortion.

In this study, we used data from the California Home Abortion by Telehealth (CHAT) study to follow a large sample of patients across the US from three virtual clinics to estimate the effectiveness and safety of medication abortion care provided via telehealth. Clinicians provided telehealth abortion care via either synchronous (video) or asynchronous (secure text messaging) methods. They screened patients using a published, standardized no-test protocol, primarily relying on patient medical history to assess medical eligibility[19]. Patients who had any risk factors for or symptoms of ectopic pregnancy or were potentially beyond the gestational limit of the virtual clinic were referred for pre-abortion ultrasonography. Eligible patients received 200 mg mifepristone and 800 or 1,600 µg buccal or vaginal misoprostol via mail order pharmacy. Outcome data were collected by scheduled follow-up interactions conducted remotely 3–7 days after intake and again 2–4 weeks after medication administration (Fig. 1). Our primary aim was to assess the effectiveness and safety of telehealth medication abortion care. Our secondary aim was to compare effectiveness and safety outcomes between synchronous and asynchronous models of telehealth.

Results

We received electronic medical records for 6,974 encounters. Among those, 6,154 patients met the eligibility criteria and had abortion medications dispensed to them in 20 states and Washington, DC. We excluded cases where the patient took neither mifepristone nor misoprostol (n = 120) leaving 6,034 patients in the analytical sample (Fig. 2). Among these, 1,600 patients provided supplementary self-reported data on their outcomes via surveys (Extended Data Table 1).

All patients were pregnant and seeking abortion. Half (50.3%) were 30 years or older and 4.6% were aged under 20 years (Table 1). Race, ethnicity or ethnic grouping was unknown for one-third (34.3%)

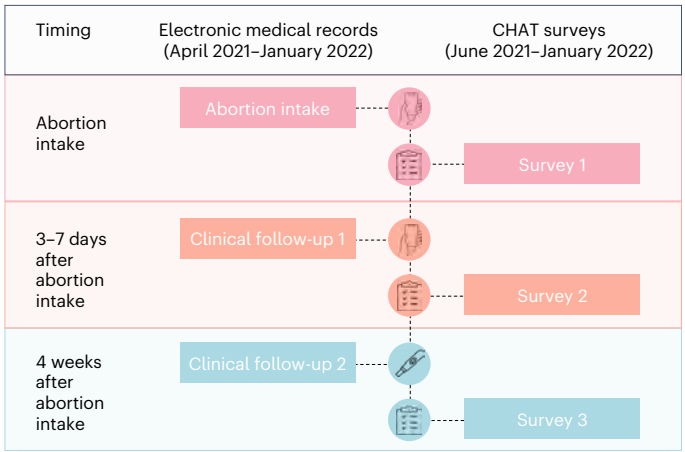

Fig. 1 | CHAT study data sources. Timing and content of the electronic medical records and survey data analyzed in the CHAT study.

of patients because one of the clinics did not record these data in their medical records for the first half of the study period. Among the subsample with known race, ethnicity or ethnic grouping, nearly two-thirds (62.7%) were white. Most (84.3%) patients had pregnancy durations under 7 weeks (≤49 days). Medical records did not document patient sex or gender.

Overall, 72.3% of patients received asynchronous care. Among patients of the clinic that offered asynchronous care but allowed patients to request a phone or video call, 0.3% requested a call with the provider. Patients who were younger (100.0% for 16–18 years, 79.3% for 18–19 years), Asian, Native Hawaiian or Pacific Islander (82.3%), Middle Eastern or North African (80.0%), living in an urban area (72.7%) and who had pregnancy durations over 56 days (74.8% for 50–56 days, 99.6% for 57–63 days and 100.0% for 64–70 days) were more likely to have received asynchronous care.

Of the sample, 76% (4,613 of 6,034) of cases had any follow-up contact with the virtual clinic or by surveys (Fig. 2). Abortion outcomes were known (ascertained using a test or the patient's history) for 74% (4,454 of 6,034) of the analytical sample. There were few sociodemographic characteristics associated with unknown outcomes. Outcomes were less likely to be known for American Indian or Alaska Native patients (57.1%), Middle Eastern or North African patients (64.0%), patients with a previous birth (70.4%), patients with a pregnancy duration of 57–63 days (66.7%) and 64–70 days (68.4%), and patients receiving asynchronous care (69.6%) (Extended Data Table 2). Among patients with unknown outcomes, two requested abortion pill reversal after they took mifepristone but before misoprostol. Both were advised that evidence-based reversal treatment does not exist and referred to urgent in-person care. No further information on their outcomes was available.

Effectiveness

Overall, results from both the complete case analysis and the imputed models found that 97.7% (95% confidence interval (CI) = 97.2–98.1%) of abortions were complete without a subsequent known intervention or ongoing pregnancy after initial treatment (Table 2 and Extended Data Table 3). The effectiveness of synchronous and asynchronous telehealth was similar; in the complete case analysis effectiveness was 98.3% (95% CI = 97.5–99.0%) in the synchronous group and 97.4% (95% CI = 96.9–98.0%) in the asynchronous group. In the final imputed analysis, effectiveness was 98.3% (95% CI = 97.7–99.0%) in the synchronous group and 97.4% (95% CI = 96.9–98.0%) in the asynchronous group. Effectiveness also did not differ according to patient age, pregnancy duration, race, ethnicity or ethnic grouping, urbanicity,

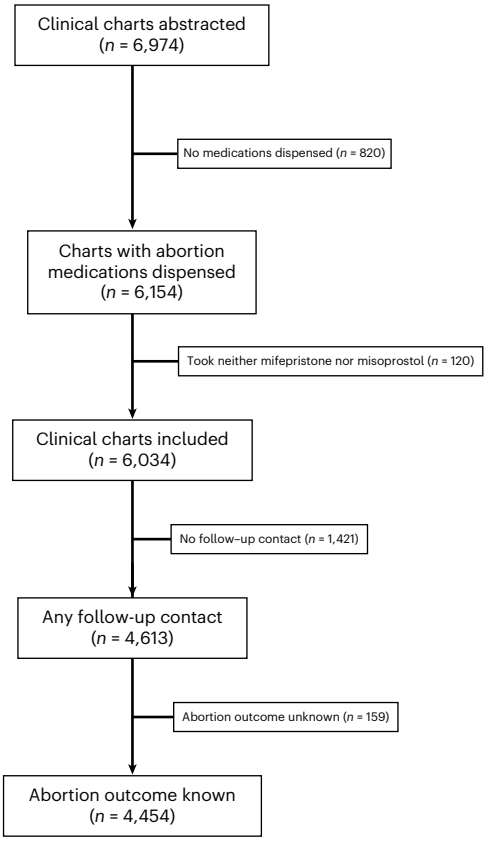

Fig. 2 | Patient flow chart. Patient flow chart depicting the exclusion criteria.

previous birth, previous abortion or whether the patient had screening ultrasonography.

Among the 2.3% (95% CI = 1.9–2.8%) of patients whose abortion was not initially complete, 0.56% were treated with more than 200 mg mifepristone, more than 1,600 µg misoprostol or other uterotonic medication to complete the abortion, 1.4% were treated with an aspiration or other abortion procedure, 0.16% were treated for an ectopic pregnancy and 0.94% had a confirmed or suspected continuing pregnancy (Table 3).

Overall, six (0.16%) patients had ectopic pregnancies; three (0.12%) were suspected ectopic pregnancies treated with methotrexate; one (0.07%) was an ectopic pregnancy treated with an unknown treatment; one (0.12%) was a cesarean scar ectopic pregnancy treated with an unknown treatment; and one (0.09%) was a ruptured ectopic pregnancy treated with a salpingectomy.

Safety

Overall, the rate of abortions that were not followed by a serious adverse event was 99.7% (95% CI = 99.5–99.8%) in the complete case analysis and 99.8% (95% CI = 99.6–99.9%) in the final imputed model (Table 2 and Extended Data Table 3). Safety was similar between patients who received synchronous and asynchronous care; in the complete case analysis, the safety rate was 99.7% (95% CI = 99.4–100.0%) in the synchronous group and 99.6% (95% CI = 99.4–99.9%) in the asynchronous group. In the final imputed model, safety was 99.8% (95% CI = 99.5–100.0%) among synchronous patients and 99.7% (95% CI = 99.6–99.9%) among asynchronous patients. In the final imputed models, safety was lower among Black or African American patients (99.3%, 95% CI = 98.7–100.0%) than among white patients (99.8%, 95% CI = 97.0–100.0%). No other factors were significantly associated with reduced safety.

Among the 0.25% of patients who experienced a serious adverse event, 0.10% received blood transfusions and 0.02% had abdominal surgery to treat a ruptured ectopic pregnancy; 0.17% of patients had hospital admissions requiring overnight stays. Among the ten (0.17%) hospital admissions, four (0.12%) received inpatient aspiration procedures, two (0.10%) were treated for infection and received an aspiration, one (0.09%) involved a blood transfusion and aspiration, one (0.09%) underwent surgery to treat a ruptured ectopic pregnancy, one (0.08%) was treated with intravenous antibiotics and one (0.09%) had a uterine infection treated with unknown treatment.

Other outcomes

Overall, 1.3% (95% CI = 1.1–1.6%) of abortions were followed by a known emergency department visit, 38.3% of which resulted in no treatment. Emergency department visits were similar between synchronous patients (1.2%, 95% CI = 0.7–1.7%) and asynchronous patients (1.4%, 95% CI = 1.0–1.7%). We identified no cases where, at the subsequent follow-up, it was determined that the abortion occurred beyond 70 days' gestation.

Sensitivity analyses

The first sensitivity analysis, where we conservatively categorized the 25 patients who were referred to in-person care and were subsequently lost to follow-up as requiring additional intervention to complete the abortion, resulted in effectiveness rates that were not significantly different from the primary analysis; overall 97.1% (95% CI = 96.5–97.6%), with 98.1% (95% CI = 97.3–98.8%) among synchronous patients and 96.7% (95% CI = 96.0–97.3%) among asynchronous patients.

In the second sensitivity analysis modeling effectiveness, we considered patients as having complete abortions regardless of the amount of misoprostol they received, which is consistent with the Medical Abortion Reporting of Efficacy (MARE) guidelines[20]. (Total misoprostol dosages according to pregnancy duration are reported in Extended Data Table 4.) This also resulted in effectiveness rates that were not significantly different from the primary analysis: 97.9% (95% CI = 97.4–98.3%) overall, 98.4% (95% CI = 97.8–99.0%) among patients who received synchronous care and 97.7% (95% CI = 97.1–98.2%) among patients who received asynchronous care.

The third sensitivity analysis, where we examined effectiveness and safety only among the subsample of patients with supplementary self-reported data on their outcomes via surveys in addition to standard clinical follow-up (n = 1,600), resulted in effectiveness rates that were not significantly different from the primary analysis: 96.7% (95% CI = 95.7–97.6%), with 97.1% (95% CI = 95.6–98.6%) among those who received synchronous care and 96.4% (95% CI = 95.2–97.6%) among those who received asynchronous care. This sensitivity analysis resulted in a similar safety rate of 99.3% (95% CI = 98.9–99.7%), and rates of 99.4% (95% CI = 98.7–100.0%) among those who received synchronous care versus 99.3% (95% CI = 98.8–99.8%) of those who received asynchronous care.

In the fourth sensitivity analysis, we conducted delta-adjusted pattern-mixture modeling to examine the potential impact of loss to follow-up on the observed results (Extended Data Table 5). Across a range of delta values, we found that the results were largely consistent with the main analysis. Under an extreme scenario in which those with unknown outcomes had ten times the odds of an incomplete abortion or serious adverse event, effectiveness for the entire sample would be 93.3% (95% CI = 92.1–94.5%) and safety would be 98.9% (95% CI = 98.3–99.4%). Under this scenario, effectiveness would be higher in the synchronous group than the asynchronous group, but there would be no differences in safety. Under the opposite and also extreme scenario in which those with unknown outcomes had ten times lower odds of an incomplete abortion, effectiveness would be 98.2% (95% CI = 97.9–98.6%) and safety would be 99.7% (95% CI = 99.6–99.9%), with no significant differences in effectiveness and safety between synchronous and asynchronous groups.

Discussion

In this large prospective cohort study, telehealth medication abortion provided primarily without tests was effective and safe. The overall 98% effectiveness rate of our primary analysis, and the effectiveness rates from the sensitivity analyses, were similar to previous large US studies of in-person medication abortion care, which found rates of 95–98%[21–24]. The serious adverse event rate of 0.25% and ectopic pregnancy rate of 0.14% were also similar to previous studies of in-person medication abortion care, which found adverse event rates of 0.2–0.5%, and ectopic pregnancy rates of 0.2%[8,23–25]. Both effectiveness and safety rates were similar to the rates for medication abortions with in-person screening tests as published on the FDA label (Fig. 3)[8].

[a]The two youngest age categories (16–17 and 18–19 years) were collapsed in the multivariable models to facilitate model convergence.[b]American Indian, Alaska Native, Middle Eastern, North African, and Multiracial groups were collapsed in the multivariable models to facilitate model convergence. Estimates were derived from marginal estimates from logistic regressions. Estimates were not adjusted for multiple comparisons. Imputation models included patient age, urbanicity, whether the patient obtained screening ultrasonography, whether the patient obtained synchronous or asynchronous telehealth care, whether the patient participated in CHAT surveys or a virtual clinic, and whether the patient used an abortion fund to pay for any portion of their abortion.

Table 3 | Medication abortion additional interventions and serious adverse events

Effectiveness and safety outcomes	*n*=4,454	Complete case *n*=4,454	Imputed[a] *n*=6,034
	No.	Estimate (95% CI)	Estimate (95% CI)

Hospital admission[c]	10	0.22 (0.09–0.36)	0.17 (0.06–0.27)
Other outcomes			
Emergency department visits	81	1.8 (1.4–2.2)	1.3 (1.1–1.6)

[a]Imputation models included patient age, urbanicity, whether the patient obtained screening ultrasonography, whether the patient obtained synchronous or asynchronous telehealth care, whether the patient participated in the CHAT study surveys or a virtual clinic, and whether the patient used an abortion fund to pay for any portion of their abortion. [b]Subcategories are not mutually exclusive. [c]Outcomes are unadjusted because of small cells. Models for estimates with $n>15$ were adjusted for synchronous versus asynchronous care, patient age, race, ethnicity or ethnic grouping, urbanicity, previous abortion, pregnancy duration at intake and pre-abortion screening ultrasonography. Estimates were calculated from logistic regression models with missing outcomes and covariates imputed using multiple imputation with chained equations.

The effectiveness and safety rates found in this study are consistent with, although slightly lower than, those found in studies of no-test telehealth abortion in other countries. A national study in the UK, which included 18,435 telehealth medication abortions, found that 99% were complete without intervention and serious adverse events occurred in 0.02% (refs. 26–28). This higher documented effectiveness rate may be explained by the lack of routine follow-up after medication abortion care in the UK; additional interventions that patients may receive may not be systematically reported to the original abortion provider.

The rates in our study are also similar to the effectiveness and safety rates documented from self-managed medication abortion models (defined as using abortion pills to end a pregnancy outside of the formal healthcare system), in the USA[29] and internationally, including in contexts where abortion is legally restricted[30,31].

The effectiveness rates for both synchronous and asynchronous services were very high and similar to in-person care. These findings have important implications for service delivery and health equity. Synchronous models with videoconferencing require strong Internet connectivity. Asynchronous models can be accessed using more types of devices; they may be more private, require shorter waiting times and can be more easily integrated into work or home schedules because no appointment is needed[32–34]. Offering patients a choice between synchronous and asynchronous care is consistent with patient-centered care and may increase access for people historically excluded from healthcare, particularly those living in rural areas or those who live far from an abortion-providing facility[1,35,36].

We used a more conservative definition of effectiveness than recommended by the MARE guidelines[20] but used in previous studies[17,37]. Our definition included an additional 22 patients who received a second medication abortion (mifepristone plus misoprostol) or more than one additional dose of misoprostol. In the context of telehealth and in the wake of the *Dobbs* decision, patients living in states that have banned abortions may experience more barriers to procedural treatment for incomplete abortion and thus be more likely to obtain additional medications to complete the abortion. Therefore, our definition of effectiveness may better account for patient experience.

While safety was over 99% among all ethnic groups, Black patients had significantly higher rates of serious adverse events than white patients. This finding is consistent with research showing higher rates of adverse obstetric outcomes among Black patients. Growing consensus finds that these disparities in obstetric health are rooted in implicit biases and structural racism[38,39].

This analysis provides an initial picture of the real-world effectiveness and safety of a rapidly expanding model of abortion care among a large US cohort. However, this analysis has several limitations. One is the lack of clinic-level variation in synchronous and asynchronous models, which may limit generalizability. However, each virtual clinic had multiple providers offering care, thereby increasing variation within each clinic and thus the generalizability of our findings. For example, different providers may use different thresholds or criteria for when to refer patients to in-person care for an ultrasound or exam, which may impact effectiveness rates. This natural variation strengthens the premise that these results could be applied to other providers offering synchronous or asynchronous care. While there was no direct comparison group, we were able to compare our results to widely accepted rates in the published literature using standardized guidelines for measuring medication abortion outcomes.

Additionally, we identified no cases of unexpected pregnancy durations beyond 70 days. This is surprising given that a previous study of no-test medication abortion found a rate of 0.38%[17]. This lack of evidence may be due to underreporting. Although most patients can accurately assess their pregnancy duration[40,41], patients who later learned that they provided a date of last menstrual period that underestimated their pregnancies may have felt that they could be held responsible and thus not reported it to the virtual clinic, particularly if it resulted in an abortion beyond 70 days.

Finally, another limitation is the follow-up rate; at 74% it was similar or higher than other studies on abortion[17,31,42,43]; attrition may have introduced selection bias given that some groups had lower follow-ups than others. In particular, we observed lower follow-up rates in the asynchronous group than the synchronous group. Telehealth is a less medicalized healthcare model, and asynchronous care even less so; those who opt for it may prefer a more autonomous experience. This differential follow-up may overestimate effectiveness and safety rates for asynchronous patients if those with concerning symptoms seek additional care without informing the virtual clinic. On the other hand, it might underestimate effectiveness rates if patients who have a negative pregnancy test or clear signs of complete abortion do not feel that they must report their outcome back to the virtual clinic. We attempted to limit this potential bias with multiple imputation. We also explored this limitation through a sensitivity analysis simulating higher and lower odds of incomplete abortions and serious adverse events among those lost to follow-up relative to those with known outcomes. This analysis demonstrated that differences in effectiveness between

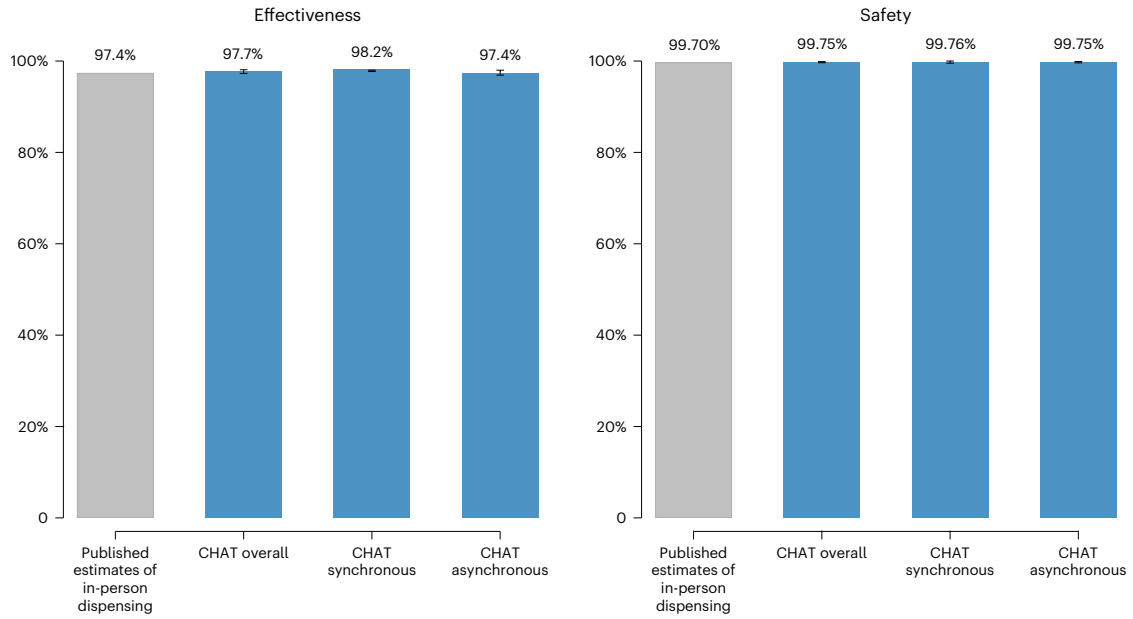

Fig. 3 | Abortion effectiveness and safety estimates: CHAT study and published estimates of in-person care. The gray bars represent published estimates from the FDA label for in-person dispensing of mifepristone; the blue bars represent the rates found in the CHAT study. Estimates for the CHAT study were calculated using marginal estimates from logistic regression analyses conducted on $n = 6{,}034$ patients. The published estimates of in-person dispensing represent the published rates drawn from the FDA label for mifepristone in 2016. The 95% CIs are represented by the black error bars.

synchronous and asynchronous groups could reach significance under extreme scenarios, but differences in safety remained nonsignificant in all scenarios tested.

These findings provide evidence that telehealth for abortion is effective and safe, with rates similar to in-person care. Additionally, synchronous and asynchronous care are comparably effective and safe. Although telehealth models cannot serve the needs and preferences of everyone, such as those who do not have electronic devices or those who are beyond the first trimester of pregnancy, offering people telehealth options has the potential to expand access to abortion care. These results are reassuring as more clinicians begin to provide telehealth abortion care to patients in US states with a ban, under the legal protections of their state's shield laws. At the same time, 11 states continue to permit abortion but have prohibitions on no-test telehealth abortion (https://www.rhites.org/state-based-resources). This study demonstrates that policies that restrict telehealth abortion owing to concerns or claims about effectiveness or safety need to be revisited and revised to ensure equitable access to this essential healthcare service.

Methods

Ethics

The CHAT study was approved by the University of California, San Francisco institutional review board (no. 20-32951) and registered with ClinicalTrials.gov (registration: NCT04432792). We used Strengthening the Reporting of Observational studies in Epidemiology guidelines to design and report the results of this study. All survey respondents provided consent to participate in the research.

Data source and study cohort

The CHAT study followed the patients of three US virtual abortion clinics: Choix (which opened in October 2020); Hey Jane (which opened in January 2021); and Abortion on Demand (which opened in April 2021). These virtual clinics were selected because they were among the first to open in the USA after the FDA temporarily suspended the in-person dispensing requirement during the COVID-19 emergency, and because they operated in states with large populations.

Medication protocols included 200 mg mifepristone orally and 800 µg misoprostol buccally or vaginally for pregnancy durations less than 63 days or 1,600 µg for pregnancy durations of 63 or more days. Care was provided based on a published protocol[19] by nurse practitioners, nurse midwives, physician assistants and physicians who specialize in abortion care. Clinics offered synchronous (video) or asynchronous (secure text messaging) telehealth abortion with mail order pharmacy delivery. One clinic offered only synchronous medication abortion care, one offered only asynchronous care and one offered asynchronous care with an option to have a phone or video call with the provider if preferred. Patients learned about the services through Web searches, social media or referrals.

During the study period, one clinic offered abortion care up to 56 days (8 weeks) of pregnancy, whereas the two other clinics offered it up to 70 days (10 weeks). As per the published protocol, patients were evaluated for medical eligibility based on the reported medical history. Pregnancy duration at intake was primarily based on self-reported date of last menstrual period or by ultrasonography, if available. Some patients had already had ultrasonography before contacting the virtual clinic. Additionally, patients were referred for pre-abortion ultrasonography if they had any risk factors for, or symptoms of, ectopic pregnancy[19] or were potentially beyond the gestational limit of the virtual clinic. Some of these patients returned to the virtual clinic after their eligibility was confirmed by ultrasonography and obtained a telehealth abortion; thus, they were included in the study. Others opted for in-person care and thus were excluded.

Each clinic had two scheduled follow-up interactions. The first confirmed medication administration and assessed symptoms of complete abortion 3–7 days after intake. The second was a low-sensitivity pregnancy test at 2 weeks or a high-sensitivity test at 4 weeks after medication administration. Follow-up interactions were conducted by text messaging, secure messaging or telephone. At each scheduled follow-up, clinicians made up to four attempts to contact patients. Clinicians referred patients to in-person care if any adverse event or incomplete abortion was suspected and outcomes of care were documented whenever possible.

For this analysis, we evaluated data collected from two sources, both imported into REDCap[44]. We obtained anonymized medical record data of consecutive patients receiving care from the participating virtual clinics between April 2021 and January 2022.

Additionally, each virtual clinic invited all patients seen between June 2021 and January 2022 to enroll in three surveys about their abortion experience, including any additional treatments received. After providing electronic informed consent, participants completed a baseline survey on the date of the intake, which included sociodemographic characteristics and medical history. Participants completed a second survey 3–7 days after the intake, to assess medication administration, additional medical care and any adverse events, and a final survey 4 weeks after the intake to assess additional medical care and adverse events (Fig. 1). The survey sample was powered to assess the acceptability of telehealth (published separately[2]); thus, we aimed to collect complete sets of surveys from 1,600 participants. Survey participants received a US$50 electronic debit card on completion of all three surveys.

Outcomes

The primary outcomes were effectiveness and safety based on standard definitions in previous studies[17,24,37,45]. We generally followed the MARE guidelines for reporting outcomes[20]. We defined effectiveness as the proportion of medication abortions that were complete after initial treatment with 200 mg mifepristone and 1,600 µg or less of misoprostol without known subsequent intervention. Abortions were not considered complete if (1) the patient had an aspiration, dilation and evacuation, other procedure or surgical intervention to complete the abortion; (2) the patient received more than 200 mg mifepristone, more than 1,600 µg misoprostol, or a uterotonic medication to complete the abortion; (3) the patient received treatment for suspected or confirmed ectopic pregnancy; or (4) the patient had a continuing pregnancy confirmed by ultrasonography or suspected at last contact. While MARE guidelines define effectiveness as successful expulsion of pregnancy without the need for procedural intervention, we chose a more conservative definition, recognizing that patients may view the need to have what constitutes a second medication abortion treatment as a failure of the medication abortion protocol.

We defined safety using standardized definitions from the Procedural Abortion Incident Reporting and Surveillance Framework[45] and Standardizing Abortion Research Outcomes protocol[46] as the proportion of abortions that were not followed by a known abortion-related serious adverse event. Serious adverse events included: blood transfusion; abdominal surgery (including salpingectomy, laparotomy and laparoscopy to treat an ectopic pregnancy); hospital admission requiring overnight stay; or death.

Effectiveness and safety outcomes were determined from all information collected in the medical records and surveys. Abortion completion was determined based on the virtual clinic's designation, either using a test (urine pregnancy test, ultrasonography or serum human chorionic gonadotrophin) or using the patient's medical history (using a checklist reflecting symptoms of complete abortion) without further contact related to the abortion for at least 6 weeks after the intake visit. Patients without outcomes noted in the medical records were determined to have complete abortions if they completed a survey at least 28 days after screening and did not report an intervention or ongoing pregnancy.

Secondary outcomes included the number of cases where, at the subsequent follow-up, it was determined that at intake the patient had been beyond 70 days' gestation. We also evaluated rates of suspected or confirmed ectopic pregnancy and emergency department visits.

Covariates

We examined the categorical covariates reflecting participant age at abortion intake in years (16–17 years, 18–19 years, 20–24 years, 25–29 years, 30–34 years and 35 years or older), and pregnancy duration in days at abortion intake (less than 35 days, 35–49 days, 50–56 days, 57–63 days, 64–70 days or unknown). We also included a measure of race, ethnicity or ethnic grouping indicated by participants on an intake form or in the surveys (American Indian or Alaska Native, Asian, Native Hawaiian or Pacific Islander, Black or African American, Middle Eastern or North African, White, Multiracial or Unknown). We included binary covariates for urbanicity (suburban or rural versus urban), whether the patient had a previous abortion, whether the patient had a previous birth and whether the patient had confirmatory pre-abortion ultrasonography.

Exposure
The key exposure was a binary measure reflecting whether the patient received care synchronously (video) or asynchronously (secure text messaging).

Statistical analysis
The study was powered to detect differences in the rarest primary outcome, that is, serious adverse events. We aimed to have outcome data from 4,202 patients. The study was designed to detect a difference of 0.4% or more in the rate of serious adverse events compared to 0.5%, the rate for in-person medication abortions as published in the FDA label[8], with 90% power and a two-sided alpha of 0.05. With a final sample size of 4,454, the study had more than 90% power to detect a difference of 2% or more in the effectiveness rate compared to the 3% rate for in-person medication abortions as published on the FDA label[8].

We described the characteristics of the overall sample and the subsample of patients who completed the surveys. We examined the extent of loss to follow-up and whether loss to follow-up differed between those who obtained synchronous and asynchronous care. We then conducted multiple imputation by chained equations to account for missing covariate and outcome data with 100 replications for primary regression analyses, assuming that missing data were related to observed patient and abortion characteristics. Multiple imputation by chained equations iteratively impute missing data using predictive models based on other variables in the dataset, and accounts for statistical uncertainty in the imputations[47]. Imputation models included patient age, urbanicity, whether the patient obtained screening ultrasonography, whether the patient obtained synchronous or asynchronous telehealth care, whether the patient participated in CHAT surveys, virtual clinics, and whether the patient used an abortion fund to pay for any portion of their abortion.

We developed logistic regression models for all effectiveness and safety outcomes. We used multivariable models for outcomes $n > 15$, adjusting for a binary measure of whether the patient received screening via synchronous or asynchronous methods. These models were also adjusted for baseline patient and abortion characteristics, including patient age, race, ethnicity or ethnic grouping, and pregnancy duration. We included binary measures reflecting whether the patient had a previous abortion or birth, and whether the patient had pre-abortion ultrasonography[21]. For rare outcomes ($n < 15$), we used unadjusted logistic regression models.

We calculated marginal estimates, the corresponding 95% CIs and *P* values from the logistic regression results to estimate the predicted probability of each effectiveness and safety outcome. Primary estimates came from logistic regression analyses performed on imputed data. *P* values correspond to a Wald test in the logistic regressions, comparing each group to the reference group. We then compared results with published estimates of effectiveness and safety. All statistical tests were two-tailed with significance set at 0.05. All analyses were conducted using Stata v.17.0 (StataCorp LLC).

We conducted several sensitivity analyses to assess the robustness of our findings. First, we replicated the effectiveness analysis, assuming that patients who were referred to in-person care after taking the medications and were then lost to follow-up required further intervention to complete the abortion. Second, we replicated the effectiveness analysis by categorizing all patients who received any additional misoprostol as completed abortions. This is consistent with the MARE guidelines and previous studies[26,48], which classified patients who received more than 1,600 µg of misoprostol (more than two doses) as successful abortions. Third, we examined both effectiveness and safety outcomes only among the subsample of patients who completed the surveys to evaluate whether the main findings held true among this sample with supplementary self-reported data on their outcomes. Finally, to test how robust our results were to the follow-up rates, we used delta-adjusted pattern-mixture model imputation[49] to simulate the outcomes under different assumptions regarding patients with missing outcome data, hypothesizing results if they had lower or higher odds of incomplete abortion or serious adverse events than those with outcome data.

Reporting summary
Further information on research design is available in the Nature Portfolio Reporting Summary linked to this article.

Data availability
The datasets analyzed during this study are not publicly available because the patients who underwent an abortion did not consent to sharing their data beyond the primary researchers and because the legal status of abortion care is continually changing. The de-identified, individual-level data used to reach the study conclusions are available to qualified investigators from the corresponding author. Requesters must include a description of their research project, the qualifications of the research team, whether the analysis has institutional review board approval and how the results will be disseminated. Requesters must also sign a data use agreement to (1) use the data only for research purposes, (2) not attempt to re-identify the data or contact the study participants, (3) secure the data using appropriate computer technology and (4) destroy the data after the analyses are completed. Responses can be expected within 1 month of a request.

Code availability
Data analyses were carried out using Stata v.17.0 (StataCorp LLC) as specified in the Methods. The code is available on GitHub (https://github.com/Upadhyay-Lab).

https://doi.org/10.1038/s41591-024-02834-w

Extended Data Table 4 | Total misoprostol dosage administered after 200 mg mifepristone according to pregnancy duration (*n*=4,454)

	<9 weeks		≥9 weeks	
	N	Effectiveness	N	Effectiveness
0 µg misoprostol	1	0.0%	0	
400 µg misoprostol	1	100.0%	0	
800 µg misoprostol	4,187	98.3%	12	100.0%
1,400 µg misoprostol	1	0.0%	0	
1,600 µg misoprostol	171	90.6%	69	95.7%
2,000 µg misoprostol [a]	2		0	
2,400 µg misoprostol [a]	7		0	
3,200 µg misoprostol [a]	2		0	
4,000 µg misoprostol [a]	1		0	

Misoprostol dose taken estimated based on clinic protocol and/or medical record notes. 800 mcg is routinely provided to patients <9 weeks and 1,600 mcg is routinely provided for patients >9 weeks. Additional misoprostol is provided to all patients as needed.

Rates are estimated from simple proportions.

[a] – Misoprostol administered beyond 1,600 mcg constitutes an additional intervention.

https://doi.org/10.1038/s41591-024-02834-w

Extended Data Table 5 | Pattern-mixture model imputation with delta correction to explore the potential impact of informative missingness in abortion outcomes

Delta, exp	Effectiveness Rate % (95% CI)				Safety Rate % (95% CI)			
	Overall	Synchronous	Asynchronous	p-value	Overall	Synchronous	Asynchronous	p-value
0.1	93.3 (92.1, 94.5)	96.6 (95.3, 97.9)	92.0 (90.3, 93.7)	<0.001	98.9 (98.3, 99.4)	99.3 (98.7, 100.0)	98.7 (97.9, 99.4)	0.227
0.2	95.5 (94.6, 96.3)	97.5 (96.5, 98.5)	94.7 (93.5, 95.9)	0.003	99.3 (98.9, 99.7)	99.5 (99.1, 100.0)	99.2 (98.7, 99.7)	0.331
0.5	97.1 (96.5, 97.6)	98.1 (97.3, 98.9)	96.7 (95.9, 97.5)	0.035	99.6 (99.3, 99.8)	99.7 (99.4, 100.0)	99.5 (99.3, 99.8)	0.523
1.0	97.7 (97.2, 98.1)	98.3 (97.5, 99.0)	97.4 (96.9, 98.0)	0.126	99.7 (99.5, 99.8)	99.7 (99.4, 100.0)	99.6 (99.4, 99.9)	0.668
2.0	98.0 (97.6, 98.4)	98.4 (97.7, 99.0)	97.8 (97.3, 98.3)	0.267	99.7 (99.6, 99.9)	99.7 (99.5, 100.0)	99.7 (99.5, 99.9)	0.777
5.0	98.2 (97.8, 98.5)	98.4 (97.8, 99.1)	98.1 (97.6, 98.5)	0.431	99.7 (99.6, 99.9)	99.8 (99.5, 100.0)	99.7 (99.6, 99.9)	0.860
10.0	98.2 (97.9, 98.6)	98.4 (97.8, 99.1)	98.2 (97.7, 98.6)	0.506	99.7 (99.6, 99.9)	99.8 (99.5, 100.0)	99.7 (99.6, 99.9)	0.892

Delta values represent the hypothetical odds ratio for the association between missing outcomes and each abortion outcome (effectiveness or safety). For example, a Delta value of 0.1 in the effectiveness analysis represents a hypothetical and extreme scenario in which the odds of incomplete abortion are 10 times higher among those with unknown abortion outcomes, compared to those with known abortion outcomes. Meanwhile, a Delta value of 10.0 in the effectiveness analysis represents a hypothetical scenario in which the odds of incomplete abortion are 10 times lower among those with missing abortion outcomes, compared to those with known abortion outcomes. P-values correspond to two-sided Wald's test in logistic regressions comparing abortion outcomes for synchronous and asynchronous care.

Reporting Summary

Nature Portfolio wishes to improve the reproducibility of the work that we publish. This form provides structure for consistency and transparency in reporting. For further information on Nature Portfolio policies, see our Editorial Policies and the Editorial Policy Checklist.

Statistics

For all statistical analyses, confirm that the following items are present in the figure legend, table legend, main text, or Methods section.

n/a	Confirmed
☐	☒ The exact sample size (*n*) for each experimental group/condition, given as a discrete number and unit of measurement
☐	☒ A statement on whether measurements were taken from distinct samples or whether the same sample was measured repeatedly
☐	☒ The statistical test(s) used AND whether they are one- or two-sided *Only common tests should be described solely by name; describe more complex techniques in the Methods section.*
☐	☒ A description of all covariates tested
☐	☒ A description of any assumptions or corrections, such as tests of normality and adjustment for multiple comparisons
☐	☒ A full description of the statistical parameters including central tendency (e.g. means) or other basic estimates (e.g. regression coefficient) AND variation (e.g. standard deviation) or associated estimates of uncertainty (e.g. confidence intervals)
☐	☒ For null hypothesis testing, the test statistic (e.g. *F*, *t*, *r*) with confidence intervals, effect sizes, degrees of freedom and *P* value noted *Give P values as exact values whenever suitable.*
☒	☐ For Bayesian analysis, information on the choice of priors and Markov chain Monte Carlo settings
☒	☐ For hierarchical and complex designs, identification of the appropriate level for tests and full reporting of outcomes
☒	☐ Estimates of effect sizes (e.g. Cohen's *d*, Pearson's *r*), indicating how they were calculated

Our web collection on statistics for biologists contains articles on many of the points above.

Software and code

Policy information about availability of computer code

Data collection	Authors used Research Electronic Data capture (REDCap) to standardize and store electronic medical record and survey data.
Data analysis	All analyses were conducted using Stata version 17.0 (College Station, TX). Code is available on GitHub (https://github.com/Upadhyay-Lab)

For manuscripts utilizing custom algorithms or software that are central to the research but not yet described in published literature, software must be made available to editors and reviewers. We strongly encourage code deposition in a community repository (e.g. GitHub). See the Nature Portfolio guidelines for submitting code & software for further information.

Data

Policy information about availability of data

All manuscripts must include a data availability statement. This statement should provide the following information, where applicable:

- Accession codes, unique identifiers, or web links for publicly available datasets
- A description of any restrictions on data availability
- For clinical datasets or third party data, please ensure that the statement adheres to our policy

The data sets analyzed during this study are not publicly available because the abortion patients did not consent to sharing their data beyond the primary researchers and because the legal status of abortion care is continually changing. De-identified individual-level data used to reach the study conclusions are available to qualified investigators from the corresponding author. Requesters must include a description of their research project, the qualifications of the research team, whether the analysis has institutional review board approval, and how the results will be disseminated. Requesters must also sign a data use agreement to: i)

use the data only for research purposes, iii) not attempt to re-identify the data or contact study participants, iv) securely store this data using appropriate computer technology, and iv) destroy the data after analyses are completed. Responses can be expected within one month of a request.

Human research participants

Policy information about studies involving human research participants and Sex and Gender in Research.

Reporting on sex and gender	This study focuses on populations who are sexually active and pregnant or able to get pregnant. This study did not exclude anyone based on their gender, but because we examined conditions related to pregnancy, participants in this study were likely assigned female at birth. We did not report information about gender identity in this study because data on gender identity were not in the electronic medical records data.
Population characteristics	This study includes a sample of consecutive patients of 3 of the major virtual clinic abortion providers in the U.S. who were provided telehealth medication abortion care in 20 states and Washington, D.C. between April 2021 and January 2022. Eligible participants were provided medication abortion care at a participating clinic and administered the provided medications. Half (50.3%) were 30 years or older and 4.6% were under 20 years old (Table 1). Race or ethnicity was unknown for one-third (34.3%) of patients, however, among the subsample with known race or ethnicities, nearly two-thirds (62.7%) were White. Most (84.3%) patients had pregnancy durations under 7 weeks (≤ 49 days).
Recruitment	Electronic medical records data included all patients provided telehealth medication abortion care by the participating virtual clinics during a defined time period, and therefore we expect the sample to be representative of patients obtaining telehealth abortion care at virtual clinics during the study period. Participants self-selected into participating in the survey subsample, however the characteristics of the survey subsample characteristics were similar to those of the medical records sample.
Ethics oversight	The study was approved by the University of California, San Francisco Institutional Review Board (#0-32951)

Note that full information on the approval of the study protocol must also be provided in the manuscript.

Field-specific reporting

Please select the one below that is the best fit for your research. If you are not sure, read the appropriate sections before making your selection.

☒ Life sciences ☐ Behavioural & social sciences ☐ Ecological, evolutionary & environmental sciences

For a reference copy of the document with all sections, see nature.com/documents/nr-reporting-summary-flat.pdf

Life sciences study design

All studies must disclose on these points even when the disclosure is negative.

Sample size	The study was powered to detect differences in the rarest primary outcome, serious adverse events. We aimed to have outcome data from 4,202 patients. The study was designed to detect a difference of 0.4% or more in the rate of serious adverse events compared to 0.5%, the rate for in-person medication abortions as published in the FDA label, with 90% power and two-sided alpha 0.05. With a final sample size of 4,454, the study had >90% power to detect a difference of 2% or more in the effectiveness rate compared to the 3% rate for in-person medication abortions as published on the FDA label.
Data exclusions	Among the 6,974 encounters for which we originally received data, 820 patients were not provided with abortion medications. These patients were excluded because they not treated with the study intervention. Among the remaining sample, 120 patients were excluded from analyses of abortions safety and effectiveness because they took neither study drug (neither mifepristone nor misoprostol).
Replication	We conducted 4 sensitivity analyses using alternative assumptions to replicate our experimental findings, the results of which supported the robustness of our primary analysis. We plan to post all code used to reach the study conclusions on Github prior to publication.
Randomization	As this was an observational study, participants were not randomly assigned to exposure arms in this study. We reviewed the literature on abortion effectiveness and safety to identify covariates potentially related to abortion safety and effectiveness and controlled for the factors available in the data in our analyses when possible.
Blinding	Blinding was not relevant for this study due to its observational design in which exposures were not assigned.

Reporting for specific materials, systems and methods

We require information from authors about some types of materials, experimental systems and methods used in many studies. Here, indicate whether each material, system or method listed is relevant to your study. If you are not sure if a list item applies to your research, read the appropriate section before selecting a response.

Materials & experimental systems

n/a	Involved in the study
☒	☐ Antibodies
☒	☐ Eukaryotic cell lines
☒	☐ Palaeontology and archaeology
☒	☐ Animals and other organisms
☐	☒ Clinical data
☒	☐ Dual use research of concern

Methods

n/a	Involved in the study
☒	☐ ChIP-seq
☒	☐ Flow cytometry
☒	☐ MRI-based neuroimaging

Clinical data

Policy information about clinical studies

All manuscripts should comply with the ICMJE guidelines for publication of clinical research and a completed CONSORT checklist must be included with all submissions.

Clinical trial registration	NCT04432792
Study protocol	The study protocol is available online at: https://clinicaltrials.gov/study/NCT04432792
Data collection	This study included two sources of data. The first was anonymized electronic medical records data from consecutive patients who received care from the three participating virtual clinics between April 2021 and January 2022. Medical records data was anonymized and exported from the virtual clinic's electronic medical record. The second data source was collected from a subsample who participated in surveys. Each virtual clinic invited all patients seen between June 2021 and January 2022 to enroll in three surveys about their abortion experience. After providing electronic informed consent, participants completed a baseline survey on the date of intake, which included sociodemographic characteristics and medical history. Survey recruitment and administration took place online on the virtual clinic's care platform to maintain continuity for participants. Both data sources were standardized in REDCap.
Outcomes	We defined effectiveness as the proportion of medication abortions that were complete after initial treatment with mifepristone 200 mg and misoprostol <1,600 mcg without known subsequent intervention. Abortions were not considered complete if (1) the patient had an aspiration, dilation and evacuation, other procedure, or surgical intervention to complete the abortion; (2) the patient received >200 mg mifepristone, >1,600 mcg misoprostol, or a uterotonic medication to complete the abortion; (3) the patient received treatment for suspected or confirmed ectopic pregnancy; or (4) the patient had a continuing pregnancy confirmed by ultrasound or suspected at last contact. We defined safety as the proportion of abortions that were not followed by a known abortion-related serious adverse event. Serious adverse events included: blood transfusion, abdominal surgery (including salpingectomy, laparotomy and laparoscopy to treat ectopic pregnancy), hospital admission requiring overnight stay, or death. Effectiveness and safety outcomes were determined from all information collected in clinical charts and surveys. Abortion completion was determined based on the virtual clinic's designation, either by test (urine pregnancy test, ultrasonography, or serum human chorionic gonadotrophin), or by history (using a checklist reflecting symptoms of complete abortion) without further contact related to the abortion for at least 6 weeks following the intake visit. Patients without outcomes noted in clinical charts were determined to have complete abortions if they completed a survey at least 28 days after screening and did not report an intervention or ongoing pregnancy. Secondary outcomes included the number of cases where at subsequent follow-up, it was determined that at intake the patient had been beyond 70 days gestation. We also evaluated rates of suspected or confirmed ectopic pregnancy and emergency department visits.

Incidence of Emergency Department Visits and Complications After Abortion

Ushma D. Upadhyay, PhD, MPH, Sheila Desai, MPH, Vera Zlidar, MHS, Tracy A. Weitz, PhD, MPA, Daniel Grossman, MD, Patricia Anderson, MPH, and Diana Taylor, PhD, RNP

OBJECTIVE: To conduct a retrospective observational cohort study to estimate the abortion complication rate, including those diagnosed or treated at emergency departments (EDs).

METHODS: Using 2009–2010 abortion data among women covered by the fee-for-service California Medicaid program and all subsequent health care for 6 weeks after having an abortion, we analyzed reasons for ED visits and estimated the abortion-related complication rate and the adjusted relative risk. Complications were defined as receiving an abortion-related diagnosis or treatment at any source of care within 6 weeks after an abortion. Major complications were defined as requiring hospital admission, surgery, or blood transfusion.

RESULTS: A total of 54,911 abortions among 50,273 fee-for-service Medi-Cal beneficiaries were identified. Among all abortions, 1 of 16 (6.4%, n=3,531) was followed by an ED visit within 6 weeks but only 1 of 115 (0.87%, n=478) resulted in an ED visit for an abortion-related complication. Approximately 1 of 5,491 (0.03%, n=15) involved ambulance transfers to EDs on the day of the abortion. The major complication rate was 0.23% (n=126, 1/436): 0.31% (n=35) for medication abortion, 0.16% (n=57) for first-trimester aspiration abortion, and 0.41% (n=34) for second-trimester or later procedures. The total abortion-related complication rate including all sources of care including EDs and the original abortion facility was 2.1% (n=1,156): 5.2% (n=588) for medication abortion, 1.3% (n=438) for first-trimester aspiration abortion, and 1.5% (n=130) for second-trimester or later procedures.

CONCLUSION: Abortion complication rates are comparable to previously published rates even when ED visits are included and there is no loss to follow-up.

With 1.1 million induced abortions in the United States each year,[1] accurate estimates of abortion complications are paramount to assess and improve quality of care and determine how public policies can most effectively safeguard women's health. Although national abortion-related mortality data exist for the United States,[2] no surveillance system captures abortion-related morbidity. Studies find varying complication rates[3–7] depending on the procedure, weeks of gestation, length of follow-up, and protocols used to detect complications. Furthermore, complication rates are underestimated by low follow-up rates.[5,7–9]

Published complication rates are considered incomplete because they usually do not include those diagnosed at sites other than the original source of care.[10]

Limited research focuses on emergency department (ED) use when examining postabortion care. Because the abortion care delivery system is concentrated in urban centers maldistributed across states,[1] women often travel to obtain abortion care. Thus, women are likely to seek postabortion care at an ED near their home.

Using state Medicaid data, we examine reasons for postabortion visits, contributing to the literature

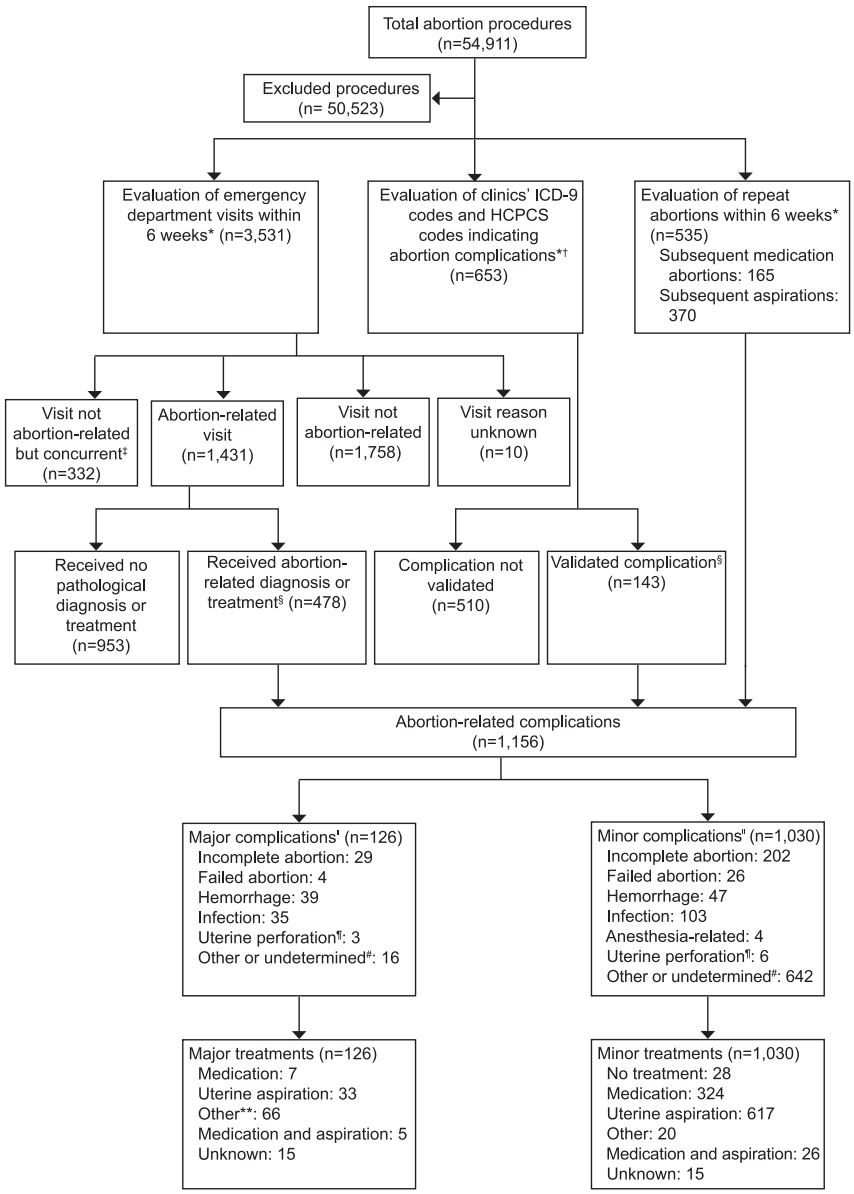

Fig. 1. Process of identification and classification of abortion complications and treatment. ICD-9, International classification of Diseases, 9th Revision; HCPCS, Healthcare Common Procedure Coding System. *Figures presented in the evaluation categories are not mutually exclusive. For example, a complication may have been identified through the evaluation of both emergency department visits and ICD-9 codes and, thus, are represented in both categories. †Includes diagnosis and treatment codes for antibiotics commonly used to treat abortion-related infections, genital tract and pelvic infection, hemorrhage, damage to pelvic organs or tissues, shock, embolism, laparoscopy, laparotomy, and hysterectomy surgeries, and blood transfusions. ‡Includes medical problems that were diagnosed and treated around the time of the abortion procedure such as ectopic pregnancy, molar pregnancy, preexisting medical condition, or concurrent problems present at the time of the procedure. §Confirmed as a complication based on the additional diagnosis or treatment codes, including laboratory tests ordered and medications. ‖Major complications were defined as serious unexpected adverse events requiring hospital admission, surgery, or blood transfusion. Minor complications were all other expected adverse events. ¶Includes one diagnosis of cervical injury requiring suture repair. #For major complications, this diagnosis includes undetermined diagnoses that required blood transfusions and surgery. For minor complications, the majority of this diagnosis consisted of cases treated with repeat abortion, but the exact diagnosis could not be determined. This category also includes diagnoses such as non-anesthesia-related allergic reactions and seizures. **Major treatments include combinations of treatments including blood transfusion (n=50) and surgery (n=13).

on ED use among patients with public insurance.[11,12] Then, using a standardized methodology for identifying and classifying complications, we estimate the incidence of postabortion complications diagnosed, treated, or diagnosed and treated at all clinical sites to see whether the rate of complications in a closed system with complete follow-up differs from the rates found in other studies.

MATERIALS AND METHODS

We used patient-level billing data from Medi-Cal, California's State Medicaid program. Medi-Cal provides pregnant low-income women immediate, temporary Medicaid coverage. California is one of 17 states that covers abortion and subsequent care for women enrolled in Medicaid. In 2011 an estimated 512 facilities in California performed 181,730 abortions,[1] approximately 51% of which were covered by Medi-Cal.[13]

The study was approved by the institutional review boards of the University of California, San Francisco and the California Health and Human Services Agency.

Medi-Cal is administered on a fee-for-service or managed care arrangement, split approximately in half across the two. Only the fee-for-service billing records contain complete information for care provided to a particular beneficiary; therefore, we received data only for those beneficiaries with fee-for-service coverage. We obtained billing records for every fee-for-service beneficiary who had an abortion

* These are medical problems that were diagnosed, treated, or diagnosed and treated at the time of the abortion procedure (eg, ectopic or molar pregnancy, preexisting medical condition, or concurrent problems present at the time of the procedure).

† These are cases in which a patient received an abortion-related diagnosis or treatment and therefore were considered a complication.

‡ These are cases in which a patient presented with abortion-related symptoms but did not receive a pathologic diagnosis or treatment (eg, observation only).

in 2009 and 2010 and all billing records for all clinical encounters for each of those beneficiaries up to 6 weeks after the abortion. Each clinical encounter results in multiple ($\bar{x}$=12) billing records; thus, we acquired 659,361 records.

Data included an encrypted beneficiary identification number, date of birth, race or ethnicity, city, state, zip code, date(s) of service, type of facility, diagnosis (International Classification of Diseases, 9th Revision [ICD-9] codes), procedure or treatment (Healthcare Common Procedure Coding System, Current Procedural Terminology [CPT] codes), facility type, and amount paid per treatment. For each abortion, we calculated the beneficiary's age and urban or rural residence (determined by zip code).

Abortions were identified using Healthcare Common Procedure Coding System codes (59840–59841, 59850–59852 and 59855–59857, X7724, Z0336); these codes also indicated the abortion type: 1) "medication abortions," which includes use of mifepristone and misoprostol up to 9 weeks of gestation; 2) "first-trimester aspiration," which includes both manual and electric aspiration abortions as well as dilation and curettage "in the first 12–14 weeks of gestation"[14]; and 3) "second-trimester or later procedures." Included in this latter category are medical and surgical abortions performed using multiple abortion techniques such as dilation and evacuation, with or without osmotic dilators and misoprostol as well as full or partial inductions used "after 12–14 weeks of gestation."[14] The billing data that we had did not allow us to make a determination of weeks of gestation nor the specific technique used.

We searched for additional claims made to MediCal up to 6 weeks after the abortion for each abortion identified. Postabortion ED visits (not including urgent care) within 6 weeks were identified using codes associated with ED use (Healthcare Common Procedure Coding System codes: 99281–99285, and Z7502). Clinically trained reviewers evaluated all available billing data (including all ICD-9 and Healthcare Common Procedure Coding System or CPT procedure codes) for each beneficiary who had an ED visit and assigned the visit to one of three categories: 1) not abortion-related; 2) not abortion-related but for a concurrent problem (diagnosed, treated, or diagnosed and treated at the time of the abortion); and 3) abortion-related. An ED visit was classified as abortion-related based on the constellation of ICD-9

Table 3. Major and Minor Abortion-Related Complication Rates by Procedure Type

Complication Type	Medication Abortion (n=11,319) Rate/100 (95% CI)	n	1st-Trimester Aspiration (n=34,755) Rate/100 (95% CI)	n
Major	0.31 (0.21–0.41)	35	0.16 (0.12–0.21)	57
Minor	4.88 (4.49–5.28)	553	1.10 (0.99–1.21)	381
Total complications	5.19 (4.79–5.60)	588	1.26 (1.14–1.38)	438

Downloaded from http://journals.lww.com/greenjournal by BhDMf5ePHKav1zEoum1tQfN4a+kJLhEZgbsIHo4XMi0hCywCX1AWnYQp/IlQrHD3i3D0OdRyi7TvSFl4Cf3VC1y0abggQZXdtwnfKZBYtws= on 05/01/2025

and Healthcare Common Procedure Coding System or CPT procedure codes for that visit. For example, in many cases, it was a combination of an ICD-9 code for an abortion, postabortion complication, or abdominal pain that indicated that the visit was abortion related along with a Healthcare Common Procedure Coding System or CPT procedure code for a pregnancy test, pelvic examination, transvaginal ultrasonography, abdominal ultrasonography, or dose of misoprostol.

Each abortion-related visit was then classified as 1) woman received an abortion-related diagnosis, treatment, or both; or 2) woman presented with abortion-related symptoms such as abdominal pain or cramping but received no pathologic diagnosis or treatment. When ED visits took place for multiple reasons, only the reason most closely related to the abortion was recorded (Fig. 1).

Additionally, we identified all ambulance transfers (Healthcare Common Procedure Coding System codes: X0030, X0034, X0036, X0400, X0402, X0412) and all self-referred ED visits on the day of the abortion regardless of whether the visit resulted in an abortion-related diagnosis or treatment.

The process of identifying and classifying abortion complications involved several steps. We defined a complication as any postabortion adverse event that received an abortion-related diagnosis or treatment at any source of care, including EDs and the original abortion facility within 6 weeks of an abortion procedure. To identify complications, the clinically trained reviewers evaluated all: 1) abortion-related diagnoses and treatments identified through the ED visit analysis described previously (excluding visits having no pathologic diagnosis or treatment); 2) ICD-9 codes that indicate abortion-related complications (635.00–635.82) and Healthcare Common Procedure Coding System or CPT codes for laparoscopy, laparotomy, and hysterectomy surgeries (49000, 49320, 49329, 58150, 58578, 58960), blood transfusions (86970, P9016–P9021, P9048, 390), and antibiotics commonly used to treat abortion-related infections and sepsis at least 1 day after the abortion; and 3) subsequent medication abortions and aspirations within 6 weeks.

The reviewers examined each case identified through this process and applied a systematic classification scheme developed by several of this study's authors and used in a recent study of abortion safety.[3] The classification system comprised a list of known abortion complications with standard definitions that included specific criteria (signs, symptoms, laboratory findings) to indicate the complication diagnosis. To validate the system, first, outside experts who work with the U.S. Agency for Health Research & Quality Evidence-Based Practice Centers and from abortion-related research or service delivery reviewed the classification system. Second, a Data and Clinical Safety Monitoring Committee reviewed incident data to further clarify complication definitions and criteria.

For this study, the clinician reviewers categorized each identified case into one of seven diagnoses: incomplete abortion, failed abortion, hemorrhage, infection, uterine perforation, anesthesia-related, and other or undetermined. The clinically trained reviewers examined all available billing data for the beneficiary, including laboratory tests ordered and medications, to validate each diagnosis. For example, to confirm a diagnosis of failed abortion, they checked for additional confirmatory evidence such as codes for aspiration or prenatal care. For diagnoses of hemorrhage, the reviewers looked for treatments such as aspiration, Methergine, or blood transfusion. One diagnosis category was assigned per abortion; when the billing records indicated more than one diagnosis, the highest level diagnosis was selected. Cases identified based on subsequent medication abortion, misoprostol dose, or aspiration within 6 weeks of the initial abortion without any ICD-9 code indicating a complication were categorized as "other or undetermined."

Downloaded from http://journals.lww.com/greenjournal by BhDMf5ePHKav1zEoum1tQfN4a+kJLhEZgbsIHo4XMi0hCywCX1AWnYQp/IlQrHD3i3D0OdRyi7TvSFl4Cf3VC1y0abggQZXdtwnfKZBYtws= on 05/01/2025

Cases with the ICD-9 code "635.8 Abortion with unspecified complication" were also categorized as other or undetermined. To produce the most conservative estimate, we included undetermined diagnoses in the overall complications estimate.

Each complication was then classified as receiving one of six treatment categories: no treatment, medication (including mifepristone and misoprostol, misoprostol alone, or other medications), uterine aspiration, both medication and aspiration, other treatment, or undetermined. Abortion-related complications were classified as major if they required hospital admission (vendor codes 50, 60), surgery, or blood transfusion with all others classified as minor.

The data analysis was done in several steps. Using Stata 13, first we described the sample characteristics: age, race, residence, abortion procedure type, facility type, and year of abortion. Second, we estimated ED visits on the day of the abortion and within 6 weeks and present reasons for visits. Third, we estimated the abortion-related complication rate by the sample characteristics and the relative risk of a complication adjusted for all other characteristics using a generalized linear mixed model that accounts for lack of independence between multiple abortions by the same woman and those performed by the same health care provider; *P* values were determined from z tests derived from the model. Women who had missing data for any characteristic were retained in the model. Fourth, we compared major and minor complications by abortion procedure type using Pearson χ^2 tests. Finally, we described complication diagnoses by abortion procedure type and treatment. The abortion was the unit of analysis because 8.3% (n=4,165) of women in the data set had more than one abortion. Statistical significance was set at $P<.05$ for all comparisons; 95% confidence intervals (CIs) are reported.

RESULTS

Among the 659,361 records received, we identified 54,911 abortions among 50,273 fee-for-service Medi-Cal beneficiaries in 2009 and 2010. The largest proportions of women were ages 20–29 years, Hispanic, urban, had a first-trimester aspiration abortion, and were seen at an outpatient clinic (Table 1).

Among all 54,911 abortions, one in 1,036 (0.10%, n=53) were followed by an ED visit on the day of the abortion, including 1 of 5,491 (0.03%, n=15) transferred by ambulance for immediate care, although not all resulted in an abortion-related diagnosis or treatment.

Among all abortions (N=54,911), 1 of 16 (6.4%, n=3,531) was followed by an ED visit within 6 weeks of the abortion. Of these, 49.8% (n=1,758) were

9 (100.0)	4 (100.0)	658 (100.0)	1,156 (100.0)

unrelated to the abortion, 9.4% (n=332) were conditions unrelated to but concurrent with the abortion, and 40.5% (n=1,431) were abortion-related. Among abortion-related visits, two thirds (66.6%, n=953) were cases in which a patient presented with abortion-related symptoms but did not receive a pathologic diagnosis or treatment. Thus, 1 of 115 (0.87%, n=478) abortions resulted in an ED visit receiving a diagnosis, treatment, or diagnosis and treatment. Among all abortion-related ED visits (n=1,431), 21.8% (n=770) followed a medication abortion, 64.2% (n=2,266) followed a first-trimester aspiration abortion, and 14.0% (n=495) followed a second-trimester or later procedure (Table 2).

Among all abortions (N=54,911), 1,156 (2.1%, 95% CI 1.99–2.23) resulted in an abortion-related complication diagnosed or treated at any source of care, including EDs and the original abortion facility. The unadjusted complication rate was 5.2% (n=588) for medication abortions, 1.3% (n=438) for first-trimester aspiration abortions, and 1.5% (n=130) for second-trimester or later procedures. Adjusted results indicate that women ages 30–39 years were 1.20 (95% CI 1.02–1.40) times as likely to have a complication compared with women ages 20–24 years, and Hispanic women were significantly less likely to have a complication compared with white women. Medication abortions were 5.96 (95% CI 5.11–6.94) times as likely to result in a complication as first-trimester aspiration abortions. Women receiving abortion care at hospitals or physician's offices or groups were significantly more likely to have a complication than women receiving care at outpatient clinics (Table 1).

The rate of major complications among all 54,911 abortions was 0.23% (95% CI 0.19–0.27) (n=126, 1/436), 0.31% (n=35) among women who had medication abortions, 0.16% (n=57) among women who had first-trimester aspiration abortions, and 0.41% (n=34) among women who had second-trimester or later procedures (Table 3). Among all women, 0.20% (n=108) were admitted to hospitals, 0.02% (n=13) had surgery, and 0.09% (n=50) received blood transfusions (data not shown). These three categories are not mutually exclusive; some women were admitted to a hospital and had surgery, received a blood transfusion, or had surgery and a blood transfusion.

The most common complications were other or undetermined diagnoses (1.20%, n=658), comprised mostly of undetermined diagnoses that lead to repeat abortion, and incomplete abortions (0.42%, n=231) (Table 4). The majority of incomplete abortions (85.7%, n=198) and failed abortions (73.3%, n=22) were treated with uterine aspiration. The majority of hemorrhage cases were treated by other treatments (including blood transfusion) (39.5%, n=34) or medication (23.3%, n=20). All anesthesia-related cases were treated with medication as were the majority of infections (72.5%, n=100).

DISCUSSION

We observed a 2.1% abortion-related complication rate after nearly 55,000 abortions diagnosed or treated at all sources of care. The majority were minor. Rates of transfers to an ED, hospital admissions, surgeries, and blood transfusions were low. The complication rate is much lower than that found during childbirth[15] and comparable to that found in the literature[3,7] even when ED visits are included and there is no loss to follow-up.

Downloaded from http://journals.lww.com/greenjournal by BhDMf5ePHKav1zEoum1tQfN4a+kJLhEZgbsIHo4XMi0hCywCX1AWnYQp/IlQrHD3i3D0OdRyi7TvSFl4Cf3VC1y0abggQZXdtwnfKZBYtws= on 05/01/2025

We observed the highest rate of complications among women obtaining medication abortions (5.2%, n=588), the vast majority of which were minor and expected. This rate may be overestimated with aspirations performed presumptively or to alleviate bleeding or cramping symptoms.[16] Nevertheless, this rate is consistent with intervention rates found in other studies.[17,18]

The complication rate for second-trimester or later procedures is lower than other studies.[4,19] This may be because the second-trimester or later category includes a large number of abortions performed earlier in the second trimester when complication rates are closer to those in the first trimester. Only 1.4% of all abortions nationally occur after 20 weeks of gestation[20]; our data should not be used to make determinations about the complication rate among the small number of procedures performed later in pregnancy.

We found a high rate (6.4%) of ED visits after abortion, half of which were not abortion-related. This finding is consistent with previous research and could reflect Medi-Cal beneficiaries' use of the ED as the health care provider of first resort.[11] Additionally, the Medi-Cal fee-for-service population has been noted as having greater health risks and more costly use compared with the Medi-Cal managed care population.[21]

Two thirds of abortion-related ED visits did not result in a diagnosis or treatment, representing visits primarily for symptoms, not complications. Strategies to reduce ED visits include increasing the number and types of Medi-Cal primary care providers, particularly in underserved areas, who can provide abortion care, postabortion care, or both, and improving health care provider–patient communication on nonurgent postprocedure side effects.

This study examines postabortion ED visits and complications up to 6 weeks and across multiple facilities without loss to follow-up, addressing a common methodologic limitation of other studies. In other studies, follow-up periods ranged from 2 to 4 weeks with most considering follow-up a return visit to the original abortion facility. When reported, loss to follow-up varies widely: 9% at 1 week,[7] 2–34% at 2 weeks,[5,8,9] and between 8 and 65% in studies where duration is not specified.[22,23] Additionally, this study has the sample size necessary to robustly estimate rare events.

Using billing codes to identify complications has methodologic limitations. Administrative data sets often contain erroneous codes[24]; however, our clinical reviewers examined all related billing records for patients with complications for inconsistencies and errors. Also, by relying on Medi-Cal codes, we could not assess whether any of the complications lead to deaths or detect complications not documented by billing codes. It is possible that complications seen or treated at the original abortion facility did not result in any Medi-Cal reimbursements, thereby underestimating the complication rate.

We were unable to determine the exact week of gestation of each abortion, which is known to be a strong predictor of complication risk.[6] Additionally, repeat abortions performed within 6 weeks were assumed to be for the same pregnancy, but they may have been for new pregnancies. This, too, may lead to overestimating the complication rate, although the proportion of new pregnancies is likely too small to have much effect.

Regarding generalizability to the national abortion population, demographically, our sample had higher rates of Hispanics, lower rates of blacks,[25] and presumably higher rates of low-income women. Medi-Cal beneficiaries may have more health problems than the general population[21] and given that the sample had insurance coverage, they may differ from women whose follow-up care is self-pay. These differences would mean that the reported complication rate is overestimated.

These new data can inform policy debates regarding abortion regulation in the United States. State legislatures have passed regulations such as ambulatory surgical center requirements (23 states), transfer agreement laws (eight states), and hospital admitting privileges requirements (13 states)[26] with the stated intent to increase safety. Given that in practice their ultimate effect often is the closure of abortion facilities,[27] there is a need to consider the public health effect of these policies, weighing any theoretical incremental reduction in patient risk that may occur against any increases in risk that may occur with reduced access to abortion care.

Outcomes and Safety of History-Based Screening for Medication Abortion
A Retrospective Multicenter Cohort Study

Ushma D. Upadhyay, PhD, MPH; Elizabeth G. Raymond, MD, MPH; Leah R. Koenig, MSPH; Leah Coplon, CNM, MPH; Marji Gold, MD; Bliss Kaneshiro, MD, MPH; Christy M. Boraas, MD, MPH; Beverly Winikoff, MD, MPH

IMPORTANCE Screening for medication abortion eligibility typically includes ultrasonography or pelvic examination. To reduce physical contact during the COVID-19 pandemic, many clinicians stopped requiring tests before medication abortion and instead screened patients for pregnancy duration and ectopic pregnancy risk by history alone. However, few US-based studies have been conducted on the outcomes and safety of this novel model of care.

OBJECTIVE To evaluate the outcomes and safety of a history-based screening, no-test approach to medication abortion care.

DESIGN, SETTING, AND PARTICIPANTS This retrospective cohort study included patients obtaining a medication abortion without preabortion ultrasonography or pelvic examination between February 1, 2020, and January 31, 2021, at 14 independent, Planned Parenthood, academic-affiliated, and online-only clinics throughout the US.

EXPOSURES Medications for abortion provided without preabortion ultrasonography or pelvic examination and dispensed to patients in person or by mail.

MAIN OUTCOMES AND MEASURES Effectiveness, defined as complete abortion after 200 µg of mifepristone and up to 1600 µg of misoprostol without additional intervention, and major abortion-related adverse events, defined as hospital admission, major surgery, or blood transfusion.

RESULTS The study included data on 3779 patients with eligible abortions. The study participants were racially and ethnically diverse and included 870 (23.0%) Black patients, 533 (14.1%) Latinx/Hispanic patients, 1623 (42.9%) White patients, and 327 (8.7%) who identified as multiracial or with other racial or ethnic groups. For most (2626 [69.5%]), it was their first medication abortion. Patients lived in 34 states, and 2785 (73.7%) lived in urban areas. In 2511 (66.4%) abortions, the medications were dispensed in person; in the other 1268 (33.6%), they were mailed to the patient. Follow-up data were obtained for 2825 abortions (74.8%), and multiple imputation was used to account for missing data. Across the sample, 12 abortions (0.54%; 95% CI, 0.18%-0.90%) were followed by major abortion-related adverse events, and 4 patients (0.22%; 95% CI, 0.00%-0.45%) were treated for ectopic pregnancies. Follow-up identified 9 (0.40%; 95% CI, 0.00%-0.84%) patients who had pregnancy durations of greater than 70 days on the date the mifepristone was dispensed that were not identified at screening. The adjusted effectiveness rate was 94.8% (95% CI, 93.6%-95.9%). Effectiveness was similar when medications were dispensed in person (95.4%; 95% CI, 94.1%-96.7%) or mailed (93.3%; 95% CI, 90.7%-95.9%).

CONCLUSIONS AND RELEVANCE In this cohort study, screening for medication abortion eligibility by history alone was effective and safe with either in-person dispensing or mailing of medications, resulting in outcomes similar to published rates of models involving ultrasonography or pelvic examination. This approach may facilitate more equitable access to this essential service by increasing the types of clinicians and locations offering abortion care.

Case 6:25-cv-01491-DCJ-DJA Document 54-16 Filed 02/03/26 Page 24 of 275 PageID #: 4526

Each year nearly 1 million people in the US seek an induced abortion.[1] Medication abortion with mifepristone and misoprostol is currently approved by the US Food and Drug Administration (FDA) for use through 70 days of pregnancy,[2] although based on evidence, many clinicians offer it up to 77 days.[3,4] Typically, clinicians perform ultrasonography or a pelvic examination before treatment to determine the duration and location of the pregnancy. However, during the COVID-19 pandemic, some clinics relied on patient history alone, without ultrasonography or pelvic examination, to reduce physical contact.[5-8] In 2020, the FDA temporarily relaxed its in-person dispensing requirement on mifepristone for the duration of the pandemic.[9] By October 2020, guidelines issued by the Society of Family Planning,[10] the American College of Obstetricians and Gynecologists[10] and the National Abortion Federation[11] had been amended to endorse this no-test approach, providing abortion medications without ultrasonography or other facility-based tests.[12] Together, these changes enabled the emergence of several new online services that offered medication abortion entirely remotely using telemedicine and mail.[13,14]

Several studies, primarily in the UK and Canada, have concluded that history-based screening for medication abortion is safe and effective.[14-18] The largest, which included 18 435 medication abortions in the UK provided without screening ultrasonography, reported that 99% were complete without intervention, and serious adverse events occurred in 0.02%.[15] An analysis of data from 425 participants in the TelAbortion study,[19] a prospective multicenter study of medication abortions provided by telemedicine and mail conducted in the US, also found high effectiveness and safety in the subset screened by history alone, although these patients had lower effectiveness rates (94%) than those who had had pretreatment tests (98%). Another study among 141 patients of a new online service in California found an effectiveness rate of 95% and no major adverse events.[14]

Many people throughout the US face insurmountable financial, transportation, legal, and other barriers to reaching an abortion facility,[20] and access to abortion care is geographically inequitable.[21,22] Longer travel distance means increased logistical and emotional burdens and costs for gas or public transit fare, hotel stays, and loss of wages from time off work, as well as arranging for childcare. Access to patient-centered abortion care could be greatly improved if more primary care and other clinicians could prescribe abortion medications locally to their patients without specialized equipment and if abortion medications could be dispensed by brick-and-mortar and mail-order pharmacies.

We conducted a multicenter retrospective cohort study assessing the effectiveness and safety of using history-based screening alone for medication abortion care among a large sample of US patients from diverse clinics. This article summarizes the protocols that the clinics adopted, describes the characteristics of patients who had no-test abortions, and estimates the effectiveness and safety of no-test medication abortion. We also compare the effectiveness of abortions with medications dispensed in-person to those dispensed by mail to patients.

Key Points

Question What are the outcomes and safety of medication abortion care provided to patients screened for eligibility by history alone without ultrasonography or pelvic examination?

Findings In this multicenter cohort study of 3779 patients with eligible abortions, 95% of abortions were complete without additional medical intervention, and 0.54% were followed by a major abortion-related adverse event.

Meaning This study provides evidence that screening patients for medication abortion using history alone maintains high effectiveness and low risk; this screening approach may facilitate more equitable access to abortion care by enabling a wider variety of clinicians to offer this essential service.

Methods

Between May 2020 and January 2021, we recruited US clinics through webinars, professional email distribution lists, and personal contacts, inviting any facility that offered medication abortion using history-based screening for at least some patients to join the study. We included clinics that offered history-based screening through the TelAbortion study (NCT02513043 and NCT04599725).[23,24] Each clinic completed a survey on its medication abortion protocol, including eligibility criteria and screening procedures. We followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guidelines for cohort studies. Allendale Institutional Review Board and University of California, San Francisco Institutional Review Board provided ethical approvals. Because this study was a retrospective medical record review, and thus presented no more than minimal risk, the institutional review boards waived the need for patient informed consent.

Staff at participating clinics abstracted medical records of all medication abortions in which both mifepristone and misoprostol were dispensed without pretreatment ultrasonography or pelvic examination during a defined subperiod between February 1, 2020, and January 31, 2021. Clinic staff were required to be familiar with their clinic's protocols and received a 1-hour training with 1 or 2 of the study coauthors (L.R.K. and sometimes E.G.R.). Staff entered data into a secure online REDCap database,[25,26] including patient age, race and ethnicity, abortion payment type, zip codes, details about mifepristone and misoprostol provision, and events after provision, such as timing of mifepristone and misoprostol administration, unscheduled clinical contacts, treatments, diagnosis and treatment of ectopic pregnancy, last known status of pregnancy (viable, nonviable, or unknown), and confirmatory test results. Race and ethnicity categories included Black, Latinx/Hispanic, White, multiracial and other, and unknown. The "other" category included Alaska Native, American Indian, Asian, Asian Indian, Filipino, Guyanian, Guamanian/Chamorro, Japanese, Middle Eastern, Native American, Native Hawaiian, Pacific Islander, and Turkish. We used 2010 Rural-Urban Commuting Area (RUCA) codes[27] to categorize participant zip codes into urban, suburban, and rural places.

We asked site staff to report the final outcome as determined by a clinician and as recorded in the medical record. Although we collected data on test results that supported the diagnosis of complete medication abortion, we did not systematically collect information on the criteria clinicians used to diagnose abortions as complete by history. The first 3 authors (U.D.U., E.G.R., and L.R.K.) reviewed selected cases to clean data and flagged any inconsistencies within a specific medical record. These records were then rereviewed by clinic staff, who made any needed corrections. Additionally, 4 clinician coauthors with experience in abortion provision (B.K., L.C., C.M.B., and M.G.) reviewed selected cases to resolve analysis outcomes.

Outcomes

Effectiveness and safety were the primary outcomes of interest and were defined during a consensus meeting held in December 2020 with experts in medication abortion research and clinical care. We defined effectiveness as a binary measure of complete medication abortion after initial treatment without subsequent known intervention. Abortions that met any of the following 4 criteria were determined not to be complete: (1) the patient had an aspiration, dilation and evacuation, other procedure, or other surgical intervention; (2) the patient received greater than 200 mg of mifepristone, more than 1600 µg of misoprostol, or other uterotonic medications; (3) the patient received treatment for ectopic pregnancy; or (4) the patient had a viable pregnancy detected by ultrasonography at last contact and no known intervention.

Among abortions recorded as complete, we coded abortions as "complete by test" if the patient had a negative urine pregnancy test result, ultrasonography or pelvic examination showing no continuing pregnancy, an expected decline in serum beta human chorionic gonadotropin (β-hCG) level, a single posttreatment serum β-hCG value less than 500 mIU/mL at least 8 days after mifepristone dispensing,[28] or clinician examination of intact fetus or fetal parts. We coded abortions as "complete by history" if the site staff indicated that the abortion was complete based on a symptom checklist or patient report, if at the time of a subsequent pregnancy the patient reported that the prior pregnancy had ended in abortion, or if the patient reported expulsion of intact fetus or fetal parts. After reviewing preliminary results, including a lower proportion of known outcomes and a lower effectiveness rate among the group who received the medications by mail rather than in person, we reviewed 230 records for which the abortion outcome was originally coded as unknown but included text pertaining to the abortion outcome in the notes field. The clinician authors reviewed all 230 of these records and recoded 67 of them as "complete by history" based on notes in the study database indicating that the treating clinician had no concern that the abortion was incomplete after phone, text, or email follow-up contact with the patient. The results presented herein incorporate the recoded data.

We defined safety as a binary measure of abortions not followed by a known abortion-related major adverse event, which was defined as hospital admission, blood transfusion, major surgery, including laparotomy and laparoscopy for ectopic pregnancy, or death. The clinician authors determined the relation of adverse events to the abortion by consensus.

We assessed 2 secondary outcomes: ectopic pregnancy and retrospective determination that the initial medication abortion treatment had been provided at greater than 70 days of gestation. While some clinics routinely offered medication abortion up to 77 days, we sought to identify any abortion where it was discovered only at follow-up that the initial medication was dispensed beyond the gestational limit on the FDA-approved mifepristone label.

Statistical Analysis

We first described the characteristics of the clinics and their protocols. We then summarized patient and service delivery characteristics and compared the characteristics of patients for whom abortion outcomes were known and unknown.

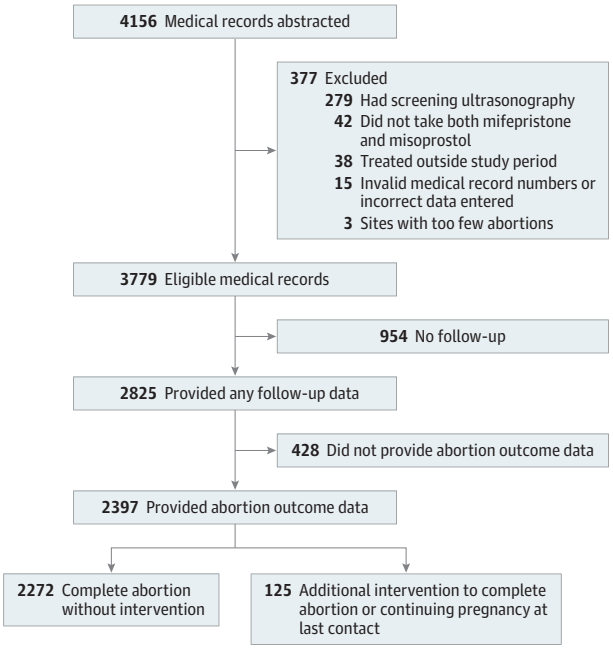
We then used mixed-effects logistic regression models to produce effectiveness and safety rates using Stata's margins and mimrgns commands. After finding no evidence of differential clustering by TelAbortion participation or by multiple abortions from the same patient, these models included only 1 random intercept to account for clinic-level clustering.

To estimate effectiveness outcomes, we originally conducted complete case analyses, examining unadjusted and adjusted effectiveness rates overall and by patient and service delivery characteristics among only those abortions with recorded outcomes. However, based on editor suggestion, we then conducted an analysis using multiple imputation by chained equations to account for missing outcomes due to loss to follow-up. We assumed data to be missing at random and imputed missing data for covariates and effectiveness and safety outcomes in the multivariable models using Stata's mi impute command.[29] Imputation models included effectiveness and safety outcome variables and age, race and ethnicity, residence, prior medication abortion, participation in the TelAbortion Study, method of mifepristone provision, and pregnancy duration. We computed 200 imputations to facilitate reproducibility for rare outcomes and combined the imputed results using Stata's mi estimate command. We then used a multivariable mixed-effects logistic regression model adjusting for age, race and ethnicity, residence, prior medication abortion, participation in the TelAbortion Study, method of mifepristone provision, and pregnancy duration to estimate adjusted effectiveness rates. We also estimated rates of intervention and continuing pregnancy using multivariable mixed-effects logistic regression, adjusting for the same variables.

We performed 2 additional sensitivity analyses for the effectiveness outcomes. The first replicated the effectiveness analysis excluding patients whose outcomes were determined by history alone. The second sensitivity analysis was ad hoc, based on reviewer suggestion, among only those at 9 weeks or shorter gestation who initially received 800 µg of misoprostol. Both of these analyses were performed on the imputed data and adjusted for the same covariates as the primary efficacy analysis.

We then estimated the overall safety rate among all abortions with any follow-up information recorded, as well as the

GBP-PET01554
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 06/18/2025



Case 6:25-cv-01491-DCJ-DJA Document 54-16 Filed 02/03/26 Page 26 of 275 PageID #: 4528

rates of each major adverse event type (blood transfusion, surgery, or hospital admission) without adjustment. Additionally, we estimated adjusted safety rates using the imputed data set, adjusting for the same covariates as in the effectiveness analysis. To facilitate model convergence for all rare outcomes (n < 9), the random intercept for clinic was omitted in the unadjusted analyses, and rates from the imputed data were calculated with random effects but without adjustment. We also described all ectopic pregnancies and the outcomes of cases found by posttreatment ultrasonography or examination of the fetus to have had pregnancy durations greater than 70 days at screening, but not identified at screening.

For both effectiveness and safety outcomes, we report both the unadjusted complete case analysis results and the adjusted multiple imputation analysis results. All rates reported in text are from the random-effects models calculated after imputation.

All analyses excluded patients who reported that they took neither mifepristone nor misoprostol. All analyses of patient data used the abortion, not patient, as the unit of analysis. All statistical tests were 2-tailed with significance set at .05. We used Stata, version 15.1 (StataCorp LLC).

Figure. Study Flow Diagram

Results

Participating Clinics

We received data from 15 clinics, representing independent, Planned Parenthood, academic-affiliated, and online-only clinics. We excluded 1 clinic that contributed only 3 abortions, leaving 14 clinics for analysis. Each clinic contributed a range of 11 to 981 eligible abortions; 5 provided no-test abortions both outside of and within the TelAbortion study, 1 provided them only within the study, and 8 only outside of the TelAbortion study. Most clinics generally followed a published protocol,[12] with modifications determined by each individual clinic. The clinical protocols are described in the eTable in the Supplement. Most (n = 9) clinics offered no-test medication abortion up to 77 days of gestation. Some clinics (n = 10) varied the number of misoprostol tablets dispensed by pregnancy duration or study participation; others routinely provided 8 tablets to all patients (n = 4). More than half of clinics (n = 9) offered multiple methods of mifepristone dispensing during the study period; 3 dispensed mifepristone to patients only in-person, and 2 dispensed only by mail, either directly from the clinic or via mail-order pharmacy. Among the 12 clinics that dispensed mifepristone in person, 4 offered a curbside pickup option that allowed patients to receive the medications without coming inside the facility. Four clinics did not require Rh factor testing for any patients. All but 1 clinic routinely called, texted, or emailed patients at 1 to 2 weeks and again at 4 weeks to determine patient outcomes, while 1 clinic offered an optional follow-up contact or visit and advised patients to take a pregnancy test at 4 to 5 weeks to confirm completion.

Description of the Sample

We received data on 4156 medication abortions. A total of 377 medical records were excluded because medical record data were invalid or incorrectly entered (n = 15), patients were treated outside the study period (n = 38), patients had screening ultrasonography (n = 279), patients did not take both mifepristone and misoprostol (n = 42), and patients were from the excluded clinic (n = 3). Some patients subsequently were entirely lost to follow-up and some provided incomplete follow-up data, for example, confirmation that they took the mifepristone and/or misoprostol but their medical records did not have sufficient data to determine whether their abortions were complete. Thus, of the remaining 3779 patients with abortions, 2825 (74.8%) had some follow-up data, and 2397 (63.4%) had abortion outcome data (**Figure**).

The sample was racially and ethnically diverse and included 870 (23.0%) Black patients, 533 (14.1%) Latinx/Hispanic patients, 1623 (42.9%) White patients, and 327 (8.7%) who identified as multiracial or with other racial or ethnic groups; race or ethnicity was unknown for 426 (11.3%) (**Table 1**). Half of the patients (1903 [50.4%]) paid for the abortion, at least in part, out of pocket. Patients lived in 34 states, and 2785 (73.7%) lived in urban areas. Nearly all abortions (3711 [98.2%]) were determined by patient history to be provided at 70 or less days of gestation. For 2511 (66.4%) abortions, the medications were dispensed in person, and for 1268 (33.6%), they were mailed to the patient. A total of 22 patients had more than 1 abortion at the same clinic and were represented more than once in the data set. Abortion outcomes were more likely to be known if the patient used private insurance to pay for the abortion, had lower pregnancy duration at treatment, received the abortion medications in person, or participated in the TelAbortion study. Among the 425 TelAbortion Study participants in this analysis, outcomes of 346 were reported in a previously published paper.[7] Additionally, we included

outcomes of 117 patients[14] and 111 patients[8] reported in previous articles.

Effectiveness

The overall adjusted effectiveness rate was 94.8% (95% CI, 93.6%-95.9%) (**Table 2**) and was not significantly different whether the patients picked up their medications (95.4%; 95% CI, 94.1%-96.7%) or received them by mail (93.3%; 95% CI, 90.7%-95.9%). Effectiveness rates were highest among patients who were younger than 24 years and among those with pregnancies of 56 days of gestation or less. The sensitivity analysis excluding cases in which the abortion was determined complete by history alone resulted in an adjusted effectiveness rate of 93.0% (95% CI, 91.2%-94.8%). The sensitivity analysis that included only those with a gestation of 9 weeks or less who initially received 800 µg misoprostol found an adjusted effectiveness rate of 95.7% (95% CI, 94.3%-97.2%). Among the sample, 46 abortions (1.7%; 95% CI, 1.1%-2.2%) were determined by ultrasonography to be continuing viable pregnancies after the initial medications were dispensed (**Table 3**). Among those, 36 were treated with a procedure or additional medication to complete the abortion, 1 had a complete abortion with 1600 µg of misoprostol, and 9 had no further known intervention, so the final outcome was recorded as continuing viable pregnancy.

Safety

The adjusted rate of major abortion-related adverse events was 0.54% (95% CI, 0.18%-0.90%) and was not statistically significantly different for patients who received medications in-person (0.46%; 95% CI, 0.09%-0.83%) and by mail (0.76%; 95% CI, 0.00%-1.57%). Among the patients with follow-up data, 12 major abortion-related adverse events occurred. These events included 8 blood transfusions, 3 major surgical procedures (including a possible but unconfirmed laparoscopic procedure for ectopic pregnancy), and 6 hospital admissions. Abortion-related hospital admissions included 1 due to pain that was treated with antibiotics and an unknown procedure to remove blood clots and residual tissue from the uterus; 2 for bleeding and pain that were treated with aspiration and transfusion; 1 for ongoing bleeding and kidney infection, which was treated with an unknown surgery, transfusion, and antibiotics; 1 for pain associated with endometritis that was treated with antibiotics; and 1 for major surgery (salpingectomy) to treat an ectopic pregnancy (Table 3). In total, 72 patients (2.6%; 95% CI, 1.9%-3.4%) were known to have visited emergency departments, including the 6 that resulted in hospital admissions described above.

We identified 4 ectopic pregnancies (0.22%; 95% CI, 0.00%-0.45%). One was detected 9 days after mifepristone ingestion after the patient contacted the clinic about unilateral

Abbreviation: NA, not applicable.

[a] Adjusted rates were calculated from mixed-effects logistic regression models fit to imputed data and adjusted for age, race and ethnicity, residence, prior medication abortion, participation in the TelAbortion Study, method of mifepristone provision, and pregnancy duration, with the exception of rare outcomes ($n \leq 9$), which were not adjusted to facilitate model convergence.

[b] Includes patients who received 800 µg of misoprostol initially followed by a single additional dose of 800 µg of misoprostol. One of these patients had a continuing viable pregnancy after the first dose and then aborted after the second.

[c] Includes 36 continuing viable pregnancies after initial treatment. In total, there were 46 (1.7%; 95% CI, 1.1%-2.2%) continuing viable pregnancies after initial medications were dispensed.

[d] Intervention and safety categories are not mutually exclusive because multiple interventions or treatments may have been provided for a single abortion.

[e] Includes 2 dilation and evacuation procedures and 1 salpingectomy.

Table 4. Patients Determined at Follow-up to Have Had Pregnancy Durations Greater Than 70 Days at Mifepristone Provision

Pregnancy duration documented at mifepristone provision, d	Corrected pregnancy duration at mifepristone provision based on pregnancy duration found at follow-up, d	Pregnancy duration at follow-up appointment, d	Abortion outcome
57	74	91	Procedure
53	80	88	Procedure

56	87	90	Lost to follow-up after ultrasonography
55	89	101	Procedure
70	90	93	Procedure
68	107	112	Complete abortion without intervention
42	230	231	Complete abortion without intervention

pelvic cramping; the patient was admitted that day to a hospital where a salpingectomy was performed. Two were diagnosed after rising serum β-hCG results and treated with methotrexate; 1 of these may have had a laparoscopic procedure in addition, but full documentation was unavailable. The fourth was reported by an outside physician, but the treatment was unknown and documentation was unavailable.

During follow-up, 9 (0.40%; 95% CI, 0.00%-0.84%) patients were found to have had pregnancy durations greater than 70 days at mifepristone dispensing although not identified at screening (**Table 4**). Of these patients, 6 had procedures to complete the abortion at 88 to 101 days of gestation, 2 had complete abortions without additional intervention at 16 and 33 weeks, and 1, who received mifepristone at 87 days, had a continuing viable pregnancy at last follow-up contact 3 days after screening. The patient who was estimated to be at 33 weeks of gestation delivered a stillborn fetus at home, brought the fetus to the clinic, and required no further medical care.

Discussion

In this retrospective cohort study of patients who obtained medication abortions with screening by history alone from 14 clinics across the US using a range of protocols, we found high effectiveness and safety rates. As the largest (to our knowledge) US study of this approach to date, it offers a generalizable picture of what medication abortion may look like as more primary care and other clinicians adopt history-based screening protocols in-person or remotely. The effectiveness rate of 95% is comparable to studies of medication abortion models with screening ultrasonography that found effectiveness rates of 93% to 98%.[24,30,31] The major adverse event rate of 0.5% (95% CI, 0.2%-0.9%) was slightly higher than previous studies finding rates of 0.2% to 0.3%[31,32] but not significantly different and still rare from a clinical perspective. This study found similarly high effectiveness and

safety rates comparing patients who received medications in-person vs by mail.

Before the COVID-19 pandemic, the FDA-mandated Risk Evaluation and Mitigation Strategy required mifepristone to be dispensed only in physicians' offices, clinics, or hospitals. The FDA allowed mailing temporarily in mid-2020 and made this change permanent in December 2021.[33] This study adds support for these actions, as we found that mifepristone can be dispensed safely either in person or by mail. Additionally, the mifepristone label could be revised to explicitly state that ultrasonography or clinical examination is not required if pregnancy duration can be reasonably estimated by history and if no symptoms or risk factors for ectopic pregnancy are present.

One of the major obstacles to expanded provision of medication abortion with history-based screening alone is clinician concern about the ability to identify an ectopic pregnancy. In this study, the ectopic pregnancy rate of 2 per 1000 suggests that the screening procedures used by the participating clinics will not triage all patients with ectopic risks to ultrasonography before the abortion. However, the potential benefits of expanded access, increased convenience, and earlier treatment conferred by removing testing requirements may outweigh potential risks of delayed identification of ectopic pregnancies.[34-36]

The risk of inadvertently treating a patient with a pregnancy duration greater than the accepted limit for medication abortion (70 or 77 days) is another concern. In this study, 9 patients were found at follow-up to have been treated at a gestation of greater than 70 days. The true number may be larger, as some advanced gestations may not have been recognized among patients who had successful abortions. We observed 1 case for which pregnancy duration was substantially underestimated; this patient passed the pregnancy and had a complete abortion at 33 weeks of gestation without additional intervention, medical complications, or sequelae. Clinicians offering the no-test approach should counsel patients about the possibility of an unidentified advanced gestation and discuss options for further evaluation and care if the patient were to encounter this situation.

Limitations

The retrospective design of this study limited the precision and detail of the data. In particular, sites did not have uniform, validated criteria for confirming complete abortion using symptoms alone without ultrasonography, serum β-hCG, or urine pregnancy tests. However, the sensitivity analysis that excluded abortion outcomes determined without any tests found only slightly lower effectiveness rates than the full analysis. This study did not include a direct comparison group of patients who received pretreatment ultrasonography and other screening tests; however, given the similarity of our effectiveness and safety findings to those from multiple prior studies, we can be assured that there are not large differences in effectiveness and safety.

The follow-up rate of 75% was comparable to the 77% follow-up rates reported in previous research,[37,38] but we may have failed to identify some additional interventions and adverse events. We aimed to mitigate the loss to follow-up with multiple imputation methods. If patients who were lost to follow-up were more likely to require additional intervention, our analysis may overestimate effectiveness. However, much of the loss to follow-up may be explained by the ubiquity of urine pregnancy tests that allow patients to assess their own outcomes. As history-based screening, telehealth, and self-assessment of outcomes using urine pregnancy tests become more common, the percentage of patients who do not experience complications and who contact the original clinician to confirm abortion completion is likely to decline. The net effect may be an apparent decline in effectiveness rates among patients who complete follow-up.

Conclusions

Given the high effectiveness and very low risks associated with omitting in-person tests and using history-based screening alone, no-test medication abortion can offer substantial benefits to clinicians and patients and is consistent with the principle of patient-centered care. The use of history-based screening may appeal to primary care and other types of clinicians without access to ultrasonography technology or other tests. A shift toward history-based screening could expand the provision of abortion care to a variety of primary care clinicians, including nurse practitioners and physicians in family medicine, adolescent medicine, and internal medicine. Because many of these clinicians work in rural and low-income communities and with marginalized racial and ethnic groups and other historically marginalized communities, increasing the types of clinicians and locations offering abortion services could also lead to more equitable access to abortion care. This expansion could enhance patient-centered care and satisfaction, given that many patients would prefer to get their abortion from their primary care clinician.[39-41]

Combining history-based screening protocols with a pharmacy prescription or mailing of abortion medications to patients can support public health efforts and reduce the numerous logistical, distance, and cost barriers to abortion.[21,22,42,43] No-test medication abortion can lower costs, result in earlier treatment, increase convenience and privacy, and allow patients to avoid harassment at clinics.[17,35] These benefits have the potential to increase equitable access to abortion for all patients, particularly marginalized racial and ethnic groups, those with low incomes, who reside in rural locations, and who face greater barriers to abortion care. Clinicians should eliminate unnecessary tests to support patient-centered care.

It Is Time to Change the Standard of Medication Abortion

Jennifer Karlin, MD, PhD; Jamila Perritt, MD, MPH

Before prescribing medication abortion, clinicians have been compelled to perform a pelvic examination or ultrasonography for gestational dating to adhere to the requirements of the US Food and Drug Administration (FDA) Risk Evaluation and Mitigation System (REMS) program for dispensing mifepristone. These examinations require an in-person clinic visit, which can be logistically burdensome and limit access to care. In this issue of *JAMA Internal Medicine*, Upadhyay et al[1] provide evidence that medication abortion using mifepristone and misoprostol is safe and effective for pregnancy termination without requiring an in-person clinical evaluation. These data should reassure clinicians and FDA evaluators that allowing history-based screening in lieu of in-person examinations is appropriate and evidence based.

Related articles pages 482 and 558

This report is particularly timely given the FDA's recently completed review of the Mifepristone REMS Program. On December 20, 2021, the FDA sent a letter to the plaintiffs in a case the American Civil Liberties Union filed in 2017 (*Chelius v Becerra*) on behalf of a Hawaiian doctor and health care associations, which argued that the FDA restricted access to abortion care with no medical basis by requiring in-person dispensing of mifepristone. Based on the available data, the FDA decided to remove the requirement for in-person dispensing of mifepristone.[2-5] This does not change current practice because the FDA had previously removed the in-person dispensing requirement during the COVID-19 public health emergency. While this decision eliminates the in-person dispensing requirement permanently, it does not adjust additional requirements for the patient agreement and the specialized clinician certification, which the FDA left in place. Moreover, the new rules added an additional restriction requiring certification of the pharmacies meant to dispense mifepristone. There are no data that we could find that these certifications of patients, clinicians, and pharmacies adds clinical benefit to an already safe and effective medication with limited contraindications and adverse effects. Moreover, the FDA's action will not affect existing state-level restrictions on access to medication abortion that are already in place. As a result, communities that already face difficulty accessing medication abortion remain vulnerable to medically unnecessary restrictions.

The study by Upadhyay et al[1] provides evidence collected before and during the COVID-19 pandemic in the US that supports a shift in the practice for initiating medication abortion to one that uses history-based screening and remote prescribing. The authors present data from a retrospective cohort study of 3779 medication abortions dispensed either in

O01
AN UPDATED ASSESSMENT OF CLINICAL OUTCOMES OF MEDICATION ABORTION WITHOUT PRETREATMENT ULTRASONOGRAPHY

H Simons
Planned Parenthood Federation of America, New York, NY, US
R Passman, S Diemert, G Dean

Objectives: Routine ultrasound before medication abortion may create an impediment to expanding abortion access. This study examines clinical outcomes among medication abortion patients without pretreatment ultrasound evaluation at Planned Parenthood health centers in multiple states.
Methods: We conducted a secondary analysis among 23 Planned Parenthood affiliates that provided medication abortion without pretreatment ultrasound for eligible patients from March 2020 to December 2021. Affiliates collected and aggregated electronic health record data from 19,041 medication abortion patients at <=77 days' gestation (based on self-report of last menstrual period) without a pretreatment ultrasound. Among patients with follow up (n=10,085, 53%), we calculated the incidence rates and 95% CI of the following outcomes: completed abortion, ongoing pregnancy, surgical intervention, emergency department and hospital admissions associated with medication abortion, and confirmed ectopic pregnancies.
Results: Among medication abortion patients with follow-up, 96.6% had a complete abortion (95% CI, 96.3–97.0%), and 2.0% had an ongoing pregnancy (95% CI, 1.7%–2.3%). Four percent of medication abortion patients had a subsequent surgical procedure (4.0%, 95% CI, 3.6%–4.4%), and 2.3% had a documented emergency department/hospital admission (95% CI, 2.0%–2.6%). About 2 in 1,000 had a confirmed ectopic pregnancy (1.7, 95% CI, 1.0–2.7 per 1,000).
Conclusions: Our calculated incidence rates of clinical outcomes align with rates from the previous literature on medication abortion with pretreatment ultrasonography and from the emerging literature on medication abortion without pretreatment ultrasonography. Findings from this analysis suggest that medication abortion without pretreatment ultrasound is safe and effective for eligible patients.

O02
ABORTION PATIENTS' PRIORITIES AND TRADEOFFS DECIDING WHERE TO OBTAIN OUT-OF-STATE CARE FOLLOWING TEXAS 2021 ABORTION BAN

K White
University of Texas at Austin, Austin, TX, US
W Arey, B Whitfield, E Vizcarra, A Dane'el, L Dixon, JE Potter, T Ogburn, A Beasley

Objectives: Explore pregnant Texans' decisions about where to obtain out-of-state abortion care following the September 2021 implementation of Senate Bill 8 (SB8), which prohibited abortions after embryonic cardiac activity.
Methods: To recruit Texans who obtained out-of-state abortion care after SB8, we provided flyers to abortion facilities in Arkansas, Colorado, Kansas, Louisiana, Mississippi, New Mexico, and Oklahoma. Between October 2021 and February 2022, we conducted in-depth telephone interviews with English-speaking participants ≥18 years of age who self-referred to the study to explore their experiences seeking care. We used inductive and deductive codes in our thematic analysis describing people's decisions about where to obtain care and how they evaluated available options.
Results: The 65 Texans who participated considered multiple factors when deciding where to obtain out-of-state care. Participants prioritized facility proximity and appointment availability. The majority called multiple facilities in surrounding states to find the earliest appointment, and were often told the next appointment was 2–4 weeks away. Some ultimately obtained care at a more distant location that had an earlier appointment, and others waited because they could not travel farther. Participants considered the economic hardships of caregiving responsibilities, lost wages, and travel expenses when weighing the tradeoffs between appointment availability and facility proximity, but few mentioned comparing abortion prices at different facilities. Informative facility websites and compassionate scheduling staff solidified participants' choice of care.
Conclusions: Pregnant Texans who could not get an in-state abortion after SB8 made difficult tradeoffs when deciding where to obtain out-of-state care that made seeking services burdensome.

O03
SAFETY AND EFFECTIVENESS OF SYNCHRONOUS AND ASYNCHRONOUS TELEHEALTH MEDICATION ABORTION PROVIDED BY US VIRTUAL CLINICS

UD Upadhyay
Advancing New Standards in Reproductive Health (ANSIRH), Bixby Center for Global Reproductive Health, Department of Obstetrics, Gynecology and Reproductive Sciences, San Francisco, CA, US
LR Koenig, J Ko, E Valladares, K Meckstroth, MA Biggs

Objectives: In 2021, new virtual clinics proliferated, offering remote-only telehealth abortion care with synchronous (phone or video) or asynchronous (messaging) communication and mailed pills. However, few large US studies have evaluated their safety and effectiveness.
Methods: We evaluated the safety and effectiveness of medication abortions provided by three virtual clinics operating in 21 states. We reviewed electronic health records for consecutive patients served between April 2021 and January 2022 and also invited the patients to participate in longitudinal surveys. We used multivariable mixed-effects models to estimate effectiveness and safety rates.
Results: Among the 6,134 included medication abortion patients, 73% received asynchronous services. Among the 5,036 (82%) abortion patients with follow-up data, 18 (0.44%, 95% CI: 0.36%-0.52%) had abortions that were followed by a serious adverse event. Abortion outcomes were confirmed for 4,106 (67%) cases, among whom 114 (2.8%, 95% CI: 2.3%-3.3%) required additional intervention to complete the abortion and 7 (0.21%, 95% CI: 0.06%-0.37%) were diagnosed with ectopic pregnancies. Rates of effectiveness (3.0% vs. 2.1%, p=0.187) and serious adverse events (0.44% vs. 0.44%, p=0.991) were similar between asynchronous and synchronous care. Among the 1,592 survey participants, 29 (2%) reported they would have had to continue the pregnancy had they not had access to telehealth abortion. Among survey participants, 47 received medications but did not take them, and among those, 36 still had the pills.

Conclusions: This real-world evidence shows that telehealth medication abortion care is safe and effective. Telehealth can increase access to this vital service while maintaining patient safety.

O04

PREVALENT BUT NOT INEVITABLE: MAPPING CONTRACEPTION DESERTS ACROSS THE AMERICAN STATES

RJ Kreitzer
University of North Carolina-Chapel Hill, Chapel Hill, NC, US
CW Smith, K Kane, T Saunders

Objectives: To provide a socio-spatial analysis of the allocation of Title X funding, the federal government's only program dedicated to reproductive healthcare; to systematically assess whether access to publicly-funded reproductive health resources are distributed in an equitable way across the US; to utilize an innovative measure of potential access that incorporates both spatial and aspatial variables to ascertain the size, scope, and demographic characteristics of geographies of concentrated disadvantage, which we refer to as "contraception deserts."
Methods: We employed methods that incorporated geographic information systems (GIS) and statistical/spatial analysis. We used the integrated two-step floating catchment area (I2SFCA) method, which incorporates both spatial (eg, distance, rurality/urbanicity) and aspatial (eg, poverty) variables, to more accurately develop a measure of potential access to Title X–funded clinics (FY2019). To map contraception deserts and to determine the demographic profile of these spaces of inequity, we used US Census data (at the tract level) and Title X–clinic location data from the Office of Population Affairs.
Results: GIS mapping techniques illustrate that significant proportions of the US can be characterized as contraception deserts, though with a great deal of variability in size across them. However, historically marginalized racial groups and those experiencing poverty are disproportionately represented in contraception deserts.
Conclusions: Given the various ways Title X can be implemented across states, results reveal that contraception deserts are prevalent but not inevitable. Speaking to policy implication, the results show that with strategic siting decisions, state-level Title X networks can mitigate inequitable access to federal resources.

CABERGOLINE FOR LACTATION INHIBITION AFTER SECOND-TRIMESTER ABORTION OR LOSS: A RANDOMIZED CONTROLLED TRIAL

A Henkel
Stanford University School of Medicine, Department of Obstetrics and Gynecology, Family Planning Services and Research, Palo Alto, CA, US
SA Johnson, EP Cahill, RF Matthew, PD Blumenthal, KA Shaw

Objectives: To assess cabergoline's efficacy at decreasing lactation after second-trimester abortion or loss.
Methods: This is a double-blinded, block-randomized superiority trial (IRB approved, NCT04701333) comparing cabergoline 1mg once to placebo for preventing bothersome breast engorgement after second-trimester uterine evacuation. April 2021-June 2022, we enrolled pregnant people 18-28-weeks gestation, English- or Spanish-speaking, without contraindication to the study drug. Participants completed a validated, piloted, electronic survey at baseline and through two weeks post-procedure assessing breast symptoms, side-effects, and bother at each time point. Our primary outcome is breast symptoms on day 4; we planned to enroll 80 patients to show a 30% difference in breast symptoms (80% power, $\alpha = 0.049$). A sub-group of participants returned for serum prolactin levels.
Results: After screening 150 patients, we enrolled 73 participants. Baseline demographics were balanced between groups: median gestational age 21 weeks (range: 18-26), 56% nulliparous, 35% self-identified as Hispanic, 37% with public insurance. At baseline, reported breast symptoms were similar between groups. At day 4, significantly fewer participants receiving cabergoline reported any symptoms compared to placebo (27.8% vs 97.0%, $p<0.0001$) and fewer reported significant bother (2.8% vs 29.7%, $p=0.002$). These differences persisted through day 14. Reported side-effects ($p=0.31$) were similar between groups: most common were constipation (44%), fatigue (32%), and headache (29%). Serum prolactin was similar at baseline. On day 4, mean serum prolactin was 6.5ng/mL (std dev 2.2) for those receiving cabergoline and 18.0ng/mL (std dev 5.9) for placebo ($p=0.04$).
Conclusions: Cabergoline is an effective strategy to prevent breast symptoms following second-trimester abortion or loss.

O06

SELF-MANAGED ABORTION OUTCOMES FOR PREGNANCIES OF 9–22 WEEKS' GESTATION: RESULTS FROM A PROSPECTIVE, OBSERVATIONAL STUDY IN THREE COUNTRIES

H Moseson
Ibis Reproductive Health, San Francisco, CA, US
R Jayaweera, C Bercu, R Motana, I Egwuatu, B Grosso, I Kristianingrum, S Nmezi, R Zurbriggen, C Gerdts

Objectives: The literature on self-managed abortion at later gestations is sparse, and more information is urgently needed in the US and elsewhere where this practice may become increasingly common. This analysis offers novel results on the effectiveness of self-managed medication abortion among people with pregnancies >9 weeks.
Methods: In 2019–2020, as a part of The Studying Accompaniment Model Feasibility and Effectiveness (SAFE) Study, we recruited callers to safe-abortion hotlines in Argentina, Nigeria, and Southeast Asia who were seeking support for self-managed medication abortion. Via phone, participants completed a baseline survey prior to taking the medications, and up to three follow-up surveys over four weeks to ascertain abortion outcomes.
Results: We recruited 1,351 participants, of which 264 self-managed an abortion for a pregnancy that was 9–22 weeks' gestation; 149 (56%) respondents used mifepristone and misoprostol, while 115 (44%) used misoprostol alone. One week after taking the pills, 222 (91%) participants had a complete abortion — 87% with pills alone, and 4% with additional intervention. At last follow-up, 95% of participants had had a complete abortion (89% with pills alone, 5% with additional intervention; 93% of combined regimen users, and 97% of misoprostol-alone users). A minority of participants sought healthcare at a clinic or hospital at any point (30% of combined regimen users, 15% of misoprostol-alone users). Among those seeking care, most (60%) did so to confirm abortion completion, and a small minority (1.5%) received treatment indicative of a serious complication (blood transfusion).
Conclusions: Self-managed medication abortion can be a safe and effective option for ending a pregnancy at 9+ weeks' gestation.

THE IMPACT OF THE TEXAS ABORTION BAN ON GESTATIONAL AGE AT TIME OF ABORTION IN A LARGE-VOLUME COLORADO CLINIC

E Dindinger
University of Colorado School of Medicine, Department of Obstetrics and Gynecology, Aurora, CO, US
K Coleman-Minahan, J Sheeder, NZ Fang

Objectives: To assess changes in the proportion of Texas residents, gestational age at time of abortion, and rates of second-trimester abortion, at a university-affiliated abortion clinic in Colorado after Texas passed Senate Bill 8 (SB8), which prohibits abortions >6 weeks' gestation.
Methods: We focused on all patients obtaining an abortion ≤22 weeks' gestation at a university-affiliated clinic between January 2018 and mid-April 2022. We created two time periods: before SB8 (January 2018–August 2021) and after SB8 (September 2021–April 2022). We compared the proportion of Texas residents obtaining care and gestational age categories before and after SB8 using chi-square tests. We determined the adjusted odds of a second-trimester abortion (≥13 weeks) after SB8 using logistic regression models adjusted for gravida, parity, age, and the proportion of Texas residents.
Results: We assessed 4,358 abortions; 3,630 before and 728 after SB8. After SB8, the proportion of patients who were Texas residents increased from 1% to 17%, $p<0.001$. Among all patients, abortions ≥15 weeks increased from 11% to 21%, $p<0.01$, and surgical abortions at 6–10 weeks decreased from 46% to 33%, $p<0.001$. There was no change in abortions at 11–14 weeks. The proportion of second-trimester abortions increased from 17% to 27%, $p<0.001$ and the odds nearly doubled after SB8 (aOR1.9, 95% CI, 1.6–2.3). Although higher among Texas residents (aOR, 2.6, 95% CI,1.1–6.9), the odds of a second-trimester abortion also increased among Colorado residents (aOR,1.8, 95% CI, 1.4–2.2).
Conclusions: Post-*Roe* abortion bans will likely delay care not only for people forced to seek care out of state, but for residents of states maintaining abortion access.

Safety and Efficacy of Telehealth Medication Abortions in the US During the COVID-19 Pandemic

Ushma D. Upadhyay, PhD, MPH; Leah R. Koenig, MSPH; Karen R. Meckstroth, MD, MPH

Author affiliations and article information are listed at the end of this article.

Introduction

Early in the COVID-19 pandemic, medication abortion, which typically includes mifepristone (ie, progesterone receptor antagonist) and misoprostol (ie, prostaglandin), gained prominence because it can be provided without physical contact. The American College of Obstetricians and Gynecologists and other professional organizations quickly endorsed telehealth and no-test abortion care.[1] These protocols omit Rh testing[2] and use patient history, rather than routine ultrasonography, to assess pregnancy duration and screen for ectopic pregnancy risks.[3,4]

To mitigate potential risk of complications, US Food and Drug Administration (FDA) Risk Evaluation and Mitigation Strategy (REMS) require that mifepristone be dispensed in a medical office, clinic, or hospital, prohibiting dispensing from pharmacies. Between a federal judge's ruling that suspended enforcement of this requirement in July 2020 and a reversal by the Supreme Court in January 2021, clinicians could offer medication abortion via telehealth and dispense from mail-order pharmacies where not prohibited by state law. During this period, a virtual clinic called Choix began providing medication abortions in California. We assessed safety and efficacy outcomes of a telehealth medication abortion model, which could inform the FDA's decision regarding removal of the REMS.

Methods

This retrospective cohort study was approved by the institutional review board at the University of California, San Francisco, and informed consent was waived because the research presented no more than minimal risk. We followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline for cohort studies.

We examined the safety and efficacy of fully remote, asynchronous medication abortion care using a published protocol.[3] Eligibility criteria, assessed using an online form, included pregnancy duration of less than 70 days (by history, including date of last menstrual period, or by ultrasonography) and no contraindications to mifepristone or misoprostol. Nurse practitioners reviewed the form within 24 hours and referred patients with unknown last menstrual period date or ectopic pregnancy risk factors for ultrasonography to confirm eligibility. A mail-order pharmacy delivered medications to eligible patients. The protocol involved 3 follow-up contacts: confirmation of medication administration, a 3-day assessment of expulsion and pregnancy symptoms, and a 4-week home pregnancy test. Follow-up interactions were conducted by text, secure messaging, or telephone. At each scheduled follow-up, clinicians made up to 4 attempts to contact patients.

In accordance with Choix's privacy policy, the service shared deidentified health record data for all patients with our research team. Efficacy was assessed as complete abortion without additional intervention (aspiration or other procedure, surgery, >1600 µg of misoprostol, or continuing pregnancy) among those with a known abortion outcome from the 3-day or 4-week follow-up. Safety was assessed by any major adverse event, including blood transfusion, abdominal surgery, hospital admission, or death. We estimated outcomes as percentages and calculated 95% CIs for key rates in Stata version 15.1 (StataCorp).

Results

The service provided abortion care for 141 patients between October 2020 and January 2021. Mean (SD) participant age was 29 (7) years, 81 (57%) had pregnancy durations 42 days or less, and 24 (17%) had screening ultrasonography (**Table 1**). At least 1 follow-up contact was made for 128 patients (91%), and abortion outcomes were collected for 110 patients (86%). Among the 110 patients with outcome data, 105 (95%) had a complete abortion without intervention. Five patients (5%) required medical care to complete the abortion, 2 of whom were treated in emergency departments. No patients reported any major adverse events (**Table 2**).

Discussion

These results represent some of the earliest data on new telehealth abortion clinics in the US. This 95% efficacy rate is similar to in-person provision[5] and recent international studies of telehealth for medication abortion.[6]

In April 2021, the FDA paused enforcement of the REMS for the duration of the COVID-19 pandemic, allowing clinics and pharmacies to mail mifepristone once again. The FDA is now considering permanently removing the REMS. This study is small with some loss to follow-up, and thus some adverse events and ongoing pregnancies may have been undetected. However, it reflects real-world data, which increases generalizability. This study provides preliminary evidence that suggests medication abortion care, administered by telehealth and delivered via mail, is feasible, safe, and efficacious.

Table 1. Description of Patient Characteristics

Characteristic	Total, No. (%), (n = 141)
Age, mean (SD)	28.5 (6.7)
Had ultrasonography before abortion	24 (17.0)
Pregnancy duration, d	
≤42	81 (57.4)
43-56	43 (30.5)
57-70	17 (12.1)
Rh type	
Positive	67 (47.5)
Unknown	60 (42.6)
Negative	14 (9.9)
Received Rh immune globulin	0
Any follow-up information collected	128 (90.8)

Table 2. Abortion Safety and Efficacy Outcomes

Follow-up data	Total, No./total No. (%), [n = 128]
Efficacy	
Outcome unknown[a]	18/128 (14.1)
Outcome known	110/128 (85.9)
Complete, No./total No. (% [95% CI])	105/110 (95.5 [91.6-99.3])
Complete by test[b]	88/110 (80.8)
Complete by history[c]	17/110 (15.5)
Required additional medical intervention for completion, No./total No. (% [95% CI])[d]	5/110 (4.5 [0.7-8.4])
Safety, No./total No. (% [95% CI])	
Confirmed or suspected ectopic pregnancy	0/128 (0 [0.0-2.3])
Any major adverse event[e]	0/128 (0 [0.0-2.3])

[a] Ten patients confirmed initial administration of medications and were subsequently lost to follow-up. Eight patients had inconclusive symptoms or test results and were subsequently lost to follow-up.

[b] Confirmed complete by 4-week urine pregnancy test.

[c] Presumed complete by symptom assessment 3 days after medications.

[d] Overall, 3 patients had an aspiration or dilation and curettage (2 treated in emergency department), and 2 patients required 2400 µg of misoprostol.

[e] No patients had a major adverse event defined as blood transfusion, surgery, hospital admission, or death.

Can midlevel health-care providers administer early medical abortion as safely and effectively as doctors? A randomised controlled equivalence trial in Nepal

I K Warriner, Duolao Wang, N T My Huong, Kusum Thapa, Anand Tamang, Iqbal Shah, David T Baird, Olav Meirik

Summary

Background Medical abortion is under-used in developing countries. We assessed whether early first-trimester medical abortion provided by midlevel providers (government-trained, certified nurses and auxiliary nurse midwives) was as safe and effective as that provided by doctors in Nepal.

Methods This multicentre randomised controlled equivalence trial was done in five rural district hospitals in Nepal. Women were eligible for medical abortion if their pregnancy was of less than 9 weeks (63 days) and if they resided less than 90 min journey away from the study clinic. Women were ineligible if they had any contraindication to medical abortion. We used a computer-generated randomisation scheme stratified by study centre with a block size of six. Women were randomly assigned to a doctor or a midlevel provider for oral administration of 200 mg mifepristone followed by 800 µg misoprostol vaginally 2 days later, and followed up 10–14 days later. The primary endpoint was complete abortion without manual vacuum aspiration within 30 days of treatment. The study was not masked. Abortions were recorded as complete, incomplete, or failed (continuing pregnancy). Analyses for primary and secondary endpoints were by intention to treat, supplemented by per-protocol analysis of the primary endpoint. This trial is registered with ClinicalTrials.gov, NCT01186302.

Findings Of 1295 women screened, 535 were randomly assigned to a doctor and 542 to a midlevel provider. 514 and 518, respectively, were included in the analyses of the primary endpoint. Abortions were judged complete in 504 (97·3%) women assigned to midlevel providers and in 494 (96·1%) assigned to physicians. The risk difference for complete abortion was 1·24% (95% CI –0·53 to 3·02), which falls within the predefined equivalence range (–5% to 5%). Five cases (1%) were recorded as failed abortion in the doctor cohort and none in the midlevel provider cohort; the remaining cases were recorded as incomplete abortions. No serious complications were noted.

Interpretation The provision of medical abortion up to 9 weeks' gestation by midlevel providers and doctors was similar in safety and effectiveness. Where permitted by law, appropriately trained midlevel health-care providers can provide safe, low-technology medical abortion services for women independently from doctors.

Introduction

Each year, 210 million women throughout the world become pregnant and nearly one in five chooses to terminate the pregnancy.[1] About 22 million pregnancies are terminated unsafely, and nearly all (98%) of these unsafe abortions take place in developing countries.[2] In many countries where abortion is not restricted by law, access to safe abortion is poor because of a shortage of skilled medical staff and surgical facilities. Early first-trimester medical abortion, by administration of an antiprogestagen (mifepristone) followed by a prostaglandin analogue (usually misoprostol), has provided millions of women worldwide with a safe, effective, and acceptable alternative to surgical abortion, which is usually done by manual vacuum aspiration. More than 20 years ago, medical abortion was recognised as likely to have particular application in those low-resource countries where skilled medical and surgical experience were in short supply.[3] Most medical abortions do not require the health-care infrastructure needed for manual vacuum aspiration, although back-up vacuum aspiration is needed for a small percentage of women.

Medical abortion remains under-used and inaccessible for many women in developing countries because almost all national regulations restrict its prescription and supervision to doctors.[4] However, the safety record of medical abortion makes it amenable to provision by midlevel health-care providers (non-physician health-care workers such as midwives and nurses) in regions where doctors are unavailable. Training of midlevel health-care providers in medical abortion with appropriate referral systems would expand access to safe abortion services and would be consistent with the global trend towards task-shifting in places where doctors are costly and scarce.[5,6] These providers have the potential to provide accessible, low-cost, and safe abortion services in developing countries in which abortion is not restricted by law. Results from a previous randomised trial[7] in

GBP-PET01567

South Africa and Vietnam showed that midlevel providers can perform first-trimester abortions by vacuum aspiration as safely as doctors do. Nonetheless, questions remain about the standard of care and safety of medical abortion provided by midlevel health-care providers.[4,8]

In Nepal, unsafe abortion is the third largest cause of maternal mortality.[9] Surgical termination of pregnancy on request up to 12 completed weeks of gestation has been provided by certified doctors at registered government sites since 2004. Midlevel providers (staff nurses) were permitted to do surgical abortions up to 8 weeks' gestation in these sites. Since 2009, medical abortion has been available for pregnancies of less than 9 completed weeks of gestation (≤63 days). At the time of the study, the provision of medical abortion services by nurses was limited to government facilities in which a doctor was present; nurses did not provide medical abortion independently from physicians' oversight. The aim of this study was to assess whether early first trimester medical abortion provided by midlevel health-care providers was as safe and effective as that provided by doctors in Nepal.

Methods

Participants and study design

Women met eligibility criteria if their pregnancy was less than 9 weeks (≤63 days) of gestation according to date of last menstrual period and as estimated by bimanual pelvic examination, if they were older than 16 years, resided no more than 90 min journey from the study clinic, and were willing to be randomly assigned to a provider, to return to the clinic 10–14 days after the start of treatment, and to provide written informed consent. A woman was ineligible if she had any contraindication to medical abortion: previous allergic reaction to any of the drugs in the medical abortion regimen; known or suspected ectopic pregnancy or undiagnosed adnexal mass; inherited porphyria; chronic adrenal failure; long-term corticosteroid therapy; haemorrhagic disorder or anticoagulant therapy; or an intrauterine device that could not be removed before administration of mifepristone.

This study was a multicentre, randomised, controlled equivalence trial to assess outcomes of medical abortion services provided by midlevel health-care providers and doctors in settings with low health-care resources. Women seeking termination of early first-trimester pregnancy were randomly assigned to medical abortion managed by doctors or by midlevel health-care providers and followed up for completeness of abortion and any complications. Data were collected between April 15, 2009, and March 17, 2010, in five district hospitals in hilly (Bhaktapur, Baglung, Dhading) and lowland regions (Rupendehi, Chitwan) in Nepal. The feasibility of the study was tested on a sample of 53 women in a pilot phase from Jan 7, to Feb 26, 2009. District hospitals are small government health facilities equipped to provide emergency obstetric services with less than 25 beds in rural and peri-urban areas. The hospitals had sufficient staff to establish a group of doctors and a group of midlevel health-care providers for implementation of the study. As a surrogate for how providers would manage in an independent setting and to reduce interactions between the two groups, each study site established separate waiting areas and examination rooms for midlevel health-care providers and doctors.

The study was developed, coordinated, and funded by the UNDP/UNFPA/WHO/World Bank Special Programme of Research Development and Research Training in Human Reproduction (HRP) at WHO, Geneva, Switzerland. A coordinating centre was established at the Centre for Research on Environment Health and Population Activities (CREHPA) in Kathmandu, Nepal. Reporting of the trial follows CONSORT reporting guidelines.[10,11] The study was approved by the Scientific and Ethical Review Group of the Reproductive Health and Research Department (RHR) and the Research Ethics Review Committee of WHO in Geneva, Switzerland, the National Health Research Council (NHRC) of Nepal, and was endorsed by the Department of Health Services, Ministry of Health and Population, Nepal.

Randomisation and masking

We used a computer-generated randomisation scheme stratified by study centre with a block size of six generated at RHR, WHO in Geneva, Switzerland. Sealed opaque envelopes containing the random allocation were consecutively numbered and were opened and assigned sequentially to women by a research assistant once written informed consent had been obtained. The random allocation sequence was generated by use of SAS software (SAS Institute, Cary, NC, USA).

Procedures

Only providers trained in manual vacuum aspiration were eligible for medical abortion training. All 25 eligible providers in the study hospitals participated in the study. Midlevel health-care providers consisted of eight staff nurses (3-year degree) and three auxiliary nurse midwives (18 months of training). The doctors were six obstetricians and gynaecologists, three general practitioners, and five doctors (with a Bachelor of Medicine and Bachelor of Surgery Degree). Participating providers underwent a 3-day training course in medical abortion and were certified by the National Health Training Centre. Table 1 summarises the characteristics of the providers. Female research assistants with backgrounds in nursing, health, and social science were employed to take part in the study. They did screening interviews for study eligibility and for provisional eligibility for medical abortion, implemented randomisation procedures, and collected data at admission, before misoprostol insertion, and at scheduled and unscheduled follow-up visits. They tracked women who

did not attend scheduled visits. Providers reviewed the forms completed by the research assistants and had full responsibility for clinical management of each case; they made the final decision on eligibility for the study and for medical abortion after physical examination, and recorded clinical data on physical examinations, administration of the drug, case management, and abortion outcome.

Clinical procedures for medical abortion followed the Nepalese medical abortion protocol and no changes were made in the procedures for the purposes of the study. Ultrasonography is not part of the Nepalese protocol for medical abortion but machines were available and used at the providers' discretion; such use was recorded for the study. Oral antibiotics were not routinely prescribed, and pregnancy tests were not done. Use of pregnancy tests and ultrasound is not routine for medical abortions in Nepal. Testing and treatment for sexually transmitted infections followed national syndromic protocols. All women were offered 400 mg ibuprofen for pain relief. Assigned providers gave counselling, and undertook vaginal and cervical inspection and abdominal and pelvic bimanual examination to establish duration of gestation.

The regimen consisted of one 200 mg tablet of mifepristone and four 200 µg tablets of misoprostol packaged in a single blister pack (Medabon, Sun Pharmaceutical Industries Ltd, Mumbai, India). The assigned provider gave the woman the mifepristone tablet orally on day 1 and administered the misoprostol tablets vaginally on day 3. After misoprostol insertion, the woman was monitored in hospital for 3 h; her assigned provider examined her bimanually to assess the status of the abortion before she left the hospital. 10–14 days after the administration of mifepristone, the woman returned for a follow-up visit to the same assigned provider for a clinical assessment of the outcome of the abortion. Additional follow-up visits were scheduled with the assigned provider if needed, and women were encouraged to return at any time for unscheduled visits.

The primary endpoint was complete abortion without manual vacuum aspiration within 30 days of treatment. Incomplete abortion was defined as products of conception remaining in the uterus with continued bleeding, bulky uterus, and open cervix at examination, possibly necessitating surgical evacuation at the discretion of the provider or at the woman's request. Failed abortion (continuing pregnancy) was recorded when clinical examination indicated continuing symptoms of pregnancy and manual vacuum aspiration was needed to terminate the pregnancy.

The secondary endpoint measured case-management decisions by recording case-management discussions and referrals between providers to assess the extent to which each group provided medical abortion services independently. Serious adverse events (haemorrhage necessitating blood transfusion, conditions necessitating hospitalisation) were recorded. The completeness of the abortion and any complications were identified by an interview with the woman and by clinical examination. Women were also asked whether they had visited any non-study hospital, clinic, or provider during the study.

Data management was organised locally by data entry personnel at CREHPA and at RHR, WHO in Geneva. Research assistants sent case record forms weekly to CREHPA and retained copies in their clinics. Data were entered at CREHPA by use of the OpenClinica clinical trial software, checked for accuracy, and corrected after consultation of clinical records and research assistants. Data were reviewed monthly by the Study Coordinator at WHO with further checking and review of clinic records as necessary.

Table 2: **Characteristics of women undergoing early medical abortion by type of provider**

Statistical analysis

This equivalence trial was designed to assess the similarity between two types of providers of medical abortion with a potential cluster effect on the primary endpoint among service providers. The margin of equivalence, Δ, was 5% and the range –5% to 5% was predefined as an acceptable range of completion rates between the two types of providers. The margin was based on clinically and statistically important differences as well as ethical criteria, cost, and feasibility.[12,13]

The sample size of 1086 women was calculated to be sufficient (with a two-sided 95% CI and 80% power) to establish equivalence.[14] The sample size calculation allowed for 10% loss to follow-up and for a potential cluster effect among service providers with an estimated intraclass correlation coefficient of 0·001 from a previous study.[7] The cluster effect could occur because some service providers might provide better medical abortion services than others due to individual variations in, for example, years of medical practice or individual aptitude.

To assess the equivalence between midlevel health-care providers and doctors, the risk difference between the two provider types together with their 95% CI was derived by use of a generalised estimating equation (GEE) model with treatment as the fixed effect and service provider as a random effect as implemented in the PROC GENMOD procedure of SAS version 9.2 (SAS Institute, Cary, NC, USA). The CI gives an interval estimate of the true population difference Δ. If the CI of the risk difference between the two groups falls within the predetermined margin of equivalence (–5% to 5%), the two types of providers can be considered equivalent. In addition, covariate-adjusted analyses were done on six prespecified baseline characteristics of participants (centre, age, duration of gestation, parity, number of previous induced abortions, and body-mass index). The number and percentage of women with each side-effect from the medical abortion were calculated and compared by use of a χ^2 test. The analyses for the primary and secondary endpoints were on an intention-to-treat basis, supplemented by per-protocol analysis of the primary endpoint.

This trial is registered with ClinicalTrials.gov, NCT01186302.

Role of the funding source

The sponsor of the study had no role in study design, data collection, data analysis, data interpretation, or writing of the report. All authors had full access to all the data in the study. The corresponding author had the final responsibility for the decision to submit for publication.

Results

Of 1295 women screened for eligibility, 190 were ineligible for medical, geographical, or follow-up scheduling reasons, and one woman declined to take part in the study (figure 1). 1104 women were randomised. After clinical examination, in the midlevel health-care providers' group ten women were excluded: in eight, the duration of gestation was longer than 9 weeks; one had signs of ectopic or adnexal mass; and one was diagnosed with cervical polyps. In the doctors' group 15 women were excluded: in 12, the duration of gestation was longer than 9 weeks; one had signs of ectopic or adnexal mass; one was not pregnant; and one had a miscarriage before receiving any drugs. Additionally, two women withdrew from the study before physical examination when they were told of their group allocation.

Loss to follow-up of women receiving treatment was 24 of 542 (4%) in the midlevel health-care providers' group and 19 of 535 (4%) in the doctors' group. Women lost to follow-up were, on average, less educated than those

GBP-PET01570

followed up. Two women in the doctors' group were excluded from the analysis because at follow-up they were shown not to have been pregnant: one was a long-time user of a 3-monthly injectable contraceptive, and the other one had had a manual vacuum aspiration 37 days before.

Participating doctors had, on average, fewer years of professional medical practice than midlevel health-care providers and a higher proportion were men (table 1). Baseline characteristics of women included in the analysis were similar by type of provider (table 2). On average, women were 28 years old and married with two children. More than 25% had had an induced abortion previously and about 30% had never attended school or had not completed primary school. Overall mean duration of gestation was 6·6 weeks as reported by the date of the last menstrual period and 6·8 weeks by clinical examination and did not differ by type of provider (table 3). In women reporting the date of their last menstrual period (84%), there was a high level of congruence between duration of gestation based on that date and that based on clinical examination. No important difference was noted between the two types of provider (data not shown). Doctors were more likely to use ultrasonography (23 cases) than were midlevel health-care providers (two cases).

The clinical outcomes of medical abortion from intention-to-treat and per-protocol analyses were similar by type of provider (table 4). For women with a recorded outcome, the overall intention-to-treat complete abortion rate was 96·7%, the incomplete abortion rate 2·8%, and continuing pregnancy rate 0·5% at 30 days from start of treatment. The risk difference for complete abortion rates between midlevel providers and doctors was 1·24% (95% CI –0·53 to 3·02), and the estimated 95% CI was well within the equivalence range for both intention-to-treat and per-protocol analyses (table 4, figure 2). Therefore, equivalence between midlevel health-care workers and doctors can be established for the primary endpoint. For the covariate-adjusted analyses, the GEE model did not converge when all six covariates were entered simultaneously. With a stepwise approach, only woman's age and duration of gestation produced converging GEE models for both the intention-to-treat and per-protocol populations (table 4, figure 2). The webappendix shows the rate of complete abortion by gestational age (see webappendix p 1).

All 34 incomplete and continuing pregnancies were terminated by manual vacuum aspiration by the assigned provider. No serious adverse events were recorded. Women reported typical side-effects such as nausea, vomiting, diarrhoea, abdominal pain, chills, and fever with no difference by type of provider (data not shown). 12 cases with midlevel health-care providers and 13 cases with physicians were discussed with another provider or referred (data not shown). Midlevel health-care providers reported discussing less than 2% of cases with doctors and referred less than 1% of cases to a doctor, a pattern similar to that of doctors.

Discussion

This randomised controlled equivalence trial assessed clinical outcomes, safety, and case management of early medical abortion provided by nurses and auxiliary nurse midwives compared with doctors. These findings provide evidence that midlevel providers with previous training in abortion care can, after additional training in medical abortion, independently administer medical abortion

See Online for webappendix

***Panel*: Research in context**

Systematic review

When developing the study protocol, we searched PubMed and Popline for relevant articles with the keywords "abortion", "medical abortion", "nurse-midwives", "midwife", "mid-level provider", "nurse practitioner", "non-physician clinician", and "physician assistant". Given the paucity of research in this area, we reviewed all studies and reports about midlevel providers of medical abortion and manual vacuum aspiration in developed and developing countries.

Interpretation

Findings from our study showed that midlevel providers of medical abortion can administer medical abortion as safely as doctors in a low-resource setting in which ultrasonography and pregnancy tests are rarely used. These results build on one previous randomised controlled trial of midlevel providers and manual vacuum aspiration that showed equivalence in safety between midlevel providers and doctors in developing countries. Several observational studies lend support to the competency of midlevel health-care providers as providers of medical abortion. Taken together, these studies show that appropriately trained and government certified midlevel providers of both medical abortion and manual vacuum aspiration can provide safe and effective abortion services independently from physicians.

safely and effectively in a low-resource setting where pregnancy tests, antibiotics, and ultrasonography are available but rarely used. These equivalence results are robust irrespective of the analysis population.

Midlevel health-care providers have been trained in medical abortion in several countries but assessments have been limited to those of in-house training. The role of these care providers in the introduction of medical abortion has been examined in India,[15] Vietnam,[16] Nepal,[8] and the USA.[17,18] Two papers reviewed the evidence on midlevel health-care providers of abortion but did not specifically address safety or acceptability by doctors and these providers (panel).[4,19]

The overall complete abortion rate of 96·7% was comparable with rates in other studies that used the same regimen (93·5% to 97·7%).[20–22] Previous studies of medical abortion in Nepal showed completion rates of 91·3%[23] with oral administration of 400 μg misoprostol and 96%[24] with vaginal administration of 800 μg misoprostol. In gestations of up to 63 days' amenorrhoea, the rate of continuation of pregnancies with the regimen used here was less than 1%,[25] in line with our results. The numbers of incomplete abortions for both types of providers were similar, 14 cases for midlevel health-care providers and 15 cases for doctors, with no difference in propensity to evacuate cases of incomplete abortion that might have become complete over time.

Despite its availability, ultrasonography was rarely used by any provider to assess duration of gestation or completeness of the abortion at follow-up. This study supports guidelines that emphasise the safety of medical abortion without the routine use of ultrasonography before or after abortion.[26] The study was designed to maximise the generalisability of the findings for the public sector in Nepal and other developing countries. It was conducted in public-sector district hospitals and all 25 full-time public-sector providers received the same government-certified training in medical abortion. The clinical procedures for medical abortion did not deviate from the national protocol. The sociodemographic characteristics of women included in our study were very similar to those of a national sample of women seeking induced abortion in Nepal done in 2006.[27]

Some issues might affect the external validity and applicability of the findings. In this study, midlevel health-care providers had more years of professional experience than did the doctors. In ad-hoc multivariate analyses, years of professional experience did not have any effect on equivalence results (data not shown). Although the socioeconomic and demographic characteristics of study participants are typical of women seeking abortions throughout Nepal, they might not be representative of women living in underserved rural areas of this country. District hospitals are also not representative of the small health facilities located in remote areas of Nepal, which are staffed exclusively by midlevel health-care providers.

A limitation of the findings is that the study was part of the first wave of medical abortion training in Nepal, and the initial training curriculum has since been revised. Future medical abortion outcomes might differ as the national protocol is adapted to follow women's needs and new regimens. A further limitation of the study is that although separate waiting and examination rooms for the two groups were set up for the duration of the study, both types of providers worked in the same hospital and in the same environment. Although this controlled environment optimised comparison, it might have led to a convergence of outcomes that would not have happened if the women had been assigned to providers at different clinics.

The Nepalese medical abortion protocol at the time of the study was rather burdensome with three clinic visits and physical examinations. Testing home use or omitting the follow-up visit are important topics for future research of medical abortion in Nepal. However, 96·3% of women reported that they would prefer having a medical abortion at the clinic and 3·7% at home, which suggests that visits to the clinic were acceptable for these women.

In conclusion, nurses and auxiliary nurse midwives could have an important role in making life-saving abortion methods accessible to women living in remote areas of developing countries, as long as timely back-up manual vacuum aspiration is accessible if providers themselves are not trained in this technique. In areas with shortages of physicians, decentralisation of medical abortion services to include government-certified midlevel health-care providers who work independently from doctors would greatly increase women's access to safe abortion services. Appropriately trained providers can administer safe, low-technology medical abortion services for women who might otherwise turn to unsafe abortion, exposing themselves to the risks of disabilities and death.

Contributors

IKW developed the protocol and study design, directed the study and the data analysis, and was the lead author of the report. DW was the statistician for the study and participated in the study design, data analysis, data interpretation, and writing of the report. NTMH was the study coordinator and participated in data collection, management, and analysis, and writing of the report. KT was the principal investigator and was responsible for the overall supervision of the trial and participated in the implementation of study, data analysis, and the writing of the report. AT was responsible for the coordination and implementation of the study in Nepal and participated in the data management, data analysis, and the writing of the report. IS participated in the development of the protocol, data analysis, and the writing of the report. DTB and OM participated in the development of the protocol and the writing of the report. All authors had access to the data, commented on subsequent drafts, and approved the final submitted version.

Complications

ABSTRACT

Objective: The objective was to compare the practical aspects of providing medication abortions through telemedicine and in-person clinic visits so that clinics can use this information when planning to add this service.
Study design: We conducted a comparative retrospective chart review comparing telemedicine medication abortions to a control group matched for date seen. We extracted and compared demographics, use of dating ultrasound, outcomes and unscheduled visits or communications with staff and physicians.
Results: During the study period, we provided 4340 medication abortions, of which 182 (4.2%) were provided through by telemedicine; 199 patients met the criteria to be in the control group. The mean age was 28.7 years for telemedicine patients and 28.1 years for in-person patients ($p = .38$). The mean gestational ages were also similar, 48.2 days for telemedicine patients and 46.5 days for in-person patients ($p = .03$). Only 33 (18.1%) of telemedicine patients had dating ultrasounds compared to 199 (100%) of in-clinic patients ($p < .001$). The proportions of documented completed abortions (164/182, 90.1% and 179/199, 89.9%, $p = .76$) were similar, as were the proportions of aspirations for completion (6/182, 3.3% and 9/199, 4.5%, $p = .54$) and the proportions lost to follow-up (5.5% and 6.6%, $p = .66$). There were 10 complications in each group (5.5% of telemedicine patients and 5.0% of in-clinic patients) ($p > 0.5$). Unscheduled communications with office assistants were greater in the telemedicine patients than the in-person patients (84/182, 46.2% vs. 43/199, 21.6% in-person, $p < .001$).
Conclusion: We found that telemedicine patients required more unscheduled communications and received ultrasounds far less often compared to in-clinic patients.
Implications: We could provide telemedicine without the need for ultrasound to most women. Larger studies without routine ultrasound use are needed to validate our findings. Unscheduled communication with clinic staff was more frequent with telemedicine medication abortion patients. This information may help clinics when planning to add this service.

1. Introduction

At Willow Clinic in Vancouver, British Columbia (BC), we have been offering medication abortions by telemedicine since 2012 [1]. Initially, we were using methotrexate 50 mg/m^2 and misoprostol 800 mcg repeated twice to induce abortions up to 7 weeks' gestation. In January 2017, mifepristone became available in Canada. At that point, Willow Women's Clinic started offering medication abortions with mifepristone and misoprostol by telemedicine up to 10 weeks' gestation, and there was a much greater uptake. We followed the Society of Obstetricians and Gynecologists of Canada (SOGC) Clinical Practice Guidelines recommending that mifepristone 200 mg with misoprostol 800 mcg be used up to 10 weeks' gestation [2].

Previous literature demonstrates that telemedicine is safe, effective and feasible [3]. In response to the high mortality and morbidity from unsafe abortions (i.e., the termination of a pregnancy by individuals lacking the necessary skills, or in an environment lacking minimal medical standards, or both) worldwide, various providers have offered telemedicine abortions using different protocols and in different settings [4–9]. Routine care of medication abortion patients in North America involves ultrasound before the procedure to determine gestational age and exclude ectopic pregnancies, home use of misoprostol and ultrasound after the procedure to evaluate for completion of the abortion [10,11]. Alternatives to routine ultrasound have been investigated to increase accessibility, including human chorionic gonadotropin (hCG) testing or phone follow-up [12–16].

We performed this study to evaluate our use of telemedicine for medication abortion in which women did not receive routine ultrasound for evaluation or follow-up. We wished to gain information that could help other clinics when planning to add this service.

2. Methods

We performed a retrospective chart review of all telemedicine abortions between January 31, 2017, and January 31, 2019, and a similar group of controls seen in the clinic during the same time frame (i.e., matched consecutively by date of initial appointment). We used a billing log to identify both the telemedicine and in-clinic patients. One or two in-clinic patients seen on the same day were selected for each telemedicine abortion patient so that the two groups were similar in regards to the staff that cared for them. We also compared the sample of women included in this study to all 4340 medication abortions done at our clinic during the same time period to check the representativeness of the sample.

The Willow Clinic provides telemedicine medical abortion to individuals who live >2 h from the clinic, have access to video chat programs on a computer or smart phone, have access to a laboratory, can get an ultrasound if necessary and are able to travel to Willow Clinic or to another community for surgical completion if necessary. The physician sees the patient by telemedicine and uses the patient's history (last normal menstrual period, regularity of menses, onset of pregnancy symptoms) to decide whether an ultrasound is necessary to assess if the gestational age was greater than 70 days. The patient has the tests done, including a hemoglobin, Rh status and ultrasound if necessary. At a second telemedicine visit, the physician reviews the results and signs the prescription for the mifepristone and misoprostol. There is not a specific hCG level cutoff, and each physician uses clinical judgment to determine that the patient is less than 10 weeks' gestation and therefore eligible for the medication abortion. The patient and a counselor then have a telemedicine visit to discuss the details of taking the medications. The patient reads the consent form and gives verbal consent witnessed by the counselor. The medications are couriered to her, or a prescription is faxed to her pharmacy Depending on the clinic scheduling, there are usually three hCG levels done: the initial one, one within 2 days of mifepristone ingestion and one a week later. The physicians at Willow Clinic have a follow-up by telemedicine to discuss the woman's reaction to the medications and her blood test results. If the quantitative hCG has fallen by 80% in 1 week, the physician tells her that the abortion is completed and that she needs no further follow-up [17]. If she needs more misoprostol, surgery or further blood tests, the physician and office assistant will arrange these. Using the SOGC and National Abortion Federation (NAF) guidelines, we tested for Rh status in pregnancies over 8 weeks' gestation in the clinic [2,18]. Since we often did not have confirmation of the exact gestational age, we were very conservative and obtained Rh status in most telemedicine patients. We accepted an HCG of under 2000 to indicate that they were <8 weeks' gestation.

In-clinic abortion patients see the physician and counselor in the clinic and receive the medication at the pharmacy to use at home. They are assessed before and after the abortion by endovaginal ultrasound. If the pregnancy is not seen by ultrasound prior to medication, the women are monitored by measuring serum quantitative hCG. Some in-clinic patients choose to have telemedicine follow-up with serial hCGs, but these were not eligible to be in the control group.

We extracted patient demographics, including age and gestational age, distance from our clinic, use of dating ultrasound, outcome, complications and unscheduled communication with clinic staff and physicians, from the charts of all evaluated patients. Our primary outcomes were the differences that matter to a clinic planning to add telemedicine care. We coded communications about appointments or lab tests as nonclinical and all other communications as clinical. Phone calls to assistants about clinical issues would have been passed to physicians, so one patient could have had unscheduled communication with both the assistant and physician for the same issue. To assess complications, we used the data required by the NAF for quality assurance [18]. We entered the data into a Statistical Package for the Social Sciences database. We compared the two groups using t tests for continuous variables and χ^2 for discontinuous variables.

3. Results

During the 2 years, we saw 4340 individuals requesting medication abortion, of whom 182 (4.2%) were seen only by telemedicine. We reviewed all their charts and a group of 199 in-clinic patients. Table 1 shows the patient characteristics. The in-clinic patients lived an average of 0.66 h (range 0–15 h) and the telemedicine patients lived an average of 5.5 h (range 1.4–21.4 h) away from the clinic ($p < .001$). We did not record the proportion of the entire population that lived >2 h from the clinic. There were 33 (18.1%) individuals who had dating ultrasounds in the telemedicine group compared to 100% of the in-clinic group.

Table 2 shows that the proportions of documented completed abortions (164/182, 90.1% and 179/199, 89.9%, $p = .76$) were similar, as were the proportions of aspirations for completion (6/182, 3.3% and 9/199, 4.5%, $p = .54$) and the proportions lost to follow-up (5.5% and 6.6%, $p = .66$). Table 2 also shows complications. Unscheduled communication with physicians or office assistants includes all phone calls patients made to the clinic after registering. These were handled by office assistants who might pass them on to physicians during clinic hours or by the after-hours emergency service that passed all calls to the physicians. There were no significant differences in the unscheduled communication with physicians (13/182, 7.3% telemedicine and 22/199, 11.1% in clinic, $p = .12$), but fewer telemedicine patients were seen by phyisicians for unscheduled in-person follow-up visits (10/182, 5.6% and 21/199, 10.6%).Unscheduled communications with office assistants were greater in the telemedicine patients than the in-person patients (84/182, 46.2% vs. 43/199, 21.6% in-person, $p < .001$), with much of this being nonclinical (27/182, 14.6% clinical vs. 57/182, 31.3% unclinical) ($p < .001$). For the in-clinic patients, 107 (53.8%) were not tested for Rh status because they were under 8 weeks' gestation by ultrasound and the five who were Rh negative were given anti-D immunoglobulin in the clinic. Only 17 (9.4%) of telemedicine patients were not tested, and there were 31 (17.0%) who were Rh negative. Eight declined anti-D because they planned no further pregnancies, four were told that they did not need anti-D on the basis of a low hCG, and 18 received anti-D at the closest hospital or clinic (one was unknown).

4. Discussion

The most important addition this study provides to the literature is the difference in the practical aspects of clinic care between telemedicine and in-clinic medication abortions; specifically, telemedicine patients required more unscheduled communications and received ultrasounds far less often compared to in-clinic patients. This information may help providers plan services. The results from this study

show that it is feasible to provide medication abortions using telemedicine. These results are similar to the results of the studies with other models of telemedicine abortion care using clinic-to-clinic video or email consultations [9,14–17]. One strength of our study was the low loss-to-follow-up rates for all our patients.

This study did not have a large enough sample size to provide evidence of the safety of telemedicine abortions because the complications rates are so low [21]. It does add to the literature about safety in a variety of settings. Women on Web set up a telemedicine medication abortion service in 2006 and uses an online questionnaire and email support to provide abortions with mifepristone and misoprostol to women in situations where safe abortions are not available [4–7]. Using a different model, Planned Parenthood clinics in Iowa offer abortions in which the patients see a counselor and nurse in the clinic but then see a doctor by videoconferencing [8]. The study showed no difference in outcomes or patient satisfaction when comparing women obtaining medication abortion by telemedicine or face-to-face with a physician. More recently, there is a report of direct-to-patient abortions with 248 women receiving medication by mail, and the authors found the service "safe, effective, efficient, and satisfactory" [9].

Canadians often need to travel long distances for abortion care because there are few providers outside of major cities. Many individuals prefer medication abortions to surgical abortions and cannot access these in their communities. Telemedicine is less expensive and more convenient for those who would need to travel long distances to an abortion clinic. The government insurance in BC pays physicians to see their patients by video-conferencing similar amounts to in-office visits. The regulators permit the use of various video platforms that are easy to access on smart phones with appropriate consents [19,20]. These factors help improve access to medication abortions in BC. Some other jurisdictions in Canada do not have billing codes for telemedicine visits between doctors and patients (only medical professionals for consults), some restrict the platforms allowed, and some jurisdictions in the United States prohibit telemedicine abortions completely.

This study highlights the differences for a clinic providing both in-clinic and telemedicine abortions. Standard in-clinic medication abortions would include one booking telephone call and two in-person visits to the clinic, while the standard telemedicine abortion includes at least two telephone calls and three video visits. In clinic, the necessary blood tests are done in the same building, and those patients getting serial hCGs receive paper requisitions with the address of the lab close to their homes. The pharmacy dispensing the mifepristone is also in the building. For telemedicine abortions, the addresses and fax numbers of the labs and pharmacies in the many different communities must be found. Not all pharmacies will dispense mifepristone; when this occurs, another pharmacy must be found or the medications must be couriered. Finding anti-D for Rh negative women was sometimes a challenge. These logistics increased the number of nonclinical communications between patients and office assistants, both scheduled and unscheduled. The unscheduled communications with physicians were not different between the two groups. This would indicate that the information provided by the clinic counselors about what to expect was adequate for telemedicine patients. One of the trade-offs in not having ultrasound dating was that we tested more individuals for Rh status.

One limitation of our study was that we gathered only the limited demographic data required for clinical care and so could not do a detailed comparison between the two groups. Our rate of emergency room (ER) visits (3.3%) was lower than that of Raymond et al. (7%) [9]. We speculate that when counselors prepare individuals to cope with the pain and side effects of medication abortions, they are less likely to go to an ER for pain and bleeding. Our loss-to-follow-up rate of 6.6% was lower than the 23.0% rate in Raymond et al., and this may have been due to the effort by staff to contact them [9]. More research is needed on using different protocols and in different settings.

Extending Outpatient Medical Abortion Services Through 70 Days of Gestational Age

Beverly Winikoff, MD, MPH, Ilana G. Dzuba, MHS, Erica Chong, MPH, Alisa B. Goldberg, MD, MPH, E. Steve Lichtenberg, MD, MPH, Carol Ball, MD, Gillian Dean, MD, MPH, Daniel Sacks, MD, William A. Crowden, BA, and Yael Swica, MD, MPH

OBJECTIVE: To estimate the efficacy and acceptability of medical abortion at 64–70 days from last menstrual period (LMP) and to compare it with the already proven 57–63 days from LMP gestational age range.

METHODS: This prospective, comparative, open-label trial enrolled 729 women with pregnancies 57–70 days from LMP requesting abortion at six U.S. clinics. Medical abortions were managed with 200 mg mifepristone and 800 micrograms buccal misoprostol and sites' service delivery protocols. Follow-up visits occurred 7–14 days after mifepristone, with an abortion considered complete if surgical intervention was not performed. Success, ongoing pregnancy, and acceptability rates were compared.

RESULTS: A total of 629 cases were analyzable for efficacy. Success rates were similar in the two groups (57–63 days group: 93.5%, 95% confidence interval [CI] 90–96; 64–70 days group: 92.8%, 95% CI 89–95). Ongoing pregnancy rates also did not differ significantly (57–63 days: 3.1%, 95% CI 1.6–5.8; 64–70 days: 3.0%, 95% CI 1.5–5.7). Acceptability was high and similar in both arms, with most women (57–63 days: 87.4%; 64–70 days: 88.3%) reporting that their experience was either very satisfactory or satisfactory.

CONCLUSION: Medical abortion with mifepristone and misoprostol in current outpatient settings is an efficacious and acceptable method of ending pregnancies 64–70 days from LMP and can be offered without alteration of existing services.

LEVEL OF EVIDENCE: II

When medical abortion with mifepristone and misoprostol was approved by the U.S. Food and Drug Administration (FDA) in 2000, the regimen was recommended for outpatient use through 49 days from the last menstrual period (LMP).[1] Extensive research and more than 11 years of experience in the United States with approximately 1.75 million uses have established that medical abortion is safe and effective through 63 days from LMP when used by women at home (May 2011, Danco Laboratories, personal communication).[2–6]

Generally, women in the United States whose first-trimester pregnancies are beyond 63 days from LMP are not offered medical abortion with mifepristone and misoprostol. Medical abortion after 63 days from LMP is occasionally available outside the United States, but only on an inpatient basis using complex regimens.[7–9] Inpatient protocols typically involve redosing of medications, vaginal speculum examination, and an overnight stay, and are burdensome for women, providers, and health care systems. Data supporting use of medical abortion past 63 days from

LMP in outpatient services are limited to one small trial, but results were not available when this study began.[10] Our study sought to estimate the efficacy and acceptability of the most common outpatient medical abortion regimen in the United States (200 mg mifepristone and 800 micrograms buccal misoprostol) through 70 days from LMP and to compare outcomes between women with pregnancies of 64–70 days' duration and women with pregnancies in the range of 57–63 days. The gestational age limit of 70 days extends the usual gestational age cutoff of 63 days by 1 week.

MATERIALS AND METHODS

The study was performed at six facilities: Family Planning Associates Medical Group (Chicago, IL), Planned Parenthood League of Massachusetts (Boston, MA), Planned Parenthood of New York City (New York, NY), Planned Parenthood of Waco (Waco, TX), Presidential Women's Center (West Palm Beach, FL), and Planned Parenthood of Minnesota, North Dakota, South Dakota (St. Paul, MN). The Quorum Review Institutional Review Board approved the protocol.

Women seeking pregnancy termination were invited to participate in the study if they were eligible for medical abortion, were at least 18 years old, and had a confirmed intrauterine pregnancy 57 through 70 days from LMP, based on routine ultrasound practices of the respective study sites (crown-rump length+42 was most commonly used). Participants had to be willing and able to provide informed consent, have access to a telephone and emergency transportation, be able to speak and read English or Spanish, and agree to follow study protocols. Screening and enrollment generally occurred during the same visit, except when a state-mandated 24-hour waiting period after informed consent required a second visit.

On day 1, participants swallowed mifepristone 200 mg (Mifeprex) in the clinic and then were provided with misoprostol 800 micrograms to take 24–48 hours later at home. Women were instructed to hold the misoprostol buccally for 30 minutes before swallowing any remains. Analgesics and antinausea medications were dispensed or prescribed according to local standards at each facility, and participants were counseled to call the clinic with questions or concerns. Participants maintained a diary for up to 15 days to record time of misoprostol administration, bleeding, expulsion time (if recognized), pain medications used, and days of missed work or school.

Participants returned to the study site 7 to 14 days after using mifepristone (according to clinic practice) for clinical assessment, which included ultrasonography. Uterine suction curettage was recommended for women with ongoing pregnancies. Women with nonviable pregnancies (eg, empty sac or static size with absent cardiac activity on ultrasonography) could opt for suction curettage, expectant management, or a second misoprostol dose. If either of the latter two options was chosen, then women were asked to return to the clinic in 1 week for further follow-up. If a persistent nonviable pregnancy was diagnosed at the extended follow-up visit, suction curettage was recommended. Providers also intervened surgically if they deemed it medically necessary or at the patient's request. After expulsion of uterine contents was confirmed, women responded to a semi-structured interview about their experiences with the medical abortion overall, the incidence of side effects and their severity (based on their own definitions of mild, moderate, and severe), and the acceptability of the procedure. If a participant failed to return for a follow-up visit, then assessment of abortion status and the interview could be conducted by telephone. Study sites were required to document at least three attempts to contact women who were lost to follow-up.

The study's primary objective was to assure that an outpatient medical abortion regimen could be used in gestations 64–70 days from LMP and achieve a success rate of at least 90%, which would characterize a clinically acceptable regimen. A cohort of women with gestations 57–63 days from LMP was also enrolled to serve as a comparison; 334 women per group were needed to detect a 5% or greater lower efficacy than the hypothesized 95% success rate in the 57–63 days group, based on previously published reports ($\alpha=0.05$, $1-\beta=0.8$, using a one-tailed test) and would allow us to estimate a success rate of 90% with a confidence interval (CI) of $\pm 3.2\%$.[2–3,11] Data were analyzed using SPSS 15.0. An independent data and safety monitoring committee reviewed the interim results for safety and efficacy after 50% of the data were available.

The primary outcome of the trial was complete abortion without surgical intervention at any point, regardless of the number of misoprostol doses used. Secondary outcomes included side effects, patient satisfaction and acceptability, days of heavy bleeding, days of missed work or school, and number of calls and unscheduled visits to the clinic. One-tailed $P<.05$ was considered to indicate statistical significance. We chose to use one-tailed P values because our objective was to determine whether use of medical abortion in

Copyright© American College of Obstetricians and Gynecologists
GBP-PET01579

the gestational age range of 64–70 days would result in worse outcomes than its current use in the 57- to 63-day age range. Binomial proportion CIs for efficacy rates were calculated. We used Fisher's exact test to determine differences in proportions, and for continuous variables we used the Student *t* test to determine differences in means.

RESULTS

Between August 2009 and February 2011, the study sites enrolled 729 women; 379 women in the 57–63 days group and 350 women in the 64–70 days group. Fifty-three (14%) women in the earlier and 45 (13%) in the later gestational age group were lost to follow-up, and two women, one from each group, withdrew before using mifepristone. Enrollment was continued to 729 women to compensate for loss to follow-up. Six-hundred twenty-nine cases had outcome data, short of the estimated sample size of 668. Analysis of the outcomes at that time were conducted to determine the utility of continuing the study and whether a statistically significant difference in success would be possible if the study were to continue and the remaining 39 analyzable case records were available. We analyzed the hypothetical scenario that maximized the possible difference in efficacy between the two groups by adding all 39 hypothetical additional cases to the 57–63 days group (because it had the higher efficacy rate) and assuming that every woman had a successful abortion (to model the maximum mathematical differences possible between the groups). This model improved the efficacy rate in the 57–63 days study group by 0.7 percentage points and doubled the difference in efficacy between the two gestational age groups from 0.7% to 1.4%. Comparing the projected success rates of the two gestational age groups resulted in $P=0.2$. It was therefore determined that enrolling all 688 women would not show a statistically significant or a clinically meaningful difference in success rates. The study would have required an additional 13,120 women with follow-up in each study group (total 26,240 analyzable cases) to be able to find a statistically significant difference between the observed success rates. Therefore, a total of 629 medical abortions, 325 in the 57–63 days group and 304 in the 64–70 days group, were analyzed for efficacy in the final analysis. Baseline characteristics of women in the two groups were similar for mean age, education level, gravidity, and previous abortions (Table 1).

Efficacy of the outpatient medical abortion regimen in the 57–63 days group was 93.5% (95% CI 90.1–95.9) and 92.8% (95% CI 89.1–95.3; $P=.41$) in the 64–70 days group (Table 2). Three percent of women in both groups had a surgical intervention because of ongoing pregnancy (57–63 days: 3.1%, 95% CI 1.6–5.8; 64–70 days: 3.0%, 95% CI 1.5–5.7; $P=.62$). Rates of surgical intervention attributable to persistent nonviable pregnancy or sac ($P=.33$), substantial uterine debris ($P=.29$), excessive prolonged bleeding ($P=.75$), or woman's request ($P=.86$) were comparable between study groups. There was no significant difference in efficacy by study site ($P=.137$).

Approximately 5.2% of women in the 57–63 days group and 5.3% of women in the 64–70 days group had incomplete abortion diagnosed (ie, persistent gestational sac or substantial debris) at their first follow-up visits ($P=.56$). The majority were treated with a second dose of misoprostol, with those in the 57–63 days group receiving a second dose at a higher rate than those in the 64–70 days group (76.5% compared with 56.3%; $P=.195$). Of those who received a second dose of misoprostol and underwent an extended follow-up evaluation, 91% (10 of 11) in the earlier and 66.7% (6 of 9) in the later gestational age group were determined to have a complete abortion ($P=.974$).

Almost 70% of participants in each group reported a time of expulsion at follow-up. Among women who reported a time of expulsion, those in

the earlier gestational age group were significantly more likely than those in the later gestational age group to expel sooner (Fig. 1; log-rank test *P*=.005). This difference in reported expulsion time was most notably seen at 3 hours after using misoprostol (37.7% in week 9 compared with 22.5% in week 10; *P*=.001), but equal numbers (93.1% compared with 92.1%, respectively; *P*=.43) reported expulsion by 24 hours (Fig. 1).

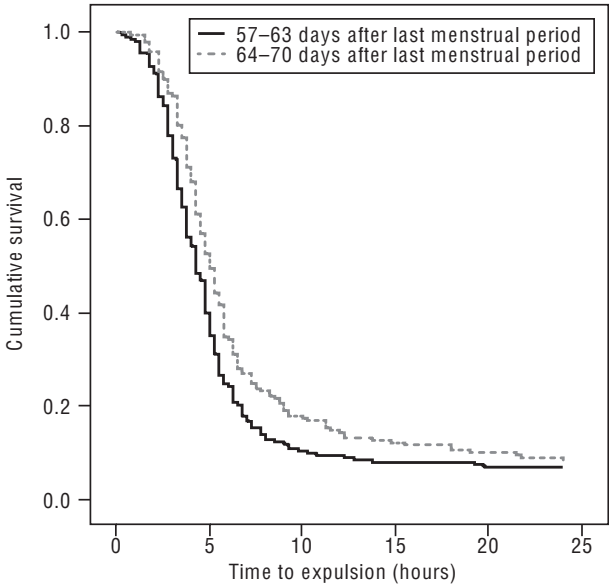

Fig. 1. Time from misoprostol administration to pregnancy expulsion. Survival curves of the number of hours since misoprostol administration until pregnancy expulsion for women 57–63 days from last menstrual period or 64–70 days from last menstrual period. Includes women who reported a time of expulsion, excluding those with ongoing pregnancies or persistent nonviable sac at follow-up. Log-rank test *P*=.005.

Winikoff. Medical Abortion Through 70 Days From LMP. Obstet Gynecol 2012.

Twenty-nine women made visits to an emergency department, primarily for pain and bleeding during the study period (3.7% from the earlier gestational age group and 4.6% from the later group (*P*=.35) (Table 2). Three women received blood transfusions, two in the 57–63 days group and one in the 64–70 days group (*P*=.52). One woman in the 57–63 days group was admitted to the hospital and was successfully treated for *Escherichia coli* sepsis, and one woman in the 57–63 days group with a history of chronic pancreatitis was admitted to the hospital for recurrence of her disease.

Eighty-five percent of participants completed and submitted the diaries they maintained for up to 15 days. Mean duration of heavy bleeding did not differ significantly by group (Table 3). There was no significant difference in mean days of work or school missed by women because of the abortion (1.85 in 57–63 days group compared with 1.80 in 64–70 days group; *P*=.81).

The side effect profiles of each study group were similar, with no significant differences except for vomiting (Table 3). A minority of women in each group experienced this side effect, but fewer in the earlier gestational age group (36% compared with 46%; *P*=.01). However, severe vomiting was no different in the two groups (10.7% for 57–63 days compared with 12.0% for 64–70 days; *P*=.35). Opiates were reportedly used more often for pain relief by women in the 64–70 days group (76% in the 57–63 days group compared with 84%; *P*=.003), but nonsteroidal anti-inflammatory drug use did not differ. Mean days of any analgesic use were the same in both groups. Fewer women in the 57–63 days group reported use of antiemetic medication (34% compared with 46%; *P*=.002). The study participants requested relatively little clinic staff time beyond the scheduled study visits. Only 20%

of women in both groups made phone calls because of concerns related to their abortion, and 4% of women in the earlier and 3% of women in the later gestational age groups made unanticipated clinic visits.

The majority of women in both groups (57–63 days: 87.4%; 64–70 days: 88.3%) reported being either satisfied or very satisfied with the medical abortion method, and 78% and 79% of women in the two groups, respectively, reported that they would choose medical abortion again instead of surgery. Women in the earlier gestational age group were as likely to report seeing the pregnancy or some part of it as those in the later gestational age group (64% compared with 69.3%; *P*=.10). There were no significant differences in women's reported reactions to what they saw, with the exception that women in the earlier gestational age group were more likely to report "nothing or no feeling" (13.9% compared with 8.2%; *P*=.04) and those in the later group were more likely to report that they were "relieved" (7.4% compared with 13.9%; *P*=.02).

DISCUSSION

The results show that medical abortion with an outpatient regimen of 200 mg mifepristone followed 24 to 48 hours later by 800 micrograms buccal misoprostol self-administered at home is efficacious and acceptable in women 64 to 70 days from LMP and is not statistically or clinically different from a current outpatient medical abortion protocol used with women 57–63 days from LMP. In 2000, the FDA approved mifepristone based on an efficacy of 92% for gestations up to 49 days from LMP.[12] The success rate achieved in this study during week 10 of gestation (92.8%) is similar to that rate and clinically acceptable. Based on this evidence, medical abortion using the study protocol can be extended from 63 days from LMP to 70 days from LMP without reconfiguration of existing outpatient clinical services. Our findings are consistent with those of Boersma et al,[10] who offered the same outpatient medical abortion regimen as in the current study to 26 women with gestational ages 64–70 days from LMP, but with an interval of 24–36 hours between the mifepristone and misoprostol doses. That study found 96% success in those women but was too small to provide reliable point estimates of success rates.

The study cannot reject the null hypothesis that there is no difference between the success rates of medical abortion among women with pregnancies of 9 and 10 weeks of gestation. Although the inability to reject the null hypothesis theoretically could be attributable to early cessation of the study, the observed differences between study groups are much smaller than those originally hypothesized and are not clinically meaningful. The additional analyses conducted also suggest that continuing enrollment to include 668 analyzable cases would not have affected the study conclusions.

The overall high efficacy of the medical abortion regimen used in this study through 63 days from LMP is well-documented, and only a very minimal decline in efficacy as gestational age increases has been noted.[2,13] The trend observed in the two point estimates for success in weeks 9 and 10 in this study is consistent with such a small decline (Fig. 2), alleviating concern of an abrupt decline in efficacy of the method beyond 63 days from LMP.

The study was not powered to detect a difference in safety outcomes because major adverse events attributable to medical abortion (eg, hospitalizations, emergency department visits, and blood transfusions) are rare. No medical abortion studies (including the pilot studies on which FDA approval was based) were powered to detect rates of rare occurrences such as transfusion or hospitalization. Similar to those studies, the occurrence of major adverse events in this study was very infrequent.

Many studies have explored women's experiences with outpatient medical abortion in the first trimester,[14]

but often the information is not disaggregated by week. Although our findings do not show any differences between the two study groups in such aspects as bleeding profiles, days of school or work missed, and reports of seeing the expulsion, women's experiences at these later weeks of gestational age may differ in some ways from women with earlier first-trimester pregnancies. The results from this study may help clinicians who provide medical abortion to women with pregnancies 57–70 days of gestational age to tailor counseling messages to prepare women for what to expect. For example, more than two-thirds of women reported witnessing uterine expulsion, so women should be counseled on that likelihood. Women with gestations in week 10 may expel their pregnancies less quickly after using misoprostol, but perhaps this is not surprising given the slightly larger size of the gestational sac at the later gestational age The fact that more women in week 10 expressed relief after their medical abortions could be an artifact of participating in the test group of a research trial.

Some women may have been misclassified into study groups based on usual variability in gestational age dating by ultrasonography. To be sure that such misclassification would not have affected study results, reanalysis of success among women with pregnancies at the opposite extremes of the gestational age spectrum considered in this study (ie, a comparison of the earlier half of the early age range with the latter half of the later age range), as well as by standardizing gestational age assessment, did not affect our outcomes or our conclusions (data not shown).

The content of counseling was not dictated by the study protocol and was based on usual counseling provided. Possible assumptions that pain, bleeding, and the size of the expelled fetus in week 10 may be more than at earlier weeks of gestation could have had an effect on women's perceptions. It is also possible that there were slight differences in counseling messages as a result of the counselors' knowledge of gestational age in each woman. Similarly, observations and experience amassed during the course of the study may have resulted in adjustments in counseling messages to later enrollees, better-preparing women with pregnancies in week 10 for what they might experience.

The study sites already were highly experienced at providing medical abortion and were accustomed to administering the specific regimen used in this study. Therefore, the observed efficacy rates may not be generalizable to clinics that are less experienced. Results also are not generalizable to regimens other than the one studied, for either efficacy or the side effects of misoprostol, which are known to vary by route and dose. Last, because adverse events were so rare in our study, the sample size was not sufficient to characterize adequately the occurrence of adverse events for women who terminate their pregnancies medically during the ninth or tenth week other than to say that serious events are infrequent and side effects are tolerable.

In conclusion, the regimen of 200 mg mifepristone and 800 micrograms buccal misoprostol is efficacious and acceptable for women seeking medical abortion with pregnancies of 70 days or less. The findings of this research are important for expanding the availability of this nonsurgical option to women seeking termination of pregnancy in the first trimester.

Two Distinct Oral Routes of Misoprostol in Mifepristone Medical Abortion

A Randomized Controlled Trial

Beverly Winikoff, MD, MPH, Ilana G. Dzuba, MHS, Mitchell D. Creinin, MD, William A. Crowden, Alisa B. Goldberg, MD, MPH, Juliana Gonzales, Michelle Howe, PA-C, Jeffrey Moskowitz, MD, Linda Prine, MD, Caitlin S. Shannon, JD, MPH

OBJECTIVE: To study the efficacy, safety, and acceptability of oral immediately swallowed and buccal misoprostol 800 mcg after mifepristone 200 mg for terminating pregnancy through 63 days since the last menstrual period (LMP).

METHODS: This seven-site study randomly assigned 966 women seeking abortions to oral or buccal misoprostol 800 mcg 24–36 hours after mifepristone 200 mg with 7–14-day follow-up.

RESULTS: Success rates in the oral and buccal groups were 91.3% (389 of 426) and 96.2% (405 of 421), respectively (*P*=.003; relative risk [RR] 0.95, 95% confidence interval [CI] 0.92–0.98). Ongoing pregnancy occurred in 3.5% (15 of 426) of women who took oral misoprostol compared with 1.0% (4 of 421) of women in the buccal group (*P*=.012; RR 3.71, 95% CI 1.24–11.07). Through 49 days since the LMP, oral and buccal regimens performed similarly, but success with oral misoprostol decreased as pregnancy advanced. In pregnancies of 57–63 days since the LMP, success with oral misoprostol fell below 90%, whereas that with buccal remained high (oral 85.1% [97 of 114], buccal 94.8% [109 of 115], *P*=.015, RR 0.90, 95% CI 0.82–0.98). Furthermore, in this gestational age group, there were significantly more ongoing pregnancies among women who took misoprostol orally (7.9% [9 of 114]) compared with buccally (1.7% [2 of 115]; *P*=.029, RR 4.54, 95% CI 1.0–20.55). Adverse effect profiles were similar, although fever and chills were reported approximately 10% more often among women who took buccal misoprostol. Satisfaction and acceptability were high for both methods.

CONCLUSION: Buccal misoprostol 800 mcg after mifepristone 200 mg is a good option for medical abortion through 63 days since the LMP. Oral misoprostol 800 mcg is also a safe and effective alternative, although success rates diminish with increasing gestational age.

After mifepristone was approved by the United States Food and Drug Administration in 2000, vaginal use of misoprostol 800 mcg became almost a standard of care in early medical abortion.[1–3] However, nonvaginal routes of misoprostol administration are now of increasing interest to women and providers because of 1) lower acceptability of vaginal administration[4,5]; 2) legal peril to women where abortion is clandestine and pill remnants may remain in the vagina; and 3) concern about infection, specifically,

Copyright© American College of Obstetricians and Gynecologists

GBP-PET01585

very rare but fatal clostridial infections[6,7] (although no association between such infections and use of vaginal misoprostol has been found). In March 2006, Planned Parenthood Federation of America changed its national guidelines to avoid vaginal administration of misoprostol, but the scanty evidence supporting a nonvaginal regimen through 63 days since the last menstrual period (LMP) meant that medical abortion was no longer an option for women with pregnancies of more than 56 days since the LMP.

Oral (immediately swallowing pills), buccal (holding pills in the cheek) and sublingual (holding pills under the tongue) misoprostol administration after mifepristone has been studied as an alternative to vaginal administration in early medical abortion. Encouraging but equivocal findings of studies on 800 mcg oral misoprostol[8–10] and unpublished claims of high clinical success and tolerance of adverse effects with this regimen in a large United Kingdom system (January 2006, Dr. Kate Worsley, personal communication) suggested the need for a more definitive trial. Similarly, because an 800 mcg buccal regimen had been shown to be as effective as a 800 mcg vaginal regimen through 56 days since the LMP[11] and the pharmacokinetic profiles and effect on uterine contractility were similar,[12,13] we decided that buccal administration was also a likely candidate for use through 63 days since the LMP. We conducted a randomized trial to explore whether 800 mcg oral and buccal misoprostol 24–36 hours after mifepristone 200 mg are effective regimens for routine clinical use in medical abortion through 63 days since the LMP.

MATERIALS AND METHODS

We report an open-label, randomized trial to characterize oral and buccal misoprostol administration after mifepristone in women with pregnancies through 63 days since the LMP. The study was implemented in seven facilities in the United States: Family Planning Associates Medical Group (Chicago); Institute of Urban Family Health (New York); Magee Womens Hospital/University of Pittsburgh (Pittsburgh); Parkmed (New York); Planned Parenthood League of Massachusetts (Boston); Planned Parenthood of Waco (Waco); and Whole Woman's Health (Austin). The Western Institutional Review Board and the institutional review boards at the University of Pittsburgh and the Institute for Urban Family Health approved the protocol.

Women seeking medical abortion were eligible if they did not have U.S. Food and Drug Administration–labeled contraindications to the method, were at least 18 years old, and had an intrauterine pregnancy not exceeding 63 days since the LMP on the day of the medical abortion. Gestational age was determined by LMP, clinical examination, and/or ultrasonography, as needed. Participants had to be willing and able to sign consent forms, have access to a telephone and emergency transportation, speak and read English or Spanish, and agree to comply with the study procedures. Screening and enrollment generally occurred during the same visit, except when state-mandated 24-hour waiting periods after informed consent required a second visit.

On day 1, participants swallowed mifepristone 200 mg (Mifeprex; Danco Laboratories, New York, NY) in the clinic and then were provided with misoprostol 800 mcg (Ivax Pharmaceuticals, Miami, FL) to take 24–36 hours later at home, either orally or buccally according to random assignment. Women assigned to take misoprostol buccally were instructed to hold two 200-mcg pills in each cheek pouch for 30 minutes and then to swallow any remnants. Women were offered prescriptions for oral narcotics to manage pain and antidiarrheal and antinausea medications, according to local standards at each facility. Participants maintained a diary for up to 15 days to record misoprostol administration, pain, bleeding, adverse effects and medications taken.

Participants returned to the study site 7 to14 days after taking mifepristone for clinical assessment, including transvaginal ultrasonography, except at one site where ß-hCG levels were routinely monitored and ultrasonography was employed only when needed. Women with ongoing pregnancies were recommended suction aspiration. Women with nonviable pregnancies (eg, sac or other evidence of products of conception, but no gestational growth and no cardiac activity on ultrasonography) could opt for suction aspiration, expectant management, or a second misoprostol dose administered by the same route as the initial dose. If either of the latter two options was chosen, women were asked to return 7 days later. If a persistent nonviable pregnancy was diagnosed at the extended follow-up visit, a suction aspiration was recommended. Providers also could intervene surgically if deemed medically necessary (eg, for excessive bleeding) or at the participant's request. After expulsion was confirmed, women responded to a semi-structured interview about the experience overall, the acceptability of the procedure, and adverse effects.

Allocation to study group was determined by computer-generated assignment concealed in sealed opaque envelopes. Randomization sequence (using random blocks of eight and stratified by study center) and envelopes were prepared by Gynuity Health Projects staff unrelated to the clinical conduct of the

Copyright© American College of Obstetricians and Gynecologists

GBP-PET01586

study. Envelopes were assigned to study participants in numerical sequence. Both providers and participants became aware of group assignment when the envelopes were opened.

The primary objective of the study was twofold: 1) to estimate the effectiveness of each regimen among women with gestations 57 to 63 days since the LMP and 2) to compare their effectiveness among all women. In determining the sample size, recruitment of women in the 57–63 day gestational age group was a limiting factor, and therefore the sample size calculation was based on the first stated objective. We determined that a sample of 105 women in the gestational age range of 57–63 days was required in each study arm to be able to estimate efficacy at 93% with a 95% confidence interval (CI) of ±5% (assuming a 5% rate of loss to follow-up). Based on U.S. abortion clinic statistics, we estimated that 15–20% of all participants would fall in the 57–63 day gestational age group, and anticipated enrolling a total of 1,200 women. With at least 425 women per arm, and assuming a 95% efficacy for the buccal regimen,[11] we would be able to detect a 5% difference between the study arms with 80% statistical power at the 95% confidence level—a difference we considered clinically important for formulating practice guidelines.

Data were analyzed using SPSS 15.0 (SPSS Inc., Chicago, IL). An interim analysis was conducted when approximately 50% of the study sample completed participation to assess safety. Baseline demographic variables were compared according to treatment group to test randomization, using the Student *t* test or the Mann-Whitney *U* test for continuous variables and χ^2; or Fisher exact test (where cell sizes were 5 or less) for categorical variables. Normality of continuous variables was assessed by graphic display.

The primary outcome variable—treatment success—was assessed both by per-protocol and intention-to-treat analyses; because no significant differences were found using the χ^2 test, only the per-protocol analysis is presented. Per-protocol analysis has been deemed more appropriate for an exploratory efficacy trial[14] and more valuable to clinicians and clinic managers who want to understand the true efficacy of the two regimens; moreover, it is commonly presented in medical abortion trials.[10] In both analyses, we included in-clinic or telephone follow-up adequate to determine that a woman's pregnancy had been terminated; for per-protocol analysis, adherence to the regimen was determined according to information provided at the follow-up visit. Successful medical abortion was defined as a complete abortion without surgical intervention at any point, regardless of the number of doses of misoprostol taken. For the final analysis of the primary outcome variable, the alpha was reduced to 0.0479, as a result of the interim analysis and according to the O'Brien and Fleming method.[15]

Secondary outcome variables were the effect of a second dose of misoprostol, adverse effects, patient satisfaction and acceptability of each of the regimens, adverse effects, and pain; these outcomes were assessed according to treatment group using χ^2 test or Fisher exact test. Finally, the effect of gestational age on primary and secondary outcome variables was assessed by χ^2 test for trend, and post-hoc, pair-wise comparisons were conducted using the Tukey HSD test, where results were significant. Efficacy within groups by site was assessed using χ^2 test or Fisher exact test. For secondary analyses, two-tailed values of $P<.05$ were considered significant.

RESULTS

Between September 2006 and May 2007, the study sites enrolled 966 participants (Fig. 1). Enrollment was discontinued after 265 women with pregnancies between 57 and 63 days since the LMP were randomly assigned, ensuring at least 210 analyzable cases. The two treatment groups were similar with respect to education level, marital status, gravidity, gestational age, and previous abortions, but there was a statistically significant difference in mean age (25.8 years for oral compared with 26.7 years for buccal $P=.02$) (Table 1).

Five participants (0.5%) withdrew from the study after randomization and 92 (9.5%) were lost-to-follow-up. The experiences of 847 women were analyzed for efficacy (Fig. 1). Overall the efficacy after buccal misoprostol administration was greater than that of oral administration (96.2% compared with 91.3%, $P=.003$) (Table 2). An intention-to-treat analysis was also conducted, which yielded no difference in conclusions (96.1%, buccal compared with 91.0%, oral, $P=.003$, RR 1.06, 95% CI 1.02–1.09). One percent of the women assigned to buccal misoprostol and 3.5% of the women assigned to oral misoprostol had a surgical intervention due to ongoing pregnancy (RR 3.71; $P=.012$). Other reasons for surgical intervention included persistent nonviable pregnancy or sac (n=14), medical indications (n=19), or woman's request (n=1), none of which varied significantly by study group. Efficacy did not vary significantly by study group among all women with gestations 56 days since the LMP or less, but among women with pregnancies 57–63 days since the LMP, efficacy was higher after buccal administration (85.1% compared with 94.8%, RR 0.90; $P=.015$). Fur-

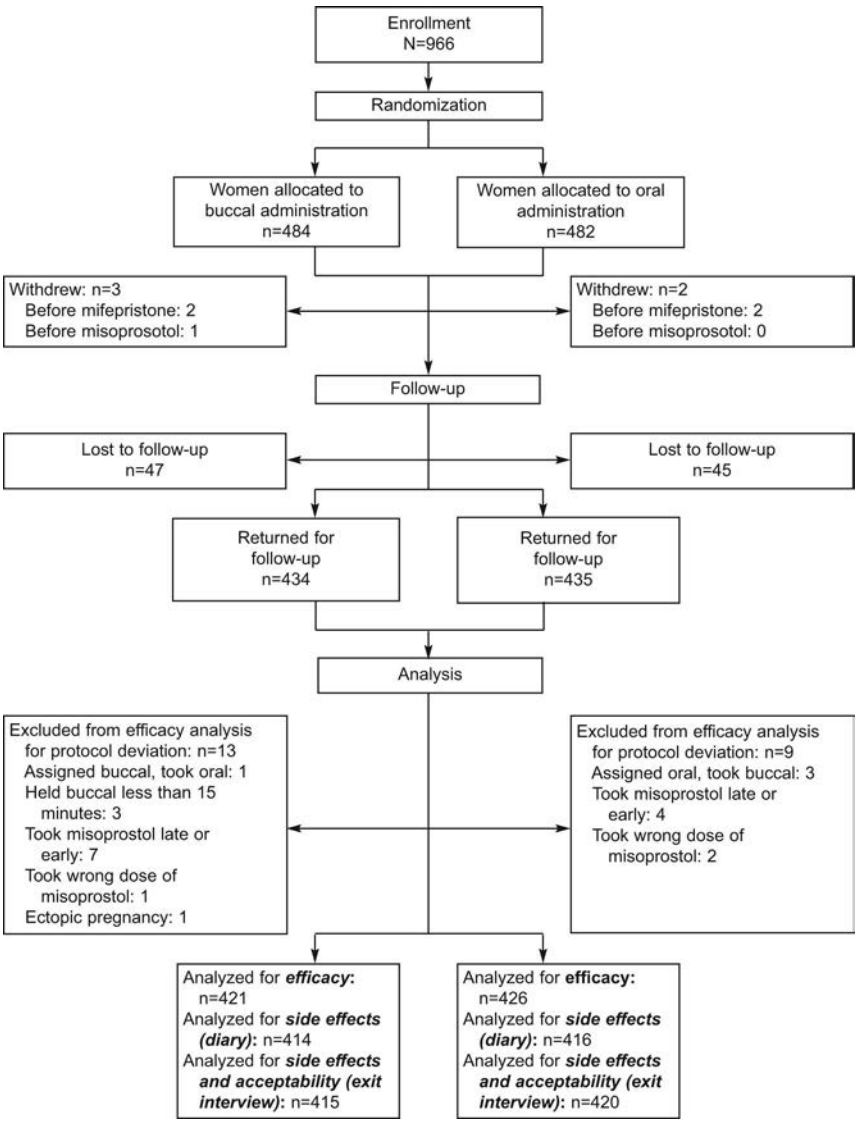

Fig. 1. Illustration of the flow and numbers of study participants through each phase of the study (enrollment, randomization, follow-up and analysis). *Winikoff. Misoprostol by Mouth in Medical Abortion. Obstet Gynecol 2008.*

ther, the frequency of ongoing pregnancy was significantly higher in that gestational age group among women administering misoprostol orally (7.9% compared with 1.7%, RR 4.54; P=.029). The success of buccal administration did not vary significantly with gestational age (χ^2 for trend 1.776; P=.183), although there was some decline in success with advancing gestational age (Fig. 2). Success after oral administration, however, was high (96.1%) among women with gestations 49 days since the LMP or less, but declined to 85.1% among those 57–63 days (P<.001).

The frequency of use of a second dose of misoprostol at follow-up to treat women with persistent nonviable pregnancies or uncertain outcomes did not vary between women in the buccal (n=14) and oral (n=12) groups (P=.668). Nonetheless, more women in the buccal group who took a second dose achieved a successful outcome (92.9% compared with 50.0%, P=.026). After a second dose of misoprostol, the success rate among women using misoprostol buccally increased by 3.1%, whereas the success rate was improved by only 1.5% for women in the oral group. This difference in improved outcome was not statistically significant.

Women reported adverse effects in diaries and in semistructured interviews at the follow-up visit (Table 3). The differences between what women recorded in diaries and what they reported in interviews were less than 10% for all effects except weakness, and approximately 80% of women's responses were consistent between the two sources (data not shown). Regardless of the source of report, the adverse effect profiles of

Illustration of how failure rates and, more specifically, ongoing pregnancy rates increased with gestational age, particularly in the group of women that took oral misoprostol. * Difference between ongoing pregnancy rates by regimen is statistically significant at 57–63 days since the LMP (P=.029). † Difference between failure rates by regimen is statistically significant at 57–63 days since the LMP (P=.015).

Winikoff. Misoprostol by Mouth in Medical Abortion. Obstet Gynecol 2008.

each study group were similar. Nausea vomiting, and diarrhea were reported equally frequently by women in each group. Fever/chills were also reported about 10% more frequently among women who took misoprostol buccally, whether reported in the diary (47.6 compared with 36.1, P=.001) or during the exit interview (41.4% compared with 33.3%, P=.020).

Twenty-six (3.0%) women made visits to an emergency room during the study period (14 from the oral group and 12 from the buccal group), 21 of whom were not admitted, primarily for pain and bleeding. Three participants from the buccal group were hospitalized during the study period for reasons that were unrelated to the study protocol (pulmonary embolus, ruptured ectopic pregnancy, and right hip pain).

Participants were highly satisfied with the procedure, regardless of the route by which they administered misoprostol: 91.9% of women were either satisfied or very satisfied (Table 4). Satisfaction decreased significantly with increasing gestational age in the oral

Data are % (n) unless otherwise specified.
* Responses were consistent between reports on diaries and in exit interviews for 83% of women reporting nausea, 87% reporting diarrhea, 83% reporting dizziness, 83% reporting headache, 79% reporting weakness, and 85% reporting fever/chills.

group (χ^2 for trend 8.708, P=.003) but not in the buccal group (χ^2 for trend 3.495, P=.062). Participant satisfaction was significantly related to success, regardless of study group (χ^2 136.8, P<.001, oral; χ^2 50.1, P<.001, buccal).

Of women having successful abortions, overall satisfaction was higher among those who took misoprostol orally (96.9% compared with 92.8%, P=.009). Among women whose abortions were successful, the difference in the acceptability of adverse effects between the study groups was statistically significant, with more women in the oral group finding the effects acceptable (78.5% compared with 72.1%, P=.037). In both study groups, pain, the time to completion, and adverse effects were considered acceptable or very acceptable to the majority of women (Table 4). In general, women's expectations of the procedure were similar to their experiences, with the majority of women experiencing the same or less pain (70.7%) and bleeding (72.5%) than expected. There was no difference between study groups in expectations of bleeding, but women were more likely to have less pain than expected with oral than with buccal administration (38.6% compared with 29.6%, P=.006). When asked about regimen preference for a future medical abortion, 93.6% of women in the oral group responded that they preferred to take misoprostol orally, whereas only 34.0% of women in the buccal group would prefer buccal administration. The primary complaint about the buccal route was a bitter

and chalky taste of the misoprostol, mentioned by 24% of women who administered it that way.

DISCUSSION

Our study demonstrates that, after 200 mg mifepristone, a dose of 800 mcg buccal misoprostol is more effective at terminating pregnancy than an 800 mcg oral dose. The buccal regimen is superior to the oral regimen between 57 days and 63 days since the LMP, with a trend over the entire gestational age range toward superiority between 49 days and 56 days since the LMP. Our results on the performance of the 800 mcg oral misoprostol regimen corroborate previous research that demonstrates a total efficacy of 90% or greater using oral regimens through 63 days since the LMP[8,10,16–20] and also corroborates that with increasing gestational age, success decreases and ongoing pregnancies rise significantly.[9,16,17,21] However, of the studies of 800 mcg oral misoprostol, one was terminated early due to low tolerance of adverse effects and reported outcomes in only 27 women.[9] In the other study, the failure rate among women 57–63 days since the LMP who took misoprostol orally was only two percentage points higher than among those who administered it vaginally (9.8% compared with 7.8%; RR 2.8, 95% CI 1.3–5.8),[10] a difference that may not be clinically relevant.

Our data also show that efficacy with buccal administration also decreases slightly with increasing gestational age (Table 2). Similar declines in efficacy may be observable regardless of route in early medical abortion.[9,10,16,22,23] There are three published trials using buccal misoprostol for pregnancy termination,[11,24,25] one of which used methotrexate, not mifepristone,[25] another was a pilot, noncomparative trial,[24] and the last of which tested the regimen only through 56 days since the LMP.[11] Our study demonstrates clearly that buccal misoprostol 800 mcg after mifepristone 200 mg is appropriate for use between 57–63 days since the LMP, whereas oral misoprostol 800 mcg is not as effective.

Differences in pharmacokinetics between oral and buccal routes offer one possible explanation for the different success rates, because the rapid peak in serum levels after oral use has been observed to result in increased uterine tone but not sustained uterine contractions. In contrast, regular and sustained uterine contractility has been documented after buccal as well as vaginal administration.[13]

Several large randomized clinical trials suggest that a repeated misoprostol dose may have a "leveling" effect on success among regimens.[10,16] A leveling effect was not observed in our study where use of additional misoprostol doses did not differ between study groups. In fact, the effect of a second dose among women who received it was a 1.5% increment in success for the oral regimen and 3.1% increment for the buccal route, widening the difference in efficacy between the routes.

Adverse effects were acceptable to women in both study groups and did not seem to affect overall satisfaction with the method, which was very high. Moreover, adverse effects did not vary significantly by study group, with the exception of more reports of fever/chills among those who took misoprostol buccally, but which were not judged clinically important. The adverse-effects profile in the buccal group was quite similar to that published by Middleton et al.[11] Despite claims that oral misoprostol leads to more gastrointestinal adverse effects (vomiting and diarrhea)[9,26] and the fact that our oral dose was higher than that used in some studies, we observed no differences in such effects between oral and buccal administration.

Clinical practices, including the timing and length of follow-up and propensity to intervene, have an important effect on observed differences in success rates in the published literature as well as in practice. A published meta-analysis and another case series have confirmed that provider practice may affect method success.[27,28] Clinicians in our study were aware of a woman's assigned regimen, and it is possible that this knowledge inadvertently influenced patient management. However, the overall differences in the reasons for surgical intervention were neither large nor significant, with the exception of ongoing pregnancies, the diagnosis of which is not as subject to provider bias.

The consideration of provider practice is particularly relevant because most of the mifepristone–misoprostol regimens tested in randomized trials are highly effective (greater than 90% overall efficacy). Moreover, management disparities may help to explain inconsistencies among randomized controlled trials, especially those done in one or only a few sites. The effect of provider practices may be unavoidable, costly to measure, and difficult to interpret, but if trial results should guide real-world practice, there is benefit to a protocol that does not overregulate clinical management.

In addition to oral and buccal, sublingual administration is another possible nonvaginal route of drug administration in medical abortion. The two randomized trials that had reported on the sublingual route through 63 days since the LMP at the time we initiated our study[22,23] examined use in a total of only

Copyright© American College of Obstetricians and Gynecologists

GBP-PET01591

169 women. These data were insufficient to assume that sublingual administration was a more promising route than buccal misoprostol, which had already been demonstrated to be at least as effective as vaginal misoprostol through 56 days since the LMP.[11] The sublingual route remains an alternative that warrants further investigation.

The findings of our research are important for expanding the availability of medical abortion to women with pregnancies beyond 56 days of gestation where providers or women are reluctant to use vaginal misoprostol. Our results support the offer of a highly effective, safe, and acceptable nonvaginal regimen for early termination of pregnancy.

c/o Rachel Tetlow, Federal Affairs Director
rtetlow@acog.org

Skye Perryman, General Counsel
sperryman@acog.org

William Grobman, MD, MBA
President
Society for Maternal-Fetal Medicine
w-grobman@northwestern.edu

Dear Drs. Phipps and Grobman,

In your letter of April 20, 2020, to former Commissioner Stephen Hahn, you expressed concerns about the in-person dispensing requirements for certain prescription drugs during the current public health emergency. In my letter to you of March 19, 2021, I indicated that staff in the Food and Drug Administration's (FDA) Center for Drug Evaluation and Research (CDER) were evaluating the issues you raised.

Following up on my March 19, 2021, letter I am writing to report the results of CDER's review and analysis.

CDER conducted a literature search for studies pertinent to the in-person dispensing requirement in the Mifepristone REMS Program during the COVID-19 pandemic. Based on this literature search, CDER identified four publications that included relevant clinical outcome data.[1] CDER

[1] Chong E, et al. Expansion of a Direct-to-Patient Telemedicine Abortion Service in the United States and Experience during the COVID-19 Pandemic. Silver Spring, MD 20993
www.fda.gov

found that although there are limitations to the study designs, the overall findings from these studies do not appear to show increases in serious safety concerns (such as hemorrhage, ectopic pregnancy, or surgical interventions) occurring with medical abortion as a result of modifying the in-person dispensing requirement during the COVID-19 pandemic.

CDER also reviewed postmarketing adverse events that reportedly occurred from January 27, 2020 - January 12, 2021, with mifepristone use for medical termination of early pregnancy, along with available information about deviations or noncompliance events associated with the Mifepristone REMS Program.[2] CDER found that the small number of adverse events reported to FDA during the COVID-19 public health emergency (PHE) provide no indication that any program deviation or noncompliance with the Mifepristone REMS Program contributed to the reported adverse events.

In summary, provided the other requirements of the Mifepristone REMS Program are met, and given that the in-person dispensing of mifepristone for medical termination of early pregnancy may present additional COVID-related risks to patients and healthcare personnel because it may involve a clinic visit solely for this purpose, CDER intends to exercise enforcement discretion during the COVID-19 PHE with respect to the in-person dispensing requirement of the Mifepristone REMS Program, including any in-person requirements that may be related to the Patient Agreement Form. Further, to the extent all of the other requirements of the Mifepristone REMS Program are met, CDER intends to exercise enforcement discretion during the COVID-19 PHE with respect to the dispensing of mifepristone through the mail either by or under the supervision of a certified prescriber, or through a mail-order pharmacy when such dispensing is done under the supervision of a certified prescriber.

CDER is communicating this decision to the approved application holders subject to the Mifepristone REMS Program.

Sincerely yours,

Janet Woodcock, M.D.
Acting Commissioner of Food and Drugs

Executive summary xix
Chapter 1. Introduction 1
1.1 Background and context 1
1.2 Guideline objective, rationale, target audience, inclusivity and structure 2
1.2.1 Objective and rationale 3
1.2.2 Target audience 3
1.2.3 Equity, inclusivity and people-centred care 3
1.2.4 Conceptual structure of the guideline 4
1.3 An enabling environment for comprehensive abortion care 5
1.3.1 Human rights including a supportive framework of law and policy 7
1.3.2 Availability and accessibility of information 12
1.3.3 Health system factors 12
1.4 Health system considerations 13
1.4.1 Universal health coverage and primary health care 13
1.4.2 Health financing 14
1.4.3. Health workforce competencies and training 16
1.4.4 Commodities 16
1.4.5 Monitoring and evaluation of quality abortion care 18
Chapter 2. Abortion regulation including relevant recommendations 21
2.1 Common approaches to abortion regulation 22
2.2 Recommendations relating to regulation of abortion 22
2.2.1 Criminalization of abortion 24
2.2.2 Grounds-based approaches to controlling access to abortion 26
2.2.3 Gestational age limits 28

Chapter 3. Recommendations and best practice statements across the continuum of abortion care 31
3.1 Background 32
3.1.1 Structure of information in this chapter 32
3.1.2 Underlying principles and assumptions relating to recommendations on health worker roles 33
3.2 Services applicable across the continuum of care 34
3.2.1 Providing information 34
3.2.2 Offering and providing counselling 37
3.2.3 Links to additional services 40
3.3 Pre-abortion 41
3.3.1 Mandatory waiting periods imposed by States, health-care facilities or health workers 41
3.3.2 Third-party authorization for abortion 42
3.3.3 Rh isoimmunization 44
3.3.4 Antibiotic prophylaxis 46
3.3.5 Determining gestational age of pregnancy 47
3.3.6 Pain management for abortion 49
3.3.7 Cervical priming prior to surgical abortion 54
3.3.8 Restrictions (in law or policy) on health workers who may lawfully provide abortion care 59
3.3.9 Conscientious objection or refusal by health workers to provide abortion care 60
3.4 Abortion 62
3.4.1 Methods of surgical abortion 63
3.4.2 Medical management of induced abortion 67
3.4.3 Missed abortion 74
3.4.4 Intrauterine fetal demise (IUFD) 76
3.5 Post-abortion 79
3.5.1 Follow-up care after abortion 79
3.5.2 Incomplete abortion 81
3.5.3 Management of non-life-threatening complications: infection and haemorrhage 85
3.5.4 Post-abortion contraception 88
3.6 Service-delivery options and self-management approaches 94
3.6.1 Supported service-delivery approaches 94
3.6.2 Self-management approaches for medical abortion in whole or in part 98
3.6.3 Self-management approaches for post-abortion contraception 100
Chapter 4. Dissemination, applicability, research gaps and future updates of the guideline and recommendations 105
4.1 Dissemination 105
4.2 Implementation and impact evaluation of the guideline 105
4.3 Research gaps/topics for further research 106

Acknowledgements

The UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP) and the World Health Organization (WHO) gratefully acknowledges the contributions of many individuals and organizations to the development of this consolidated guideline.

WHO extends sincere thanks to the **chair and members of the Guideline Development Group (GDG)**: Laura Castleman (Chair) and Fauzia Akhter Huda, Karla Berdichevsky, Marge Berer, Michalina Drejza, Joanna Erdman, Kristina Gemzell Danielsson, Caitlin Gerdts, Laura Gil, Selma Hajri, Guyo Jaldesa, Godfrey Kangaude, Vinoj Manning, Hiromi Obara, Alongkone Phengsavanh, Akila Radhakrishnan, Michelle Remme and Chi Chi Undie; and also the **human rights adviser** for the GDG meeting and all three Evidence and Recommendation Review Group (ERRG) meetings: Christina Zampas. Sincere thanks also to the following additional **ERRG members**: Nana Yaa Appiah, Suchitra Dalvie, Jemima Araba Dennis-Antwi, Surendra Dhital, Daniel Maceira, Sybil Nkeiru, Karan Parikh, Dhammika Perera, Judiac Ranape, Kitihoun Serge and Karthik Srinivasan; and to the following **human rights advisers** who contributed to the ERRG on law and policy: Abhijit Das, Sara Hossain, Karima Khalil, Primah Kwagala, Monica Arango Olaya and Xian Warner. Thanks are also due to the members of the **External Review Group**: Safia Ahsan, Traci Baird, Sharon Cameron, Jane Harries, Thoai Ngo, Yvette Raphael, Mariana Romero, Rachel Simon-Kumar and Beverly Winikoff. Institutional affiliations for these and other contributors are provided in Annex 1 of this guideline.

Special thanks are due to the **Evidence Synthesis Teams**, who prepared the Grading of Recommendations Assessment, Development and Evaluation (GRADE) systematic reviews, especially the **lead researchers**: Alison Edelman, Taylor King, Makalapua Motu'apuaka, Robyn Paynter, Maria Rodriguez (Clinical services domain); Nicholas Henschke, Yanina Sguassero and Gemma Villanueva (Service delivery domain); Scott Burris, Amanda Cleeve, Fiona de Londras and Maria Rodriguez (Law and policy domain). Special thanks also to the **guideline methodologists**, Jeppe Schroll (Clinical services domain); Nicholas Henschke, Yanina Sguassero and Gemma Villanueva (Service delivery domain), and Maria Rodriguez (Law and policy domain). We also thank the team from the London School of Hygiene and Tropical Medicine, led by Veronique Filippi, for their work on monitoring and evaluation issues related to quality abortion care. We thank the "Economics of abortion" review team, led by Ernestina Coast, Samantha Lattof, Brittany Moore and Yana Rodgers, for their collaboration and contributions to the guideline. We also extend our thanks to the International Youth Alliance for Family Planning (IYAFP) for their close collaboration and contributions from their Youth Taskforce members to the guideline development process.

We acknowledge the following **GDG meeting observers** including representatives from United Nations agencies: Patricia Lohr (British Pregnancy Advisory Service, and member of the Royal College of Obstetricians and Gynaecologists [RCOG] Making Abortion Safe Programme Advisory Group), Jaydeep Tank (Federation of Obstetrics and Gynaecological Societies of India and International Federation of Obstetrics and Gynaecology [FIGO] Working Group for safe abortion, India), Francelle Toedtli (United Nations Population Fund, USA), Ann Yates (International Confederation of Midwives, the Netherlands); and the following **individual reviewers from**

implementing organizations who provided feedback on the draft guidelines: Bethan Cobley (MSI Reproductive Choices, United Kingdom), Rasha Dabash (Ipas, USA), Eva Lathrop (Population Services International, USA), Steve Luboya (Pathfinder, USA) and Rebecca Wilkins (International Planned Parenthood Federation, United Kingdom of Great Britain and Northern Ireland).

The following WHO staff members contributed as members of the **WHO Guideline Steering Group**, which managed the guideline development process (all from WHO's Department of Sexual and Reproductive Health and Research [SRH], Prevention of Unsafe Abortion [PUA] Unit): Mekdes Daba Feyssa (provided support for the clinical services domain and overall guideline development process), Bela Ganatra (PUA Unit head, co-lead coordinator for the service delivery domain), Heidi Johnston (provided support for the service delivery domain, especially monitoring and evaluation work), Caron Kim (responsible technical officer, lead coordinator for the clinical services domain and co-lead for the service delivery domain, and overall coordinator for the guideline development process), Antonella Lavelanet (lead coordinator for the law and policy domain and human rights). During initial stages of guideline planning, Steering Group members also included Roopan Gill and Lemi Tolu (formerly with the PUA Unit) and Rajat Khosla (formerly with the Office of the SRH Department's Director).

Writing was provided by Fiona de Londras, Bela Ganatra, Heidi Johnston, Caron Kim, Antonella Lavelanet, Jane Patten and Maria Rodriguez. WHO administrative support was provided by Claire Garabedian and Hannah Hatch, and communications support was provided by Sarah Kessler and Elizabeth Noble, all from the SRH Department, with additional communications support from Laura Keenan and Sarah Russell of the WHO Director of Communications Office and from Helen Palmer of Weber Shandwick. We are grateful to the following additional WHO headquarters staff and consultants, who provided input at various stages during the development of the guideline: Laurence Codjia, Fahdi Dkhimi, Carolin Ekman, Veloshnee Govender, Lisa Hedman, Laurence Läser, Bruno Meessen, Ulrika Rehnström Loi, Marta Schaaf, Patricia Titulaer; and also colleagues from WHO regional offices: Chilanga Asmani, Ibadat Dhillon, Rodolfo Gómez Ponce de León and Nilmini Hemachandra. Review and comments were kindly provided by Ian Askew, Director of the SRH Department.

Special acknowledgement to the Office of the United Nations High Commissioner for Human Rights (OHCHR) for their review of the final draft of the guideline, in particular on the aspects relevant to international human rights standards and the integration of a human rights-based approach.

Special thanks to the **WHO Guidelines Review Committee (GRC)** and in particular to the WHO GRC Secretariat, Rebekah Thomas-Bosco, Marion Blacker and Maria Pura Solon, for their valuable feedback at every stage of the guideline development process.

Editing and proofreading was provided by Green Ink, United Kingdom.

Funding for the development of the guideline was provided by HRP, a cosponsored programme executed by the WHO.

Acronyms and abbreviations

AAAQ	availability, accessibility, acceptability and quality
AN	auxiliary nurse
ANM	auxiliary nurse midwife
CEDAW	Convention on the Elimination of All Forms of Discrimination against Women
CESCR	United Nations Committee on Economic, Social and Cultural Rights
CRC	United Nations Convention on the Rights of the Child
CRVS	civil registration and vital statistics
CSE	comprehensive sexuality education
D&C	dilatation and (sharp) curettage
D&E	dilatation and evacuation
EML	WHO Model List of Essential Medicines (or Essential Medicines List)
EmOC	emergency obstetric care
ERG	External Review Group
ERRG	Evidence and Recommendation Review Group
EST	Evidence Synthesis Team
EtD	Evidence to Decision
EVA	electric vacuum aspiration
GDG	Guideline Development Group
GRADE	Grading of Recommendations Assessment, Development and Evaluation
GRC	Guidelines Review Committee
HMIS	Health management information systems
IUD	intrauterine device
IUFD	intrauterine fetal demise
IV	intravenous
LMIS	logistics management information systems
LMP	last menstrual period
MVA	manual vacuum aspiration
NEML	national essential medicines list
NGO	nongovernmental organization
NMRA	national medicines regulatory authorities
NSAID	non-steroidal anti-inflammatory drug
OCP	oral contraceptive pill
PCB	paracervical block
PHC	primary health care
PICO	population, intervention, comparator, outcome(s)
Rh	Rhesus (blood group)
SDG	Sustainable Development Goal
SRH	sexual and reproductive health
STI	sexually transmitted infection
UHC	universal health coverage
UNDP	United Nations Development Programme
UNFPA	United Nations Population Fund
USA	United States of America
VAS	visual analogue scale
WHO	World Health Organization

Glossary

For the sake of mutual understanding and consistency, below follows a list of how key terms and concepts are used throughout the guideline:

- **Community-based care**: Services delivered by a broadly defined community health workforce, according to their training and capacity, encompassing a range of health workers, lay and professional, formal and informal, paid and unpaid, as well as facility-based personnel who support and supervise them and provide outreach services and campaigns *(1)*.
- **Comprehensive abortion care (CAC)**: Provision of information, abortion management (including induced abortion and care related to pregnancy loss), and post-abortion care.
- **Concluding observations**: Following submission of a State report and a constructive dialogue with the State party to the particular convention, treaty monitoring bodies issue concluding observations to the reporting State, which are compiled in an annual report and sent to the United Nations General Assembly *(2)*.
- **Conscious sedation**: The use of a combination of medicines – a sedative to relax and an anaesthetic to block pain – to induce a depressed level of consciousness during a medical procedure.
- **Conscientious objection or conscientious refusal**: The practice of health-care professionals refusing to provide abortion care on the basis of personal conscience or religious belief.
- **Decriminalization**: Removing abortion from all penal/criminal laws, not applying other criminal offences (e.g. murder, manslaughter) to abortion, and ensuring there are no criminal penalties for having, assisting with, providing information about, or providing abortion, for all relevant actors.
- **Dilatation and evacuation (D&E)**: D&E is used after 12–14 weeks of pregnancy. It is the safest and most effective surgical technique for later abortion, where skilled, experienced practitioners are available. D&E requires preparation of the cervix using osmotic dilators and/or pharmacological agents, and evacuating the uterus primarily with forceps, using vacuum aspiration (refer to entry in this list) to remove to remove any remaining blood or tissue.

- **Gestational age (duration of pregnancy)**: The number of days or weeks since the first day of the woman's last normal menstrual period (LMP) in women with regular cycles (see Table 1). For women with irregular cycles or when LMP is unknown, gestational age is the size of the uterus, estimated in weeks, based on clinical examination or ultrasound, that corresponds to a pregnant uterus of the same gestational age dated by LMP.

Table 1. Equivalent gestational ages in weeks and days during early pregnancy

Weeks of gestation	Days of gestation
0	0–6
1	7–13
2	14–20
3	21–27
4	28–34
5	35–41
6	42–48
7	49–55
8	56–62
9	63–69
10	70–76
11	77–83
12	84–90
13	91–97
14	98–104

Note: Day 0 is the first day of the last menstrual period (LMP), and is also the first day of Week 0 of gestation (*not* Week 1).

Source: Adapted from 2012 *Safe abortion* guidance *(2)* based on International Statistical Classification of Diseases and Related Health Problems, tenth revision (ICD-10), 2004 *(3)*.

- **General comments/recommendations**: A treaty monitoring body's interpretation of the content and operation of human rights conventions. General comments seek to clarify the reporting duties of States Parties with respect to certain provisions, and suggest approaches to implementing treaty provisions *(2)*.
- **Health**: A state of complete physical, mental and social well-being and not merely the absence of disease or infirmity *(4)*.
- **Health system:** A health system consists of all organizations, people and actions whose primary intent is to promote, restore or maintain health *(5)*.
- **Health workers**: All people engaged in actions whose primary intent is to enhance health. While, strictly speaking, this includes unpaid carers (e.g. parents caring for sick children, and self-carers), the data available on health worker numbers are generally limited to people engaged in paid activities *(6; Chapter 1: Health workers)*.
- **Human rights standards**: The meaning and scope of human rights as provided for in international human rights treaties and as interpreted and applied by the human rights bodies tasked with this work, which can include international, regional and national courts, and human rights committees *(2)*.
- **Incomplete abortion**: Clinical presence of an open cervical os and bleeding, whereby all products of conception have not been expelled from the uterus, or the expelled products are not consistent with the estimated duration of pregnancy. Common symptoms include vaginal bleeding and abdominal pain. Uncomplicated incomplete abortion can result after an induced or spontaneous abortion (i.e. miscarriage).
- **International human rights treaty** (also sometimes called a covenant or a convention): An international legal instrument adopted by the international community of States, normally at the United Nations General Assembly. Each treaty sets out a range of human rights and corresponding obligations which are legally binding on States that have ratified the treaty *(2)* (Annex 2 includes a list of relevant treaties).

- **Intrauterine fetal demise (IUFD; fetal death)**: The intrauterine death of a fetus at any point in time during the pregnancy *(7)*.
- **Mandatory waiting period**: A requirement imposed by law or policy, or in practice, to wait a specified amount of time between requesting and receiving abortion care.
- **Medical methods of abortion (medical abortion)**: Use of pharmacological agents to terminate a pregnancy *(2)*.
- **Mental health**: A state of well-being in which every individual realizes their own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to their community *(8)*.
- **Miscarriage (spontaneous abortion)**: Spontaneous loss of a pregnancy prior to 24 weeks' gestation, that is, before the fetus is usually viable outside the uterus. The clinical signs of miscarriage are vaginal bleeding, usually with abdominal pain and cramping. If the pregnancy has been expelled, the miscarriage is termed "complete" or "incomplete" depending on whether or not tissues are retained in the uterus *(9)*.
- **Missed abortion**: Arrest of pregnancy development where the embryo/fetus/embryonic tissue or empty gestational sac remains in the uterus and the cervical os is closed. Symptoms may include pain and/or bleeding, or there may be no symptoms at all *(10)*.
- **Osmotic dilators**: Short, thin rods made of seaweed (laminaria) or synthetic material. After placement in the cervical os, the dilators absorb moisture and expand, gradually dilating the cervix *(2)*.
- **Policy**: A law, regulation, procedure, administrative action, incentive or voluntary practice of governments and other institutions *(11)*.
- **Post-abortion care**: Provision of services after an abortion, such as contraceptive services and linkage to other needed services in the community or beyond. It can also include management of complications after an abortion.
- **Primary health care (PHC)**: A whole-of-society approach to health that aims at ensuring the highest possible level of health and well-being and their equitable distribution by focusing on people's needs and preferences as early as possible along the continuum from health promotion and disease prevention to treatment, rehabilitation and palliative care, and as close as feasible to people's everyday environment *(12)*.
- **Quality of care**: QOC encompasses six areas or dimensions of quality that are required in relation to health care:
    - *effective*, delivering health care that is adherent to an evidence base and results in improved health outcomes for individuals and communities, based on need;
    - *efficient*, delivering health care in a manner which optimizes resource use and avoids waste;
    - *accessible*, delivering health care that is timely, geographically reachable, and provided in a setting where skills and resources are appropriate to medical need;
    - *acceptable/person-centred*, delivering health care that takes into account the preferences and aspirations of individual service users and the cultures of their communities;
    - *equitable*, delivering health care that does not vary in quality because of personal characteristics such as gender, race, ethnicity, geographical location or socioeconomic status;
    - *safe*, delivering health care that minimizes risks and harm to service users *(13; p. 9)*.
- **Regulation of abortion**: All formalized laws, policies and other instruments (e.g. facility-level protocol) that regulate pregnancy and abortion.
- **Self-care**: The ability of individuals, families and communities to promote health, prevent disease, maintain health, and cope with illness and disability with or without the support of a health worker. The scope of self-care thus includes health promotion, disease prevention and control, self-medication, providing care to dependent people, seeking hospital/specialist/primary care if necessary, and rehabilitation, including palliative care. It includes a range of self-care practices and approaches *(14)*.

- **Self-management of abortion**: Self-management of the entire process of medical abortion or one or more of its component steps, such as self-assessment of eligibility for medical abortion, self-administration of medicines without the direct supervision of a health worker, and self-assessment of the success of the abortion process.
- **Social enterprise (social business)**: Defined as a business that has specific social objectives that serve its primary purpose. Social enterprises seek to maximize profits while maximizing benefits to society and the environment. Their profits are principally used to fund social programmes *(15)*.
- **Social franchising**: Defined as a system of contractual relationships usually run by a nongovernmental organization which uses the structure of a commercial franchise to achieve social goals. The overarching difference between social and commercial franchising is that social franchising seeks to fulfil a social benefit whereas commercial franchising is driven by profit *(16, 17)*.
- **Social marketing**: Broadly defined as the application of marketing techniques to social problems. Aims to persuade or motivate people to adopt specific courses of action or behaviour which are generally accepted as being beneficial. It is the design, implementation and control of programmes seeking to increase acceptability of a social idea or practice in a target group(s). It cannot create the behaviour, it can only help to gain acceptance and a willingness to adopt the behaviour. Its strategy is predominately preventive *(18)*.
- **Surgical methods of abortion (surgical abortion)**: Use of transcervical procedures for terminating pregnancy, including vacuum aspiration, and dilatation and evacuation (D&E). (See definitions in this list) *(2)*.
- **Telemedicine (or Telehealth)**: A mode of health service delivery where providers and clients, or providers and consultants, are separated by distance *(19)*. That interaction may take place in real time (synchronously), e.g. by telephone or video link. But it may also take place asynchronously (store-and-forward), when a query is submitted and an answer provided later, e.g. by email or text/voice/audio message.
    - **Client-to-provider telemedicine**: Provision of health services at a distance; delivery of health services where clients/patients and health workers are separated by distance (e.g. consultations between remote client/patient and health worker; clients/patients transmit medical data [images, notes, videos] to health worker) *(20)*.
- **Third-party authorization**: A requirement imposed by law or policy, or in practice, that a party other than the woman, girl or other pregnant person (typically a parent, guardian, spouse, partner, health worker, health authority or judicial authority) must authorize an abortion where other applicable legal requirements for lawful abortion have been met.
- **Treaty monitoring body**: Each of the international human rights treaties (see above) is monitored by a designated treaty monitoring body (see Annex 2). The treaty monitoring bodies are committees composed of independent experts. Their main function is to monitor the States' compliance with the treaty in question, including through the examination of State reports *(2)*.
- **Universal health coverage (UHC)**: Ensuring that all people have access to needed promotive, preventive, curative, rehabilitative, and palliative health services, of sufficient quality to be effective, while also ensuring that the use of these services does not expose any users to financial hardship *(12)*.
- **Vacuum aspiration (electrical or manual; EVA or MVA)**: Vacuum aspiration involves evacuation of the contents of the uterus through a plastic or metal cannula, attached to a vacuum source. Electric vacuum aspiration (EVA) employs an electric vacuum pump. With manual vacuum aspiration (MVA), the vacuum is created using a hand-held, hand-activated, plastic 60 ml aspirator (also called a syringe). MVA aspirators accommodate 4–12 mm cannulae. Suction tubing for EVA can be used with cannulae up to 16 mm in diameter, permitting VA to be used up to 15–16 weeks of pregnancy or for post-abortion care cases presenting with dilated cervix where a higher number of cannulae is required for effective vacuum.

Executive summary

Sexual and reproductive health is fundamental to individuals, couples and families, and to the social and economic development of communities and nations. As provided in the Constitution of the World Health Organization (WHO), the organization's objective is "the attainment by all peoples of the highest possible level of health", and to fulfil that objective, WHO's functions include providing technical assistance to countries in the field of health. Universal access to sexual and reproductive health (SRH) information and services is central to both individual and community health, as well as the realization of human rights. In the wake of the COVID-19 pandemic and based on lessons learnt from previous disease outbreaks – when SRH services have been severely disrupted, causing individuals to feel disempowered and be exposed to preventable health risks – WHO has included comprehensive abortion care in the list of essential health services in certain recent technical publications.[1]

Comprehensive abortion care includes the provision of information, abortion management (including induced abortion, and care related to pregnancy loss/spontaneous abortion and post-abortion care. Strengthening access to comprehensive abortion care within the health system is fundamental to meeting the Sustainable Development Goals (SDGs) relating to good health and well-being (SDG3) and gender equality (SDG5). WHO's Global Reproductive Health Strategy, which seeks to accelerate progress towards achievement of international development goals, identifies elimination of unsafe abortion[2] as a priority mandate. The importance of quality abortion care to health is similarly underscored by the United Nations Global Strategy for Women's, Children's and Adolescents' Health, which includes evidence-based interventions for abortion and post-abortion care as one effective way to help individuals thrive and communities transform.

Quality of abortion care is foundational to this abortion care guideline. Quality of care (see Glossary) encompasses multiple components. It is defined as care that is: effective, efficient, accessible, acceptable/patient centred, equitable and safe. Effective care includes the delivery of evidence-based care that improves the health of individuals and communities, and is responsive to their needs. Efficient care optimizes resource use and minimizes waste. Quality abortion care must also be both accessible (timely, affordable, geographically reachable, and provided in a setting where skills and resources are appropriate to medical need) and acceptable (incorporating the preferences and values of individual service users and the cultures of their communities). It is imperative that access to abortion care is equitable, and that the quality of care does not vary based on the personal characteristics of the person seeking care, such as their gender, race, religion, ethnicity, socioeconomic status, education, if they are living with a disability, or based on their geographic location within a country. And finally, quality abortion care implies that it is safely delivered and minimizes any risks and harms to service users.

1 When considering the concept of "essential health services", it is important to note that different areas, even within the same country, may require different approaches to designate essential health services and to reorient health system components to maintain these services. Please refer to: *Maintaining essential health services: operational guidance for the COVID-19 context, interim guidance, 1 June 2020* (https://www.who.int/publications/i/item/WHO-2019-nCoV-essential-health-services-2020.1). For additional relevant references, see Chapter 1, section 1.1.

2 "Unsafe abortion" refers to abortion when it is carried out by a person lacking the necessary skills or in an environment that does not conform to minimal medical standards, or both.

Abortion is a safe and non-complex health-care intervention that can be effectively managed using medication or a surgical procedure in a variety of settings. Complications are rare with both medical and surgical abortion, when abortions are safe – meaning that they are carried out using a method recommended by WHO, appropriate to the gestational age, and by someone with the necessary skills. Globally, abortion is a common procedure, with 6 out of 10 unintended pregnancies and 3 out of 10 of all pregnancies ending in induced abortion. However, global estimates demonstrate that 45% of all abortions are unsafe. This is a critical public health and human rights issue; unsafe abortion is increasingly concentrated in developing countries (97% of unsafe abortions) and among groups in vulnerable and marginalized situations. Legal restrictions and other barriers mean many women find it difficult or impossible to access quality abortion care and they may induce abortion themselves using unsafe methods or seek abortion from unskilled providers. The legal status of abortion makes no difference to a woman's need for an abortion, but it dramatically affects her access to safe abortion. Between 4.7% and 13.2% of all maternal deaths are attributed to unsafe abortions, which equates to between 13 865 and 38 940 deaths caused annually by the failure to provide safe abortion.

Medical abortion has revolutionized access to quality abortion care globally. Medicines for abortion can be safely and effectively administered at a health-care facility or self-administered outside of a facility (e.g. at home) by individuals with a source of accurate information and quality-assured medicines. Those managing their abortions safely at home in the first 12 weeks of gestation may still need or want support from a trained health worker at some stage of the process. Service delivery with minimal medical supervision can significantly improve access to – and privacy, convenience and acceptability of – the abortion process, without compromising safety or effectiveness.

Multiple actions are needed at the legal, health system and community levels so that everyone who needs it has access to comprehensive abortion care. A person's environment plays a crucial role in shaping their access to care and influencing their health outcomes. An enabling environment is the foundation of quality comprehensive abortion care. The three cornerstones of an enabling environment for abortion care are:

1. respect for human rights including a supportive framework of law and policy
2. availability and accessibility of information, and
3. a supportive, universally accessible, affordable and well functioning health system.

Abortion is lawful in almost all countries, although there is variation in the specific circumstances under which an individual may access abortion. In addition, almost all countries where abortion is lawfully available regulate abortion differently to other forms of health care. Unlike other health services, abortion is commonly regulated to varying degrees through the criminal law in addition to regulation under health-care law. This has an impact on the rights of pregnant individuals, and can have a chilling effect (e.g. suppression of actions due to fear of reprisals or penalties) on the provision of quality care. This is why clear, accessible and rights-based law and policy is part of ensuring an enabling environment.

Objectives, scope and conceptual structure of the guideline

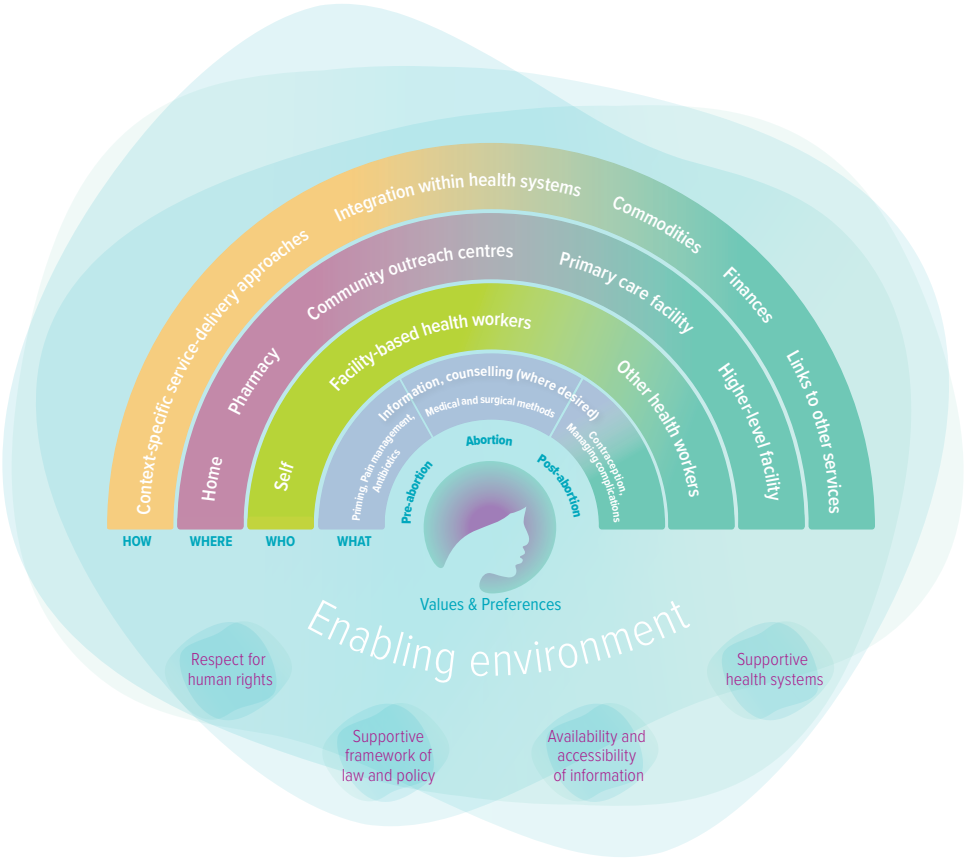
Guidelines are the fundamental means through which WHO fulfils its technical leadership in health. WHO guidelines are subject to a rigorous quality assurance process that generates recommendations for clinical practice or public health policy with the aim of achieving the best possible individual or collective health outcomes. Towards this aim, WHO has made a commitment to integrate human rights into health-care programmes and policies at national and regional levels by looking at underlying determinants of health as part of a comprehensive approach to health and human rights.

The objective of this guideline is to present the complete set of all WHO recommendations and best practice statements relating to abortion. While legal, regulatory, policy and service-delivery contexts may vary from country to country, the recommendations and best practices described in this document aim to enable evidence-based decision-making with respect to quality abortion care.

This guideline updates and replaces the recommendations in the following previous WHO guidelines:

- *Safe abortion: technical and policy guidance for health systems, second edition* (2012)
- *Health worker roles in providing safe abortion care and post-abortion contraception* (previously known as the "task sharing" guidance) (2015), and
- *Medical management of abortion* (2018).

This guidance contains new recommendations consolidated here in an integrated manner with existing recommendations that remain unchanged and those that have been updated after re-assessment using the same rigorous methods for both new and updated recommendations (see more information in the "Guideline development methods" section below).



In this guideline, recommendations are presented across three domains that are essential to the provision of abortion care: Law and policy, Clinical services and Service delivery. The recommendations concerning the laws and policies that should or should not be in place in order to fully implement and sustain quality abortion care cover seven areas: criminalization of abortion, grounds-based approaches to permitting abortion, gestational age limits set for abortion, mandatory waiting periods before receiving a requested abortion, third-party authorization for abortion, restrictions on which health workers can provide abortion services, and conscientious objection/refusal by providers.[3] Clinical service recommendations address methods of abortion and related clinical care – from provision of information, counselling and pain management to methods and regimens for abortion (including for different clinical indications) – and provision of post-abortion care, including all methods of contraception.[4] Service delivery recommendations include those relating to which categories of health workers can provide the relevant clinical services. Self-management recommendations are also presented relating to tasks that can be managed by the woman herself: medical abortion in early gestation and use of many contraceptives, including self-administration of injectable contraceptives. A recommendation relating to telemedicine to facilitate early medical abortion has also been formulated, alongside best practice statements on other service-delivery approaches for abortion care. Together, the guidance presented in this document reflects recent changes in all these aspects of abortion care. Research gaps and priorities and emerging areas of interest are identified in the final chapter.

As indicated by the arrangement of the guidance in this document, as a woman, girl or other pregnant person moves through the abortion care pathway – pre-abortion, abortion and post-abortion care – health services must be integrated within the health system to ensure that service delivery meets their needs equitably and without discrimination. The conceptual framework for abortion care in this guideline (see Figure 1) recognizes and acknowledges the needs of all individuals with respect to abortion and is centred on the values and preferences of abortion seekers, considering them as active participants in – as well as beneficiaries of – health services. Individual health preferences may vary; no one model of abortion care will meet the needs of everyone seeking abortion care. However, the core values of dignity, autonomy, equality, confidentiality, communication, social support, supportive care and trust are foundational to abortion care and are reflected throughout this guidance. Important work is still needed to incorporate linkages to quality abortion care throughout the health system, and the focus on human rights and gender equality must be applied in all contexts providing services to people seeking health care.

3 The previous edition of the *Safe abortion* guidance (WHO, 2012) addressed these issues and related interventions and provided a composite recommendation. In this guideline, these have each been addressed separately as seven individual recommendations (Recommendations 1,2,3,6,7,21,22).

4 A full consideration of all contraceptive methods is beyond the scope of this guideline, but all contraceptive methods can be considered after an abortion, including a range of self-administered methods.

Figure 1: Conceptual framework for abortion care

Target audience and inclusivity

This guidance seeks to provide recommendations for national and subnational policy-makers, implementers and managers of sexual and reproductive health (SRH) programmes, members of nongovernmental organizations and other civil society organizations and professional societies, as well as health workers and other stakeholders in the field of sexual and reproductive health and rights (SRHR), to support them in ensuring that evidence-based, quality abortion care is available and accessible globally.

All individuals have the right to non-discrimination and equality in accessing SRH services. The right to be free from discrimination is stated in the Universal Declaration of Human Rights and in other universal human rights treaties and regional human rights instruments. It has been affirmed that the right to non-discrimination guaranteed by the International Covenant on Economic, Social and Cultural Rights (ICESCR) includes sexual orientation, gender identity and sex characteristics. As stated in the 2018 report of the Independent Expert on protection against violence and discrimination based on sexual orientation and gender identity to the United Nations General Assembly, "the right to effective recognition of one's gender identity is linked to the right to equal recognition before the law".

In this guideline, we recognize that most of the available evidence on abortion can be assumed to be derived from research among study populations of cisgender women, and we also recognize that cisgender women, transgender men, nonbinary, gender-fluid and intersex individuals with a female reproductive system and capable of becoming pregnant may require abortion care. To be concise and facilitate readability of this guideline, when referring to all gender diverse people who may require abortion care, we use the word "women" most often, although we also variously use the terms "individual", "person" and "abortion seeker". Providers of SRH services, including abortion care, must consider the needs of – and provide equal care to – all individuals; gender identity or its expression must not lead to discrimination.

Guideline development methods

The WHO Guideline Steering Group and wider WHO Secretariat, including staff members from both WHO headquarters and regional offices, led a wide-ranging guideline development process involving a vast range of expert contributors and support personnel. The process began in September 2018 with an online survey on the subject of updating WHO guidance on safe abortion, followed by scoping meetings between November 2018 and June 2019 to determine the key topic areas and to formulate key questions to be assessed through searches and analysis of the evidence base, for each of the three domains: Law and policy, Clinical services and Service delivery. In order to ensure broad representation, the following meetings were convened to further inform our guideline: (i) Implementation considerations for abortion care in humanitarian settings, (ii) Global values and preferences relating to abortion care, and (iii) Youth and safe abortion.

Global experts were invited by the Steering Group to convene three expert panels – the Evidence and Recommendation Review Groups (ERRGs) for each domain – involving active participation in a series of two-day meetings to discuss and draft the new and updated recommendations, based on the evidence provided by the Evidence Synthesis Teams (ESTs). The Guideline Development Group (GDG) members were selected and invited by the Steering Group from among the ERRG members for each domain, to bring together a single multidisciplinary group, including a youth representative and a human rights adviser, to finalize the recommendations.

In accordance with the WHO guideline development process, the formulation and refinement of recommendations by the ERRGs and the GDG was based on the available evidence (with quality of evidence ranging from high to very low), using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach to recommendation development, with reference to the Evidence-to-Decision (EtD) tables prepared by the ESTs, and also guided by the participants' own expertise and experience. The WHO-INTEGRATE framework was used as a basis for deciding on the direction and strength of each recommendation (see notes accompanying the summary table below). For the law and policy recommendations, this same framework was used but an innovative approach was developed to evaluate the evidence in a manner that effectively integrated human rights protection and enjoyment as part of health outcomes and analysis.

After the conclusion of the ERRG and GDG meetings, the revised draft recommendations and full draft guideline were reviewed by GDG members and members of the External Review Group of peer reviewers. The GDG meeting observers and individual reviewers from several implementing organizations were also invited to comment on the same draft. Further revisions were made and the guideline was submitted to and approved by the WHO Guidelines Review Committee, followed by final revisions from the Office of the United Nations High Commissioner for Human Rights (OHCHR), final editing and planning for publication and launch. The full guideline development methods are presented in Annex 4.

Summary table of recommendations presented in this guideline

Important notes:

i. Each recommendation and its direction (for or against) and strength (strong or weak) has been determined by the panels of experts convened by WHO for this purpose. The determinations were based on the six substantive criteria of the WHO-INTEGRATE framework as applied to each intervention for the specified population – balance of health benefits and harms; human rights and sociocultural acceptability; health equity, equality and non-discrimination; societal implications; financial and economic considerations; and feasibility and health system considerations – while also taking into account the meta-criterion, quality of evidence (i.e. type, size and limitations of the available studies used as evidence). Wording used is as follows:

- **Recommend** – a strong recommendation in favour of the intervention
- **Suggest** – a weak recommendation in favour of the intervention
- **Recommend against** – a strong recommendation against the intervention/in favour of the comparison.

ii. Most of the recommendations are labelled as LP for "Law and policy", CS for "Clinical services" or SD for "Service delivery", referring to the broad domain under which the evidence for these recommendations was reviewed and evaluated by the respective expert panels (ERRGs). In addition, five recommendations are labelled as SELF-MANAGEMENT.

iii. The SD recommendations that refer to health worker categories assume that the people working within the categories mentioned have the skills and competencies required for the intervention specified. The roles, skills and competencies of each type of health worker mentioned in these recommendations are described in the table on health worker categories and roles in Annex 5, and further information can be found in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care*, which describes the competencies (including skills and knowledge) required for each task.

iv. Recommendations were considered "new" (as labelled in this table and in Chapter 3) if no recommendation existed in a previous WHO guideline on the specific topic or intervention in question. In particular it should be noted that the 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy; in this guideline, this has been developed this into seven separate recommendations, but they are not considered to be "new" (i.e. Recommendations 1,2,3,6,7,21,22).

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
ABORTION REGULATION		
Criminalization		
1 (LAW & POLICY; LP)	**Recommend** the full decriminalization of abortion. **Remarks:** • Decriminalization means removing abortion from all penal/criminal laws, not applying other criminal offences (e.g. murder, manslaughter) to abortion, and ensuring there are no criminal penalties for having, assisting with, providing information about, or providing abortion, for all relevant actors. • Decriminalization would ensure that anyone who has experienced pregnancy loss does not come under suspicion of illegal abortion when they seek care. • Decriminalization of abortion does not make women, girls or other pregnant persons vulnerable to forced or coerced abortion. Forced or coerced abortion would constitute serious assaults as these would be non-consensual interventions.	24
Grounds-based approaches		
2 (LP)	**a. Recommend against** laws and other regulations that restrict abortion by grounds. **b. Recommend** that abortion be available on the request of the woman, girl or other pregnant person. **Remarks:** • Grounds-based approaches to restricting access to abortion should be revised in favour of making abortion available on the request of the woman, girl or other pregnant person. • Until they are replaced with abortion on request, any existing grounds should be formulated and applied in a manner consistent with international human rights law. This means that the content, interpretation and application of grounds-based law and policy should be revised to ensure human rights compliance. This requires that: i. existing grounds are defined, interpreted and applied in a human rights-compliant way; ii. abortion is available when carrying a pregnancy to term would cause the woman, girl or other pregnant person substantial pain or suffering, including but not limited to situations where the pregnancy is the result of rape or incest or the pregnancy is not viable; iii. abortion is available where the life and health of the woman, girl or other pregnant person is at risk; iv. health grounds reflect WHO's definitions of health and mental health (see Glossary); and v. there are no procedural requirements to "prove" or "establish" satisfaction of grounds, such as requiring judicial orders or police reports in cases of rape or sexual assault (for sources to support this information, refer to Web annex A: Key international human rights standards on abortion).	26
Gestational age limits		
3 (LP)	**Recommend against** laws and other regulations that prohibit abortion based on gestational age limits.	28
SERVICES ACROSS THE CONTINUUM OF CARE		
Provision of information on abortion care		
4 (SERVICE DELIVERY; SD)	Across the continuum of abortion care: **a. Recommend** provision of information on abortion care by community health workers, pharmacists, traditional and complementary medicine professionals, auxiliary nurses/auxiliary nurse midwives (ANMs), nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** provision of information on abortion care by pharmacy workers. • Condition: In contexts where the pharmacy worker is under the direct supervision of a pharmacist and there is access or referral to appropriate health services.	35
Provision of counselling		
5 (SD)	Across the continuum of abortion care: **a. Recommend** provision of counselling by community health workers, traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** provision of counselling by pharmacy workers and pharmacists. • Condition: Balanced counselling is provided (i.e. about both medical and surgical methods) and there is access or referral to appropriate health services should the woman choose a surgical method.	38

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
PRE-ABORTION		
Mandatory waiting periods		
6 (LP)	**Recommend against** mandatory waiting periods for abortion.	41
Third-party authorization		
7 (LP)	**Recommend** that abortion be available on the request of the woman, girl or other pregnant person without the authorization of any other individual, body or institution. **Remark:** • While parental or partner involvement in abortion decision-making can support and assist women, girls or other pregnant persons, this must be based on the values and preferences of the person availing of abortion and not imposed by third-party authorization requirements.	43
Rh isoimmunization for abortion at gestational ages < 12 weeks		
8 (CLINICAL SERVICES; CS) (NEW)	For both medical and surgical abortion at < 12 weeks: **Recommend against** anti-D immunoglobulin administration. **Remark:** • Standard of care applies for anti-D administration at gestational ages ≥ 12 weeks.	44
Antibiotic prophylaxis for surgical and medical abortion		
9 (CS)	**a.** For surgical abortion, regardless of the individual's risk of pelvic inflammatory infection: **Recommend** appropriate prophylactic antibiotics pre- or perioperatively. **b.** For medical abortion: **Recommend against** the use of prophylactic antibiotics. **Remark:** • Lack of antibiotics should not limit access to abortion services.	46
Determining gestational age of pregnancy: pre-abortion ultrasound scanning		
10 (CS)	For both medical and surgical abortion: **Recommend against** the use of ultrasound scanning as a prerequisite for providing abortion services.* **Remark:** • Legal regulation that limits the availability of abortion by gestational age may require or result in ultrasounds being used to verify gestational age prior to abortion, even though this is not necessary from a clinical perspective. Removing legal gestational age limits on access to abortion (see Recommendation 3) should result in unnecessary pre-abortion ultrasound being avoided, and increase the availability of abortion in settings where ultrasound is difficult to access. * On a case-by-case basis, there may be clinical reasons for using ultrasound scanning prior to abortion.	47`

SECTION **Topic area** Recommendation or best practice statement number and type	**Recommendation or best practice statement**	**Page number**
Pain management for abortion		
11–14 (CS) for surgical abortion and for prior cervical priming *NOTE: NEW recommendations 12, 13 and 14 indicate pain management that is ADDITIONAL to NSAIDS (11a)*	11. For pain management for surgical abortion at any gestational age: **a. Recommend** that pain medication should be offered routinely (e.g. non-steroidal anti-inflammatory drugs [NSAIDS]) and that it should be provided to those who want it; and **b. Recommend against** the routine use of general anaesthesia. 12. (NEW) For pain management for surgical abortion at < 14 weeks: **a. Recommend** the use of a paracervical block; and **b. Suggest** that the option of combination pain management using conscious sedation plus paracervical block should be offered, where conscious sedation is available. 13. (NEW) For pain management for cervical priming with osmotic dilators prior to surgical abortion at ≥ 14 weeks: **Suggest** the use of a paracervical block. **Remark:** • For cervical priming, additional pain medication can be considered, such as the use of intravaginal gel. (See Recommendations 17–20 below on cervical priming) 14. (NEW) For pain management for surgical abortion at ≥ 14 weeks: **a. Recommend** the use of a paracervical block; and **b. Suggest** that the option of combination pain management using conscious sedation plus paracervical block should be offered, where conscious sedation is available.	49
15 and 16 (CS) for medical abortion *NOTE: NEW recommendation 16 indicates pain management that is ADDITIONAL to NSAIDS (15)*	15. For medical abortion at any gestational age: **Recommend** that pain medication should be offered routinely (e.g. non-steroidal anti-inflammatory drugs [NSAIDs]) and that it should be provided for the individual to use if and when wanted. 16. (NEW) For pain management for medical abortion at ≥ 12 weeks: **Suggest** consideration of additional methods to control pain or discomfort due to increased pain with increasing gestational age. Such methods include certain anti-emetics and epidural anaesthesia, where available. **Remark:** • For medical abortion at gestational ages < 14 weeks, if NSAIDS (e.g. ibuprofen) are not available or not an option, then acetaminophen can be considered for pain control.	51
Cervical priming prior to surgical abortion		
17 (CS) at < 12 weeks	Prior to surgical abortion at < 12 weeks: **a.** If cervical priming is used: **Suggest** the following medication regimens: • Mifepristone 200 mg orally 24–48 hours prior to the procedure • Misoprostol 400 µg sublingually 1–2 hours prior to the procedure • Misoprostol 400 µg vaginally or buccally 2–3 hours prior to the procedure **b. Recommend against** the use of osmotic dilators for cervical priming. **Remarks:** • The sublingual route is more effective for misoprostol administration. • Appropriate pain medication should be provided.	54

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
18 (CS) (NEW) at ≥ 12 weeks	Prior to surgical abortion at later gestational ages: **a.** For surgical abortion at ≥ 12 weeks: **Suggest** cervical priming prior to the procedure. **b.** For surgical abortion between 12 and 19 weeks: **Suggest** cervical priming with medication alone (a combination of mifepristone plus misoprostol is preferred) or with an osmotic dilator plus medication (mifepristone, misoprostol, or a combination of both). **c.** For surgical abortion between 12 and 19 weeks, when using an osmotic dilator for cervical priming: **Suggest** that the period between osmotic dilator placement and the procedure should not extend beyond two days. **d.** For surgical abortion at ≥ 19 weeks: **Recommend** cervical priming with an osmotic dilator plus medication (mifepristone, misoprostol, or a combination of both). **Remark:** • There was limited evidence for cervical priming for gestational ages between 12 and 14 weeks and therefore health workers should use clinical judgement to decide on the most convenient method for cervical priming prior to vacuum aspiration for this gestational age range.	55
19 (SD) with medication, at any gestational age	Prior to surgical abortion at any gestational age: **a. Recommend** cervical priming with medication by traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** cervical priming with medication by community health workers, pharmacy workers and pharmacists. • Condition: Provision of medication for the purpose of cervical priming is part of the surgical abortion process so the health worker needs to ensure continuity of care of the woman obtaining the medicines prior to the abortion procedure.	56
20 (SD) with osmotic dilators, at ≥ 12 weeks	Prior to dilatation and evacuation (D&E) at ≥ 12 weeks: **a. Recommend** cervical priming with osmotic dilators by auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** cervical priming with osmotic dilators by traditional and complementary medicine professionals. • Condition: Health worker ensures continuity of care from the time of cervical priming to the D&E.	57
Provider restrictions		
21 (LP)	**Recommend against** regulation on who can provide and manage abortion that is inconsistent with WHO guidance. **Remark:** • Where law or policy regulate who may provide or manage abortion, that regulation should be consistent with WHO guidance, which is presented throughout Chapter 3 of this guideline.	59
Conscientious objection		
22 (LP)	**Recommend** that access to and continuity of comprehensive abortion care be protected against barriers created by conscientious objection. **Remarks:** • In spite of the human rights obligation to ensure conscientious objection does not hinder access to quality abortion care, and previous WHO recommendations aimed at ensuring conscientious objection does not undermine or hinder access to abortion care, conscientious objection continues to operate as a barrier to access to quality abortion care. It is critical that States ensure compliance with regulations and design/organize health systems to ensure access to and continuity of quality abortion care. If it proves impossible to regulate conscientious objection in a way that respects, protects and fulfils abortion seekers' rights, conscientious objection in abortion provision may become indefensible. • The evidence reviewed considered the impact of conscientious objection on access to and availability of abortion care and not the effectiveness of regulating conscientious objection in terms of improvements in those outcomes. However, international human rights law provides some guidance as to how States can ensure that human rights of abortion seekers are respected, protected and fulfilled (see details in main text).	60

SECTION **Topic area** Recommendation or best practice statement number and type	**Recommendation or best practice statement**	**Page number**
ABORTION		
Methods of surgical abortion		
23 (CS) at < 14 weeks	For surgical abortion at < 14 weeks: **a. Recommend** vacuum aspiration. **b. Recommend against** the practice of dilatation and sharp curettage (D&C), including sharp curette checks (i.e. to "complete" the abortion) following vacuum aspiration. **Remarks:** • Observational studies indicate that vacuum aspiration is associated with fewer complications than D&C; however, randomized controlled trials were underpowered to detect a difference in complication rates. • No evidence supports the use of sharp curette checks following vacuum aspiration. • The quality of the evidence based on randomized controlled trials is low to moderate.	63
24 (SD) vacuum aspiration at < 14 weeks	For surgical abortion at < 14 weeks: **a. Recommend** vacuum aspiration by traditional and complementary medicine professionals, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** vacuum aspiration by auxiliary nurses/ANMs. • Condition: In contexts where established health system mechanisms involve auxiliary nurses/ANMs in providing basic emergency obstetric care, and where referral and monitoring systems are strong.	64
25 (CS) at ≥ 14 weeks	For surgical abortion at ≥ 14 weeks: **Recommend** dilatation and evacuation (D&E). **Remark:** • Vacuum aspiration can be used during a D&E (i.e. for the purpose of amniotomy or tissue removal at the end of the D&E).	65
26 (SD) D&E at ≥ 14 weeks	For surgical abortion at ≥ 14 weeks: **a. Recommend** D&E by generalist medical practitioners and specialist medical practitioners. **b. Suggest** D&E by traditional and complementary medicine professionals, midwives and associate/advanced associate clinicians. • Condition: In settings where established health system mechanisms exist to include these health workers in other tasks related to maternal and reproductive health.	65
Medical management of induced abortion		
27 (CS) at < 12 weeks	For medical abortion at < 12 weeks: **a. Recommend** the use of 200 mg mifepristone administered orally, followed 1–2 days later by 800 µg misoprostol administered vaginally, sublingually or buccally. The minimum recommended interval between use of mifepristone and misoprostol is 24 hours.* **b.** When using misoprostol alone: **Recommend** the use of 800 µg misoprostol administered vaginally, sublingually or buccally.* **c.** (NEW) **Suggest** the use of a combination regimen of letrozole plus misoprostol (letrozole 10 mg orally each day for 3 days followed by misoprostol 800 µg sublingually on the fourth day) as a safe and effective option.*‡ **Remarks:** • Evidence from clinical studies demonstrates that the combination regimen (Recommendation 27a) is more effective than misoprostol alone. • All routes are included as options for misoprostol administration, in consideration of patient and provider preference. • The suggested combination regimen of letrozole plus misoprostol may be safe and effective up to 14 weeks of gestation. * Repeat doses of misoprostol can be considered when needed to achieve success of the abortion process. In this guideline we do not provide a maximum number of doses of misoprostol. ‡ Further evidence is needed to determine the safety, effectiveness and acceptability of the letrozole plus misoprostol combination regimen at later gestational ages, especially in comparison with that of the mifepristone plus misoprostol combination regimen (the available evidence focused on comparison with the use of misoprostol alone).	68

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
28 (SD) at < 12 weeks* in whole or in part (i.e. performing all or some of the subtasks)‡	For medical abortion at < 12 weeks: **Recommend** medical management by self (see Recommendation 50), community health workers, pharmacy workers, pharmacists, traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. * Available evidence for the independent provision of medical abortion by non-physicians is for pregnancy durations up to 10 weeks (70 days). ‡ For this recommendation, the medical abortion regimens covered in the available evidence were mifepristone plus misoprostol, or misoprostol alone (the regimen using letrozole was not included).	69
29 (CS) at ≥ 12 weeks	For medical abortion at ≥ 12 weeks: **a. Suggest** the use of 200 mg mifepristone administered orally, followed 1–2 days later by repeat doses of 400 µg misoprostol administered vaginally, sublingually or buccally every 3 hours.*‡ The minimum recommended interval between use of mifepristone and misoprostol is 24 hours. **b.** When using misoprostol alone: **Suggest** the use of repeat doses of 400 µg misoprostol administered vaginally, sublingually or buccally every 3 hours.*‡ **Remarks:** • The combination regimen (Recommendation 29a) is more effective than use of misoprostol alone. • Evidence suggests that the vaginal route is the most effective. Consideration for patient and provider preference suggests the inclusion of all routes. • Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise. * Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. Providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with later gestational age. ‡ The dose of misoprostol should be reduced for induced abortion beyond 24 weeks due to limited data. Clinical judgement should be used to determine the appropriate dosage, recognizing the greater sensitivity of the uterus to prostaglandins.	71
30 (SD) at ≥ 12 weeks	For medical abortion at ≥ 12 weeks: **a. Recommend** medical management by generalist medical practitioners and specialist medical practitioners. **b. Suggest** medical management by traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives and associate/advanced associate clinicians. • Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	71
Missed abortion		
31 (CS) (NEW) Medical management at < 14 weeks	For missed abortion at < 14 weeks, for individuals preferring medical management: **Recommend** the use of combination mifepristone plus misoprostol over misoprostol alone. • Recommended regimen: 200 mg mifepristone administered orally, followed by 800 µg misoprostol administered by any route (buccal, vaginal or sublingual).* • Alternative regimen: 800 µg misoprostol administered by any route (buccal, vaginal or sublingual).‡ **Remarks:** • The decision about the mode of management (expectant, medical or surgical) of missed abortion should be based on the individual's clinical condition and preference for treatment. • Expectant management can be offered as an option on the condition that the woman, girl or other pregnant person is informed of the longer time for expulsion of the pregnancy tissue and the increased risk of incomplete emptying of the uterus. • Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise. * The minimum recommended interval between use of mifepristone and misoprostol is 24 hours. ‡ If using the alternative regimen (misoprostol alone), it should be noted that at gestational ages ≥ 9 weeks, evidence shows that repeat dosing of misoprostol is more efficacious to achieve success of the abortion process. In this guideline we do not provide a maximum number of doses of misoprostol.	74

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
Intrauterine fetal demise		
32 (CS) Medical management at ≥ 14 to ≤ 28 weeks	For medical management of IUFD at ≥ 14 to ≤ 28 weeks: **Suggest** the use of combination mifepristone plus misoprostol over misoprostol alone. • Suggested regimen: 200 mg mifepristone administered orally, followed 1–2 days later by repeat doses of 400 µg misoprostol administered sublingually or vaginally every 4–6 hours.*‡ The minimum recommended interval between use of mifepristone and misoprostol is 24 hours. • Alternative regimen: repeat doses of 400 µg misoprostol administered sublingually or vaginally every 4–6 hours.*‡ **Remarks:** • Evidence from clinical studies indicates that the combination regimen is more effective than the use of misoprostol alone. • Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise. * Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. Providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with later gestational age. ‡ The dose of misoprostol should be reduced for IUFD beyond 28 weeks due to limited data. Clinical judgement should be used to determine the appropriate dosage, recognizing the greater sensitivity of the uterus to prostaglandins.	76
33 (SD) (NEW) Medical management at ≥ 14 to ≤ 28 weeks	For IUFD at ≥ 14 to ≤ 28 weeks: **a. Recommend** medical management by generalist medical practitioners and specialist medical practitioners. **b. Suggest** medical management by traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives and associate/advanced associate clinicians. • Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	76
POST-ABORTION		
Follow-up care or additional services		
34 (CS)	Following uncomplicated surgical abortion or medical abortion: **Recommend** that there is no medical need for a routine follow-up visit. However, information should be provided about the availability of additional services if they are needed or desired. **Remarks:** • Women, girls and other pregnant persons must be adequately informed about symptoms of ongoing pregnancy (which may or may not indicate failure of the abortion) and other medical reasons to return for follow-up, such as prolonged heavy bleeding, no bleeding at all with medical management of abortion, pain not relieved by medication, or fever. • The quality of the evidence was low (observational studies and indirect evidence).	80
Incomplete abortion		
35 and 36 (CS)	**35.** For incomplete abortion at < 14 weeks: **Recommend** either vacuum aspiration or medical management. **36a.** For the medical management of incomplete abortion at < 14 weeks uterine size: **Suggest** the use of 600 µg misoprostol administered orally or 400 µg misoprostol administered sublingually. **36b.** For the medical management of incomplete abortion at ≥ 14 weeks uterine size: **Suggest** the use of repeat doses of 400 µg misoprostol administered sublingually, vaginally or buccally every 3 hours.* **Remarks:** • The decision about the mode of management of incomplete abortion should be based on the individual's clinical condition and preference for treatment. • Expectant management of incomplete abortion can be as effective as misoprostol; it can be offered as an option on the condition that the woman, girl or other pregnant person is informed of the longer time for expulsion of the pregnancy tissue and the increased risk of incomplete emptying of the uterus. • Recommendation 35 was extrapolated from research conducted in women with reported spontaneous abortion. * Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. At gestational ages ≥ 14 weeks, providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with advanced gestational age.	81

SECTION Topic area Recommendation or best practice statement number and type	Recommendation or best practice statement	Page number
37 (SD) Medical management with misoprostol at < 14 weeks	For uncomplicated incomplete abortion at < 14 weeks: **Recommend** medical management with misoprostol by community health workers, pharmacy workers, pharmacists, traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners.	82
38 (SD) Vacuum aspiration at < 14 weeks	For uncomplicated incomplete abortion at < 14 weeks: **a. Recommend** vacuum aspiration by traditional and complementary medicine professionals, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** vacuum aspiration by auxiliary nurses/ANMs. • Condition: In contexts where established health system mechanisms involve auxiliary nurses/ANMs in providing basic emergency obstetric care, and where referral and monitoring systems are strong.	83
Management of non-life-threatening complications		
39 (SD) Infection	For non-life-threatening post-abortion infection: **Recommend** initial management by traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners.* * For the pharmacists, pharmacy workers and community health workers, it is important that they are equipped with the knowledge to recognize signs and symptoms of this complication.	85
40 (SD) Haemorrhage	For non-life-threatening post-abortion haemorrhage: **Recommend** initial management by traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners.* * For the pharmacists, pharmacy workers and community health workers, it is important that they are equipped with the knowledge to recognize signs and symptoms of this complication.	86
Timing of post-abortion contraception		
41 (CS) Medical eligibility criteria (MEC) for contraceptive use	The following contraceptive methods may be started immediately (MEC Category 1 – no restrictions) after a surgical or medical abortion (first and second trimester, and also after a septic abortion): combined hormonal contraceptives (CHCs), progesterone-only contraceptives (POCs) and barrier methods (condoms, spermicide, diaphragm, cap – note: The diaphragm and cap are unsuitable until 6 weeks after second-trimester abortion). Intrauterine devices (IUDs) may be started immediately after a first-trimester surgical or medical abortion (MEC Category 1 – no restrictions) or after second-trimester abortion (MEC Category 2 – the advantages generally outweigh the risks), but should not be started immediately after septic abortion (MEC Category 4 – insertion of an IUD may substantially worsen the condition). Fertility-awareness-based (FAB) methods: Symptom-based methods should only be started after abortion with "caution" (special counselling may be needed to ensure correct use of the method in this circumstance) and the use of calendar-based methods should be delayed (until the condition is evaluated; alternative temporary methods of contraception should be offered).	88
42 (CS) Contraception and surgical abortion	For individuals undergoing surgical abortion and wishing to use contraception: **Recommend** the option of initiating the contraception at the time of surgical abortion. **Remark:** • The quality of evidence based on randomized controlled trials was very low.	89

SECTION **Topic area** Recommendation or best practice statement number and type	**Recommendation or best practice statement**	**Page number**
43 (CS) Contraception and medical abortion	For individuals undergoing medical abortion with the combination mifepristone and misoprostol regimen or with misoprostol alone: **a.** For those who choose to use **hormonal contraception** (pills, patch, ring, implant or injections): **Suggest** that they be given the option of starting hormonal contraception immediately after the first pill of the medical abortion regimen. **b.** For those who choose to have an **IUD** inserted: **Suggest** IUD placement at the time that success of the abortion procedure is determined. **Remark (for Recommendations 43a and b):** • This recommendation applies to the combination mifepristone plus misoprostol regimen and the use of misoprostol alone. The letrozole plus misoprostol combination regimen is not mentioned here because the included studies informing these recommendations did not assess this regimen. **Remarks (for Recommendation 43a only):** • Immediate initiation of intramuscular depot medroxyprogesterone acetate (DMPA) is associated with a slight decrease in the effectiveness of medical abortion regimens. However, immediate initiation of DMPA should still be offered as an available contraceptive method after an abortion. • Indirect evidence was used as a basis for decision-making on initiation of hormonal contraception as an option for individuals undergoing medical abortion with misoprostol alone. • No data were available on the use of combined hormonal contraception (pills or injections) by those undergoing medical abortion. • Individuals who choose to initiate the contraceptive ring should be instructed to check for expulsion of the ring in the event of heavy bleeding during the medical abortion process.	89
44 (SD) Intrauterine devices (IUDs)	For intrauterine devices (IUDs): **a. Recommend** insertion/removal by auxiliary nurse midwives, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** insertion/removal by traditional and complementary medicine professionals (TCMPs) and auxiliary nurses (ANs). • Condition (TCMPs): In contexts with established health system mechanisms for the participation of these professionals in other tasks related to maternal and reproductive health. • Condition (ANs): In the context of rigorous research.	90
45 (SD) Contraceptive implants	For contraceptive implants: **a. Recommend** insertion/removal by nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** insertion/removal by community health workers (CHWs), traditional and complementary medicine professionals (TCMPs), auxiliary nurses (ANs)/ANMs. • Condition (CHWs): In the context of rigorous research. • Condition (TCMPs): In contexts with established health system mechanisms for the participation of these professionals in other tasks related to maternal and reproductive health and where training in implant removal is given along with training in insertion. • Condition (ANs/ANMs): In the context of targeted monitoring and evaluation.	90
46 (SD) Injectable contraceptives	For injectable contraceptives (initiation and continuation): **Recommend** administration by self (see Recommendation 51), community health workers, pharmacy workers, pharmacists, traditional and complementary medicine professionals, auxiliary nurses/ANMs, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners.	91
47 (SD) Tubal ligation	For tubal ligation: **a. Recommend** tubal ligation by associate/advanced associate clinicians, generalist medical practitioners and specialist medical practitioners. **b. Suggest** tubal ligation by nurses and midwives. • Condition: In the context of rigorous research.	92

SECTION **Topic area** Recommendation or best practice statement number and type	**Recommendation or best practice statement**	**Page number**
SERVICE-DELIVERY OPTIONS AND SELF-MANAGEMENT APPROACHES		
Telemedicine approaches to delivering medical abortion care		
48 (SD) (NEW)	**Recommend** the option of telemedicine as an alternative to in-person interactions with the health worker to deliver medical abortion services in whole or in part. **Remarks:** • The above recommendation applies to assessment of eligibility for medical abortion, counselling and/or instruction relating to the abortion process, providing instruction for and active facilitation of the administration of medicines, and follow-up post-abortion care, all through telemedicine. • Hotlines, digital apps or one-way modes of communication (e.g. reminder text messages) that simply provide information were not included in the review of evidence for this recommendation.	95
Service-delivery approaches for provision of information, counselling and medical abortion		
49 (SD) (NEW)	**Best Practice Statement on service delivery** **Part 1.** There is no single recommended approach to providing abortion services. The choice of specific health worker(s) (from among the recommended options) or management by the individual themself, and the location of service provision (from among the recommended options) will depend on the values and preferences of the woman, girl or other pregnant person, available resources, and the national and local context. A plurality of service-delivery approaches can co-exist within any given context. **Part 2.** Given that service-delivery approaches can be diverse, it is important to ensure that for the individual seeking care, the range of service-delivery options taken together will provide: • access to scientifically accurate, understandable information at all stages; • access to quality-assured medicines (including those for pain management); • back-up referral support if desired or needed; • linkages to an appropriate choice of contraceptive services for those who want post-abortion contraception.	96
Self-management of medical abortion at < 12 weeks		
50 (SELF-MANAGEMENT)	For medical abortion at < 12 weeks (using the combination of mifepristone plus misoprostol or using misoprostol alone): **Recommend** the option of self-management of the medical abortion process in whole or any of the three component parts of the process: • self-assessment of eligibility (determining pregnancy duration; ruling out contraindications) • self-administration of abortion medicines and management of the abortion process outside of a health-care facility and without the direct supervision of a trained health worker • self-assessment of the success of the abortion. **Remarks:** • There was more evidence for self-management of medical abortion (with either of the regimens) for pregnancies before 10 weeks of gestation. • This recommendation applies to the combination regimen of mifepristone plus misoprostol, and the use of misoprostol alone. The included studies informing these recommendations did not assess the letrozole plus misoprostol regimen. • All individuals engaging in self-management of medical abortion must also have access to accurate information, quality-assured medicines including for pain management, the support of trained health workers and access to a health-care facility and to referral services if they need or desire it. • Restrictions on prescribing and dispensing authority for abortion medicines may need to be modified or other mechanisms put in place for self-management within the regulatory framework of the health system.	98

SECTION **Topic area** Recommendation or best practice statement number and type	**Recommendation or best practice statement**	**Page number**
Self-management approaches for post-abortion contraception (see also Timing of post-abortion contraception, Recommendations 41–47 above)		
51 (SELF-MANAGEMENT) Injectable contraception (initiation and continuation)	**Recommend** the option of self-administration of injectable contraception in the post-abortion period. **Remark:** • The administration of an injectable contraceptive involves using a syringe and may be intramuscular or subcutaneous. Compact pre-filled auto-disable devices have been developed to facilitate the self-administration process.	100
52 (SELF-MANAGEMENT) Over-the-counter oral contraceptive pills	**Recommend** that over-the-counter oral contraceptive pills (OCPs) should be made available without a prescription for individuals using OCPs.	101
53 (SELF-MANAGEMENT) Over-the-counter emergency contraceptive pills	**Recommend** making over-the-counter emergency contraceptive pills available without a prescription to individuals who wish to use emergency contraception.	101
54 (SELF-MANAGEMENT) Condom use	The consistent and correct use of male and female condoms is highly effective in preventing the sexual transmission of HIV; reducing the risk of HIV transmission both from men to women and women to men in serodiscordant couples; reducing the risk of acquiring other STIs and associated conditions, including genital warts and cervical cancer; and preventing unintended pregnancy.	101

Chapter 1.

Introduction

1.1 Background and context

Sexual and reproductive health is fundamental to individuals, couples and families, and to the social and economic development of communities and nations *(1)*. As provided in the Constitution of the World Health Organization (WHO), the organization's objective is "the attainment by all peoples of the highest possible level of health", and to fulfil that objective, WHO's functions include providing technical assistance to countries in the field of health *(2, Articles 1 and 2)*. Universal access to sexual and reproductive health (SRH) information and services is central to both individual and community health, as well as the realization of human rights, including the right to the highest attainable standard of SRH *(3)*. In addition, the increased SRH risks in humanitarian settings, including armed conflict, require specific attention from a human rights perspective *(4 [para. 7], 5, 6 [paras 19-24])*.

In the wake of the COVID-19 pandemic and based on lessons learnt from previous disease outbreaks – when SRH services have been severely disrupted, causing individuals to feel disempowered and be exposed to preventable health risks – WHO has included comprehensive abortion care in the list of essential health services in certain recent technical publications and guidance *(7-12)*.[1] Abortion care encompasses management of various clinical conditions including spontaneous and induced abortion (of both non-viable and viable pregnancies) and intrauterine fetal demise, and also post-abortion care, including management of incomplete abortion. Strengthening access to abortion care within the health system is fundamental to meeting the Sustainable Development Goals (SDGs) relating to good health and well-being (SDG3) and gender equality (SDG5) *(13)*. WHO's Global Reproductive Health Strategy, which seeks to accelerate progress towards achievement of international development goals, identifies elimination of unsafe abortion[2] as a priority mandate *(1)*. The importance of quality abortion care to health is similarly underscored by the United Nations Global Strategy for Women's, Children's and Adolescents' Health, which includes evidence-based interventions for abortion and post-abortion care as one effective way to help individuals thrive and communities transform *(14)*.

Quality abortion care is foundational to this guidance. Quality of care (see Glossary) encompasses multiple components: effectiveness, efficiency, accessibility, acceptability (e.g. patient centred), equity and safety. Effective care includes the delivery of evidence-based care that improves the health of individuals and communities, and is responsive to their needs. Efficient care optimizes resource use and minimizes waste. Quality abortion care must be both accessible (timely, affordable, geographically reachable, and provided in a setting where skills and resources are appropriate to medical need) and acceptable (incorporating the preferences and values of individual service users and the cultures of their communities). It is imperative that abortion care is equitable, and that health care does not vary in quality based on the personal characteristics of the person seeking care, such as their gender, race, ethnicity, socioeconomic status, education, if they are living with a disability, or based on

1 When considering the concept of "essential health services", it is important to note that different areas, even within the same country, may require different approaches to designate essential health services and to reorient health system components to maintain these services *(7)*.

2 "Unsafe abortion" refers to abortion when it is carried out by a person lacking the necessary skills or in an environment that does not conform to minimal medical standards, or both.

their geographic location within a country. And finally, quality abortion care implies that it is safely delivered and minimizes risks and harms to service users *(15)*. Underpinning these components is the principle that provision of quality abortion care would be in compliance with human rights.

Globally, abortion is a common procedure, with 6 out of 10 unintended pregnancies and 3 out of 10 of all pregnancies ending in induced abortion *(16)*. When abortion is safe – defined as being carried out using a method recommended by WHO, appropriate to the gestational age, and by someone with the necessary skills *(17)* – the risks are very low. However global estimates demonstrate that 45% of all abortions are unsafe, including 14.4% considered to be "least safe" *(18)*. This is a critical public health and human rights issue; unsafe abortion is increasingly concentrated in developing countries and among groups in vulnerable and marginalized situations. In countries where induced abortion is highly restricted by law or unavailable due to other barriers, safe abortion has often become the privilege of the rich, while poor women have little choice but to resort to the services of unskilled providers in unsafe settings, or induce abortion themselves often using unsafe methods, leading to deaths and morbidities that become the social and financial responsibility of the public health system, and denial of women's human rights. The legal status of abortion has no effect on a woman's likelihood of seeking induced abortion, but it dramatically affects her access to safe abortion *(19)*.

Between 4.7% and 13.2% of all maternal deaths are attributed to unsafe abortions *(20, 21)*. This equates to between 13 865 and 38 940 lives lost annually, due to the failure to provide safe abortion, with many more experiencing serious morbidities. Developing countries bear the burden of 97% of unsafe abortions *(18)*. The proportion of abortions that are unsafe is also significantly higher in countries with highly restrictive abortion laws than in those with less restrictive laws *(18)*. Over half (53.8%) of all unsafe abortions occur in Asia (the majority of those in south and central Asia), while another quarter (24.8%) occur in Africa (mainly in eastern and western Africa), and a further fifth (19.5%) in Latin America and the Caribbean *(18)*. The subregions where the highest proportions of abortions have been categorized as "least safe" are northern, eastern, western and middle Africa (approximately 45–70% of all abortions are "least safe"), followed by the Caribbean, Oceania and Central America (approximately 25–30% of all abortions are "least safe") *(18)*. A review of facility-based treatment for complications of unsafe abortion in 26 developing countries in 2012 indicated that 7 million women were treated in developing countries for complications of unsafe abortion that year – a rate of 6.9 per 1000 women aged 15–44 years *(22)*.

Abortion, using medication or a simple outpatient surgical procedure, is a safe health-care intervention, when carried out with a method appropriate to the gestational age of pregnancy and – in the case of a facility-based procedure – by a person with the necessary skills. In these circumstances, complications or serious adverse effects are rare. Medical abortion has revolutionized access to quality abortion care globally. Studies have demonstrated that medicines for abortion can be safely and effectively self-administered outside of a facility (e.g. at home). Individuals with a source of accurate information and access to a trained health worker (in case they need or want support at any stage of the process) can safely self-manage their abortion process in the first 12 weeks of gestation. Service delivery with minimal medical supervision can significantly improve access, particularly in restricted settings and crisis situations, as well as improve privacy, convenience and acceptability of the abortion process without compromising safety and effectiveness *(23)*.

However, in both low- and high-resource settings, law, policy and practical barriers can make it difficult to access quality abortion care. Multiple actions are needed at the legal, health system and community levels so that everyone who needs it has access to comprehensive abortion care (CAC), i.e. information, abortion management (including induced abortion, and care related to pregnancy loss/spontaneous abortion) and post-abortion care.

1.2 Guideline objective, rationale, target audience, inclusivity and structure

Guidelines are the fundamental means through which WHO fulfils its technical leadership in health (24). WHO guidelines are subject to a rigorous quality assurance process that generates recommendations for clinical practice or public health policy with the aim of achieving the best possible individual or collective health outcomes. Towards this aim, WHO has made a commitment to integrate human rights into health-care programmes and policies at national and regional levels by looking at underlying determinants of health as part of a comprehensive approach to health and human rights.

1.2.1 Objective and rationale

The objective of this guideline is to present the complete set of all WHO recommendations and best practice statements relating to abortion, with the goal of enabling evidence-based quality abortion care globally.

This guideline updates and replaces the recommendations in the following previous WHO guidance:

- *Safe abortion: technical and policy guidance for health systems, second edition* (2012)
- *Health worker roles in providing safe abortion care and post-abortion contraception* (previously known as the "task sharing" guidance) (2015), and
- *Medical management of abortion* (2018).

This guideline is intended to provide concrete information and guidance, integrating aspects of care across all domains needed to provide quality abortion care: Law and policy, Clinical services and Service delivery. This guidance contains new recommendations consolidated with existing recommendations that remain unchanged and some that have been updated after re-assessment, using the same rigorous methods for both new and updated recommendations (see Annex 4: Methods). Among the recommendations are seven concerning the laws and policies that should or should not be in place, in order to fully implement and sustain quality abortion care: three recommendations relating to abortion regulation are presented in Chapter 2 and four more relating to laws and policies affecting clinical and health worker practices are presented in Chapter 3. All the other recommendations address methods of abortion and related clinical care as well as service delivery by a range of health workers and approaches, including self-management by the abortion seeker, reflecting recent changes in all these aspects of abortion care. Emerging areas of interest and research priorities in abortion care are identified in Chapter 4.

As a key part of the rationale for developing this updated and consolidated guideline, important contextual information – which is integral to this guidance, as context for the recommendations and best practice statements – is presented in the remainder of this first chapter. This information is not in the form of WHO recommendations but rather it describes the underlying determinants of quality abortion care, and thus must be carefully considered. Section 1.3 below describes an enabling environment for comprehensive abortion care (i.e. a law and policy framework supportive of human rights; access to information; and health system factors) and section 1.4 delves further into key health system considerations (universal health coverage and primary health care; health financing; health workforce training; health-care commodities; and monitoring and evaluation). Where relevant, this document incorporates and builds upon considerations captured in other existing WHO guidance, including *Consolidated guideline on the sexual and reproductive health and rights of women living with HIV (25)* and *WHO consolidated guideline on self-care interventions for health: sexual and reproductive health and rights (26)*.

1.2.2 Target audience

This guidance seeks to provide recommendations for national and subnational policy-makers, implementers and managers of sexual and reproductive health (SRH) programmes, members of nongovernmental organizations and other civil society organizations and professional societies, as well as health workers and other stakeholders in the field of sexual and reproductive health and rights (SRHR), to support them in ensuring that evidence-based, quality abortion care is available and accessible globally.

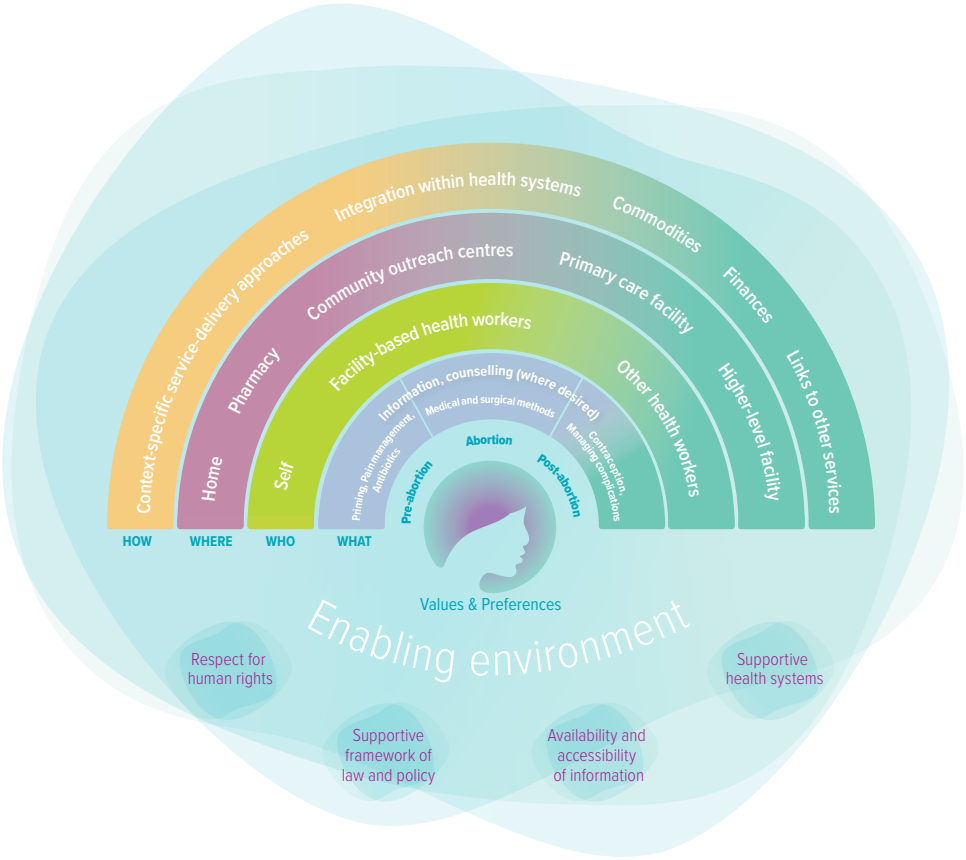
1.2.3 Equity, inclusivity and people-centred care

The needs of all individuals with respect to abortion are recognized and acknowledged in this guidance. A human rights approach that advances gender equality is essential and must be applied in all contexts providing services to people seeking health care. To provide quality abortion care throughout the health system, services should also be integrated where possible with other SRH services, such as evidence-based HIV and sexually transmitted infection (STI) testing and treatment, and family planning/contraception, and should be friendly and welcoming to youth and people from sexual and gender minorities, people living with disabilities, and all groups in vulnerable and marginalized situations.

WHO guidelines systematically incorporate consideration of the values and preferences of end-users of the recommended or suggested interventions into the process of developing the guidance. To gain more in-depth understanding of the values and preferences of individuals seeking abortion care, WHO conducted a global

survey and convened a technical meeting on this subject with stakeholders in September 2019 attended by 19 participants from 15 different countries/organizations. The key themes that emerged were the importance of equity, inclusivity and meeting the needs of those living in the most vulnerable and marginalized situations. In addition, a youth-led technical meeting was convened in April 2021 with 16 youths (representing 13 countries across all WHO regions) from the Youth for Abortion Task Force, to learn about the concerns of youth. The Task Force was formed by the International Youth Alliance for Family Planning (IYAFP) – a collective of young individuals, youth associations, organizations and communities with a common mission to support provision of and access to comprehensive reproductive health services (see Web annex B: Technical meetings during guideline development). Women living with HIV are one example among many of a marginalized population with unique vulnerabilities in the context of abortion care. Women living with HIV face unique challenges and are vulnerable to SRH-related human rights violations within their families and communities, as well as at health-care facilities where they seek care. An enabling environment is essential to promote more effective interventions and better health outcomes for all abortion seekers (see section 1.3).

All individuals have the right to non-discrimination and equality in SRH care and services. The right to be free from discrimination is stated in the Universal Declaration of Human Rights and in other universal human rights treaties and regional human rights instruments. It has been affirmed that the right to non-discrimination guaranteed by the International Covenant on Economic, Social and Cultural Rights (ICESCR) includes sexual orientation, gender identity and sex characteristics. The international human rights system has been strengthening the promotion and protection of human rights without distinction. The protection of persons based on their sexual orientation and gender identity are based on international law, complemented and supplemented by State practice *(27)*. As stated in the 2018 report of the Independent Expert on protection against violence and discrimination based on sexual orientation and gender identity to the United Nations General Assembly, "The right to effective recognition of one's gender identity is linked to the right to equal recognition before the law" *(28, para. 20)*.



In this guideline, we recognize that most of the available evidence on abortion can be assumed to be derived from research among study populations of cisgender women, and we also recognize that cisgender women, transgender men, nonbinary, gender-fluid and intersex individuals with a female reproductive system and capable of becoming pregnant may require abortion care. To be concise and facilitate readability of this guideline, when referring to all gender diverse people who may require abortion care, we use the word "women" most often, although we also variously use the terms "individual", "person" and "abortion seeker". Providers of SRH services, including abortion care, must consider the needs of – and provide equal care to – all individuals; gender identity or its expression must not lead to discrimination.

This guideline takes an integrated, people-centred approach to health services *(29)*. People-centred care requires that individuals have the education and support they need to make decisions and participate in their own health care *(30)*. Individual health preferences may vary; no one model of abortion care will meet the needs of everyone seeking abortion care. The core values of dignity, autonomy, equality, confidentiality, communication, social support, supportive care, and trust are foundational to abortion care and are reflected throughout this guidance *(31)*.

1.2.4 Conceptual structure of the guideline

As illustrated in Figure 1.1, this guideline is centred on the values and preferences of abortion seekers, and considers them as active participants in as well as beneficiaries of health services. This guidance emphasizes that – as a woman, girl or other pregnant person moves through the abortion care pathway (pre-abortion, abortion, post-abortion) – health services must be integrated within the health sector to ensure that service delivery meets their needs equitably and without discrimination. As each individual moves through this pathway, the guideline provides specific recommendations on the interventions needed (i.e. the "what"), and guidance on the individuals who may safely carry them out (i.e. the "who"). The guideline also provides information on the locations where services can be provided (i.e. the "where") and outlines service-delivery models that can be used (i.e. the "how"). The enabling environment, described in the remainder of this chapter, provides the context for the effective implementation of these interventions.

Figure 1.1: Conceptual framework for abortion care

1.3 An enabling environment for comprehensive abortion care

A person's environment plays a crucial role in shaping their access to care and influencing their health outcomes. An enabling environment is the foundation of quality, comprehensive abortion care. The three cornerstones of an enabling environment for abortion care are outlined in Box 1.1 and elaborated in the text of this section:

1. respect for human rights including a supportive framework of law and policy
2. the availability and accessibility of information, and
3. a supportive, universally accessible, affordable and well functioning health system.

For clarification, this section of the guideline document does not provide recommendations – rather it details the components and aspects that would comprise an overall enabling environment for quality abortion care, based on WHO best practices, which would provide the ideal context to best facilitate the recommendations in the later sections of this chapter and in Chapter 3. While this enabling environment represents an ideal context, complete implementation of the components of this enabling environment is not necessarily a precondition to implementation and application of the recommendations contained in this guideline.

BOX 1.1: Core components of an enabling environment for abortion care

Respect for human rights including a supportive framework of law and policy

- Countries ratify international and regional human rights treaties and conventions addressing health, including sexual and reproductive health (SRH).
- Laws and policies promote SRH for all, and are consistent with sexual and reproductive health and rights.
- There are appropriate administrative, political and judicial arrangements to facilitate quality abortion care, including accessible, transparent and effective mechanisms providing remedies. These include:
  - accessible mechanisms for women to challenge denial of abortion in a timely manner, and
  - appropriate monitoring mechanisms for failure to facilitate quality care, including regular review and reform of law and policy to recognize and remove barriers to quality abortion care.
- Policies minimize the rate of unintended pregnancy by providing quality contraceptive information and services, including a full range of contraceptive methods (emergency, short-acting and long-acting methods).
- All people and communities receive the health services they need, without suffering financial hardship and without any discrimination.

Availability and accessibility of information

- Evidence-based comprehensive sexuality education (CSE) is provided for all individuals and made available in multiple and accessible forms and languages.
- Accurate, non-biased and evidence-based SRH information, including on abortion and contraceptive methods, is widely available in multiple and accessible forms and languages.

Supportive, universally accessible, affordable and well functioning health system

- Universal health coverage (UHC) ensures that all individuals can receive the care they need without financial hardship (see section 1.4.1).
- The health system is adequately resourced, meaning that resources including essential medicines, supplies, equipment, workforce and financial allocations are available, accessible, acceptable, affordable and of good quality.
- Equitable access to quality-assured essential medicines and health products is ensured.
- Leadership and clinical standards promote evidence-based SRH services.
- The organization of the health system ensures respect for SRH and human rights, including non-discrimination and equality, and for autonomy in decision-making.
- The workforce is robust and receives competency-based training and is skilled in the provision of evidence-based SRH counselling and service delivery.
- In addition to technical training, SRH services are provided by persons who are trained in the content and meaning of the law and trained and empowered to interpret and apply law and policy in rights-compliant ways.
- Confidentiality and privacy of care are ensured, and there are efforts to counteract abortion stigma.
- There is access to safe and timely comprehensive abortion care and women do not have to resort to unsafe abortion.
- Health financing policies should avoid making access to SRH services conditional on direct payment from patients at the point of service.
- Care is always provided respectfully and with compassion.
- Communities are engaged and supportive.

1.3.1 Human rights including a supportive framework of law and policy

An enabling environment is one in which the human rights of individuals are respected, protected and fulfilled. This entails regular review and, where necessary, revision of regulatory, law and policy frameworks, and the adoption of measures to ensure compliance with evolving international human rights standards (see Annex 2).

Throughout this guideline we refer to human rights standards in international law, the applicability of which in a specific setting will depend on factors such as the State's ratification of relevant human rights instruments. The sources of these human rights standards are detailed in Web annex A: Key international human rights standards on abortion.

(i) Sexual and reproductive health and rights

Sexual and reproductive health and rights are grounded in a range of human rights recognized and guaranteed in national and international law, and are inextricably linked to the achievement of public health policy goals, including the SDGs *(32, 33)*. People have a range of sexual and reproductive rights, which are relevant to information and services across the continuum of care for abortion (see Box 1.2). Overarching all of them are principles of non-discrimination and equality, and the right to the highest attainable standard of physical and mental health, including in the provision of SRH services *(3, para. 7)*. These are all underpinned by States' obligations to ensure that laws and policies, institutional arrangements and social practices do not prevent people from the effective enjoyment of their right to SRH *(3, para. 8)*.

Box 1.2 provides a general description of certain human rights as established by international law instruments and their associated obligations and principles relevant to SRH.

(ii) Prevention of unsafe abortion and reduction of maternal mortality and morbidity

Taking measures to prevent unsafe abortion is a core obligation of the right to SRH *(3, para. 49)*. International human rights law requires States to take steps to reduce maternal mortality and also to effectively protect women from the physical and mental risks (morbidity) associated with unsafe abortion *(43, paras 6, 9, 24, 30-33)*. Treaty monitoring bodies (see Annex 2) have confirmed that States must revise their laws to ensure this protection *(36, para. 8)*. Thus, the United Nations Committee on Economic, Social and Cultural Rights (CESCR) has confirmed that States must liberalize restrictive abortion laws, guarantee access to quality abortion and post-abortion care, and respect the right of women to make autonomous decisions about their SRH *(3, para. 28)*. In all situations, States have a duty under international human rights law to ensure that the regulation of abortion (see Chapter 2) does not cause women and girls to resort to unsafe abortions *(36, para. 8)*. As a matter of international human rights law, States must provide essential medicines listed under WHO's Action Programme on Essential Drugs *(46, para. 12a)*. States must also take steps to prevent the stigmatization of people seeking abortion *(36, para. 8)*. In addition, policies must seek to minimize the rate of unintended pregnancy by ensuring provision of quality contraceptive information and services, including a full range of contraceptive methods (emergency, short-acting and long-acting methods).

(iii) Rights-based regulation of abortion

The right to SRH requires States to ensure that health-care facilities, goods and services are available, accessible, acceptable and of good quality *(46, paras 8, 12)*. This should inform all parts of the regulation of abortion.

Treaty monitoring bodies have called for the decriminalization of abortion in all circumstances. They have further clarified States' human rights obligations in relation to abortion. These include that:

- States may not regulate pregnancy or abortion in a manner that runs contrary to their core obligation to ensure that women and girls do not have to resort to unsafe abortions. If they do, their restrictions on access to abortion must be revised *(36, para. 8)*.
- The regulation of abortion must not jeopardize the lives of pregnant women, subject them to physical or mental pain or suffering (including where this constitutes torture or cruel, inhuman or degrading treatment or punishment), discriminate against them, or interfere arbitrarily with their privacy *(36, para. 8)*.
- The regulation of abortion must be evidence based and proportionate to ensure respect for human rights *(37, para. 18)*.

BOX 1.2: Selected human rights, as specified in relevant international law instruments, and their associated obligations and principles relevant to sexual and reproductive health and rights and abortion in particular

Human right	Selected human rights principles and obligations relevant to abortion
The right to the highest attainable standard of physical and mental health, including sexual and reproductive health and rights	• States have an obligation to respect, protect and fulfil the right of everyone to sexual and reproductive health and rights *(34, Article 12)*. This includes: ▫ the removal of legal provisions, including criminal laws, which penalize women who have undergone abortion or medical practitioners who offer these services *(3, 35-38)*; ▫ ensuring that women are not prevented from accessing health services by health professionals' exercise of conscientious objection (e.g. where abortion is legal, if a doctor refuses to perform it, the health system must provide a referral to an alternative health-care provider) *(3, 39)*; ▫ eliminating barriers to the provision of abortion services including barriers that lead women to resort to unsafe abortions – this should include eliminating unacceptable delays in providing medical attention *(3, 36, 38, 40-42)*; ▫ undertaking measures to prevent unsafe abortions and ensure access to post-abortion care in all circumstances, on a confidential basis and without the threat of criminal prosecution or punitive measures *(3, 36-38, 40, 41, 42 [para. 33], 43-47);* ▫ undertaking measures to prevent and eliminate discrimination, stigmatization and negative stereotyping that hinder access to sexual and reproductive health (SRH), including against people seeking abortion and health-care providers offering abortion care services *(36, 38)*. • States must ensure that sexual and reproductive health-care facilities, goods and services are available, acceptable and of good quality. This includes: ▫ ensuring an adequate number of sexual and reproductive health-care facilities, goods and services (e.g. trained and skilled medical and health-care personnel *[42, 46, 48]* and scientifically approved and unexpired medicines for abortion and post-abortion care *[49]*, as well as the availability of safe abortion in cases of rape and incest *[3, 36, 42, 50, 51]*); ▫ ensuring that health care and services, including SRH and essential medicines are physically and geographically accessible and affordable to all individuals, either provided at no cost or based on ensuring that health expenses do not expose individuals to suffering financial hardship *(46)*; ▫ ensuring that information about SRH is accessible *(3, 52)* (e.g. institutions and individuals should be able to provide accurate health-care information, including information on abortion, without fear of criminal sanction *[41, 50, 51]*); ▫ ensuring that delivery of services is respectful of the culture of individuals, minorities, peoples and communities, and sensitive to gender, age, disability, sexual diversity and life-cycle requirements *(53, para. 20)*.
The right to non-discrimination and equality	• States must ensure that individuals enjoy equal access to the same range, quality and standard of SRH information, goods and services *(36, 45, 52)*. • States must acknowledge and take measures to address access to safe abortion and post-abortion care for particular groups of individuals, especially those who are marginalized, have limited resources, live in rural areas, and/or are from minorities, as they are more likely to experience intersecting forms of discrimination *(3, 36-38, 40, 41, 42 [para. 33], 43-47, 49, 54 [para. 45])*. • States must repeal or reform discriminatory laws, policies and practices that nullify or impair the ability of individuals to access SRH, such as criminalization of abortion and restrictive abortion laws *(3, 35-38, 41, 42 [para. 22], 55)*. • States must remove all legal, procedural, practical and social barriers impeding individuals' equal and non-discriminatory access to SRH, including abortion, and should repeal measures such as third-party authorization requirements (i.e. from husbands, partners, parents or guardians, or health authorities), biased counselling, mandatory waiting periods, and restrictions based on being an unmarried woman *(3, 35-38)*. • States must take steps to prevent the imposition of forced abortion, in particular on women and girls from marginalized groups *(37, 40, 47, 52, 56)*.
The right to life	• States must ensure that measures designed to regulate access to abortion do not jeopardize the life of the woman, girl or other pregnant person, subject them to physical or mental pain or suffering or discriminate against them, or arbitrarily interfere with their privacy *(36)*. • States must provide effective and confidential access to safe, legal abortion where the life or health of the woman, girl or other pregnant person is at risk, or where carrying a pregnancy to term would cause the pregnant individual substantial pain or suffering, and in cases where the pregnancy is the result of rape or incest or where the pregnancy is not viable *(36)*. • States must take steps to reduce maternal morbidity and mortality, including addressing unsafe abortion, taking into account exacerbated challenges in certain settings *(3, 36-38, 40, 43)*.

Human right	Selected human rights principles and obligations relevant to abortion
The right to privacy	• States must respect the right of individuals to make autonomous decisions about their sexual and reproductive health, including whether or not to undergo an abortion *(35, 36, 57)*. • SRH services including abortion and post-abortion care must be provided in a way that respects fully the woman's, girl's or other pregnant person's privacy and guarantees confidentiality *(35, 36)*. • Medical and health-care professionals must not be required or mandated to report cases of women who have undergone abortions *(36, 37, 40, 48)*. • Denial of therapeutic abortion may interfere arbitrarily with the right to privacy *(57)*. • Third-party authorization requirements may violate the right to privacy *(3, 36, 38)*.
The right to be free from torture, cruel, inhuman and degrading treatment and punishment, including the right to physical and mental integrity	• Forced abortion, criminalization of abortion, denial or delay of safe abortion care and/or post-abortion care, and abuse and mistreatment of women and girls seeking SRH information, goods and services are forms of gender-based violence *(44, 55)*, which – depending on the circumstances – may amount to torture, cruel, inhuman or degrading treatment *(55)*. • States must ensure that measures regulating abortion do not subject individuals to substantial physical or mental pain or suffering, such as where a pregnancy is the result of rape *(36)*. • State laws and policies must not permit abortions without the free and informed consent of the concerned individual *(40, 41, 48, 52, 56, 58)*. • States must prevent and prosecute forced abortions conducted by public officials and private actors, including when conducted on women with disabilities or according with coercive family planning laws and policies as well as in the context of a conflict *(40, 41, 48, 52, 56, 58)*. • States should ensure that individuals seeking a safe legal abortion are not subjected to humiliating and judgemental attitudes leading to the denial or delay of such services in a context of extreme vulnerability for these individuals and where timely health care is essential *(35)*. • Criminalization of abortion may amount to torture, cruel, inhuman or degrading treatment, including the practice of extracting confessions for prosecution purposes from individuals seeking emergency medical care because of illegal abortion in a particular context *(55)*.
The right to decide freely and responsibly on the number, spacing and timing of children and to have the information and means to do so	• States must ensure access to family planning and SRH information and services, including affordable contraceptive methods to enable women and adolescents to make autonomous and informed decisions on their reproductive health *(42 [para. 33], 49 [para. 33])*. • States must ensure that women with disabilities can exercise their right to decide on the number and spacing of children *(52, 59 [Article 3(3)])*.
The right to information and education including on sexual and reproductive health	• States must take measures to ensure up-to-date, accurate information on SRH is publicly available and accessible to all individuals, in appropriate languages and formats *(3, 50-52)*. • States must ensure that educational institutions incorporate unbiased, scientifically accurate, evidence-based, age-appropriate and comprehensive sexuality education into their required curricula *(3, para. 63)*. • States must make accurate, evidence-based abortion information available to individuals on a confidential basis *(3 [para. 63], 50-52)*. • This information must be presented in a way that can be understood by the person receiving it *(3, 52)*. • The choice by an individual to refuse information when offered must be respected. • States must ensure that informed consent is provided freely, safeguarded effectively, and based on complete provision of high-quality, accurate and accessible information.
The right to benefit from scientific progress and its realization	• States must ensure adequate access to essential medicines in an affordable manner *(46, 49, 54)*. • States must ensure access to necessary, up-to-date scientific technologies, in particular contraception and medicines for abortion, without discrimination *(42, 49)*.

Note: For further information, see Web annex A: Key international human rights standards on abortion. Wording used in this box reflects original language used in the source documents (human rights treaties).

- Access to abortion must be available when carrying a pregnancy to term would cause the woman substantial pain or suffering. This includes but is not limited to situations where her life and health are at risk, where the pregnancy is the result of rape or incest, or where the pregnancy is not viable *(36, para. 8)*. Treaty monitoring bodies have also recommended making abortion available in cases of fetal impairment, while putting in place measures to protect against discrimination on the basis of disability in society *(60)*.
- States should not criminalize having an abortion, those who have an abortion, or those who support someone having an abortion *(3 [paras 20, 34], 36 [para. 8], 55 [para. 18], 61 [para. 51(l)], 62 [para. 60], 63 [paras 82, 107])*.
- States should not require health workers to report women who have had or who are suspected to have had an abortion *(40, para. 20)*.
- States must provide essential primary health care *(64, para. 10)* (see also section 1.4.1: Universal health coverage and primary health care; section 1.4.4: Commodities; Annex 2: Selected human rights treaties and their treaty monitoring bodies; and also Web annex A: Key international human rights standards on abortion).

(iv) Accessibility of abortion care

Where it is lawful, abortion must be accessible in practice. This requires both ensuring that health-care facilities, commodities and services are accessible (including sufficient providers; see section 3.3.8 on provider restrictions), and that law and policy on abortion is formulated, interpreted and applied in a way that is compatible with human rights. Thus, where abortion is currently available on the basis of grounds, meaning under specified circumstances, and in anticipation of moving to a system of abortion on request as recommended (see Recommendation 2: Grounds-based approaches, section 2.2.2), those grounds must be defined and interpreted in a way that gives full effect to women's human rights and that aligns with the following WHO definitions:

> **Health**: a state of complete physical, mental and social well-being and not merely the absence of disease or infirmity *(2)*.
>
> **Mental health**: a state of well-being in which every individual realizes their own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to their community *(65)*.

States must take effective steps to prevent third parties (e.g. parent, spouse, health authority) undermining a person's enjoyment of their right to SRH (see section 3.3.2: Third-party authorization) *(3, para. 59)*, and must also ensure that provider refusal is not a barrier to accessing abortion care (see section 3.3.9: Conscientious objection) *(3 [paras 14, 43], 39 [Ch.1, paras 11, 13])*.

(v) Free and informed consent

International human rights law requires that the provision of abortion be based on the free and informed consent of the person having the abortion with no further authorization required.

International human rights law obliges States to ensure that accurate, evidence-based abortion information *(3 [para. 9], 36 [para. 8])* is available to individuals on a confidential basis *(36 [para. 8], 43)*, and also that their choice to refuse such information when offered is respected *(58, para. 15)*. Receipt of such information is vital as this underpins the right and the ability to make informed decisions and choices about matters regarding one's body and SRH, and to give informed consent (see also section 1.3.2 below).

As a matter of international human rights law, States are obligated to ensure that "informed consent" is:

- documented in advance of a health-care intervention, and provided without coercion, undue influence or misrepresentation *(58, para. 13)*;
- safeguarded through legislative, political and administrative means *(58, para. 7)*, as a fundamental aspect of a range of human rights (i.e. the rights to health, information, freedom from discrimination, and security and dignity of the person);
- based on provision of complete information about the associated benefits, risks and alternatives;
- based on information that is of high quality, accurate and accessible (including ensuring it is available in a range of formats and languages, and in forms that make it accessible to people with reduced capacity), and presented in a manner acceptable to the person consenting.

Further relevant information is provided in section 3.2 on information provision and counselling related to abortion for individual abortion seekers, and in section 3.5.1 on follow-up care and section 3.5.4 on post-abortion contraception. States are obliged to protect women from arbitrary interference when they seek SRH services, and to ensure respect for autonomous decision-making by women, including women with disabilities, regarding their SRH and well-being *(60)*.

Even though women have a right to accurate information, some health workers who object to abortion on the basis of conscience either provide deliberately misleading information or refuse to provide any information about abortion *(66-68)*. States where health workers are allowed to invoke conscientious objection *(3, para. 43)* must regulate and monitor such refusals of abortion care to ensure that women can access accurate information and appropriate services (refer to section 3.3.9: Conscientious objection).

As a matter of international human rights law, States may not restrict women's access to health services on the ground that they do not have the authorization of husbands, partners, parents/guardians or health authorities, because they are unmarried, or because they are women *(39 [Ch.1, paras 14, 21], 3 [paras 41, 43])*. For adolescents, the authorization or consent of parents should not be required before the provision of abortion care (see also section 3.3.2: Third-party authorization). As a general matter, States must recognize children's and adolescents' evolving capacity and their associated ability to take decisions that affect their lives *(69, Article 5)*. In order to ensure protection of adolescents' sexual and reproductive health and rights, the United Nations Special Rapporteur on the right of everyone to the enjoyment of the highest attainable standard of physical and mental health has suggested that States should consider introducing "a legal presumption of competence that an adolescent seeking preventive or time-sensitive health goods or services, including for sexual and reproductive health, has the requisite capacity to access such goods and services" *(35, para. 60)*. The United Nations Committee on the Rights of the Child (CRC) has also urged States to "review and consider allowing children to consent to certain medical treatments and interventions without the permission of a parent, caregiver or guardian, such as … sexual and reproductive health services, including … safe abortion" *(45, para. 31)*.

People with disabilities have a right to autonomy *(59, Article 3a)*, but face continuing and systemic discrimination in access to SRH services. States are obliged to prohibit and prevent discriminatory denial of SRH services to people with disabilities *(70, para. 66)*. States may not undertake, and must take steps to prevent forced or coerced abortion *(40, para. 11)*, which constitutes torture, cruel, inhuman or degrading treatment *(40 [para. 11], 52 [para. 62])*.

(vi) Post-abortion care

Provision of post-abortion care is a core obligation of States under the right to SRH *(3, para. 49e)*. Regardless of whether abortion is legal or restricted, States are required to ensure access to post-abortion care *(45, para. 70)*. Such care must be available on a confidential basis, without discrimination, and without the threat of criminal prosecution or other punitive measures *(36, para. 8)*. States must also ensure access to a wide range of modern, safe and affordable contraceptive methods *(36 [para. 8], 49 [para. 33])*.

(vii) Accountability for human rights violations

Accountability mechanisms are essential to the protection, respect and fulfilment of sexual and reproductive health and rights. Monitoring and accountability for human rights compliance takes place at national, regional and international levels, as appropriate to the law in question. Monitoring and accountability involve a variety of actors, such as the State itself, civil society organizations, national human rights institutions or international or regional human rights mechanisms. Some such accountability mechanisms include administrative mechanisms for recording and monitoring relevant health outcomes relating to abortion law and policy, and including them in reports to human rights institutions *(39, Ch.1, paras 9, 10, 12, 17)* (see also section 1.4.5 on monitoring and evaluation of abortion care). States must ensure that all persons have access to justice and to a meaningful and effective remedy where their human rights are violated *(39, Ch.1, para. 13)*. These remedies can include adequate, effective and prompt reparation in the form of restitution, compensation, rehabilitation, satisfaction and guarantees of non-repetition *(3, para. 64),* including by reform of law and policy. Mindful of the above, an enabling environment for abortion care would ensure that there are appropriate accountability mechanisms for failures to facilitate quality abortion care, including accessible, transparent and effective accountability mechanisms for women to challenge denial of abortion in a timely manner. In addition, an enabling environment would include appropriate remedies for failure to facilitate quality abortion care, including regular review and reform of law and policy to recognize and remove barriers to quality abortion care. As confirmed by the Committee on the Elimination

of Discrimination against Women (CEDAW), such reform should include "[a]bolish[ing] discriminatory criminalization and review[ing] and monitor[ing] all criminal procedures... [and] decriminaliz[ing] forms of behaviour that can be performed only by women, such as abortion" *(61, para. 51[l])*.

1.3.2 Availability and accessibility of information

An essential first step in improving access to and quality of abortion care is ensuring that all individuals can access relevant, accurate and evidence-based health information and counselling if and when desired. This is required by international human rights law – grounded in the right to information and the right to privacy (see Box 1.2) – and facilitates individual decision-making relating to SRH services, including abortion. Two different types of information about abortion must be available: (i) information of a general nature for the public (described below), and (ii) specific information tailored to be relevant to each person seeking abortion (see section 3.2.1) and underpinning free and informed consent, which was described in section 1.3.1(v).

States parties are to ensure that everyone has a right to receive accurate, non-biased and evidence-based information on SRH. Relatedly, as part of their obligation to reduce maternal mortality and morbidity, States must ensure the provision of comprehensive, non-discriminatory, scientifically accurate and age-appropriate education on sexuality and reproduction, including information on abortion, both in and out of schools *(46, 71 [Articles 10, 16], 72)* and must ensure that comprehensive sexuality education (CSE) is available to minors without the consent of their parents or guardians *(45, para. 31)*. In an enabling environment all persons would be provided with all the necessary information to make an informed decision regarding the use of contraception, including information on where and how to obtain an abortion or contraception, the costs of services, and the specifics of any local laws. The growing use of self-management of abortion (see section 3.6.2) underlines the need to ensure that accurate information about abortion is available to all who may seek it.

As a matter of international human rights law, the provision of information on abortion should not be criminalized, even in contexts where the procedure itself may be illegal (see section 2.2.1: Criminalization of abortion). To ensure that accurate information is broadly accessible, including for those with low literacy, an enabling environment would provide that such information is shared using a variety of formats/media as appropriate for the intended audience (e.g. videos, social media). The United Nations CESCR has confirmed that "[t]he dissemination of misinformation and the imposition of restrictions on the right of individuals to access information about SRH also violates the duty to respect human rights. ... Such restrictions impede access to information and services, and can fuel stigma and discrimination" *(3, para. 41)*.

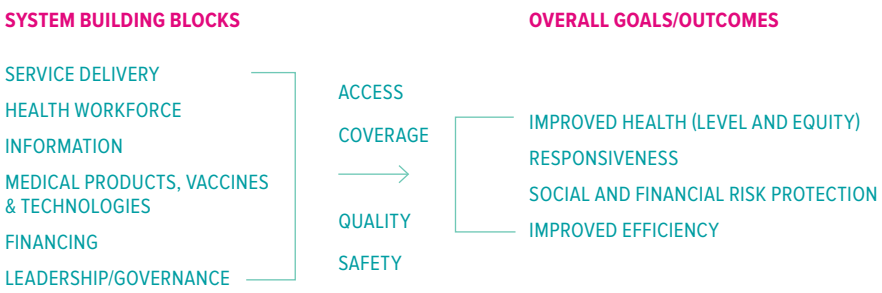
1.3.3 Health system factors

Within the health system, multiple actions are needed to realize human rights obligations. Actions to facilitate and strengthen abortion-related service delivery should be based on human rights, local health needs and a thorough understanding of the service-delivery system and the broader social, cultural, political and economic context. National standards and guidelines for abortion care should be evidence based and periodically updated, and should provide the necessary guidance to achieve equal access to comprehensive abortion care. Leadership should also promote evidence-based SRH services according to these standards and guidelines.

The right to the highest attainable standard of physical and mental health includes the right to respectful health care as well as the right to be free from violence and discrimination *(73)*. The right to benefit from scientific progress and its realization entitles women to access to up-to-date scientific technologies necessary for women. This means States must ensure access to modern and safe forms of contraception (including emergency contraception), abortion medicines, assisted reproductive technologies, and other SRH goods and services, on the basis of non-discrimination and equality *(49, para. 33)*. To achieve a high standard of respectful care, health systems should be organized and managed in a manner that ensures respect for people's SRH and human rights *(73)*. Respectful health care recognizes individuals' rights, respects their agency and autonomy in decision-making, and incorporates their values and preferences into care.

In addition to policy and regulatory barriers, other barriers may further limit the availability of abortion services, including: stigma; formal and informal costs; lack of commodities, services, trained providers and information; and/or the unwillingness of some health workers to provide care. This leaves particular groups of people – such as those living in rural settings, those facing financial hardship, adolescents, unmarried, transgender or nonbinary individuals, those with less access to education and those living with HIV – disproportionately vulnerable to

barriers to obtaining abortion care. As part of an enabling environment, a health system should be adequately resourced, meaning that resources (e.g. essential medicines, supplies, equipment, workforce, financial allocations) are available, fairly distributed and efficiently used. In this way, adequate and equitable access to quality-assured essential medicines and equipment should be assured. Relatedly, health financing policies should avoid making access to SRH services conditional on direct payment from patients at the point of service, and the health workforce should be skilled in providing evidence-based SRH services, including counselling.



Abortion stigma is common, and has negative psychological consequences for individuals seeking abortion and health workers providing abortion care *(31, 74, 75),* and can also be detrimental to health outcomes. Abortion stigma is a social process, and is dependent upon the context, but may be considered as an exercise of power and control of one group over members of a less powerful group, who are considered different, negatively stereotyped, discriminated against and marginalized within society *(75, 76).* Work is needed across sectors to counteract stigma; health systems should recognize the risks and effects of stigma, and implement solutions to not only ensure privacy and confidentiality, but also to support health workers. Care should always be provided respectfully and with compassion. In an enabling environment, communities are also engaged and supportive. Those who assist and support abortion seekers – their partners, friends, family members – also require support within the health system and broader environment.

More in-depth consideration of key health system factors is provided in section 1.4 below.

1.4 Health system considerations

The health system refers to all organizations, people and actions whose *primary intent* is to promote, restore or maintain health *(77).* The health system consists of the six core building blocks, as listed in Figure 1.2, which support four overall goals and outcomes, as shown below. This section addresses in detail health system considerations relevant to an enabling environment for abortion care.

Figure 1.2: The WHO health system framework

Source: WHO, 2007 *(77).*

A well functioning health system, with all the "blocks" working in harmony, depends upon having trained and motivated health workers, a well maintained infrastructure and a reliable supply of medicines and technologies, backed by adequate financing, strong health plans and evidence-based policies. Health-care services provided via the health system are not restricted to those provided at a health-care facility; health care and services can also be received through community-based providers (e.g. health visitors, pharmacists), digital interventions or self-care approaches (e.g. telemedicine).

1.4.1 Universal health coverage and primary health care

Universal health coverage (UHC) means ensuring that all people have access to the promotive, preventive, curative, rehabilitative and palliative health services they need, which must be of sufficient quality to be effective, while also ensuring that the use of these services does not expose any users to financial hardship *(30).* UHC is integral to the achievement of SDG target 3.8: Achieve universal health coverage, including financial risk protection, access to quality essential health-care services and access to safe, effective, quality and affordable

essential medicines and vaccines for all. The aim of this target is to accelerate efforts to ensure that all people and communities receive the full spectrum of essential, quality health services they need across the life course, without suffering financial hardship.

To establish an enabling environment, there is a need for abortion care to be integrated into the health system across all levels (including primary, secondary and tertiary) – and supported in the community – to allow for expansion of health worker roles, including self-management approaches. Such integration is a complex process that can occur through service delivery, financing mechanisms and/or inclusion in health benefits packages. While inclusion in health benefits packages may enhance access to and delivery of abortion care, in many countries abortion care is not explicitly recognized in the standard package, contributing to inequitable access to services *(78)*.

From a health financing perspective, improving access to comprehensive abortion care, as part of UHC, requires shifting the burden of financing away from individuals towards domestic public funding, which combines tax revenue and prepayment schemes to cover the costs of care *(78)*. Further information is provided in section 1.4.2 below. Meanwhile, from a service-delivery perspective, integrating abortion care within national maternal care and family planning programmes is technically the most straightforward option as abortion services require few, if any, additional provider skills, medicines, equipment or supplies. Furthermore, it is the most efficient option, as it minimizes any additional/marginal costs of implementing abortion services.

Health systems strengthening, by improving performance across all six health system building blocks (see above), is essential to progress towards UHC *(77)*. The use of new and innovative technologies and approaches for providing, facilitating or supporting abortion services must be incorporated into country programmes and health benefits packages. WHO's UHC Compendium provides a list of all interventions related to abortion care to be considered for inclusion within a country's UHC package *(79)*.[3]

To ensure both access to abortion and achievement of UHC, abortion must be centred within primary health care (PHC), which itself is fully integrated within the health system, facilitating referral pathways for higher-level care when needed. PHC is a multisectoral, societal approach to health that aims to ensure the highest possible level of health and well-being for all individuals, by focusing on people's needs and preferences (as individuals, families and communities) along the continuum of care from health promotion and disease prevention to treatment, rehabilitation and palliative care *(30)*. Quality PHC is evidence-informed, community-delivered and person-centred. Making abortion available and accessible within PHC is a safe and effective strategy to advance equitable access to, and provide an enabling environment for, abortion.

1.4.2 Health financing

Health financing is a core function of health systems that can enable progress towards UHC by improving effective service coverage and financial protection. To improve effective service coverage, health financing arrangements for abortion services should ensure the production costs are met so that health-care providers have the means to carry out these activities without financial constraints. To improve financial protection, the health system must guarantee that the share of the costs – production costs and the costs of access to services – borne by patients is not a barrier to full use of services. WHO's approach to health financing focuses on the following core functions:

- raising revenue – establishing sources of funds, including government budgets, compulsory or voluntary prepaid insurance schemes, direct out-of-pocket payments by users, and external aid;
- pooling funds – the accumulation of prepaid funds on behalf of some or all of the population; and
- purchasing services – the payment or allocation of resources to health-care providers.

In addition, all countries have policies indicating which services the population is entitled to, even if not explicitly stated by the government, and by extension any services not covered are usually paid for out of pocket by patients as user fees or co-payments.

To provide an enabling environment, financing of abortion services should take into account costs to the health system while ensuring that services are free or affordable and readily available to all who need them, in support of the goal of achieving UHC. A recent scoping review captured the costs to the health system and to the woman

3 Available by selecting "Sexual and reproductive health" at this link: https://www.who.int/universal-health-coverage/compendium/interventions-by-programme-area or by searching the database at this link: https://www.who.int/universal-health-coverage/compendium/database

by categorizing the economic consequences of abortion and abortion policies through three levels: micro-, meso- and macroeconomic. Assessment of the micro-, meso- and macroeconomic levels provided insight into the documented economic consequences of abortions at the individual, community and health system levels *(80-82)*.

Cost to the facility or health system

In regard to costs to the health-care facility and health system, the findings of the review on the mesoeconomic outcomes confirmed that limited resources negatively affect facilities' ability to meet demand and provide quality services *(81)*. Furthermore, the costs of post-abortion care, including treatment of post-abortion complications, consume a disproportionate amount of facilities' resources in many settings, posing a burden to health systems by further depleting their overstretched resources. Therefore, financial savings can be made by maintaining or even improving the quality of abortion care services, and also by decentralizing services and legalizing abortion, as indicated in the macroeconomic assessment *(82)*.

Providing access to quality abortion care is considerably less costly than treating the complications of unsafe abortion *(83-87)*. Costs for providing abortion care with vacuum aspiration include infrequent, modest capital investments, such as purchase of a suction machine for electric vacuum aspiration (EVA) or manual vacuum aspiration (MVA) equipment, an examination table, a steam sterilizer or autoclave, and possibly also renovation of waiting, consultation and recovery rooms, and toilets. Recurrent costs for surgical or medical abortion include those associated with purchasing instruments and supplies that will need to be restocked regularly, such as cannulae and MVA aspirators, antiseptic solutions and high-level disinfectants used for instrument processing, and medicines for pain management, infection prevention and medical abortion.

Decisions about which abortion methods to offer and how to organize services directly influence the cost of providing services and their affordability. Two organizational issues are of particular importance for both increasing safety and reducing costs: (i) preferential use of either vacuum aspiration or medical abortion, and (ii) facilitating the provision of abortion (e.g. improved access to abortion services, integration into primary health care). Expanding the role of health workers in abortion provision and exploring innovative modes of service-delivery, such as telemedicine and hotlines, have also been identified as cost-saving strategies for national health systems *(82)*.

Making services affordable for women

In countries where legal access to abortion is available, it remains a challenge to provide abortion services that are publicly funded and free at the point of care *(88)*. Furthermore, in some settings, financial protection is restricted to specific demographic groups of individuals seeking abortion or certain legal categories of abortion. Abortion seekers may be charged substantial additional fees (on top of the official charges), creating a barrier for many, especially when combined with travel expenses and opportunity costs, such as time lost from paid and unpaid work. In some settings, reimbursement rates for private or public providers working with nongovernmental organizations are well below the cost of providing care. The barrier of high costs of abortion medicines and/or services is likely to generate higher costs for the health system, since these costs force many – especially among the adolescent population *(89)* – to present at a later gestational age or to use unsafe providers or methods, thus increasing the rates of hospitalization for serious complications *(80, 90-92)*. Higher rates of complications, additional fees and high costs all also contribute to the stigmatization of abortion.

Respect, protection and fulfilment of the right to health requires States to guarantee, at a minimum, universal and equitable access to affordable, acceptable and quality SRH services, goods and facilities, in particular for women and disadvantaged and marginalized groups *(3, para. 49)*. Thus, in order to provide an enabling environment for abortion care, ability to pay should not have any bearing on women's ability to access legal abortion services *(3 [para. 17], 35 [para. 31], 39 [Ch.1, para. 21])*.

As part of an enabling environment, considerations of gender equality, human rights and equity should guide the design of health financing policy to reduce if not eliminate the financial barriers for the most vulnerable, and to ensure equitable access to good-quality services *(93)*. The CEDAW Committee has described fees for abortion as being burdensome to women's informed choice and autonomy *(94, para. 37)*. Where user fees are charged for abortion, this should be based on careful consideration of ability to pay, and fee waivers should be available for those who are facing financial hardship and adolescent abortion seekers. It should be noted, however, that evidence on the success of fee waivers in addressing financial barriers and improving access to quality

abortion care is mixed and inconclusive *(95)*. Numerous treaty monitoring bodies (see Annex 2) have recognized that abortion services must be economically accessible, recommending that States lower the cost of abortion or otherwise provide financial support when needed *(96 [paras 37(b), 38(b)], 97 [para. 24], 98 [paras 38, 39])*. Relatedly, the Committee against Torture (CAT) has called on States to ensure free access to abortion in cases of rape *(99, para. 15a)*. With the above in mind, as far as possible, abortion services and supplies should be mandated for coverage under insurance plans as inability to pay is not an acceptable reason to deny or delay abortion care. Furthermore, having transparent procedures in all health-care facilities can ensure that informal charges are not imposed by staff.

1.4.3 Health workforce competencies and training

Health workers are all people engaged in actions whose primary intent is to enhance health *(100)*. The delivery of high-quality care requires an adequate supply of competent health workers, who are equitably distributed, and with an optimal skills mix at the facility, outreach and community levels *(101)*. All health workers need to be adequately supported to provide competent care. The competencies required to provide or support abortion care align with competencies required in many different areas of health *(102, 103)*. WHO is currently developing a global competency framework for universal health coverage (UHC), which identifies the required competencies for primary health care workers to provide the full spectrum of promotive, preventive, diagnostic, curative and palliative care *(104, 105)*.

Delivery of care and treatment services should be accomplished in a people-centred, non-judgemental and non-directive way, allowing individuals to lead the decision-making about their own care in an informed and supported fashion *(106)*. As part of ensuring an enabling environment, it is particularly important that training for health workers involved with SRH services incorporates:

- the unique competencies required for SRH services, in particular for abortion care;
- provision of people-centred care;
- human rights, and the content and meaning of the law, and how to interpret and apply law and policy in rights-compliant ways;
- communication to enable informed decision-making;
- values clarification;
- interprofessional teamworking; and
- empathetic and compassionate approaches to care *(105)*.

These skills should be included in training programmes and promoted by professional societies. It is especially critical that the attitudes and behaviours of health workers be inclusive, non-judgemental and non-stigmatizing, and that they promote safety and equality. Managers of health care – whether in the public or private sector – are responsible for delivering services appropriately and meeting standards based on professional ethics and internationally agreed human rights principles.

1.4.4 Commodities

Provision of primary health care includes access to safe, effective, quality-assured and affordable medicines, including medicines for abortion and post-abortion care (i.e. antibiotics and pain control medicines as well as abortion medicines and post-abortion contraceptives).

The WHO Model List of Essential Medicines (also known as the Essential Medicines List, or EML) includes the minimum medicines needed for a basic health-care system, listing the most efficacious, safe and cost-effective medicines for priority conditions. Priority conditions are selected based on current and estimated future public health relevance, and potential for safe and cost-effective treatment. Both mifepristone and misoprostol have been included in the WHO Model Lists of Essential Medicines since 2005. In 2019, these medicines were moved from the complementary to the core list of essential medicines in the 21st EML and the requirement for “close medical supervision” for their use was removed *(107)*. The relevant abortion medicines included in the 21st EML and also the more recent 22nd EML are indicated in Table 1.1.

Table 1.1 Medicines included in the WHO Model List of Essential Medicines (EML) and their indications

Indication included in EML	Medicines included in the EML
Induced abortion	• Mifepristone (200 mg) and misoprostol (200 µg) • The medicines are available individually or co-packaged. • The EML specifically mentions the following co-packaged formulation: 1 tablet mifepristone (200 mg) + 4 tablets misoprostol (200 µg).
Management of incomplete abortion and miscarriage	• Misoprostol (200 µg)

Source: WHO EML – 21st list, 2019 *(107)*, 22nd list, 2021 *(108)*.

Within a country, the key elements of a commodity strategy include policy, regulation, procurement and supply chain, as well as links to financing and reimbursement systems *(109)*.

Mifepristone and misoprostol should be listed in relevant national EMLs (NEMLs) or their equivalent, and should be included in the relevant clinical care/service delivery guidelines. In the case of pregnancy tests and MVA equipment, countries may have an Essential Medical Devices List or a similar list for medical devices. Pregnancy tests and quality MVA devices should be included on these lists as part of a commodity strategy.

Inclusion in the NEML is one important component of ensuring that quality medicines are available. Misoprostol, mifepristone, surgical abortion equipment and other relevant health products should be included in national procurement tenders as well as in supply chain monitoring activities. Procurement activities should include forecasting methods that are appropriate to the products and to the country context with a goal of ensuring continuous supply *(110)*. Central Medical Stores (CMS) entities should ensure that specifications for the procurement of safe abortion medicines are coordinated with national medicines regulatory authorities (NMRAs) and that they clearly specify quality assurance standards and all other requirements, such as strength, packaging and shelf life.

WHO recommends that the highest level of quality assurance be pursued but recognizes that risk-based approaches may be needed in countries where access to international markets is limited. Risk-based approaches will depend on the context of a given country but may include exceptions based on prior information about a manufacturer, or reliance on information from other regulators *(111)*. Quality-assured medicines include those approved by stringent regulatory authorities (SRAs) *(112)*[4] or listed through WHO Prequalification (PQ).[5] Where such medicines are not available, approval by an NMRA that includes inspection and testing according to accepted standards should be undertaken for mifepristone and misoprostol.[6]

NMRAs are the bodies that provide registration and market authorization for specific products. The NMRA reviews the safety, efficacy and quality of medicines as part of granting market authorization. Such authorization is specific to each medicine made in a particular location by a particular manufacturer. Market authorizations are granted based on an evaluation of a technical dossier presented by the manufacturer, or their agent, confirming the efficacy, quality and safety of the product. Through prequalification, WHO supports a regulatory reliance mechanism where it provides detailed assessment information to NMRAs on products that have been prequalified by WHO, so that the regulatory decision can be made based on WHO's assessment rather than having to duplicate it. Based on the same principle, WHO also supports the sharing of assessment information for SRA-approved products. These processes are both known as WHO Collaborative Registration Procedures (CRPs).[7]

Regulators make determinations regarding the authority to prescribe and dispense medicines. There are examples, including emergency contraception, where regulators have made decisions to change the prescribing authority to improve access and appropriate use, including "over the counter" sales or prescription by a pharmacist without physician consultation. The information that is typically considered includes whether a condition can be reasonably self-diagnosed, the overall safety of the medicine, and the likelihood of misuse

4 SRAs are listed at this web page: https://www.who.int/initiatives/who-listed-authority-reg-authorities/SRAs. In the cited reference (pp. 34–35), SRAs are defined as "a regulatory authority which is a member or an observer of ICH [International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use], or is associated with an ICH member through a legally-binding mutual recognition agreement" (as before 23 October 2015).

5 WHO Prequalification is one standard for all types of products, including medicines (pharmaceuticals and biotherapeutics), vaccines and immunization devices, in vitro diagnostics and vector control products. This listing implies a recommendation but not market authorization.

6 For further information, refer to The International Pharmacopoeia, available at: https://digicollections.net/phint/2020/index.html#p/home

7 For further information, see: https://extranet.who.int/pqweb/medicines/collaborative-procedure-accelerated-registration

or complications with less supervised or unsupervised use of the medicine, among others *(113, 114)*. National programmes should work with regulators to determine the most appropriate evidence-based prescribing and dispensing authorities for the medicines. Restrictions on prescribing authority for some categories of health workers may need to be modified or other mechanisms put in place to make the medicines available for these health workers within the regulatory framework of the health system.

A comprehensive commodity strategy and effective approach to access will require: inclusion of the necessary commodities in the NEML; approval from the NMRA (i.e. market authorization or registration); development of mechanisms for forecasting, procurement, distribution and guidance on prescribing and dispensing; and a plan for post-marketing surveillance.

1.4.5 Monitoring and evaluation of quality abortion care

Effective monitoring and evaluation (M&E) are essential for measuring abortion quality and trends, as a basis for policy dialogue and evidence-based decision-making to further improve service delivery and quality. To support national scale M&E of the quality of abortion care, WHO is developing a quality abortion care M&E framework based on WHO's *Monitoring and evaluation of health systems strengthening: an operational framework (115).* The structure, domains and indicator areas of the framework, categories for inequality disaggregation and standard data sources are presented in Table 1.2. A set of abortion care indicators is under development and will be published in the near future (see Annex 6 for a summary about the progress of this M&E work).

The quality abortion care M&E framework will support M&E at the levels of health system input, service delivery, population outcome and impact. M&E of abortion-related services remains weak in most national health systems. Specific gaps in data collection and use must be identified and addressed.

Health system input monitoring covers governance, health financing, health workforce, health commodities and health information. Within these five categories, quality abortion care health system inputs to track over time include among others:

- Governance: clarification of the legal status of abortion, adherence of induced abortion protocols in national guidelines to global normative guidance (see also section 1.3.1[vii]);
- Financing: inclusion of health financing arrangements for abortion-related care in leading health benefits packages (see section 1.4.2);
- Health workforce: inclusion of competency-based induced abortion care (in line with global normative guidance) in national curricula for relevant categories of health workers (see section 1.4.3);
- Health commodities: inclusion in national essential medicines lists (NEMLs) of mifepristone and misoprostol, monitoring of stock-outs of abortion service commodities at service-delivery points (see section 1.4.4);
- Health management information systems (HMIS): integration of indicators for quality abortion care into the national HMIS.

For this level of input monitoring, data are typically available from administrative sources, including national policy documents, health finance tracking systems, national curricula, logistics management information systems (LMIS) and HMIS.

Service-delivery monitoring tracks the availability of providers trained in and providing induced abortion care, availability of necessary medicines and products at service-delivery points, readiness of the system to provide abortion care to a defined minimum standard, and quality of service delivery, including person-centred care, assessed in part through user and community perspectives. National-level abortion service-delivery monitoring data should be included in health-care facility-level assessments, HMIS and population-based surveys.

Population outcome monitoring for abortion care assesses coverage including (i) access to quality, affordable abortion care, and (ii) population knowledge of access to quality, affordable abortion care. Efforts should be made to disaggregate data by dimensions of inequality, such as ability, age, caste, education, ethnicity, gender, geography and wealth. Population outcome data sources typically include health-care facility-level assessments and population-based surveys and can include HMIS and education management information systems. In many settings, abortion-related population outcome data is a neglected area of data collection and reporting.

Impact measurement for quality abortion care includes abortion-related mortality and morbidity. Estimates in these areas should be disaggregated by dimensions of inequality as much as possible. Data sources include population-based surveys, HMIS and civil registration and vital statistics (CRVS) registries.

Where gaps in data availability are identified, investment should be made to address these. In the short term, statistical modelling may be required to estimate indicator values, particularly at the impact level.

Table 1.2 Monitoring and evaluation of the quality of abortion care

Categories	Indicator areas	Inequality disaggregation	Data sources
Health system input	Governance	Geography: intranational, international	Administrative sources (including national policy documents, health finance tracking systems, national curricula, LMIS and HMIS)
	Health financing		
	Health workforce		
	Health commodities		
	Health information		
Service delivery	Availability of services	Geography: intranational, international	Health-care facility assessment (including patient interviews), population-based survey, HMIS
	Readiness for service delivery		
	Quality of services		
Population outcome	Access to quality, affordable abortion care	Ability, age, caste, education, ethnicity, gender, geography, wealth	Health-care facility assessment, population-based survey, HMIS, education management information systems
	Population knowledge of access to quality, affordable abortion care		
Impact	Abortion-related mortality	Ability, age, caste, education, ethnicity, gender, geography, wealth	CRVS, HMIS, population-based survey
	Abortion-related morbidity		

CRVS: civil registration and vital statistics; HMIS: health management information system; LMIS: logistics management information system

Chapter 2.

Abortion regulation including relevant recommendations

As outlined in Chapter 1, section 1.3, one element of an enabling environment is that law and policy promote and protect sexual and reproductive health and rights (SRHR). A number of common approaches to law and policy on abortion mentioned in Chapter 1 (section 1.3.1) pose barriers to access to abortion, are inconsistent with international human rights legal instruments, and can have negative effects on the exercise of human rights. This chapter reflects evidence on the impacts of these law and policy approaches, considers their human rights implications, and presents evidence-based recommendations to improve law and policy relating to abortion as part of an enabling environment for universal access to quality abortion care. Box 2.1 summarizes the principles of abortion law and policy that would be consistent with key principles of human rights law.

BOX 2.1: Abortion law and policy that are consistent with key principles of human rights law

States must respect, protect and fulfil abortion seekers' rights, including their sexual and reproductive health and rights (SRHR).

States should take positive steps to secure an enabling regulatory and policy environment that will ensure the universal availability, accessibility, acceptability and quality (AAAQ) of abortion and post-abortion care.

Abortion should be fully decriminalized. Regulatory, policy and programmatic barriers – as well as barriers in practice – that hinder access to and timely provision of quality abortion care should be removed. These include grounds-based approaches, gestational age limits, mandatory waiting periods, third-party authorization requirements and provider restrictions. States should also protect access to and continuity of abortion care against barriers created by conscientious objection (refer to Recommendations 1,2,3,6,7,21 and 22 in this guidance).

The regulation of abortion should have the objective of respecting, protecting and fulfilling the SRHR of women; achieving positive health outcomes for women; providing good-quality contraceptive information and services; and meeting the particular needs of marginalized persons, including women facing financial hardship, adolescents, women with disabilities, survivors of sexual and gender-based violence, transgender and non-binary persons, women from ethnic, religious and racial minorities, migrant and displaced women, and women living with HIV, among others. The regulation of abortion should be grounded on and should promote equality and non-discrimination.

Source: Refer to Box 1.2 for references.

2.1 Common approaches to abortion regulation

Almost all countries where abortion is lawfully available regulate abortion differently to other forms of health care *(116)*. Unlike other essential health services, abortion is commonly regulated to varying degrees through the criminal law in addition to regulation under health-care law. Even where abortion is available on certain grounds or until specified gestational ages (often linked to particular grounds), it is usually designated in those cases as a criminal offence if it occurs outside of those specific permitted situations. As a result, people can experience significant barriers in accessing abortion and post-abortion care in such contexts. These barriers persist even though abortion is a safe, effective and non-complex part of sexual and reproductive health (SRH) care, in spite of significant advancements in international human rights law, and notwithstanding the growing frequency with which self-management of abortion occurs safely with little or no contact with the formal health system.

Typical barriers to access to quality abortion care, which may or may not be codified in law, include lack of access to accurate information, the provision of biased information or counselling, the imposition of mandatory waiting periods, third-party authorization requirements, restrictions on the type of facilities or settings where abortion services can lawfully be provided, restrictions on the type of health workers that can lawfully provide services, lack of affordable services, breaches of confidentiality and privacy, failure to safeguard access to and continuity of care where health workers refuse care on the basis of conscientious objection, failure to license or make available essential medicines, and failure to recognize women as individuals who can manage their own abortions.

Restrictive laws, policies and practices often have the effect of making health workers, health-care facilities, committees, ethics boards, police, courts or others the "gatekeepers" for access to quality abortion care by requiring them to determine whether someone "qualifies" for legal abortion. In many cases, this introduces delay in accessing abortion. Such gatekeepers are not always sufficiently informed about the law or willing to interpret and apply law and policy in a way that respects, protects and fulfils abortion seekers' rights. Criminalization of abortion can also have a "chilling effect" more broadly, as it can result in narrow interpretation of applicable law by health workers, including to avoid possible criminal liability (i.e. suppression of actions due to fear of reprisals or penalties). As a consequence, in many settings women's experiences of seeking, accessing and managing abortion are highly variable, with much depending not only on the law but also on the approach of the gatekeeper with whom they interact. Thus, including information on relevant rights, laws and policies in the training and education of health workers is a crucial part of ensuring an enabling environment for quality abortion care (see also Chapter 1, section 1.4.3).

As described above, clear, accessible and rights-based laws and policies are part of an enabling environment for abortion care (see section 1.3). However, in some countries the law on abortion is incoherent, with seemingly conflicting provisions articulated in constitutions, penal codes, health legislation or policy guidance *(117)*. Furthermore, in some cases domestic laws are inconsistent with international human rights standards and incompatible with current public health evidence. Additionally, in certain cases there is a lack of guidance from government to assist providers in identifying when abortion is lawful. Such incoherence can create uncertainty about the law for both those seeking and providing abortion care. The recommendations in this guideline build on human rights law and public health evidence to outline an approach under which abortion is regulated similarly to other health-care interventions, that is, by general health-care law and policy, best practice, training and evidence-based guidelines.

2.2 Recommendations relating to regulation of abortion

Three recommendations relating specifically to the regulation of abortion are presented in this section (Recommendations 1–3) and four additional recommendations, also relating to law and policy and abortion, are presented in Chapter 3, section 3.3: Pre-abortion (Recommendations 6,7,21 and 22). These seven recommendations were formulated by the expert panels formed for the development of this guideline, including expert human rights advisers (all contributors are listed in Annex 1 and the roles of the contributing groups are described in Annex 4).[8] The evidence was first systematically reviewed for each prioritized topic and question, and

8 The expert panels included the Evidence and Recommendations Review Groups (ERRGs) for each of the three domains (Law and policy, Clinical services and Service delivery) and later the Guideline Development Group (GDG), and each phase and each meeting of these groups also involved at least one human rights adviser. For further details on the roles of these groups and the full methodology for the guideline development process, see Annex 4: Methods.

the level of certainty of that evidence was assessed (i.e. based on the quality of the evidence, including the types and sizes of studies conducted and their various limitations).

The direction (in favour or against) and strength of each recommendation was determined by the panel of experts based on the six substantive criteria of the WHO-INTEGRATE framework as applied to each intervention for the specified population – balance of health benefits and harms; human rights and sociocultural acceptability; health equity, non-discrimination and equality; societal implications; financial and economic considerations; feasibility and health system considerations – while also taking into account the meta-criterion: quality of evidence *(118)*.

Recommendations in favour of an intervention are qualified as either strong or weak (with the conditions of use specified for the latter), with the third alternative being a recommendation against the intervention. To clearly indicate the strength and direction of each recommendation, the following wording is used:

- **Recommend** – a strong recommendation in favour of the intervention
- **Suggest** – a weak recommendation in favour of the intervention (requiring additional wording to qualify the recommendation, specifying the conditions of use)
- **Recommend against** – a strong recommendation against the intervention/in favour of the comparison.

For each topic covered, both in this chapter and also in Chapter 3, first brief background information is presented, then the recommendation itself, followed next by a list of remarks (if any) from the expert panel that reviewed the evidence in detail, explaining the conditions and context relevant to the recommendation, and then the rationale, or summary of the evidence base and decision-making process for the recommendation, and finally a box listing any key human rights considerations relevant to the recommendation or broader topic. It should be noted that the 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy; in this guideline, this has been developed into seven separate recommendations using GRADE methodology, but they are not considered to be "new" (i.e. Recommendations 1,2,3,6,7,21,22). The methods are described in full in Annex 4, including the differences in the methods applied for the seven recommendations relating to law and policy issues compared with the other types of recommendations. A summary table linking the topics covered, the research questions, the systematic reviews conducted and the recommendation numbers is provided in Annex 7. The full Evidence-to-Decision (EtD) frameworks are provided online as supplementary material and hyperlinked cross-references to these are supplied with the rationale for new and updated recommendation presented.[9]

9 Supplementary material 1: EtD frameworks for law and policy topics, available at: https://www.who.int/publications/i/item/9789240039483.

2.2.1 Criminalization of abortion

Unlike other health services, abortion is commonly regulated to varying degrees through the criminal law (i.e. criminalized), in addition to regulation under health-care law.

Abortion remains a criminal offence in most countries, with penalties against those who have abortions and/or those who provide abortion services or assist with accessing or managing abortion, sometimes including those who provide information about abortion. In some countries, all of these actions are criminal offences.

Decriminalization is a necessary step for the legalization of abortion, but ensuring that abortion is available, accessible and of high quality may require further legal or regulatory changes beyond decriminalization, including, as applicable, implementing the other recommendations contained in this guideline.

LAW & POLICY Recommendation 1: Criminalization

Recommend the full decriminalization of abortion.

Remarks:

- Decriminalization means removing abortion from all penal/criminal laws, not applying other criminal offences (e.g. murder, manslaughter) to abortion, and ensuring there are no criminal penalties for having, assisting with, providing information about, or providing abortion, for all relevant actors.
- Decriminalization would ensure that anyone who has experienced pregnancy loss does not come under suspicion of illegal abortion when they seek care.
- Decriminalization of abortion does not make women, girls or other pregnant persons vulnerable to forced or coerced abortion. Forced or coerced abortion would constitute serious assault as these are non-consensual interventions.

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

Numerous human rights bodies and mandate holders, including the CEDAW Committee *(38)*, the CESCR *(3)*, the United Nations Human Rights Committee *(36)*, and the Special Rapporteur on the right of everyone to the enjoyment of the highest attainable standard of physical and mental health *(37)*, support the full decriminalization of abortion. They have clarified that States should not criminalize medical procedures needed only by women, including abortion nor criminalize those who have undergone an abortion, or punish or apply criminal sanctions against those who assist women in having abortions. Under international human rights law, States must not require health workers to report cases of women or girls who have had abortions, or whom they suspect of having had abortions, and States must provide post-abortion care in all circumstances and without the risk of criminal sanction. In addition, States must take steps, including revising laws, to reduce maternal morbidity and mortality (including abortion-related morbidity and mortality), and to effectively protect women and girls from the physical and mental risks associated with resorting to unsafe abortion due to the criminalization of abortion (see also Chapter 1, section 1.3.1 on human rights, and Web annex A: Key international human rights standards on abortion, which provides further information as well as references for the above assertions).

In order to identify the impacts of criminalization of abortion on abortion seekers and health workers, a systematic review of studies published between 2010 and 2019 was undertaken, identifying 22 studies conducted in Australia, Brazil, Chile, El Salvador, Ethiopia, Ireland, Mexico, Northern Ireland (United Kingdom), the Philippines, Rwanda, Senegal, the United Republic of Tanzania, Uruguay and Zambia. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Criminalization. The evidence from these studies demonstrated that criminalization delayed access to abortion, including in some cases causing providers to wait until a woman's life was in danger so that abortion could be provided within the legal exceptions to criminal prohibitions. Furthermore, criminalization imposes a range of burdens on women including unnecessary travel and cost, delayed or no access to post-abortion care, distress and stigma. The evidence indicated that criminalization did not impact the decision to have an abortion, prevent women having abortions, or prevent women from seeking information on and referral to services abroad where they can access abortion. Instead, criminalization limits

access to safe and legal abortion, and increases recourse to unlawful and unsafe abortion. When prosecutions take place they may be disproportionately pursued against young, unmarried women and those facing financial hardship and with less access to education. Some countries require health workers to report women and girls when they seek abortion or post-abortion care.

Criminalization can cause health workers to act cautiously, fearing criminal prosecution. As a result, they may be hesitant to provide abortion care even in cases of rape, incest and fatal fetal impairment, when denial of abortion could constitute torture, cruel and inhuman treatment or punishment.

Criminalization contributes to the lower availability of trained abortion providers and a loss of relevant skills in the health workforce. This can have negative effects on health workers who do provide abortion, and can increase bureaucracy within health systems.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO CRIMINALIZATION OF ABORTION

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health (SRH) services.
- Seeking, having, assisting with, or providing abortion to which the pregnant person has provided free and informed consent should never be criminalized.
- States must not require health workers to report cases of women or girls who have had abortions, or whom they suspect of having had abortions.
- Post-abortion care must always be available without the risk of criminal sanction.
- Seeking or providing accurate, evidence-based and non-biased information on abortion must never be criminalized.
- States must take steps, including revising laws, to reduce maternal morbidity and mortality, and to effectively protect women and girls from the physical and mental risks associated with resorting to unsafe abortion.
- Everyone has a right to non-discrimination and equality in accessing SRH services.
- SRH services must be provided in a way that ensures privacy and confidentiality.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

2.2.2 Grounds-based approaches to controlling access to abortion

National laws in most countries permit some abortions, even in settings where abortion is criminalized. Usually abortions will still be permitted under prescribed "grounds", or specific circumstances. The circumstances under which abortion is permitted vary widely across different countries. Some of these circumstances reflect clinical indications (e.g. risk to the health of the pregnant woman or fetal impairment), some relate to the circumstances of conception (e.g. rape), and some relate to socioeconomic circumstances (e.g. economic hardship). Grounds-based approaches are commonly accompanied by gestational age limits, often varying depending on the specific condition under which abortion is permitted. In some countries, abortion is available on request up to a specified gestational age and then limited to specific grounds thereafter.

LAW & POLICY Recommendation 2: Grounds-based approaches

a. Recommend against laws and other regulations that restrict abortion by grounds.

b. Recommend that abortion be available on the request of the woman, girl or other pregnant person.

Remarks:

- Grounds-based approaches to restricting access to abortion should be revised in favour of making abortion available on the request of the woman, girl or other pregnant person.
- Until they are replaced with abortion on request, any existing grounds should be formulated and applied in a manner consistent with international human rights law. This means that the content, interpretation and application of grounds-based law and policy should be revised to ensure human rights compliance. This requires that:
  i. existing grounds are defined, interpreted and applied in a human rights-compliant way;
  ii. abortion is available when carrying a pregnancy to term would cause the woman, girl or other pregnant person substantial pain or suffering, including but not limited to situations where the pregnancy is the result of rape or incest or the pregnancy is not viable;
  iii. abortion is available where the life and health of the woman, girl or other pregnant person is at risk;
  iv. health grounds reflect WHO's definitions of health and mental health (see Glossary); and
  v. there are no procedural requirements to "prove" or "establish" satisfaction of grounds, such as requiring judicial orders or police reports in cases of rape or sexual assault (for sources to support this information, refer to Web annex A: Key international human rights standards on abortion).

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

International human rights law requires that abortion be available where carrying a pregnancy to term would cause a woman substantial pain or suffering, or where her life or health is at risk. States may not regulate abortion in a manner that forces women to resort to unsafe abortion and must take steps, including revising laws, to reduce maternal morbidity and mortality, and to effectively protect women and girls from the physical and mental risks associated with unsafe abortion (for further information, please refer to Chapter 1, section 1.3.1[i] and Web annex A: Key international human rights standards on abortion). Grounds-based approaches are often (i) too narrowly defined or (ii) too conservatively applied to ensure abortion is available in these circumstances. The aim to reduce maternal morbidity and mortality, and protect women and girls from the risks associated with unsafe abortion, can be effectively achieved by making abortion available on the request of the pregnant woman or girl.

In order to identify the impacts of grounds-based approaches on abortion seekers and health workers, a systematic review of studies published between 2010 and 2021 was undertaken, identifying 21 studies conducted in Argentina, Australia, Brazil, Chile, Colombia, Ethiopia, Ghana, the Islamic Republic of Iran, Ireland, Israel, Mexico, Rwanda, Thailand, the United Republic of Tanzania, the United Kingdom of Great Britain and Northern Ireland, Uruguay and Zambia. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Grounds-based approaches. The reviewed evidence showed that grounds-based laws contributed to delayed abortion, with delays occurring because of inconsistencies in interpretation or application of health grounds, women waiting for determination of their eligibility for abortion or having their claim that pregnancy resulted from rape

questioned or disbelieved, overly restrictive interpretation of grounds, or disagreement within a medical team about whether a woman satisfies a legal ground. Misinterpretation of the law can also result in denial of abortion. In some cases, health workers waited for a health condition to deteriorate sufficiently to ensure that a woman satisfied a "risk to life" ground, clearly endangering the right to life and potentially violating the right to be free from torture, cruel, inhuman and degrading treatment.

Interpretation of grounds, and thus eligibility for lawful abortion, varies between providers, and providers are not always certain about the law or how it should be applied; interpretation is often narrow and incompatible with human rights law and/or with WHO's definitions of health and mental health, leading to denial of abortion. Women reported significant challenges in accessing care in circumstances where they could not obtain legal support and advice on the permitted grounds. Grounds-based approaches were found to have a particularly negative impact on women facing financial hardship and women with lower educational attainment.

The evidence reviewed for this guidance showed that grounds-based approaches have a disproportionate negative impact on women who seek abortion following rape. These women were often subjected to questioning, protracted delay and bureaucratic processes due to requirements such as reporting the crime to the police or need for a court order, even though it is not human rights compliant to make such reporting or processes a prerequisite for accessing abortion. Even where the law provides that a woman's claim of rape is sufficient to satisfy the legal requirement, providers may require a document or authorization (e.g. court order or police report). In reality this means that obtaining an abortion following rape is laborious and time-consuming. In some cases, delays are so long that women give birth before legal eligibility is determined; in others, women choose instead to resort to unsafe abortion. Thus, "rape grounds" do not satisfy the requirement from international human rights law that abortion be available and accessible in situations of rape. These restrictions also subject the individual to unnecessary trauma, may put them at increased risk from the perpetrator, and may cause women to resort to unsafe abortion.

The evidence also showed that grounds-based approaches that require fetal impairments to be fatal for abortion to be lawful frustrate providers who wish to support patients and leave women no choice but to continue with pregnancy. Being required to continue with a pregnancy that causes significant distress violates numerous human rights. States are obligated to revise these laws to make them compatible with international human rights law.

Under international human rights law, States are required to ensure that women do not have to resort to unsafe abortion. The evidence from the studies described above suggests that grounds-based laws may contribute to an increase in the incidence of unsafe abortion, with people who do not satisfy a ground resorting to unlawful abortion, including unlawful self-management of abortion, some of which may be unsafe. The evidence from the studies also indirectly suggests that grounds-based laws contribute to maternal mortality, because when States shift from a grounds-based approach to permitting abortion on request in the first trimester there is a reduction in maternal mortality (especially for adolescents) as well as a reduction in fertility (birth rates). This suggests a connection between the international obligation to take steps to reduce maternal mortality and morbidity and a shift away from grounds-based approaches.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO GROUNDS-BASED APPROACHES

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health (SRH) services.
- Abortion must be available where carrying a pregnancy to full term would cause a woman substantial pain or suffering, where pregnancy is a result of rape or incest, or where her life or health is at risk.
- States may not regulate abortion in a manner that forces women to resort to unsafe abortion.
- States must take steps, including revising laws, to reduce maternal morbidity and mortality, and to effectively protect women and girls from the physical and mental risks associated with resorting to unsafe abortion.
- Everyone has a right to non-discrimination and equality in accessing SRH services.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

2.2.3 Gestational age limits

Gestational age limits are commonly specified in both liberal and restrictive abortion laws and policies. Imposed through formal law, institutional policy or personal practice by individual health workers, these limits restrict when lawful abortion may be accessed by reference to the gestational age of a pregnancy. In many countries gestational age limits are linked to grounds-based approaches, with gestational age limits varying according to the grounds or circumstances under which abortion is permitted. While methods of abortion may vary by gestational age (see Chapter 3, section 3.4), pregnancy can safely be ended regardless of gestational age. Gestational age limits are not evidence-based; they restrict when lawful abortion may be provided by any method.

International human rights law requires that quality of care be central to the provision and regulation of SRH, and thus that regulation of abortion is evidence-based, scientifically and medically appropriate, and up to date *(3, para. 21)*. Under international human rights law, States may not regulate pregnancy or abortion in a manner that is contrary to their duty to ensure that women and girls do not have to resort to unsafe abortion, and are required to revise their laws accordingly (see Web annex A: Key international human rights standards on abortion).

LAW & POLICY Recommendation 3: Gestational age limits

Recommend against laws and other regulations that prohibit abortion based on gestational age limits.

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

In order to identify the impacts of gestational age limits on abortion seekers and health workers, a systematic review of studies published between 2010 and 2020 was undertaken, identifying 21 studies conducted in Australia, Belgium, Mexico, Nepal, South Africa, the United Kingdom and the United States of America (USA). A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Gestational age limits. The reviewed evidence demonstrated that – alone or in combination with other regulatory requirements, including grounds-based approaches – gestational age limits delayed access to abortion, especially among women seeking abortions at later gestational ages, women close to the gestational age limit and those living in areas with limited access to clinics. Gestational age limits have been found to be associated with increased rates of maternal mortality and poor health outcomes. International human rights law requires States to reform law in order to prevent unsafe abortion and reduce maternal mortality and morbidity.

The studies also showed that where women requested an abortion and were denied care due to gestational age this could result in the unwanted continuation of pregnancy, especially among women with cognitive impairments or those who presented at 20 weeks' gestation or later. This outcome can be viewed as incompatible with the requirement in international human rights law to make abortion available when carrying a pregnancy to term would cause the woman substantial pain or suffering, regardless of pregnancy viability.

The evidence from these studies showed that women with cognitive impairments, adolescents, younger women, women living further from clinics, women who need to travel for abortion, women with lower educational attainment, women facing financial hardship and unemployed women were disproportionately impacted by gestational age limits. This points to the disproportionate impact of gestational age limits on certain groups of women, with implications for States' obligation to ensure non-discrimination and equality in provision of SRH services.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO GESTATIONAL AGE LIMITS

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health (SRH) services.
- States may not regulate abortion in a manner that forces women to resort to unsafe abortion.
- States must take steps, including revising laws, to reduce maternal morbidity and mortality, and to effectively protect women and girls from the physical and mental risks associated with resorting to unsafe abortion.
- Everyone has a right to non-discrimination and equality in accessing SRH services.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Chapter 3.
Recommendations and best practice statements across the continuum of abortion care

3.1 Background

As a standard approach to human rights-based health care, all norms, standards and clinical practice related to abortion should promote and protect:

- individuals' health and human rights
- informed and voluntary decision-making
- autonomy in decision-making
- non-discrimination (including intersectional discrimination) and equality
- confidentiality and privacy
- adequate referral mechanisms
- the continuum of care.

New and updated recommendations presented in this guideline were formulated by the expert panels formed for the development of this guideline, including expert human rights advisers (all contributors are listed in Annex 1, and the roles of the groups of contributors are described in Annex 4).[10] The evidence was first systematically reviewed for each prioritized topic and question, using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) methodology *(24, 119),* and the level of certainty of that evidence was assessed (i.e. based on the quality of the evidence, including the types and sizes of studies conducted and their various limitations).

The direction (in favour or against) and strength of each recommendation was determined by the panel of experts based on the six substantive criteria of the WHO-INTEGRATE framework as applied to each intervention for the specified population – balance of health benefits and harms; human rights and sociocultural acceptability; health equity, non-discrimination and equality; societal implications; financial and economic considerations; and feasibility and health system considerations – while also taking into account the meta-criterion: quality of evidence *(118)*. The methods are described in full in Annex 4, including the differences in the methods applied for the recommendations relating to law and policy issues (Recommendations 1,2,3,6,7,21,22) compared with the other types of recommendations. The full Evidence-to-Decision (EtD) frameworks are provided online as supplementary materials, and hyperlinked cross-references to these are supplied with the rationale for each new and updated recommendation presented.[11]

10 The expert panels included the Evidence and Recommendations Review Groups (ERRGs) for each of the three domains (Law and policy, Clinical services and Service delivery) and later the Guideline Development Group (GDG), and each phase and each meeting of these groups also involved at least one human rights adviser. For further details of the roles of these groups and the full methodology for the guideline development process, see Annex 4: Methods.

11 EtD frameworks for this guideline can be accessed online: Supplementary material 1: EtD frameworks for law and policy topics https://www.who.int/publications/i/item/9789240039483; Supplementary material 2: EtD frameworks for clinical service topics https://www.who.int/publications/i/item/9789240039483; Supplementary material 3: EtD frameworks for service delivery topics https://www.who.int/publications/i/item/9789240039483.

Recommendations in favour of an intervention are qualified as either strong or weak (with the conditions of use specified for the latter), with the third alternative being a recommendation against the intervention. To clearly indicate the strength and direction of each recommendation, the following wording is used:

- **Recommend** – a strong recommendation in favour of the intervention
- **Suggest** – a weak recommendation in favour of the intervention (requiring additional wording to qualify the recommendation, specifying the conditions of use)
- **Recommend against** – a strong recommendation against the intervention/in favour of the comparison.

New and updated recommendations resulted from the review of the PICO questions (i.e. population, intervention, comparator, outcomes) that had been identified during the scoping meetings for this guideline. While 10 recommendations in this guideline are completely "new" (as labelled in the Executive summary table and in this chapter), updated recommendations are those that had been published in prior WHO guidance but had undergone an updated process of scoping, search and review of relevant evidence, application of the GRADE methodology and reconsideration of the WHO-INTEGRATE criteria for the purposes of this guideline, which may or may not have resulted in any substantive change to the strength, direction or substance of the recommendation *(19, 23, 120)*. Finally, there are some existing recommendations that are carried forward unchanged from previous WHO guidance;[12] in these cases, the topic had not been scoped prior to the development of this guideline and thus no new search or review was conducted or, in some cases, an updated literature search *was* conducted to review the current evidence base but did not lead to any change in the existing recommendation. In particular it should be noted that the 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy; in this guideline, this has been developed into seven separate recommendations using GRADE methodology, but they are not considered to be "new" (i.e. Recommendations 1,2,3,6,7,21,22). A summary table linking the topics covered, the research/PICO questions, the systematic reviews conducted and the recommendation numbers is provided in Annex 7.

3.1.1 Structure of information in this chapter

The information and recommendations in this chapter are presented in sections that reflect the continuum of abortion care and modes of service delivery: (i) services applicable across the continuum of care, (ii) pre-abortion, (iii) abortion, (iv) post-abortion, (v) service-delivery options and self-management approaches. In each section, the following aspects are covered as appropriate: "what" (specific clinical interventions), "who" (which type of health worker can provide the intervention, or self-management), "where" (facility-based versus off-site/ remote service-delivery models/no requirement for on-site versus off-site location), and "how" (service-delivery models, implementation considerations). It should be noted that four recommendations relating to law and policy considerations are presented in the pre-abortion section (section 3.3), while three were presented in Chapter 2, section 2.2.

For each topic covered in this chapter, brief background information is first supplied, followed by the recommendation boxes or tables, providing information on the "what" and the "who" for the intervention in question. Each recommendation is immediately followed by a list of related remarks (if any) from the expert panel that reviewed the evidence in detail, explaining the conditions and context in which the recommendation applies. When appropriate, there is also a section indicating where the intervention can be carried out – in particular whether the intervention must be undertaken at a particular level of health-care facility, or whether there is no such requirement and an "off-site" location (e.g. at home, or other location) would be appropriate if preferred by the individual or if that is the only option available (the "where" is often closely tied to the "who", e.g. tasks provided by pharmacists would be provided in a pharmacy). The remarks for existing unchanged recommendations are repeated from the original cited guidance where still relevant, including revisions as appropriate, based on the results of any relevant updated evidence reviews conducted.

12 Existing recommendations are presented exactly as in previous guidance or with wording updated to use the wording "recommend/ recommend against" for strong recommendations and "suggest" for weak recommendations (previously termed "conditional" recommendations), and reference is provided to the original guidance for further details.

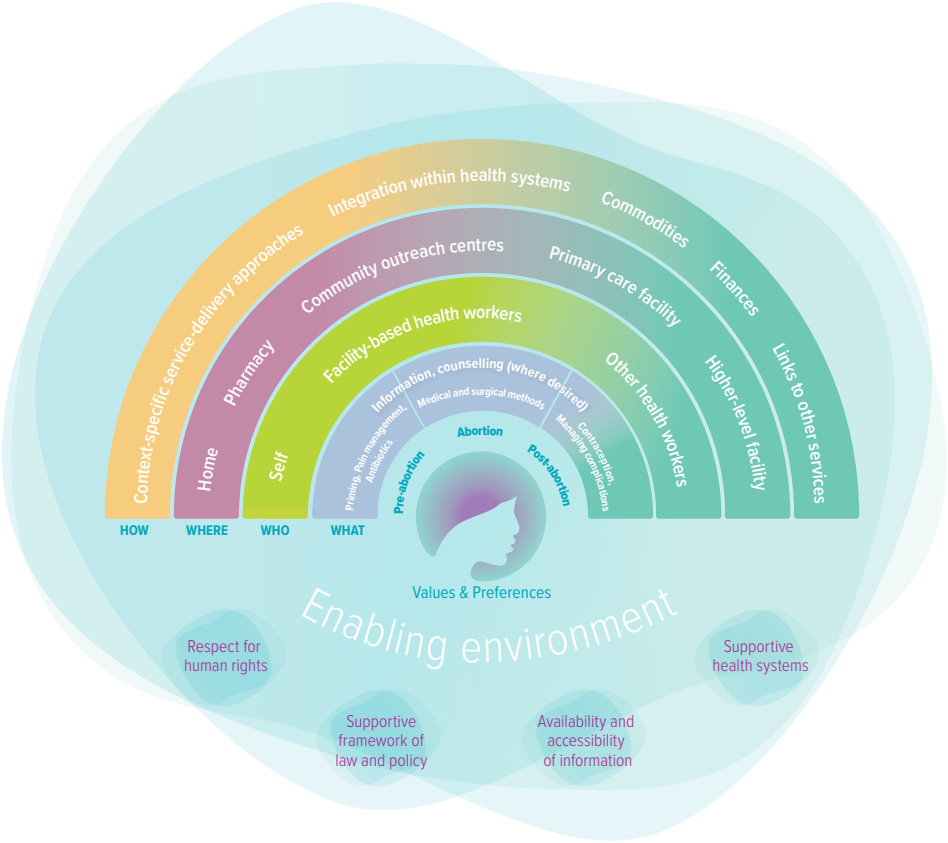
For each of the new/updated recommendations, additional information is presented in the following order after the box presenting the recommendation(s) and remarks:

i. Rationale: This includes a brief summary of the type and extent of the evidence included in the review(s) that form the evidence base, and an explanation of the rationale for the direction (for or against) and strength of the recommendation (strong or weak), with reference to the key judgements on effects of the intervention (benefits and risks), the level of certainty of the evidence and any relevant information on the other criteria of the WHO-INTEGRATE framework. Any additional evidence of potential harms or unintended consequences is highlighted. Such considerations may have been derived from studies and additional evidence that may not directly address the PICO question but provide pertinent information in the absence of direct evidence. This may be extracted from single studies, systematic reviews or other relevant sources.

ii. Implementation considerations: Points to bear in mind regarding implementation, including those relating to "how".

Finally, in each topic section, a box is presented listing any key human rights considerations relevant to the recommendation or broader topic, as well as a box providing cross-references and hyperlinks to related topics within this guideline.

Full details for all related PICO questions can be found in Annexes 8, 9 and 10, and the summaries of the evidence (i.e. from the systematic reviews; listed in Annex 7) and the EtD frameworks relevant to each new or updated recommendation are made available online as supplementary material.



3.1.2 Underlying principles and assumptions relating to recommendations on health worker roles

Health workers are all people engaged in actions whose primary intent is to enhance health *(100)*. This includes all categories of health workers listed and described in Annex 5, from community health workers all the way through to specialist medical practitioners (e.g. obstetricians and gynaecologists), and including traditional and complementary medicine professionals (i.e. non-allopathic physicians). Abortions can be done safely using tablets (medical abortion) or a simple outpatient procedure, such that most no longer require a specialist or even a general practice doctor. The recommendations presented in this guideline provide guidance on how to involve a wider range of health workers and pregnant individuals themselves in the provision or self-management of abortion care, to encourage optimization of the available health workforce, address health system shortages of specialized health-care professionals, reduce costs and improve affordability, improve equity and equality in access to health care and increase the acceptability of health services for those who need them.

The following principles and assumptions apply to all health workers:

- The recommendations are appropriate for and intended for all resource settings, i.e. high-, middle- and low-resource settings.
- The recommendations refer to a range of types of health workers who can safely, effectively and satisfactorily perform some or all of the specific abortion-related tasks mentioned. The options for who can perform the same task are intended to be inclusive and do not imply either a preference for or an exclusion of any particular type of health worker. The choice of health worker for a specific task will depend upon the needs, preferences and conditions of the individual, and the local context.
- Training of health workers must ensure that they have the competencies to provide good-quality, gender-sensitive care in accordance with national standards and guidelines and human rights. Ensuring quality abortion care requires ongoing supervision, quality assurance, monitoring and evaluation, as well as access to the necessary equipment and commodities.
- It is assumed that any health worker discussed in this guideline has the basic training required of that type of health worker (and in the case of individuals acting as their own provider – i.e. self-management – that they have the appropriate information and understanding). In addition, the recommendations all assume that health workers who are in a category that is recommended or suggested to perform specific tasks will have received the appropriate task-specific training and information prior to performing that task.

3.2 Services applicable across the continuum of care

This section covers information, counselling and linkage to additional care or services, any or all of which may be needed or desired before, during and/or after the abortion procedure or process.

The provision of scientifically accurate and easy-to-understand information to all women undergoing an abortion, and non-directive voluntary counselling to anyone who requests it, is a core element of good-quality, human rights-compliant abortion services (see Chapter 1, section 1.3.2). The provision of information and counselling (where desired), as well as access or referrals to other related services, starts pre-abortion but should continue across the continuum of care. In addition, everyone should be provided with all the necessary information to make an informed decision regarding the use of contraception.

What

3.2.1 Providing information

Abortion-related information for individuals considering or seeking abortion or in the post-abortion period should include:

- the available options for abortion methods and pain management;
- information related to free and informed consent;
- what will occur before, during and after the abortion procedure or process, including any tests and/or pain relief that may be needed and any aspects of the care that could be self-managed if desired, with or without remote support;
- what the individual is likely to experience during and after the abortion procedure or process, and how long the procedure/process and the recovery are likely to take;

- when normal activities can be resumed, including sexual intercourse;
- how to recognize potential side-effects and symptoms of ongoing pregnancy (which may persist temporarily even when abortion has been successful, or which may indicate failure of the abortion), and other medical reasons to return for follow-up care, including complications such as prolonged heavy bleeding or fever; and
- when, where and how to access follow-up care or additional services that may be desired such as counselling (section 3.2.2), contraception (see section 3.5.4) and other services (section 3.2.3).

Who

SERVICE DELIVERY Recommendation 4: Provision of information on abortion care

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Recommend**	Provision of health promotion interventions by CHWs is generally well accepted and feasible in many contexts where there is a strong CHW programme (moderate-certainty evidence). The potential to expand equitable access to information and quality abortion care by equipping CHWs to provide essential information on abortion is high.
Pharmacy workers	**Suggest** Condition: In contexts where the pharmacy worker is under the direct supervision of a pharmacist and there is access or referral to appropriate health services.	Insufficient direct evidence was found for the safety, effectiveness and acceptability of this option. However, in many contexts, pharmacy workers are often consulted by women seeking advice on how to deal with delayed menstruation (moderate-certainty evidence). Although the effectiveness of training interventions with pharmacy workers is uncertain, the potential benefits of equipping them to provide essential information outweighs the potential harms of them not providing information or providing incorrect information.
Pharmacists	**Recommend**	Pharmacists are qualified to provide information about the medicines they dispense. Evidence was found for the effectiveness of provision of education and counselling on chronic illnesses by pharmacists (low to moderate certainty). In many contexts, pharmacists are often consulted by women seeking advice on how to deal with delayed menstruation (moderate-certainty evidence).
Traditional and complementary medicine professionals **Auxiliary nurses/auxiliary nurse midwives (ANMs)** **Nurses** **Midwives** **Associate/advanced associate clinicians** **Generalist medical practitioners** **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to pharmacy workers was reviewed using GRADE methodology, since that was the only category of health worker that didn't already have a strong recommendation ("recommend") for this task. After review, no change was made to the existing weak recommendation ("suggest"). A summary of the evidence is presented in Supplementary material 3, EtD framework on Information provision by pharmacy workers.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

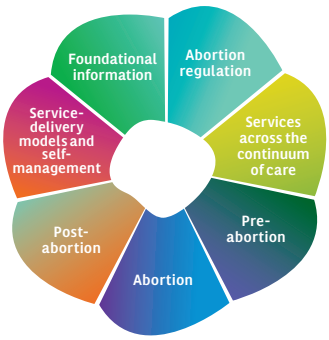
[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

There is no requirement for location (on-site vs off-site), but privacy and confidentiality should be ensured during the provision of information, with particular attention needed to this requirement in the off-site (out-of-facility) settings, such as pharmacies and community-based sites, where infrastructure and procedures may make this more challenging.

How

Implementation considerations



- Different modalities exist for the provision of information on abortion, e.g. remote access via hotlines and telemedicine, and through approaches such as harm reduction and community-based outreach (see section 3.6) as well as in-person interactions with health workers.
- Information should be accessible and understandable, including formats catering to low-literacy and differently abled populations.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO THE PROVISION OF INFORMATION

- Informed consent requires the provision of complete and accurate, evidence-based information.
- Accurate information on abortion must be available to individuals in a way that respects privacy and confidentiality.
- The right to refuse such information when offered must be respected.
- Abortion information should be available to all persons without the consent or authorization of a third party. This includes abortion information being available to adolescents without the consent or authorization of a parent, guardian or other authority.
- Information must be non-discriminatory and non-biased and presented in a respectful manner. It should not fuel stigma or discrimination.
- Dissemination of misinformation, withholding of information and censorship should be prohibited.
- Information should be acceptable to the person receiving it and of high quality; it should be presented in a way that can be understood and it must be accurate and evidence based.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations related to law and policy (Recommendations 1,2,3,6,7,21,22)

Informed consent (section 1.3.1: Human rights)

Availability and accessibility of information (section 1.3.2)

What

3.2.2 Offering and providing counselling

Some individuals may wish to receive counselling before or after an abortion. Counselling is more than information provision. It is a focused, interactive process through which a person voluntarily receives support, information and non-directive guidance from a trained person *(122)*, in an environment that is conducive to openly sharing thoughts, feelings, perceptions and personal experiences. In addition to the specific knowledge about abortion services and care required for both information provision and counselling, the latter also requires specialized counselling training. Counselling is a core element of provision of abortion and post-abortion care.

When offering and providing counselling, it is essential to apply the following guiding principles:

- ensure that the individual is requesting the counselling and make it clear that counselling is not required;
- ensure privacy and confidentiality;
- ask the individual what they want or need, what their concerns are, given them the time they need, and actively listen to their expressed needs and preferences;
- highlight relevant information during the counselling session (such as the information provided in section 3.2.1);
- communicate information respectfully and non-judgementally, and in a manner understandable to/tailored to the individual;
- support the individual and check to ensure they receive adequate responses to their questions and that they understand the information provided;
- present all suitable options tailored to individual's needs, while avoiding imposing one's personal values and beliefs onto them; and
- make it clear that the individual will need to decide what services to receive.

Who

SERVICE DELIVERY Recommendation 5: Provision of counselling

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Recommend**	Insufficient direct evidence was found for the safety, effectiveness or acceptability of this option, but indirect evidence did show that health promotion interventions by CHWs are generally well accepted, effective and feasible in many contexts, and that CHWs are often intermediaries between the health system and women seeking abortion-related care (moderate-certainty evidence). The expert panel affirmed the feasibility of this option and its ability to expand equitable access to quality abortion care.
Pharmacy workers	**Suggest** Condition: Balanced counselling is provided (i.e. about both medical and surgical methods) and there is access or referral to appropriate health services should the woman choose a surgical method.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed the feasibility of this option and its ability to expand equitable access to quality abortion care.
Pharmacists	**Suggest** Condition: Balanced counselling is provided (i.e. about both medical and surgical methods) and there is access or referral to appropriate health services should the woman choose a surgical method.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.a Pharmacists are qualified to provide information about the medicines they dispense. There is evidence for the effectiveness of provision of counselling on the management of chronic illnesses by pharmacists (low certainty evidence). In many contexts, pharmacists are often consulted by women seeking advice on how to deal with delayed menstruation (moderate-certainty evidence). Pharmacists have been recommended to provide medical abortion at < 12 weeks across all three subtasks (Recommendation 28). Therefore, the expert panel affirmed that it is feasible for pharmacists to provide balanced counselling on abortion, including surgical options.
Traditional and complementary medicine professionals	**Recommend**	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a]
Auxiliary nurses/ANMs **Nurses**	**Recommend**	Counselling is a core competency for these health workers[a] and this task is within their typical scope of practice.[b]
Midwives	**Recommend**	Counselling is a core competency for midwives[a] and this task is within their typical scope of practice.[b]
Associate/advanced associate clinicians	**Recommend**	Counselling is a core competency for these clinicians[a] and this task is within their typical scope of practice.[b]
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals, pharmacists, pharmacy workers and community health workers was reviewed using GRADE methodology, since the other health workers already had a strong recommendation for this task. After review, the recommendations were upgraded for all four of those health worker categories, from "recommend against" to "suggest" for pharmacists and pharmacy workers, and from "suggest" to "recommend" for traditional and complementary medicine professionals and CHWs. A summary of the evidence is presented in Supplementary material 3, EtD framework on Pre- and post-abortion counselling.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

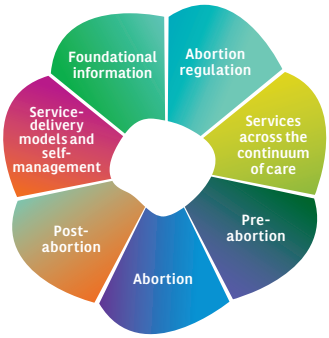
[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

There is no requirement for location (on-site vs off-site), but privacy and confidentiality should be ensured during counselling, with particular attention needed to this requirement in the off-site (out-of-facility) settings, such as the pharmacies and community-based sites, where infrastructure and procedures may make this more challenging.

How

Implementation considerations



- Counselling can be provided to those seeking abortion services but also jointly to their partners, family members or other individuals, should the woman wish them to be present.
- While counselling should be made available and accessible, it should always be voluntary for women to choose whether or not they want to receive it.
- Counselling should be person-centred and may need to be tailored according to the needs of the individual; young people, survivors of sexual and gender-based violence or members of marginalized groups may have different information or counselling requirements.
- The content of and approach to counselling will need to be adjusted depending on the reason for seeking abortion services (e.g. induced abortion, intrauterine fetal demise [IUFD], fetal anomaly). Therefore, it is important for the counsellor to be aware of and sensitive to the individual's situation and needs.
- Different service-delivery models exist for pre- and post-abortion counselling, e.g. remote access via hotlines and telemedicine and through approaches such as harm reduction counselling and community-based outreach.

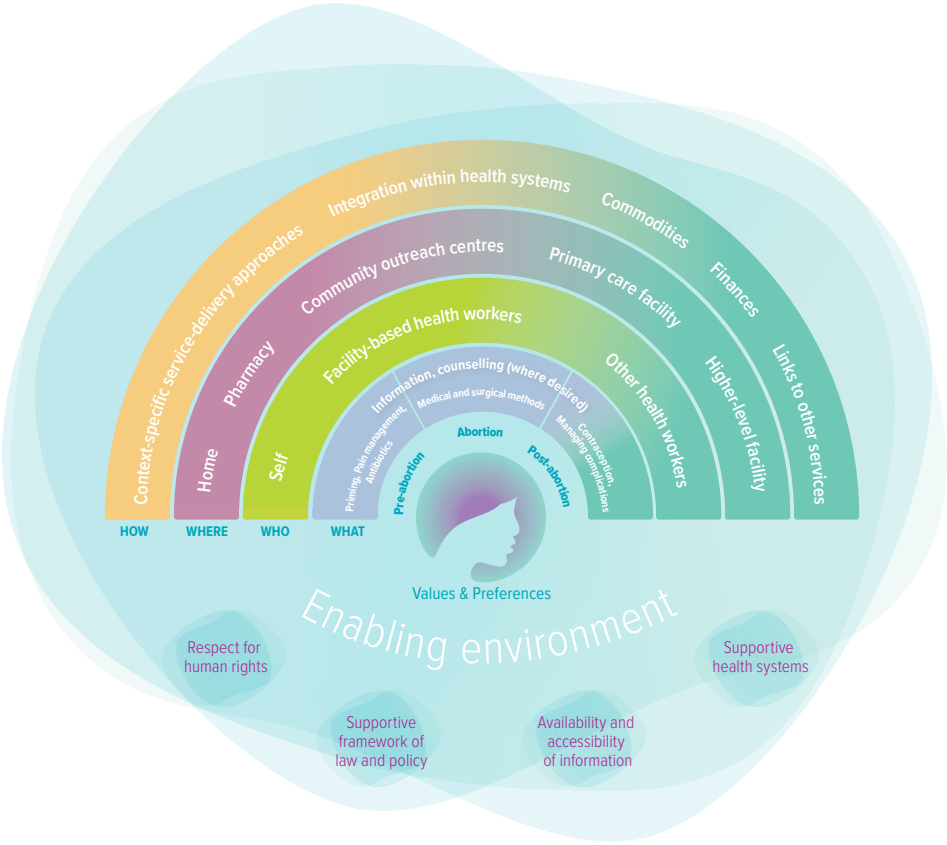
KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO COUNSELLING

- Counselling must be entered into freely and voluntarily, i.e. it should not be mandatory. The right to refuse counselling when offered must be respected.
- Where provided, counselling must be available to individuals in a way that respects privacy and confidentiality.
- Counselling must be acceptable and of good quality, i.e. it must be provided in a way that can be understood by the recipient and it must be accurate and evidence based.
- Counselling must be non-discriminatory and non-biased.
- Dissemination of misinformation, withholding of information, and censorship should be prohibited.
- Counselling should be available to all persons without the consent or authorization of a third party. This includes counselling being available to adolescents without the consent or authorization of a parent, guardian or other authority.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations related to law and policy (Recommendations 1,2,3,6,7,21,22)



Information provision (section 3.2.1)

Recommendations 41, 42 and 43 on post-abortion contraception

3.2.3 Links to additional services

Individuals seeking abortion may require additional services *(122)*. As needed, provide management or referral to other service providers for other health conditions or urgent needs. This includes facilitating linkages (access or referrals) to counselling and testing for sexually transmitted infections including HIV, contraception where desired, and support services for survivors of gender-based violence.

3.3 Pre-abortion

This section includes information and recommendations first on the issues of mandatory waiting periods and third-party authorization, followed by recommendations on Rh isoimmunization, antibiotic prophylaxis, determination of gestational age of pregnancy, pain management, and cervical priming prior to surgical abortion, and finally also recommendations on the issues of restrictions on health workers who can provide abortions and conscientious objection.

3.3.1 Mandatory waiting periods imposed by States, health-care facilities or health workers

In a number of countries, health-care facilities or health workers require women to wait a specified amount of time between requesting and receiving an abortion. These imposed delays are known as mandatory waiting periods. In some cases, women must also receive (sometimes biased) counselling or advice (see sections 3.2.1 and 3.2.2), attend the facility at the start and end of the waiting period, and/or undergo mandated ultrasound during these waiting periods (see section 3.3.5, Recommendation 10 on pre-abortion ultrasound).

LAW & POLICY Recommendation 6: Mandatory waiting periods

Recommend against mandatory waiting periods for abortion.

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

In order to identify the impacts of mandatory waiting periods on abortion seekers and health workers, a systematic review of studies published between 2010 and 2020 was undertaken, identifying 33 studies all conducted in the USA. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework on Mandatory waiting periods. The evidence reviewed showed that mandatory waiting periods delayed access to abortion, sometimes to the extent that women's access to abortion or choice of abortion method was restricted in that setting.

The evidence also indicates that mandatory waiting periods increase the cost of abortion and they may make abortion unattainable, resulting in the continuation of pregnancy against the wishes of the abortion seeker, especially among women with fewer resources, adolescents, younger women, those from racial or ethnic minorities and those who need to travel further for an abortion.

Among those seeking an abortion, the studies showed that mandatory waiting periods were experienced negatively, as a restriction on their access to abortion. For some women, the logistical and economic challenges of completing a mandatory waiting period, such as the need for time off work or education, extra travel and/or childcare, meant that they were forced to disclose their pregnancy to others even though international human rights law requires States to ensure that SRH services are provided in a way that ensures privacy and confidentiality. The evidence did not establish any benefits of mandatory waiting periods for women.

For health-care facilities, mandatory waiting periods increase staffing costs and logistical difficulties, by mandating additional visits or interventions outside of standard clinical practice (e.g. unnecessary ultrasound, specific counselling that is not evidence-based).

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO MANDATORY WAITING PERIODS

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health (SRH) services.
- States may not regulate abortion in a manner that forces women to resort to unsafe abortion.
- Everyone has a right to non-discrimination and equality in accessing SRH services.
- SRH services must be provided in a way that ensures privacy and confidentiality.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

3.3.2 Third-party authorization for abortion

Third-party authorization requirements exist where there is a requirement imposed by law or policy, or in practice, that a party other than the pregnant woman must authorize an abortion, even though other applicable legal requirements for lawful abortion have been met (e.g. grounds or gestational age limits, see sections 2.2.2 and 2.2.3). Common third parties required to provide authorization include a parent, guardian, spouse, partner, health worker, health authority or judicial authority. Third-party authorization requirements operate without regard to whether the person who seeks to end a pregnancy has capacity to consent to medical treatment.

Regardless of whether third-party authorization requirements apply, informed consent of the person availing of abortion is a prerequisite for the provision of abortion (refer to Chapter 1, section 1.3.1[v] for information on free and informed consent, and also Web annex A: Key international human rights standards on abortion).

LAW & POLICY Recommendation 7: Third-party authorization

Recommend that abortion be available on the request of the woman, girl or other pregnant person without the authorization of any other individual, body or institution.

Remark:

- While parental or partner involvement in abortion decision-making can support and assist women, girls or other pregnant persons, this must be based on the values and preferences of the person availing of abortion and not imposed by third-party authorization requirements.

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

In order to identify the impacts of third-party authorization requirements on abortion seekers and health workers, systematic reviews of studies published between 2010 and 2019 were undertaken. A total of 32 studies were included, conducted in Hong Kong Special Administrative Region (China), Turkey and the USA. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Third-party authorization. The reviewed evidence showed that third-party authorization requirements were associated with delays to abortion. For minors, these delays were sometimes, although not always, reduced when judicial authorization was used to bypass parental authorization requirements. However, bypass can be burdensome and time-consuming, and minors from ethnic minorities or of lower socioeconomic status are significantly more likely to need to use it. The evidence showed that adolescents and women sought to bypass parental/spousal authorization requirements to avoid anticipated violence, reproductive coercion and family disharmony.

A number of studies described "parental notification" or "parental involvement" rather than using the term "parental authorization". As these terms may encompass parental authorization requirements and mandate the disclosure of the fact that a minor is seeking an abortion, thus creating opportunities for parental veto, these studies were included within the evidence base for this topic. These studies reinforced the associations between mandated parental involvement (including authorization) and barriers to accessing abortion (including delay, continuation of pregnancy, anticipated interpersonal violence or exploitation, reproductive coercion, family disharmony and recourse to unsafe abortion).

Third-party authorization requirements are incompatible with international human rights law, which provides that States may not restrict women's access to health services on the ground that they do not have the authorization of husbands, partners, parents or health authorities, because they are unmarried, or because they are women. Therefore, the evidence underlines the importance of the requirements stated in international human rights law that SRH services be provided in a way that respects and maintains women's and girls' privacy and confidentiality, that States protect women and girls seeking abortion, and that States recognize adolescents' evolving capacity (see section 1.3.1[v], Box 1.2 and Web annex A: Key international human rights standards on abortion).

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO THIRD-PARTY AUTHORIZATION

- States may not restrict women's access to health services on the ground that they do not have the authorization of husbands, partners, parents or health authorities, because they are unmarried, or because they are women.
- Sexual and reproductive health (SRH) services must be provided in a way that ensures privacy and confidentiality.
- States may not regulate abortion in a manner that forces women to resort to unsafe abortion.
- States must take steps, including revising laws, to reduce maternal morbidity and mortality, and to effectively protect women and girls from the physical and mental risks associated with resorting to unsafe abortion.
- Everyone has a right to privacy and confidentiality in accessing SRH services.
- Availability, accessibility, acceptability and quality must be central to the regulation of SRH services.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

3.3.3 Rh isoimmunization

Rh isoimmunization is a type of haemolytic disease of the fetus and newborn (HDFN). Specifically, it is the development of antibodies against the Rh antigens on the surface of red blood cells of another individual (i.e. one's own fetus) *(123)*.

What

CLINICAL SERVICES Recommendation 8 (NEW):
Rh isoimmunization for abortion at gestational ages < 12 weeks

For both medical and surgical abortion at < 12 weeks: **Recommend against** anti-D immunoglobulin administration.

Remark:

- Standard of care applies for anti-D administration at gestational ages ≥ 12 weeks.

Who

Not applicable.

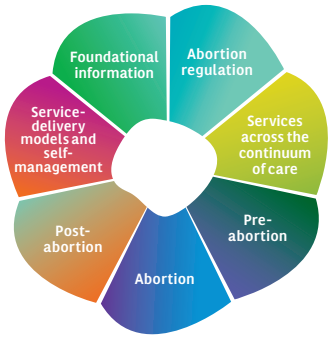
Rationale

A systematic review assessed the effect of routine anti-D administration among unsensitized Rh-negative individuals undergoing an abortion. There are few studies examining Rh isoimmunization in unsensitized Rh-negative individuals seeking abortion before 12 weeks of gestation. Only two studies, conducted in Israel and the USA, met the inclusion criteria for the review, both published in 1972 *(124, 125)*. A summary of the evidence is presented in Supplementary material 2, EtD framework on Rh isoimmunization.

The evidence on the effectiveness of the intervention may favour the intervention, because fewer women in the intervention group (anti-D administration) had antibody formation after the initial pregnancy compared to the women in the comparison group (no anti-D), and no harms (undesirable effects) of the intervention were noted. However, after consideration of the resources required, cost-effectiveness and feasibility of administering anti-D, as well as the very low certainty of the evidence on effectiveness, the expert panel concluded that overall, the evidence does not favour the intervention and decided to recommend against it for gestational ages < 12 weeks, rather than < 9 weeks, as mentioned in the 2012 guidance *(19)*. The justification for this new recommendation is outlined in the following points: (i) The presence of fetal blood in Rh-negative women at early gestational ages does not necessarily correlate with development of Rh alloimmunization and if we apply the results of an experimental study to this scenario, then theoretically there is zero chance of antibody formation if the Rh-negative woman is exposed to the Rh antigen of the fetal blood cells *(126)*; (ii) A study comparing Rh alloimmunization rates in two countries demonstrated the safety of not treating Rh-negative women with spontaneous abortion under 10 weeks of gestation *(127)*; (iii) WHO only recommends antenatal prophylaxis with anti-D immunoglobulin in non-sensitized Rh-negative pregnant women at 28 and 34 weeks of gestation to prevent RhD alloimmunization in the context of rigorous research *(128)*.

How

Implementation considerations



- Routine laboratory testing, including Rh testing, is not a requirement for abortion services at any gestational age.
- Determination of Rh status and the offer of anti-D prophylaxis are not considered prerequisites for early medical abortion at gestational ages before 12 weeks.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO Rh ISOIMMUNIZATION

- States must ensure access to up-to-date scientific technologies necessary for women.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations related to law and policy (Recommendations 1,2,3,6,7,21,22)

3.3.4 Antibiotic prophylaxis

The role of antibiotics is pertinent for surgical abortion. The presence of infection in the lower reproductive tract at the time of surgical abortion is a risk factor for post-abortion reproductive tract infections *(129)*. Provision of antibiotics at the time of abortion (prophylaxis) is to prevent such complications after a surgical abortion.

What

CLINICAL SERVICES Recommendation 9: Antibiotic prophylaxis for surgical and medical abortion

a. For surgical abortion, regardless of the individual's risk of pelvic inflammatory infection: **Recommend** appropriate prophylactic antibiotics pre- or perioperatively.

b. For medical abortion: **Recommend against** the use of prophylactic antibiotics.

Remark:

- Lack of antibiotics should not limit access to abortion services.

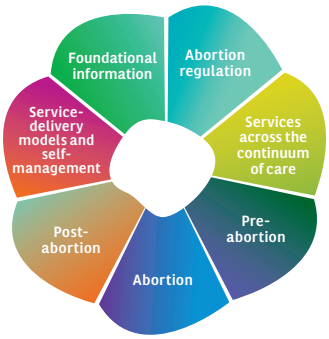
Source: Recommendation 11 carried forward from WHO (2012) *(19)*. The wording has been revised to use the word "recommend" to clarify that these are strong recommendations, and the former wording "routine use" (in 9b) has been changed to "use", following discussion among the expert panel.

How

Implementation consideration

- Single-dose administration of nitroimidazoles, tetracyclines or penicillins has been shown to be effective when used as prophylactic antibiotics for surgical abortion.

Who



For information regarding which health workers can provide this intervention, refer to Recommendation 24 on vacuum aspiration (< 14 weeks) and Recommendation 26 on dilatation and evacuation (D&E) (≥ 14 weeks).

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO ANTIBIOTIC PROPHYLAXIS

- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

Recommendations 24 (on vacuum aspiration) and 26 (on D&E)

3.3.5 Determining gestational age of pregnancy

Determining the gestational age of the pregnancy is a preliminary step before selecting the most appropriate abortion method. There are multiple ways to determine gestational age. Pregnancy dating can be done based on last menstrual period (LMP) alone or in combination with the use of a validated tool (i.e. mobile app, checklist or pregnancy wheel), thus enabling the option of self-assessment of gestational age. When LMP is uncertain, gestational age can be determined by way of a clinical/physical examination (i.e. bimanual pelvic and abdominal examination) or by ultrasound, both of which are used to assess the size of the uterus, estimated in weeks, that corresponds to a pregnant uterus of the same gestational age dated by LMP. In general, the least invasive method that is appropriate in the circumstances and available in the setting should be used.

Routine screening for ectopic pregnancy is not necessary prior to medical abortion. The incidence of ectopic pregnancy is lower in abortion seekers then in the general population *(130)*. Even for continuing pregnancies, WHO only recommends one ultrasound scan before 24 weeks of gestation (early pregnancy ultrasound) to estimate gestational age, improve detection of fetal anomalies and multiple pregnancies, reduce induction of labour for post-term pregnancy, and improve a woman's pregnancy experience *(128)*.

What

CLINICAL SERVICES Recommendation 10: Pre-abortion ultrasound scanning

For both medical and surgical abortion: **Recommend against** the use of ultrasound scanning as a prerequisite for providing abortion services.*

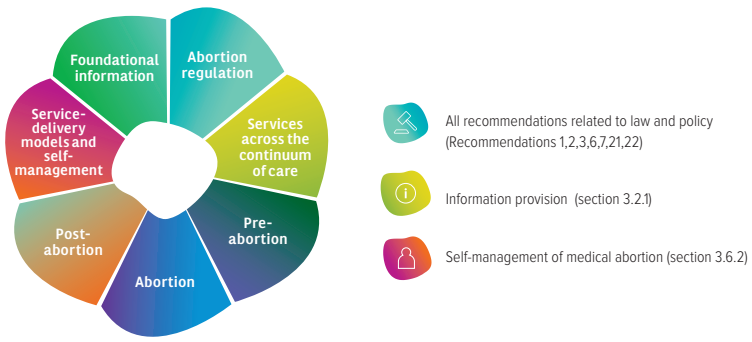
Remark:

- Legal regulation that limits the availability of abortion by gestational age may require or result in ultrasounds being used to verify gestational age prior to abortion, even though this is not necessary from a clinical perspective. Removing legal gestational age limits on access to abortion (see Recommendation 3) should result in unnecessary pre-abortion ultrasound being avoided, and increase the availability of abortion in settings where ultrasound is difficult to access.

* On a case-by-case basis, there may be clinical reasons for using ultrasound scanning prior to abortion.

Source: Recommendation 12 carried forward from WHO (2012) *(19)*. The wording has been revised to use the word "recommend against" to clarify that this is a strong recommendation against the intervention, and the former wording "routine" has been changed to use "prerequisite" for greater clarity, following discussion among the expert panel.

Who



Not applicable.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO DETERMINING THE GESTATIONAL AGE OF PREGNANCY

- Any information on gestational age should be complete, accurate and evidence based. It should not be provided with the aim of directing decision-making.
- As a form of health information, information on gestational age should be of high quality, accurate and accessible. It should be presented a respectful manner and acceptable to the person receiving it. It should not fuel stigma and discrimination.
- Where information on gestational age is made available, it must be provided to individuals in a way that respects privacy and confidentiality.
- The right to refuse such information when offered must be respected. This includes the right to refuse to view ultrasound images.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

3.3.6 Pain management for abortion

There is generally some degree of pain with abortion. The need for pain management increases with gestational age. The degree of the pain varies with the age, parity, prior vaginal delivery, history of dysmenorrhoea and anxiety/fear level of the woman undergoing the abortion *(131-134).* A shorter procedure time has been associated with less pain *(131).* Neglecting this important element of care needlessly increases anxiety, discomfort and pain, thereby seriously compromising the quality of care and potentially increasing the difficulty of performing the procedure. Pain management should always be available and it should be administered in advance, in anticipation of the onset of pain, or provided to the woman in case it is needed for later use at home.

What

CLINICAL SERVICES Recommendations 11–14: Pain management for surgical abortion and for prior cervical priming

11. For pain management for surgical abortion at any gestational age:

a. Recommend that pain management should be offered routinely (e.g. non-steroidal anti-inflammatory drugs [NSAIDS]) and that it should be provided to those who want it; and

b. Recommend against the routine use of general anaesthesia**.**

NEW RECOMMENDATIONS BELOW INDICATE PAIN MANAGEMENT THAT IS *ADDITIONAL* TO NSAIDS.

12. (NEW) For pain management for surgical abortion at < 14 weeks:

a. Recommend the use of a paracervical block; and

b. Suggest that the option of combination pain management using conscious sedation[13] plus paracervical block should be offered, where conscious sedation is available.

13. (NEW) For pain management for cervical priming with osmotic dilators prior to surgical abortion at ≥ 14 weeks:

Suggest the use of a paracervical block. (See also section 3.3.7 on cervical priming prior to surgical abortion.)

Remark:

- For cervical priming (Recommendation 13), additional pain medication can be considered, such as the use of intravaginal gel.

14. (NEW) For pain management for surgical abortion at ≥ 14 weeks:

a. Recommend the use of a paracervical block; and

b. Suggest that the option of combination pain management using conscious sedation plus paracervical block should be offered, where conscious sedation is available.

Source: Recommendation 11 updated from WHO (2012) *(19).* Recommendations 12–14 are new.

Note on updating of the recommendation: Recommendation 11a was previously published as part of Recommendation 14 in WHO (2012) *(19),* and evidence for it was reviewed using GRADE methodology. After review, in this updated version, we have split the first part of the original recommendation wording to apply to surgical abortion here (11a) and medical abortion in a separate recommendation (15) and revised the wording to mention provision, and we have separated and revised the wording of the second part of the recommendation referring to general anaesthesia (Recommendation 11b).

13 Conscious sedation is also known as intravenous (IV) sedation or moderate sedation. See definition in Glossary.

In a health-care facility.

Rationale for Recommendations 11b and 12

An update of an existing Cochrane Review[14] served as the evidence base for assessing the pain management regimens for surgical abortions at < 14 weeks of gestation. Thirty studies reporting on pain management for surgical abortion were identified by the search strategy. Of these studies, nine studies – conducted in France, the Islamic Republic of Iran, Norway, Turkey and the USA – are the focus of the evidence base for these recommendations. Six studies compared the paracervical block (PCB) with a placebo. One study compared the PCB with general anaesthesia. Two studies compared conscious sedation[15] plus PCB versus PCB alone. A summary of the evidence is presented in Supplementary material 2, EtD framework for Pain management for surgical abortion < 14 weeks.

Combination pain management using conscious sedation plus PCB: Mean pain scores were lower in the group of women who received conscious sedation and PCB compared with the women who received a PCB alone, based on moderate-certainty evidence. In addition, satisfaction with their pain management was higher among the former group of women, based on high-certainty evidence.

Paracervical block (PCB): Both with and without conscious sedation, mean pain scores were lower in the group of women who received a PCB compared with the women who received a placebo, based on moderate-certainty evidence. Fewer women required additional analgesic medication, based on high-certainty evidence, and satisfaction in the former group of women was high, based on moderate-certainty evidence.

General anaesthesia: Pain scores were lower in the group of women who received general anaesthesia compared with PCB alone, based on moderate-certainty evidence. However, discussions on the resources required, cost effectiveness, feasibility and equity related to administering general anaesthesia resulted in a conclusion that did not favour the intervention. In addition, Recommendation 11b aligns with the existing statement that vacuum aspiration does not require an operating theatre *(19)*.

Rationale for Recommendations 13 and 14

A systematic review assessed the pain management regimens for surgical abortions at gestational ages ≥ 14 weeks. Three studies reporting on pain management for D&E were identified by the search strategy, all of which focused on pain management during the cervical priming prior to the surgical procedure. A summary of the evidence is presented in Supplementary material 2, EtD framework for Pain management for surgical abortion ≥ 14 weeks.

Mean pain scores were lower in the group of women who received a PCB compared with the women who received a placebo, based on high-certainty evidence. Satisfaction in the former group of women was high, based on moderate-certainty evidence. An intravaginal gel can be used as an alternative method of pain control; more women had a lower pain score after receiving the gel compared with those who had a PCB, based on low-certainty evidence. Cervical priming was performed with laminaria. Discussions on the values and preferences of women regarding pain management during surgical abortion, and on the resources required and the feasibility of PCB administration resulted in a determination that favoured the intervention.

No studies were identified that focused on pain management for the D&E procedure. Therefore, the expert panel came to a consensus to align the recommendations to those for pain management for surgical abortion at < 14 weeks of gestation (see Recommendation 12).

For information regarding which health workers can provide this intervention, refer to Recommendations 24 and 26 for surgical abortion (vacuum aspiration and D&E).

14 A Cochrane Review is a systematic review of research in health care and health policy that is published in the *Cochrane Database of Systematic Reviews*.

15 Conscious sedation is also known as intravenous (IV) sedation or moderate sedation. See definition in Glossary.

How

Implementation considerations

- Sufficient supplies and stocks of pain medications should be ensured.
- Training of providers in abortion care should include pain management, in particular the technique for administration of paracervical block.

What

CLINICAL SERVICES Recommendations 15 and 16: Pain management for medical abortion

15. For medical abortion at any gestational age:

Recommend that pain management should be offered routinely (e.g. non-steroidal anti-inflammatory drugs [NSAIDs]) and that it should be provided for the individual to use if and when wanted.

NEW RECOMMENDATION BELOW INDICATES PAIN MANAGEMENT THAT IS *ADDITIONAL* TO NSAIDS.

16. (NEW) For pain management for medical abortion at ≥ 12 weeks:

Suggest consideration of other methods to control pain or discomfort due to increased pain with increasing gestational age. Such methods include certain anti-emetics and epidural anaesthesia, where available.

Remark:

- For medical abortion at gestational ages < 14 weeks, if NSAIDS (e.g. ibuprofen) are not available or not an option, then acetaminophen can be considered for pain control.

Source: Recommendation 15 updated from WHO (2012) *(19).* Recommendation 16 is new.

Note on updating of the recommendation: Recommendation 15 was previously published as part of Recommendation 14 in WHO (2012) *(19),* and evidence for it was reviewed using GRADE methodology. After review, in this updated version, we have split the first part of the original recommendation wording to apply to surgical abortion (see Recommendation 11a) and medical abortion (here in Recommendation 15), and revised the wording to mention provision.

Where

No requirement for location (on-site vs off-site).

Rationale for Recommendation 15 (specifically for gestational ages < 14 weeks)

A Cochrane Review served as the evidence base for this key question. Five studies reporting on pain management for medical abortion at gestational ages < 14 weeks were identified by the search strategy, conducted in Israel, the United Kingdom and the USA. A summary of the evidence is presented in Supplementary material 2, EtD framework for Pain management for medical abortion < 14 weeks.

Of these studies, three were assessed using the following comparisons:

- ibuprofen versus placebo
- prophylactic versus therapeutic NSAIDs
- ibuprofen versus paracetamol.

Women who received NSAIDs had lower mean pain scores and fewer women from that group required additional analgesic medication, based on high-certainty evidence. Discussions on the values and preferences of women with pain management during medical abortion and the resources required, cost-effectiveness and feasibility for NSAID administration resulted in a determination that favoured the intervention.

Rationale for Recommendations 15 (specifically for gestational ages ≥ 14 weeks) and 16

A systematic review was undertaken to address this key question. Eleven studies reporting on pain management for medical abortion at gestational ages ≥ 14 weeks were identified by the search strategy, conducted in Belgium, Canada, Germany, Israel, Italy, Sweden, Thailand and the USA. A summary of the evidence is presented in Supplementary material 2, EtD framework for Pain management for medical abortion ≥ 14 weeks.

Using data from these studies, the following comparisons were made:

- paracervical block (PCB) versus oral pain medication
- NSAIDs versus non-NSAIDs/placebo
- anti-emetics versus placebo
- anti-epileptics versus anxiolytics
- intermittent versus continuous epidural
- patient controlled epidural versus patient-controlled intravenous (IV) fentanyl
- patient controlled fentanyl versus patient-controlled morphine
- patient controlled IV tramadol versus patient-controlled IV fentanyl.

Comparison of PCB versus oral pain medication: In the studies that assessed this comparison, fewer women experienced severe pain and there was a lower expulsion time with the use of oral pain medication compared with PCB, based on moderate-certainty evidence.

Comparison of NSAIDs versus non-NSAIDs/placebo: In the studies that assessed this comparison, fewer women required supplemental narcotics after the use of NSAIDs, based on high certainty of evidence. In addition, fewer women receiving NSAIDs experienced side-effects, based on moderate-certainty evidence.

Comparison of anti-emetics versus placebo: In the studies that assessed this comparison, there was lower use of supplemental narcotics and lower expulsion time with the use of anti-emetics, based on moderate-certainty evidence.

Comparison of anti-epileptics versus anxiolytics: In the studies that assessed this comparison, there were lower mean pain scores, lower use of additional analgesics and lower mean expulsion times with the use of anti-epileptics, based on moderate-certainty evidence.

Comparison of intermittent versus continuous epidural: In the studies that assessed this comparison, there were fewer side-effects with the use of intermittent epidural, based on low- to high-certainty evidence. Satisfaction was higher among women who had intermittent epidural for their pain management, based on high-certainty evidence.

Comparison of patient-controlled epidural (PCE) versus patient controlled IV fentanyl: In the studies that assessed this comparison, there were lower mean pain scores and fewer side-effects of vomiting and sedation with the use of PCE, based on moderate-certainty evidence. In addition, satisfaction was higher among women in the PCE group, based on moderate-certainty evidence.

Comparison of patient-controlled morphine versus patient-controlled IV fentanyl: In the studies that assessed this comparison, there were lower pain scores and fewer side-effects with the use of patient-controlled fentanyl (50 µg), based on moderate- to high-certainty evidence.

Comparison of patient controlled IV tramadol versus patient controlled IV fentanyl: In the studies that assessed this comparison, pain control was comparable with the use of patient-controlled tramadol and fentanyl, based on low- to moderate-certainty evidence. Satisfaction ratings were also similar between the two groups, based on high-certainty evidence.

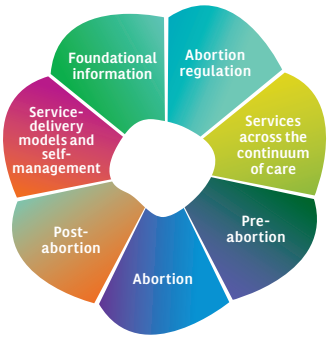
Discussions on the values and preferences of women regarding pain management during medical abortion, and on the resources required, cost-effectiveness and feasibility for NSAID administration resulted in a determination that favoured the intervention.

Who

For information regarding which health workers can provide this intervention, refer to Recommendations 28 and 30 on medical abortion.

How

Implementation consideration for Recommendations 15 and 16



- Regardless of the service modality, there should be clear communication to the woman on the pain she may experience, which may vary based on pain perceptions and tolerance. In any event, she should be provided with information on pain management, and access to adequate pain medicines should be ensured.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO PAIN MANAGEMENT

- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- Denial of pain medication may violate a wide range of human rights, including the right to health and autonomy in decision-making.
- Denial of pain medication as punishment for abortion or because it is part of abortion care may violate the right to equality and non-discrimination.
- Denial of pain medication may violate the right to be free from cruel, inhuman and degrading treatment.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

- Universal health coverage (UHC) (section 1.4.1)
- Commodities (section 1.4.4)
- Information provision (section 3.2.1)

3.3.7 Cervical priming prior to surgical abortion

Prior to surgical abortion, cervical priming (also known as cervical preparation) may be considered for all women with a pregnancy of any gestational age, in particular for women with a pregnancy over 12 weeks of gestation. Cervical priming before surgical abortion is especially beneficial for women with cervical anomalies or previous surgery, adolescents and those with advanced pregnancies, all of whom have a higher risk of cervical injury or uterine perforation that may cause haemorrhage *(135, 136)*. It may also facilitate the abortion procedure for inexperienced providers. However, cervical priming has disadvantages, including additional discomfort for the woman, and the extra cost and time required to administer it effectively.

Whether osmotic dilators or medication is used for cervical priming prior to the surgical abortion, this is done in advance of the procedure. As such, cervical priming may be initiated by a health worker other than the provider who will conduct the D&E.

What

CLINICAL SERVICES Recommendation 17: Cervical priming prior to surgical abortion at < 12 weeks of gestation

Prior to surgical abortion at < 12 weeks:

a. If cervical priming is used: **Suggest** the following medication regimens:

- Mifepristone 200 mg orally 24–48 hours prior to the procedure
- Misoprostol 400 µg sublingually 1–2 hours prior to the procedure
- Misoprostol 400 µg vaginally or buccally 2–3 hours prior to the procedure

b. Recommend against the use of osmotic dilators for cervical priming.

Remarks:

- The sublingual route is more effective for misoprostol administration.
- Appropriate pain medication should be provided.

Source: Recommendation updated from Recommendation 7.2 in WHO (2012) *(19)*.

Note on updating of the recommendation: This recommendation was reviewed using GRADE methods. The suggested mifepristone regimen is unchanged, but the misoprostol regimens have been updated, in terms of timing and route of administration, and laminaria is no longer a recommended option; these recommendations therefore replace the prior recommendation.

Rationale

An update of an existing Cochrane Review serves as the evidence base for this key question. The update identified 8 new studies, which makes a total of 61 included studies that assessed cervical priming methods for vacuum aspiration. From this review, approximately half of the included studies were evaluated to contribute towards the development of the Evidence-to-Decision (EtD) framework. The review includes the following cervical priming methods: medication with mifepristone and/or misoprostol and mechanical methods (i.e. natural or synthetic osmotic dilators). A summary of the evidence is presented in Supplementary material 2, EtD framework for Cervical priming prior to surgical abortion < 12.[16]

For Recommendation 17a, we suggest the option of misoprostol or mifepristone as a cervical priming agent prior to surgical abortion less than 12–14 weeks. For the studies that compared misoprostol versus mifepristone, time to complete the procedure was less for misoprostol, based on moderate-certainty evidence. However, the pre-procedure cervical dilation was greater with mifepristone use, based on moderate-certainty evidence. The side-effects profile was comparable between the two groups, based on very low-certainty evidence.

Regarding the timing of misoprostol administration, studies that compared the interval timing for administration of misoprostol for cervical priming revealed that the highest efficacy was seen (i.e. greater pre-procedure cervical

16 For the sake of consistency across the recommendations, the cut-off gestational age is 12 weeks, but evidence did include women with pregnancies up to 14 weeks of gestation who underwent vacuum aspiration.

dilation) with the 3-hour interval. This finding was based on high-certainty evidence. Although the 3-hour interval is considered optimal, the 1-hour interval is also included as a result of the expert panel members' discussions on the feasibility and acceptability of the shorter duration of waiting time prior to a woman's surgical abortion.

For Recommendation 17b, the reasoning is due to the longer time to complete the procedure if osmotic dilators are used compared with when misoprostol is used for cervical priming, based on high-certainty evidence. In addition, satisfaction rates were higher among those who received misoprostol compared with the laminaria group, based on moderate-certainty evidence.

The expert panel added the buccal route (this was added along with the vaginal route due to buccal and misoprostol concentration curves being similar in pharmacokinetics data), and their remark highlights the sublingual route as being the more effective route.

What

CLINICAL SERVICES Recommendation 18 (NEW): Cervical priming prior to surgical abortion (MVA or D&E) at ≥ 12 weeks of gestation

Prior to surgical abortion at later gestational ages:

a. For surgical abortion at ≥ 12 weeks: **Suggest** cervical priming prior to the procedure.

b. For surgical abortion between 12 and 19 weeks: **Suggest** cervical priming with medication alone (a combination of mifepristone plus misoprostol is preferred) or with an osmotic dilator plus medication (mifepristone, misoprostol, or a combination of both).

c. For surgical abortion between 12 and 19 weeks, when using an osmotic dilator for cervical priming: **Suggest** that the period between osmotic dilator placement and the procedure should not extend beyond two days.

d. For surgical abortion at ≥ 19 weeks: **Recommend** cervical priming with an osmotic dilator plus medication (mifepristone, misoprostol, or a combination of both).

Remark:

- There was limited evidence for cervical priming for gestational ages between 12 and 14 weeks and therefore health workers should use clinical judgement to decide on the most convenient method for cervical priming prior to vacuum aspiration for this gestational age range.

Note: These are new recommendations and they replace Recommendations 8.1 and 8.2 in WHO (2012) *(19)*, which were for D&E after 14 weeks; these new recommendations now include information on methods/regimens for cervical priming at different gestational age ranges.

Rationale

A Cochrane Review provided the evidence base on cervical priming methods for surgical abortion at later gestational ages. From this review, 16 studies were included in the development of the EtD framework relating to the following cervical priming methods: medication with mifepristone and/or misoprostol; mechanical methods with osmotic dilators and synthetic dilators; one-day versus two-day procedures with laminaria. The study settings included Israel, South Africa, Spain, the United Kingdom and the USA. A summary of the evidence is presented in Supplementary material 2, EtD framework for Cervical priming prior to surgical abortion ≥ 12 weeks.

The inclusion of all medication options for cervical priming was based on the expert panel's discussion of the feasibility and acceptability of these interventions. The use of mifepristone with misoprostol is favoured over misoprostol alone for cervical priming due to higher pre-procedure cervical dilatation and shorter time to complete the procedure, based on moderate-certainty evidence. The combined use of medication and laminaria is favoured over laminaria alone due to the higher pre-procedure cervical dilatation, decreased need for further dilatation and shorter time to complete the procedure. This is based on high-certainty evidence. Sub-analyses of the included studies showed that the combined use of medication and laminaria appears to be more effective at higher gestational ages.

How

Implementation consideration

- The use of medication for cervical priming prior to surgical abortion beyond 12–14 weeks of gestation can be self-managed and can save travel time for the woman and staff time spent on insertion of osmotic dilators.

Who

SERVICE DELIVERY Recommendation 19: Cervical priming with medication prior to surgical abortion at any gestational age

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Suggest** Condition: Provision of medication for the purpose of cervical priming is part of the surgical abortion process so the health worker needs to ensure continuity of care of the woman obtaining the medicines prior to the abortion procedure	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, CHWs have been recommended to provide medical abortion at < 12 weeks (see Recommendation 28), which requires similar skills and knowledge as for this task.
Pharmacy workers	**Suggest** Condition: Provision of medication for the purpose of cervical priming is part of the surgical abortion process so the health worker needs to ensure continuity of care of the woman obtaining the medicines prior to the abortion procedure	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, pharmacy workers have been recommended to provide medical abortion at < 12 weeks (see Recommendation 28), which requires similar skills and knowledge as for this task.
Pharmacists	**Suggest** Condition: Provision of medication for the purpose of cervical priming is part of the surgical abortion process so the health worker needs to ensure continuity of care of the woman obtaining the medicines prior to the abortion procedure	Although no evidence was found on the safety, effectiveness or acceptability of this option, dispensing medicines with a prescription is within the typical scope of practice of pharmacists. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, pharmacists have been recommended to provide medical abortion at < 12 weeks (see Recommendation 28), which requires similar skills and knowledge as for this task.
Traditional and complementary medicine professionals **Auxiliary nurses/ANMs** **Nurses** **Midwives**	**Recommend**	Evidence was found for the safety and effectiveness of this option (low-certainty evidence). Cervical priming is part of the training for provision of manual vacuum aspiration. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a]
Associate/advanced associate clinicians	**Recommend**	Evidence was found for health workers with similar or less comprehensive basic training (e.g. midwives, nurses, ANMs) using such medicines to provide medical abortion (moderate-certainty evidence). Cervical priming is part of the training for provision of manual vacuum aspiration. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a]
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to all types of health workers was reviewed using GRADE methodology, except for specialist and generalist medical practitioners, which were already "recommend". After review, the recommendations were upgraded for all reviewed health workers, from "recommend against" to "suggest" for pharmacists, pharmacy workers and CHWs, and from "suggest" to "recommend" for all other health worker categories. The gestational age for this recommendation was also amended from "beyond 12 weeks" to "at any gestational age" after conferring with the expert panel. A summary of the evidence is presented in Supplementary material 3, EtD framework for Cervical priming using medication and osmotic dilators.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

No requirement for location (on-site vs off-site).

How

Implementation consideration

- Given that cervical priming initiates the process and is done prior to a surgical procedure, with an interval of up to 1–2 days, it is important that the health worker ensures the continuity of care for the woman by ensuring that there is a clear plan for the surgical abortion prior to the woman taking the priming agent and she has access to the existing health system should she desire or need additional support during that interval.

Who

SERVICE DELIVERY Recommendation 20: Cervical priming with osmotic dilators prior to D&E at gestational ages ≥ 12 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Suggest** Condition: Health worker ensures continuity of care from the time of cervical priming to the D&E	Although insufficient direct evidence was found for the safety and effectiveness of this option, these health workers have been suggested to do other transcervical procedures (e.g. inserting an IUD and vacuum aspiration; see Recommendations 43 and 24). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option has the potential to increase equitable access to quality abortion care in regions where these professionals constitute a significant proportion of the health workforce.
Auxiliary nurses/ANMs	**Recommend**	Although insufficient direct evidence was found for the safety and effectiveness of this option, ANMs have been recommended to do other transcervical procedures (e.g. inserting an IUD; see Recommendation 43), and auxiliary nurses have been recommended in certain contexts to do other transcervical procedures (e.g. inserting an IUD; see Recommendation 43). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option may help optimize workflow within a facility and decrease waiting times for women.
Nurses	**Recommend**	Although insufficient direct evidence was found for the safety or effectiveness of this option, nurses have been recommended to do other transcervical procedures (e.g. inserting an IUD; see Recommendation 43), and there is evidence that provision of manual vacuum aspiration by nurses is safe and effective (moderate-certainty evidence). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option may help optimize workflow within a facility and decrease waiting times for women.
Midwives	**Recommend**	Although insufficient direct evidence was found for the safety or effectiveness of this option, midwives have been recommended to do other transcervical procedures (e.g. inserting an IUD; see Recommendation 43), and there is evidence that provision of manual vacuum aspiration by midwives is safe and effective (moderate-certainty evidence). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option may help optimize workflow within a facility and decrease waiting times for women.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Associate/advanced associate clinicians	**Recommend**	Indirect evidence was found for the safety and effectiveness of these clinicians providing vacuum aspiration (moderate-certainty evidence), which includes cervical priming with osmotic dilators for select cases. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option may help optimize workflow within a facility and decrease waiting times for women.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

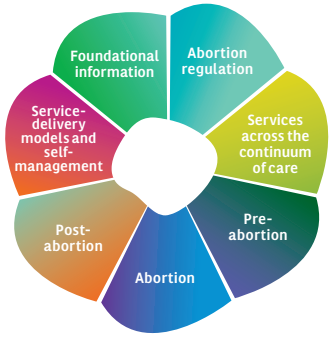
Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to all types of health workers was reviewed using GRADE methodology, except for specialist and generalist medical practitioners, which were already "recommend". After review, the recommendations were upgraded for associate/advanced associate clinicians, midwives and nurses from "suggest" to "recommend", for auxiliary nurses and ANMs from "recommend against" to "recommend", and for traditional and complementary medicine professionals from "recommend against" to "suggest". For pharmacists, pharmacy workers and community health workers, the recommendations remain "recommend against" (not listed). The gestational age for this recommendation was also amended from "beyond 12 weeks" to "12 weeks and above" (≥ 12 weeks) to align this recommendation with Recommendation 18. A summary of the evidence is presented in Supplementary material 3, EtD framework for Cervical priming using medication and osmotic dilators.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where



In a health-care facility.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO CERVICAL PRIMING

- Denial of cervical priming as punishment for abortion or because it is part of abortion care may violate the right to non-discrimination and equality.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

Recommendations 11–15: Pain management

Recommendation 23–26: Surgical abortion (vacuum aspiration and dilatation and evacuation)

3.3.8 Restrictions (in law or policy) on health workers who may lawfully provide abortion care

In a number of countries, law and policy restrict which type of health workers may lawfully provide abortion care *(137),* most often limiting this to gynaecologists. Since the advent of vacuum aspiration and medical abortion, however, abortion can be safely provided by a wide range of health workers in diverse settings, and safely self-managed in earlier pregnancy (see Recommendations 24, 28, 30, 33). Provider restrictions are inconsistent with WHO's support for the optimization of the roles of health workers; such restrictions are arbitrary and not evidence based *(138)*. Reflecting States' obligation to respect, protect and fulfil the right to health, health-care facilities, goods and services must be available, accessible, adequate and of good quality *(46)*. This includes facilities, goods and services for SRH care. Thus, States must ensure an adequate number of medical and professional personnel and skilled providers in the health system as well as adequate stocks of essential medicines *(46)*. Furthermore, the Special Rapporteur on the right of everyone to the enjoyment of the highest attainable standard of physical and mental health, has stressed that abortion law must be evidence based *(37)* (see Chapter 1, section 1.3.1[i], and also Web annex A: Key international human rights standards on abortion).

LAW & POLICY Recommendation 21: Provider restrictions

Recommend against regulation on who can provide and manage abortion that is inconsistent with WHO guidance.

Remark:

- Where law or policy regulate who may provide or manage abortion, that regulation should be consistent with WHO guidance, which is presented throughout this chapter.

Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

In order to identify the impacts of provider restrictions on abortion seekers and health workers, a systematic review of studies published between 2010 and 2019 was undertaken, identifying seven studies conducted in Australia, Ethiopia, Nepal and the USA. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Provider restrictions. The reviewed evidence showed that restrictions on who can provide and manage abortion resulted in delays to and burdens in accessing abortion. By contrast, expanding the range of health workers who can provide abortion care improved timely access to early medical and surgical abortion; reduced costs, travel and waiting time; shifted components of care away from physicians; made abortion more available including in rural areas and at primary health care level; prevented unsafe self-management of abortion; and reduced system costs. This evidence indicates that provider restrictions produce inefficiencies, administrative burdens and workload burdens within health systems, and reduce in practice the number of available providers.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO PROVIDER RESTRICTIONS

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health care.
- Abortion regulation should be based on human rights and evidence.
- States must ensure an adequate number of medical and professional personnel and skilled providers in the health system as well as adequate stocks of essential medicines.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

3.3.9 Conscientious objection or refusal by health workers to provide abortion care

Refusal of abortion care on the basis of conscience operates as a barrier to access to safe and timely abortion *(3 [para. 14], 36 [para. 8], 139 [para. 109], 140 [para. 353], 141 [paras 42, 43])*, and unregulated conscientious refusal/objection can result in human rights violations, or lead women to seek unsafe abortion *(142 [para. 23], 143 [para. 106], 144)*. In some countries conscientious objection is expressly regulated through employment law, employment contracts or the law on abortion. As a matter of international human rights law, States that allow conscientious objection must organize their health system and abortion provision in a way that ensures that conscientious objection does not result in the refusal of legally available abortion care, and regulate the exercise of conscientious objection in a way that reflects best international clinical practice, protects abortion seekers, and ensures that provider refusal does not undermine or hinder access to quality abortion care *(145 [para. 12], 146 [para. 28])*. WHO has also advised that "health services should be organized in such a way as to ensure that an effective exercise of the freedom of conscience of health professionals in the professional context does not prevent patients from obtaining access to services to which they are entitled under the applicable legislation" *(19)*.

LAW & POLICY Recommendation 22: Conscientious objection

Recommend that access to and continuity of comprehensive abortion care be protected against barriers created by conscientious objection.

Remarks:

- In spite of the human rights obligation to ensure conscientious objection does not hinder access to quality abortion care, and previous WHO recommendations aimed at ensuring conscientious objection does not undermine or hinder access to abortion care, conscientious objection continues to operate as a barrier to access to quality abortion care. It is critical that States ensure compliance with regulations and design/organize health systems to ensure access to and continuity of quality abortion care. If it proves impossible to regulate conscientious objection in a way that respects, protects and fulfils abortion seekers' rights, conscientious objection in abortion provision may become indefensible.
- The evidence reviewed considered the impact of conscientious objection on access to and availability of abortion care and not the effectiveness of regulating conscientious objection in terms of improvements in those outcomes. However, international human rights law provides some guidance as to how States can ensure that human rights of abortion seekers are respected, protected and fulfilled. These include:
  - organizing the health system to ensure that sufficient, non-objecting providers are employed and distributed fairly across the country *(3)*;
  - putting in place clear and enforceable regulation of conscientious objection *(147 [paras 30, 31], 148 [para. 41(f)], 149 [para. 37(b)])*;
  - ensuring adequate enforcement of the regulation of conscientious objection, including identifying, addressing and sanctioning non-compliance *(147 [paras 30, 31], 148 [para. 41(f)], 149 [para. 37(b)])*;
  - outlining clearly who may object to what components of care *(150 [paras 30-31], 148 [para. 41(f)], 3 [para. 43])*;
  - prohibiting institutional claims of conscience *(147, 150 [para. 33(c)], 148 [para. 41(f)])*;
  - requiring objectors to provide prompt referral to accessible, non-objecting providers *(3 [para. 43], 37 [para. 65(m)], 39 [para. 11], 150 [para. 33(c)], 146 [para. 28])*;
  - requiring conscientious objection to be exercised in a respectful and non-punitive manner; and
  - prohibiting conscientious objection in urgent or emergency situations *(3, para. 43)*.

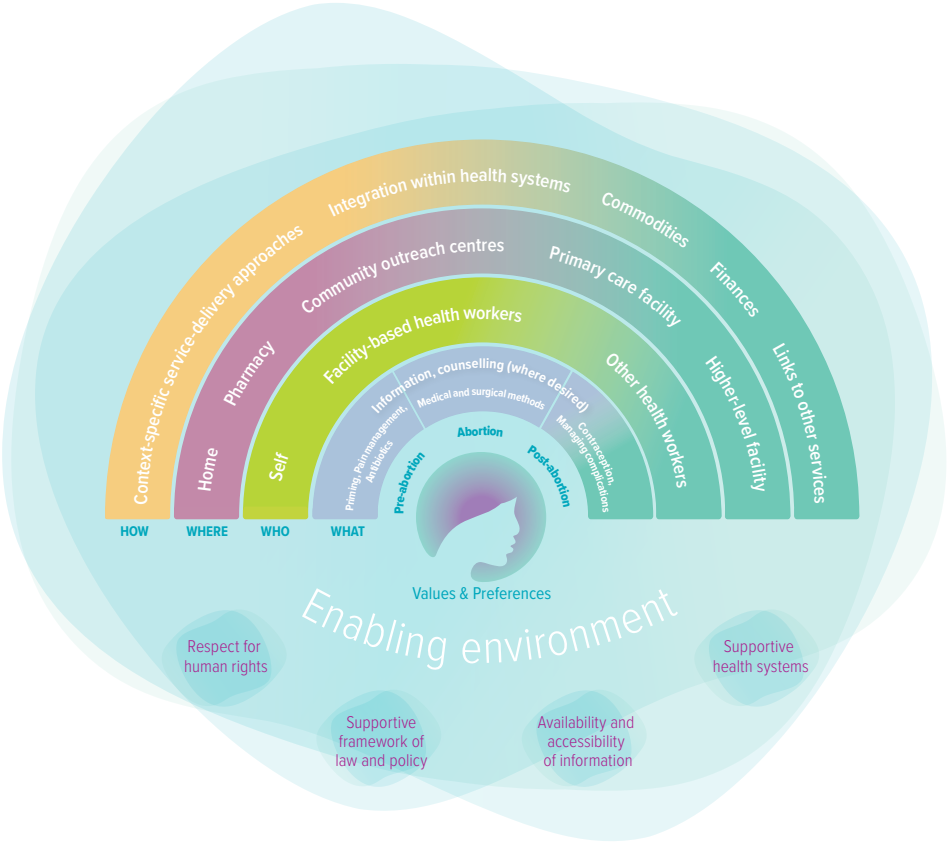
Note on updating of the recommendation: This and other law and policy recommendations are not new recommendations. WHO's 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy *(19)*; in this guideline, this has been developed into seven separate recommendations using GRADE methodology.

Rationale

In order to identify the impacts of conscientious objection on abortion seekers and health workers, a systematic review of studies published between 2010 and 2020 was undertaken, identifying 26 studies conducted in Australia, Brazil, Colombia, Ghana, Italy, Mexico, Nigeria, Norway, Portugal, South Africa, Slovakia, Switzerland, Tunisia, the United Kingdom, the USA and Zambia. A summary of the evidence from these studies is presented in Supplementary material 1, EtD framework for Conscientious objection. The evidence reviewed established that conscientious objection may delay timely access to abortion and abortion care. Delay in care is exacerbated where there is a higher proportion of objecting health workers, and sometimes even in emergency cases where abortion is needed to save a woman's life. Delays are sometimes deliberately imposed by objectors. The evidence also suggests that conscientious objection contributes to increased abortion-related morbidity and mortality, and that some health workers claim conscientious objection and refuse abortion in the public sector, while providing abortion for payment in their private practices.

The studies showed that conscientious objection imposes increased barriers on populations in specific settings: rural areas; settings where abortion law has recently been changed and there is insufficient clarity on who may object to what aspects of abortion care; places where conscientious objection is not effectively regulated; and settings where objecting health workers intentionally refuse referrals or use biased counselling, or inaccurate legal and medical information to try to dissuade and obstruct people from accessing abortion (refer to section 3.2.1: Provision of information).

Refusal of abortion on the basis of conscience has been shown to impose significant burdens on women and girls, especially uncertainty about whether and where they can access abortion. Some objectors decide whether to provide abortion on a case-by-case basis depending on their view of the reason a woman seeks abortion, which means availability is not clear or consistent. Furthermore, objectors' referral practices are highly variable. The evidence demonstrated that while most objectors were willing to refer, this was not true for all, with some objectors referring on a case-by-case basis. Additionally, referral pathways may be circuitous and burdensome, which imposes additional difficulties and delays.



Conscientious objection has significant workload implications for health workers. Where there are many objectors, non-objecting health workers have an increased workload, abortion provision is often stigmatized, and those who do provide abortion care may experience career limitation or discrimination. Unclear, unenforced or non-existent regulation and legal frameworks for conscientious objection can create burdens on health workers, including in navigating challenges associated with their conscience or ethics, cause workplace conflicts, result in non-clinical staff attempting to claim conscientious objection, and undermine organizational models for the delivery of abortion.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO CONSCIENTIOUS OBJECTION

- Availability, accessibility, acceptability and quality must be central to the regulation of sexual and reproductive health (SRH) services.
- States that allow conscientious objection must organize their health system and abortion provision in a way that ensures that conscientious objection does not hinder access to or result in the refusal of legally available abortion care.
- States that allow conscientious objection should regulate the exercise of conscientious objection in a way that reflects best international clinical practice, protects abortion seekers, and ensures that provider refusal does not undermine or hinder access to quality abortion.
- Everyone has the right to accurate information on SRH.
- Everyone has a right to privacy and confidentiality in SRH services.
- Everyone has a right to non-discrimination and equality in accessing SRH services.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

3.4 Abortion

Abortion management is needed for both induced and spontaneous abortion, including for clinical indications such as missed abortion and intrauterine fetal demise (fetal death).

Recommended management options include medical management, or surgical management using manual or electric vacuum aspiration (MVA or EVA) or dilatation and evacuation (D&E). The method of surgical abortion would depend on gestational age: generally vacuum aspiration at < 14 weeks of gestation and D&E at ≥ 14 weeks, but there is flexibility in the use of these methods between 12 and 16 weeks. Medical abortion regimens include sequential use of mifepristone followed by misoprostol or, in settings where mifepristone is not available (or is restricted for certain clinical indications), the use of misoprostol alone. A new alternative medical method, in particular using letrozole in combination with misoprostol, is also available.

For missed abortion and intrauterine fetal demise (see sections 3.4.5 and 3.4.6), in addition to the options of medical and surgical management, expectant management can be offered as an option on the condition that the woman is first informed of the longer time for expulsion of the pregnancy tissue and the increased risk of incomplete emptying of the uterus (the same applies in the case of incomplete abortion, which is addressed in section 3.5.2 on post-abortion care).

Medical abortion care for all indications plays a crucial role in providing wider access to safe, effective and acceptable abortion care. This may increase the availability and accessibility of abortion and realization of the right to SRH. Across all resource settings, the use of medical abortion has contributed to the expansion of health worker roles, more efficient use of resources and reduced maternal mortality and morbidity from unsafe abortions. Moreover, medical abortion – particularly in early pregnancy – can now be provided at the primary-care level and on an outpatient basis, or from a pharmacy, which further increases access to abortion care. Medical abortion care

reduces the need for skilled surgical abortion providers and offers a non-invasive and highly acceptable and safe option to pregnant women. As a matter of international human rights law, States must provide essential medicines listed under WHO's Action Programme on Essential Drugs, which include abortion medicines *(46, para. 12a)*.

The recommendations presented below address surgical and medical management of abortion. Implementation of all of the recommendations in this section are conditional upon women's values and preferences, the acceptability of each intervention, and the availability of resources to provide the chosen method safely. It should be noted that a woman's choice of method for abortion management may be limited or not applicable if she has medical contraindications to one of the methods. The recommendations below relate only to the method of abortion, and should not be read as suggesting gestational age limits for the availability of abortion.

3.4.1 Methods of surgical abortion

The provision of vacuum aspiration includes the assessment of gestational age, cervical priming (if needed), the actual procedure, pain management including the provision of a paracervical block and the assessment of completeness of abortion through the visual inspection of products of conception. Health workers with the skills to perform a bimanual pelvic examination to diagnose and date a pregnancy, and to perform a transcervical procedure such as intrauterine device (IUD) insertion, can be trained to perform vacuum aspiration.

Recommended methods of surgical abortion at later gestational ages are vacuum aspiration and dilatation and evacuation (D&E). Although the recommendations in this section indicate differences before and after 14 weeks of gestation, it should be noted that there is flexibility in the use of one surgical method versus the other between the gestational ages of 12 and 16 weeks.

What

CLINICAL SERVICES Recommendation 23: Vacuum aspiration for induced abortion at gestational ages < 14 weeks

For surgical abortion at < 14 weeks:

a. Recommend vacuum aspiration.

b. Recommend against the practice of dilatation and sharp curettage (D&C), including sharp curette checks (i.e. to "complete" the abortion) following vacuum aspiration.

Remarks:

- Observational studies indicate that vacuum aspiration is associated with fewer complications than D&C; however, randomized controlled trials were underpowered to detect a difference in complication rates.
- No evidence supports the use of sharp curette checks following vacuum aspiration.
- The quality of the evidence based on randomized controlled trials is low to moderate.

Source: Recommendation 1 carried forward from WHO (2012) *(19)*. Some of the wording has been revised, and the gestational age range has been changed from "up to 12 to 14 weeks" to "before 14 weeks" (< 14 weeks).

Who

SERVICE DELIVERY Recommendation 24: Vacuum aspiration for induced abortion at gestational ages < 14 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Recommend**	Very low-certainty evidence was found for the effectiveness of this option for components of the task (e.g. assessing uterine size with bimanual examination as part of medical abortion provision). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] These professionals perform transcervical procedures (e.g. IUD insertion) in some settings. The expert panel affirmed that the benefits outweigh possible harms and this option has the potential to increase equitable access to quality abortion care in regions where these professionals constitute a significant proportion of the health workforce.
Auxiliary nurses/ANMs	**Suggest** Condition: In contexts where established health system mechanisms involve auxiliary nurses/ANMs in providing basic emergency obstetric care, and where referral and monitoring systems are strong.	Although insufficient direct evidence was found for the safety and effectiveness of this option, the benefits outweigh any possible harms. This option has been shown to be feasible, including at scale in low-resource settings, and has the potential to decrease inequities by extending quality abortion care to rural and underserved populations.
Nurses	**Recommend**	Evidence was found for the safety and effectiveness (low certainty) and for women's satisfaction (low certainty) with this option. Women often consider care received from nurses as more supportive compared with other health workers (moderate-certainty evidence). This option is feasible and may decrease inequities by extending quality abortion care to underserved populations.
Midwives	**Recommend**	This task is recognized as a core competency in midwifery.[a] Evidence was found for the safety and effectiveness (moderate certainty) and for women's satisfaction with the overall abortion experience (low certainty) with this option. Women often consider care received from midwives as more supportive compared with other health workers (moderate-certainty evidence). This option has been shown to be feasible, including in low-resource settings.
Associate/advanced associate clinicians	**Recommend**	Evidence was found for the safety and effectiveness (moderate certainty) and for women's satisfaction with the overall abortion experience (low certainty) with this option. This option is feasible in all resource settings, and may decrease inequities by extending quality abortion care to underserved populations.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals, auxiliary nurses and auxiliary nurse midwives was reviewed using GRADE methodology. After review, only the recommendation for traditional and complementary medicine professionals was upgraded, from "suggest" to "recommend"; the recommendations for all the other health worker categories remained unchanged. A summary of the evidence is presented in Supplementary material 3, EtD framework for Vacuum aspiration for all indications < 14 weeks.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

In a health-care facility. Both types of vacuum aspiration can be performed in a primary care facility and on an outpatient basis.

How

Implementation considerations

- While MVA is more commonly used and more likely in primary care settings, the skills required for EVA are similar, thus the recommendations above apply to the provision of either form of vacuum aspiration.
- MVA is used earlier in pregnancy and in the absence of access to a stable source of electricity.
- Dilatation and sharp curettage (D&C) should be replaced with MVA.

What

CLINICAL SERVICES Recommendation 25: Methods of surgical abortion at gestational ages ≥ 14 weeks

For surgical abortion at ≥ 14 weeks: **Recommend** dilatation and evacuation (D&E).

Remark:

- Vacuum aspiration can be used during a D&E (i.e. for the purpose of amniotomy or tissue removal at the end of the D&E).

Source: Recommendation 5 carried forward from WHO (2012) *(19)*. The wording has been revised to use the word "recommend" to indicate that this is a strong recommendation, and the gestational age has been changed from "over 12 to 14 weeks" to "14 weeks and above" (≥ 14 weeks), and medical methods were removed (medical methods at later gestational ages are covered in Recommendation 29 in this guidance).

Who

SERVICE DELIVERY Recommendation 26: Dilatation and evacuation (D&E) for surgical abortion at gestational ages ≥ 14 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Suggest** Condition: In settings where established health system mechanisms exist to include these health workers in other tasks related to maternal and reproductive health.	Although no direct evidence was found for the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] This type of health worker has been suggested (weak recommendation) to do other transcervical procedures, such as cervical priming with osmotic dilators, vacuum aspiration and inserting an IUD (see Recommendations 20, 24 and 43). The expert panel affirmed that this option has the potential to increase equitable access to quality abortion care in regions where these professionals constitute a significant proportion of the health workforce.
Midwives	**Suggest** Condition: In settings where established health system mechanisms exist to include these health workers in other tasks related to maternal and reproductive health.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] This type of health worker has been recommended to do other transcervical procedures, such as cervical priming with osmotic dilators, vacuum aspiration and inserting an IUD (see Recommendations 20, 24 and 43).
Associate/advanced associate clinicians	**Suggest** Condition: In settings where established health system mechanisms exist to include these health workers in other tasks related to maternal and reproductive health.	Although no direct evidence was found on the safety or effectiveness of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that the potential benefits outweigh the possible harms, and this option has the potential to increase equitable access to quality abortion care beyond 14 weeks of gestation.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Generalist medical practitioners	**Recommend**	No direct evidence was found on the safety or effectiveness of this option as compared with provision by specialist medical practitioners. However, it appears to be feasible in both high- and low-resource settings where D&E use is common. Such doctors routinely perform other surgical procedures, such as caesarean section, vacuum aspiration and tubal ligation. The potential benefits of this option outweigh the harms. A specialist provider may not always be available on-site and this option may therefore increase equitable access to quality abortion care.
Specialist medical practitioners	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to associate/advanced associate clinicians (previously only suggested in the context of rigorous research), midwives and traditional and complementary medicine professionals (both previously recommended against) was reviewed using GRADE methodology. After review, the recommendations were upgraded for all of them to a weak recommendation ("suggest"). The gestational age range was also amended from "beyond 12 weeks" to "14 weeks and above" (≥ 14 weeks) to align with Recommendation 25 on this topic. A summary of the evidence is presented in Supplementary material 3, EtD framework for D&E for surgical abortion ≥ 14 weeks.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

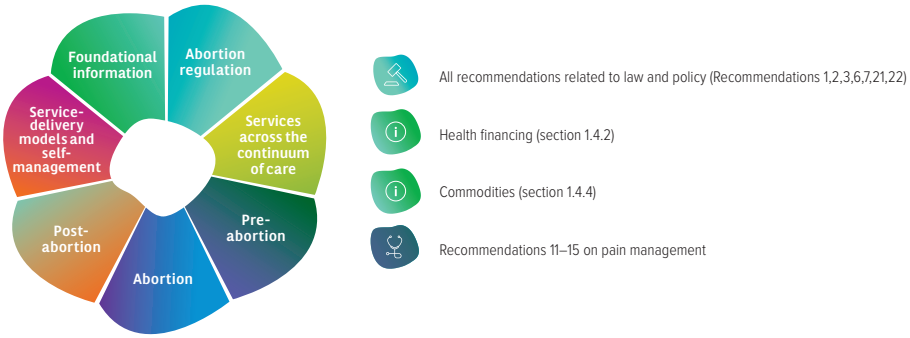
[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

In a health-care facility. The procedure can be provided on an outpatient basis.

How

Implementation considerations



- For all providers, skills needed for D&E provision are greater than for a vacuum aspiration done in earlier pregnancy and training needs are higher.
- D&E includes the use of vacuum aspiration and therefore skills and knowledge of vacuum aspiration are relevant for this task.
- Health workers providing abortion or caring for women undergoing abortion at gestational ages ≥ 12 weeks may have additional needs for professional and mentoring support.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO SURGICAL ABORTION

- Health-care facilities, commodities and services must be available, accessible, acceptable and of good quality. This means they must be evidence-based and scientifically and medically appropriate and up to date.
- **AT < 14 WEEKS OF GESTATION:** As dilatation and sharp curettage (D&C) causes pain and suffering to women and is not recommended for use, its use is incompatible with numerous human rights including the right to health.
- **AT ≥ 14 WEEKS OF GESTATION:** States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

3.4.2 Medical management of induced abortion

Medical management of spontaneous and induced abortion (for both viable and non-viable pregnancies) at early or later gestational ages involves the use of a single-dose regimen or a combination regimen of medicines used in sequence, with specific dosages and routes of administration.

The medicines that have been used for some decades for medical abortion are mifepristone in combination with misoprostol, or misoprostol alone. Similar to mifepristone, letrozole can be used in combination with misoprostol for medical abortion at early gestational ages. Letrozole is a third-generation selective aromatase inhibitor. Its mechanism of action involves suppression of estrogen levels, which modifies the progesterone receptor concentration, subsequently leading to pregnancy loss.

Medical abortion is a process that takes place over a period of up to several days rather than being a discrete procedure. In addition to information provision (including reasons to seek urgent care at any point during the process), medical abortion includes the following components or subtasks:

i. assessing eligibility for medical abortion (diagnosing and dating the pregnancy, ruling out medical contraindications);

ii. administering the abortion medicines with instructions on their appropriate use and managing the common side-effects;

iii. assessing whether the abortion process has had a successful outcome and whether any further intervention is required.

One health worker can provide the whole package of care for medical abortion, but it is equally possible for the subtasks to be carried out by different health workers and at different locations, including remotely. In addition, given the nature of the medical abortion process, it is also possible for women to manage the process by themselves outside of a health-care facility (e.g. at home), with support if and when needed. Such self-assessment and self-management approaches can be empowering for women and help to triage care, leading to a more woman-centred and more optimal use of health resources.

Routes of administration for misoprostol used for medical abortion:

- Oral – pills are swallowed immediately
- Buccal – pills are placed between the cheek and gums and swallowed after 20 to 30 minutes
- Sublingual – pills are placed under the tongue and swallowed after 30 minutes
- Vaginal – pills are placed in the vagina

What

CLINICAL SERVICES Recommendation 27: Medical management of induced abortion at gestational ages < 12 weeks

For medical abortion at < 12 weeks:

a. **Recommend** the use of 200 mg mifepristone administered orally, followed 1–2 days later by 800 µg misoprostol administered vaginally, sublingually or buccally. The minimum recommended interval between use of mifepristone and misoprostol is 24 hours.*

b. When using misoprostol alone: **Recommend** the use of 800 µg misoprostol administered buccally, sublingually or vaginally.*

c. **(NEW) Suggest** the use of a combination regimen of letrozole plus misoprostol (letrozole 10 mg orally each day for 3 days followed by misoprostol 800 µg sublingually on the fourth day) as a safe and effective option.*‡

Remarks:

- Evidence from clinical studies demonstrates that the combination regimen (Recommendation 27a) is more effective than misoprostol alone.
- All routes are included as options for misoprostol administration, in consideration of patient and provider preference.
- The suggested combination regimen of letrozole plus misoprostol may be safe and effective up to 14 weeks of gestation.

* Repeat doses of misoprostol can be considered when needed to achieve success of the abortion process. In this guideline we do not provide a maximum number of doses of misoprostol.

‡ Further evidence is needed to determine the safety, effectiveness and acceptability of the letrozole plus misoprostol combination regimen at later gestational ages, especially in comparison with that of the mifepristone plus misoprostol combination regimen (the available evidence focused on comparison with the use of misoprostol alone).

Source: Recommendations 27a and 27b carried forward from WHO (2018) where they were Recommendation 3a *(120)*. Recommendation 27c is new.

Rationale for Recommendation 27c (combination regimen of letrozole plus misoprostol)

A systematic review assessed the efficacy, safety and acceptability of alternative methods of medical abortion to the standard regimens using mifepristone and/or misoprostol. The literature search identified seven studies, all of which reported on the combination of letrozole plus misoprostol (intervention) versus misoprostol alone (comparison) for medical abortion. No studies were identified that compared letrozole plus misoprostol versus mifepristone plus misoprostol. The study settings included China, Egypt and the Islamic Republic of Iran. A summary of the evidence is presented in Supplementary material 2, EtD framework for New medical methods for abortion.

Overall, the evidence favoured the intervention. The use of letrozole in combination with misoprostol showed lower rates of ongoing pregnancy and higher rates of successful abortion, based on low- to very low-certainty evidence. In addition, fewer women experienced side-effects, based on moderate-certainty evidence.

Discussion on the cost-effectiveness, equity, feasibility and acceptability favoured the intervention. Letrozole's typical use for infertility and cancer treatment makes it more readily accessible than mifepristone in certain parts of the world. In addition, the low cost of letrozole is another contributing factor to making this an alternative method for medical abortion.

Who

SERVICE DELIVERY Recommendation 28: Medical management of induced abortion at gestational ages < 12 weeks,* in whole or in part (i.e. performing all or some of the subtasks; see list at start of section 3.4.2) using mifepristone plus misoprostol, or misoprostol alone‡

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Recommend**	Evidence was found for the safety, effectiveness and acceptability of this option, for all three subtasks of medical abortion (moderate certainty). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] Indirect evidence also demonstrated the feasibility and acceptability of CHWs facilitating assessment of eligibility and outcome.
Pharmacy workers	**Recommend**	Limited evidence was found for the safety, effectiveness, acceptability or feasibility of this option (non-comparative studies). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] Indirect evidence on CHWs was applied to support the feasibility of this option.
Pharmacists	**Recommend**	Although insufficient evidence was found for the safety, effectiveness and acceptability of pharmacists performing the three subtasks of medical abortion, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] Dispensing medicines on prescription is within their typical scope of practice. The expert panel affirmed that, with the aid of tools for assessment of eligibility and outcome, it would be feasible for pharmacists to provide all three subtasks of medical abortion.
Traditional and complementary medicine professionals	**Recommend**	Evidence was found for the safety and effectiveness of this option, and for women's satisfaction with this type of provider and services provided by them (very low certainty). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that the benefits outweigh any possible harms, and the potential to increase equitable access to quality abortion care in regions where these professionals constitute a significant proportion of the health workforce is high.
Auxiliary nurses/ANMs	**Recommend**	Evidence was found for the safety and effectiveness of this option (moderate certainty). This option is feasible and is already being implemented in some low-resource settings.
Nurses	**Recommend**	Evidence was found for the safety and effectiveness of this option, and for women's satisfaction with abortion services with this option (moderate certainty).
Midwives	**Recommend**	Evidence was found for the safety and effectiveness of this option (moderate certainty). More women are satisfied with the provider when midwives provide medical abortion (moderate-certainty evidence). This option is feasible and is already being implemented in several countries.
Associate/advanced associate clinicians	**Recommend**	Insufficient direct evidence was found for the effectiveness of these clinicians carrying out components of the task, e.g. assessing gestational age as part of provision of manual vacuum aspiration. Evidence was also found that health worker types with similar or less comprehensive basic training (e.g. midwives, nurses, auxiliary nurse midwives) can provide medical abortion safely and effectively (moderate certainty). This option is feasible and the potential to expand access to underserved populations is high.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Individual/self		
Pregnant woman, girl or other pregnant person	**Recommend**	Please refer to Recommendation 50 in section 3.6.2 for rationale, remarks and implementation considerations for this recommendation and further information on self-management approaches.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals (previously only recommended in contexts with established health system mechanisms for the participation of these health workers in other tasks related to maternal and reproductive health), pharmacists (previously only suggested in the context of rigorous research), pharmacy workers (previously "recommend against"), community health workers (previously only suggested in the context of rigorous research) and individual/self (self-management; previously "suggest") was reviewed using GRADE methodology. After review, the recommendations were upgraded for all of those health worker categories to "recommend", including all three subtasks of this intervention. A summary of the evidence is presented in Supplementary material 3, EtD framework for Medical abortion at < 12 weeks.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

* Available evidence for the independent provision of medical abortion by non-physicians is for pregnancy durations up to 10 weeks (70 days).

‡ For this recommendation, the medical abortion regimens covered in the available evidence were mifepristone plus misoprostol, or misoprostol alone (the regimen using letrozole was not included).

No requirement for location (on-site vs off-site).

Implementation considerations

- It is not essential that the person providing the medical abortion should also be trained and competent in vacuum aspiration provision.
- Restrictions on prescribing and dispensing authority for some categories of health workers may need to be modified within the regulatory framework of the health system or other mechanisms put in place to allow these providers to make the medicines available to abortion seekers.
- Privacy should be ensured in all settings, in particular in places where a private space may be challenging (e.g. pharmacies).
- Support tools can be used to assess eligibility and outcome (e.g. high-sensitivity pregnancy tests, checklists).
- A range of service-delivery models exist to facilitate the medical abortion process, such as telemedicine or community outreach (see section 3.6.1).
- Mechanisms to ensure access to quality medicines need to be set up. Development of tools like point-of-care tests to assess quality could support both the pharmacy worker and the individual.
- It is important to note that as with all other medicines, pharmacy workers should dispense mifepristone and misoprostol as indicated by prescription.
- The person undergoing medical abortion should have access/referral to emergency care in case this becomes necessary.
- As part of the enabling environment, health workers should recognize self-management as a legitimate pathway to abortion care and to adapt health systems to facilitate and support women in their self-management of abortion, e.g. adapting clinical protocols.
- Mechanisms need to be established to ensure access or referrals to post-abortion contraception services and provision of contraceptives for women who want them.

What

CLINICAL SERVICES Recommendation 29: Medical management of induced abortion at gestational ages ≥ 12 weeks

For medical abortion at ≥ 12 weeks:

a. **Suggest** the use of 200 mg mifepristone administered orally, followed 1–2 days later by repeat doses of 400 µg misoprostol administered buccally, sublingually or vaginally every 3 hours.*‡ The minimum recommended interval between use of mifepristone and misoprostol is 24 hours.

b. When using misoprostol alone: **Suggest** the use of repeat doses of 400 µg misoprostol administered vaginally, sublingually or buccally every 3 hours.*‡

Remarks:

- The combination regimen (Recommendation 29a) is more effective than use of misoprostol alone.
- Evidence suggests that the vaginal route is the most effective. Consideration for patient and provider preference suggests the inclusion of all routes.
- Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise.

* Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. Providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with a prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with later gestational age.

‡ The dose of misoprostol should be reduced for induced abortion beyond 24 weeks due to limited data. Clinical judgement should be used to determine the appropriate dosage, recognizing the greater sensitivity of the uterus to prostaglandins.

Source: Recommendation 3b carried forward from WHO (2018) *(120)*.

Who

SERVICE DELIVERY Recommendation 30: Medical management of induced abortion at gestational ages ≥ 12 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, these professionals have been recommended to provide medical abortion at < 12 weeks (Recommendation 28). The potential to increase equitable access to quality abortion care in regions where these professionals form a significant proportion of the health workforce is high.
Auxiliary nurses/ANMs	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, these health workers have been recommended to provide medical abortion at < 12 weeks (Recommendation 28). This option is feasible and acceptable and has the potential to increase equitable access to quality abortion care.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Nurses	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety and effectiveness of nurses providing this intervention as a whole, these health workers are often responsible for the monitoring and care of women from the time of misoprostol administration to completion of the abortion. Women often find abortion care provided by nurses to be more acceptable (moderate-certainty evidence).
Midwives	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety and effectiveness of midwives providing this intervention as a whole, these health workers are often responsible for the monitoring and care of women from the time of misoprostol administration to completion of the abortion. Women often find abortion care provided by midwives to be more acceptable (moderate-certainty evidence).
Associate/advanced associate clinicians	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety of effectiveness of this option, these clinicians routinely carry out tasks of similar complexity (e.g. vacuum aspiration and manual removal of placenta) *(138)*. These clinicians are often present at higher-level facilities where care during advanced gestation is provided. A trained specialist medical practitioner may not always be present at higher-level facilities and the potential to sustain services for advanced gestational ages is increased with more than one trained provider on site.
Generalist medical practitioners	**Recommend**	Although insufficient direct evidence was found for the safety and effectiveness of this option, generalist medical practitioners routinely carry out tasks of similar or greater complexity (e.g. conducting deliveries, manual removal of placenta, vacuum aspiration). The potential benefits of this option outweigh the harms and the intervention has proven feasible in several settings. A specialist medical practitioner may not always be available on-site and therefore this option may increase equitable access to quality abortion care.
Specialist medical practitioners	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

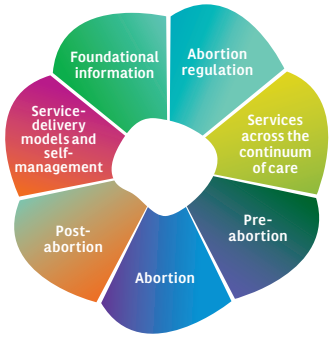
Notes on updating of the recommendation: This was an existing recommendation for which evidence relating to all health worker categories was reviewed using GRADE methodology, except for specialist and generalist medical practitioners, for whom there was already a strong recommendation for this task. After review, the recommendations were upgraded for traditional and complementary medicine professionals and auxiliary nurses/ANMs from "recommend against" to "suggest" with specified conditions. For the other health worker categories reviewed, the recommendations remain unchanged. A summary of the evidence is presented in Supplementary material 3, EtD framework for Medical abortion at ≥ 12 weeks.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Medical abortion for pregnancies at gestational ages ≥ 12 weeks has been practised and researched as a facility-based procedure during which women should remain under observation until the process is complete.

Implementation consideration



- Health workers providing abortion or caring for women undergoing abortion at gestational ages ≥ 12 weeks may have additional needs for professional and mentoring support.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO MEDICAL ABORTION

- Everyone has a right to privacy and confidentiality in sexual and reproductive health (SRH) care.
- Abortion regulation should be human rights and evidence based.
- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- Everyone has the right to scientific progress and right to health, which requires the availability and accessibility, acceptability, and quality of medical abortion. This means that States should ensure access to abortion medicines, and that evidence-based standards and guidelines for the provision and delivery of SRH services, are (i) in place and (ii) routinely updated to incorporate medical advancements.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations related to law and policy (Recommendations 1,2,3,6,7,21,22)

Information provision and counselling (section 3.2.1 and 3.2.2)

Determining gestational age (section 3.3.5)

Pain management for abortion (section 3.3.6)

Self-management of medical abortion (section 3.6.2)

3.4.3 Missed abortion

Missed abortion is when a pregnancy stops developing, where the embryo/fetus/embryonic tissue or empty gestation sac remains in the uterus and the cervical os is closed. Symptoms may include pain, bleeding or no symptoms at all. If an ultrasound is done, the scan may show an embryo or fetus without cardiac activity, or what appears to be an early developing pregnancy, with only a fluid-filled sac visible within the uterus *(151)*. Medical, surgical (vacuum aspiration) and expectant management are all options for management of missed abortion.

What

CLINICAL SERVICES Recommendation 31 (NEW): Medical management of missed abortion at gestational ages < 14 weeks

For missed abortion at < 14 weeks, for individuals preferring medical management: **Recommend** the use of combination mifepristone plus misoprostol over misoprostol alone.

- Recommended regimen: 200 mg mifepristone administered orally, followed by 800 µg misoprostol administered by any route (buccal, sublingual, vaginal).*
- Alternative regimen: 800 µg misoprostol administered by any route (buccal, sublingual, vaginal).‡

Remarks:

- The decision about the mode of management (expectant, medical or surgical) of missed abortion should be based on the individual's clinical condition and preference for treatment.
- Expectant management can be offered as an option on the condition that the woman, girl or other pregnant person is informed of the longer time for expulsion of the pregnancy tissue and the increased risk of incomplete emptying of the uterus.
- Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise.

* The minimum recommended interval between use of mifepristone and misoprostol is 24 hours.

‡ If using the alternative regimen (misoprostol alone), it should be noted that at gestational ages ≥ 9 weeks, evidence shows that repeat dosing of misoprostol is more effective to achieve success of the abortion process. In this guideline we do not provide a maximum number of doses of misoprostol.

Rationale

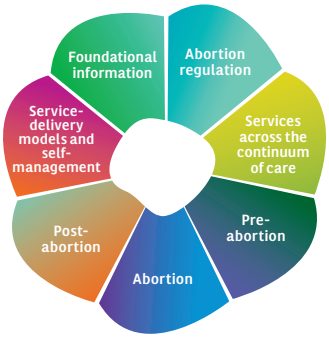
A systematic review was undertaken to address this key question. Twenty studies reporting on management for missed abortion were identified by the search strategy. These studies were conducted in China, Germany, India, Israel, Malaysia, Pakistan, Sweden, Thailand, United Kingdom, USA and Yemen. A summary of the evidence is presented in Supplementary material 2, EtD framework for Medical management of missed abortion at < 14 weeks.

Of these studies, 19 were assessed that included one of the following comparisons:

- Mifepristone and misoprostol versus misoprostol alone
- Medical versus expectant management
- Surgical versus medical/expectant management

Medical management in comparison to expectant management produced lower rates of ongoing pregnancy and higher rates of successful abortion (uterine evacuation without surgical intervention), based on moderate- to high-certainty evidence. When comparing the combination regimen with misoprostol alone, the combination regimen produced higher rates of successful abortion. This recommendation is based on moderate-certainty evidence. Complications and side-effects were also fewer, based on moderate- to high-certainty evidence. Women expressed greater satisfaction with the combination mifepristone plus misoprostol regimen, based on high-certainty evidence. Surgical management in comparison to medical and expectant management produced higher rates of successful abortion, based on low- to moderate-certainty evidence. Discussion of women's values and preferences underlined the importance of offering the option of all three types of management to the woman. For the medical regimen, the expert panel determined that given the varied regimens of the included studies, the recommended and suggested regimens for induced abortion at < 12 weeks of gestation can be applied (see Recommendation 27).

Who



Regarding who is recommended to provide medical management of missed abortion at < 14 weeks of gestation, refer to Recommendation 28 for medical management of induced abortion at gestational ages < 12 weeks.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO MANAGEMENT OF MISSED ABORTION

- Everyone has a right to privacy and confidentiality in sexual and reproductive health (SRH) care.
- Abortion regulation should be human rights and evidence based.
- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- Everyone has the right to scientific progress and right to health, which requires the availability and accessibility, acceptability, and quality of medical abortion. This means that States should ensure access to abortion medicines, and that evidence-based standards and guidelines for the provision and delivery of SRH services, are (i) in place and (ii) routinely updated to incorporate medical advancements.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Commodities (section 1.3.4)

Information provision and counselling (sections 3.2.1 and 3.2.2)

Recommendation 27: Medical management of induced abortion < 12 weeks

3.4.4 Intrauterine fetal demise (IUFD)

Fetal demise (fetal death) refers to situations in which the fetus is no longer alive, but the uterus has not yet started to expel its contents and the cervical os remains closed *(152)*. The diagnosis is made by ultrasound scan following the clinical findings, which can include vaginal bleeding, absent fetal heart sounds on electronic auscultation, a failure to feel fetal movements or a uterus that is significantly smaller than the expected size *(152)*. IUFD may be managed expectantly, or treated surgically (D&E) or medically.

What

CLINICAL SERVICES Recommendation 32: Medical management of IUFD at gestational ages ≥ 14 to ≤ 28 weeks

For medical management of IUFD at ≥ 14 to ≤ 28 weeks: **Suggest** the use of combination mifepristone plus misoprostol over misoprostol alone.

- Suggested regimen: 200 mg mifepristone administered orally, followed 1–2 days later by repeat doses of 400 µg misoprostol administered sublingually or vaginally every 4–6 hours.*‡ The minimum recommended interval between use of mifepristone and misoprostol is 24 hours.
- Alternative regimens: repeat doses of 400 µg misoprostol administered sublingually or vaginally every 4–6 hours.*‡

Remarks:

- Evidence from clinical studies indicates that the combination regimen is more effective than the use of misoprostol alone.
- Pregnancy tissue should be treated in the same way as other biological material unless the individual expresses a desire for it to be managed otherwise.

* Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. Providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with later gestational age.

‡ The dose of misoprostol should be reduced for IUFD beyond 28 weeks due to limited data. Clinical judgement should be used to determine the appropriate dosage, recognizing the greater sensitivity of the uterus to prostaglandins.

Source: Recommendation 2 carried forward from WHO (2018) *(120)*. Wording has been revised to match that used for Recommendation 31 on missed abortion.

Who

SERVICE DELIVERY Recommendation 33 (NEW): Medical management of intrauterine fetal demise (IUFD) at gestational ages ≥ 14 to ≤ 28 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, these professionals have been recommended to provide medical abortion at < 12 weeks (Recommendation 28). The expert panel affirmed that the potential to increase equitable access to quality abortion care in regions where such professionals constitute a significant proportion of the health workforce is high.
Auxiliary nurses/ANMs	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although no direct evidence was found on the safety, effectiveness or acceptability of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, these health workers have been recommended to provide medical abortion at < 12 weeks (Recommendation 28). The expert panel determined that this option is feasible and acceptable with the potential to increase equitable access to quality abortion care.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Nurses	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety and effectiveness of this option, these health workers are often responsible for the monitoring and care of women from the time of misoprostol administration to completion of the abortion. Women often find abortion care provided by nurses to be more acceptable compared with other health workers (moderate-certainty evidence).
Midwives	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety and effectiveness of this option, these health workers are often responsible for the monitoring and care of women from the time of misoprostol administration to completion of the abortion. Women often find abortion care provided by midwives to be more acceptable compared with other health workers (moderate-certainty evidence).
Associate/advanced associate clinicians	**Suggest** Condition: In contexts where established and easy access to appropriate surgical backup and proper infrastructure is available to address incomplete abortion or other complications.	Although insufficient direct evidence was found for the safety and effectiveness of this option, these clinicians routinely carry out tasks of similar complexity, such as vacuum aspiration and manual removal of placentas *(138)*. These clinicians are often present at higher-level facilities where care is provided in advanced gestation. A trained specialist medical practitioner may not always be present at a higher-level facility and the potential to sustain services for advanced gestational ages is increased with more than one trained provider on site.
Generalist medical practitioners	Recommend	Although insufficient direct evidence was found for the safety and effectiveness of this option, these professionals routinely carry out tasks of similar or greater complexity (e.g. conducting deliveries, manual removal of placentas, vacuum aspiration). The potential benefits of this option outweigh the harms, and the intervention has proven feasible in several settings. A specialist medical practitioner may not always be available on site and therefore this option may increase equitable access to quality abortion care.
Specialist medical practitioners	Recommend	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Note: This is a new recommendation. There was no recommendation on medical management of IUFD in WHO's 2015 guideline on health worker roles *(23)*, but a clinical services recommendation on this intervention was provided in WHO's 2018 guideline, *Medical management of abortion (120)*. Due to the lack of direct evidence on this topic and the similarity between the two tasks, Recommendation 30 for medical abortion at ≥ 12 weeks of gestation was applied here. A summary of the evidence is presented in Supplementary material 3, EtD framework on Medical management of intrauterine fetal demise.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

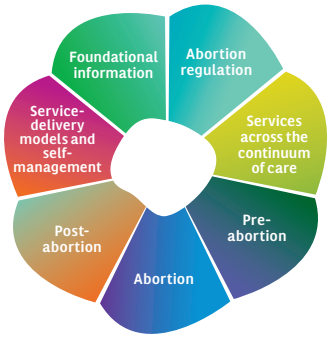
[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

Medical abortion for pregnancies at gestational ages ≥ 12 weeks has been practised and researched as a facility-based procedure during which women should remain under observation until the process is complete.

How

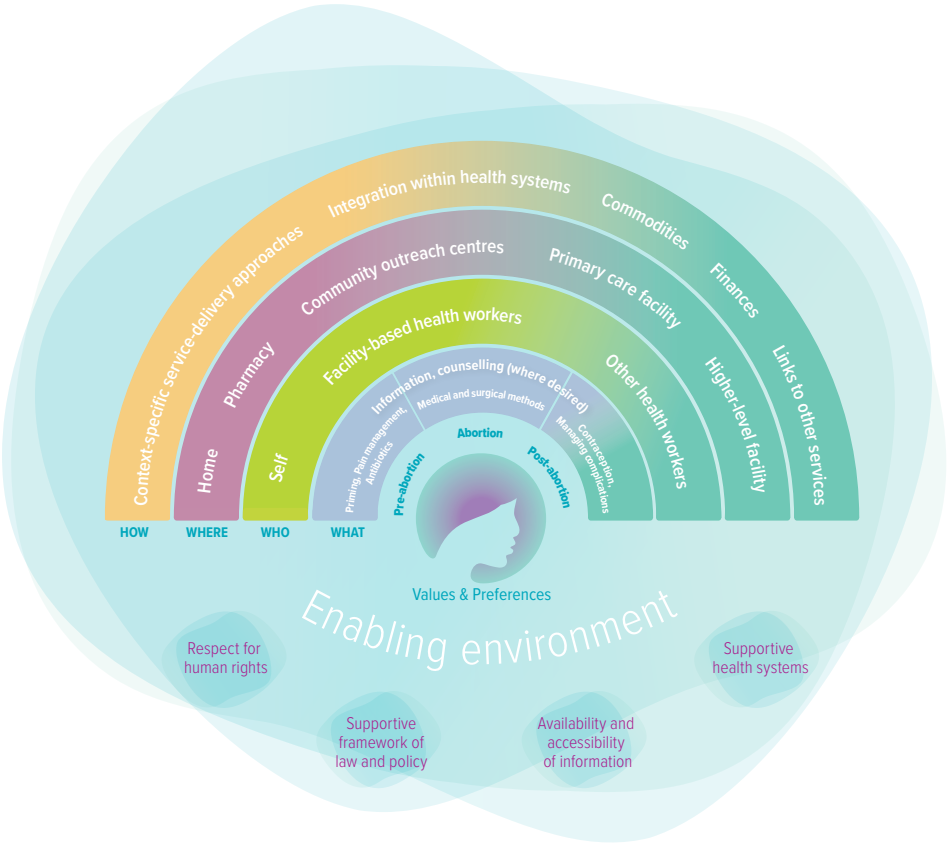
Implementation consideration



- Any regulation around the management/disposal of pregnancy remains and birth or death certificates should not pose a burden or a breach of confidentiality for women or providers.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO MANAGEMENT OF IUFD

- Everyone has a right to privacy and confidentiality in sexual and reproductive health (SRH) care.
- Abortion regulation should be human rights and evidence based.
- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- Everyone has the right to scientific progress and right to health, which requires the availability and accessibility, acceptability, and quality of medical abortion. This means that States should ensure access to abortion medicines, and that evidence-based standards and guidelines for the provision and delivery of SRH services, are (i) in place and (ii) routinely updated to incorporate medical advancements.



For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations relating to law and policy (Recommendations 1,2,3,6,7,21,22)

3.5 Post-abortion

The post-abortion period is the third and final part of the continuum of care for abortion. Post-abortion care includes any or all of the following, as needed or desired: optional follow-up check-up, management of residual side-effects or complications, and contraception services. When done safely, abortion complications are rare, but they can include incomplete abortion, haemorrhage, infection, uterine perforation, anaesthesia-related complications, uterine rupture. In line with international human rights law and medical best practice, post-abortion care should always be provided regardless of whether abortion is restricted in a particular setting.

3.5.1 Follow-up care after abortion

Routine follow-up is not necessary following an uncomplicated surgical or medical abortion, if the individual has adequate information about when to seek care for complications and has received any appropriate supplies or information to meet contraceptive needs. However, an optional follow-up visit 7–14 days after the procedure may be offered to provide contraceptive services, emotional support or management of any medical concerns.

If the woman chooses to attend a follow-up appointment, then use the contact to:

- assess the individual's recovery and inquire about any signs or symptoms of ongoing pregnancy;
- review any available medical records and referral documents;
- ask about any symptoms experienced since the procedure;
- perform a focused physical examination if needed to assess any complaints; and
- assess the individual's fertility goals and need for contraceptive services.
    - If no contraceptive method was provided or started at the time of the abortion, provide information on contraception and offer contraceptive counselling and provision of contraceptive services, if desired by the woman.
    - If a contraceptive method was already started, assess the method used and address any concerns or resupply as needed *(122)*.

What

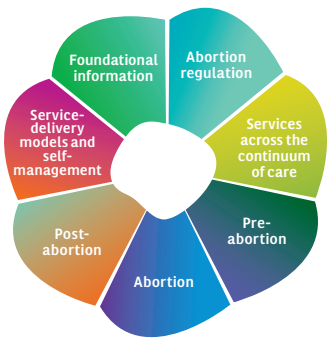
CLINICAL SERVICES Recommendation 34: Follow-up care or additional services after abortion

Following uncomplicated surgical abortion or medical abortion: **Recommend** that there is no medical need for a routine follow-up visit. However, information should be provided about the availability of additional services if they are needed or desired.

Remarks:

- Women, girls and other pregnant persons must be adequately informed about symptoms of ongoing pregnancy (which may or may not indicate failure of the abortion) and other medical reasons to return for follow-up, such as prolonged heavy bleeding, no bleeding at all with medical management of abortion, pain not relieved by medication, or fever.
- The quality of the evidence was low (observational studies and indirect evidence).

Source: Recommendation 9 updated from WHO (2012) *(19)*.



Note on updating of the recommendation: This was an existing recommendation for which an updated literature search was conducted, but GRADE methodology was not applied. The wording of the recommendation was revised to remove the medical abortion regimen that was mentioned (this recommendation now applies to all abortion methods and regimens, see section 3.4) and to use the word "recommend" to make clear this is a strong recommendation.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO FOLLOW-UP CARE

- Regardless of whether abortion is legal, States are required to ensure access to post-abortion care where it is needed.
- Post-abortion care must be available on a confidential basis, including in situations where abortion is illegal.
- Post-abortion care must be available without the threat of criminal prosecution or punitive measures. States must not require health workers to report persons suspected of undertaking unlawful abortion, or require them to provide any potentially incriminating information during or as a prerequisite to receiving post-abortion care.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Information provision (section 3.2.1)

3.5.2 Incomplete abortion

Incomplete abortion is defined by clinical presence of an open cervical os and bleeding, whereby all products of conception have not been expelled from the uterus, or the expelled products are not consistent with the estimated duration of pregnancy. Common symptoms include vaginal bleeding and abdominal pain. Uncomplicated incomplete abortion can result after an induced or spontaneous abortion (i.e. miscarriage); the management in both cases is the same. Incomplete abortion may be managed expectantly, medically or surgically (vacuum aspiration). Managing uncomplicated incomplete abortion with vacuum aspiration (when uterine size is less than 14 weeks) includes recognizing the condition, assessing uterine size, the actual procedure and pain management.

What

CLINICAL SERVICES Recommendation 35 and 36:
Management of incomplete abortion

35. For incomplete abortion at < 14 weeks: **Recommend** either vacuum aspiration or medical management.

36a. For the medical management of incomplete abortion at < 14 weeks uterine size: **Suggest** the use of 600 µg misoprostol administered orally or 400 µg misoprostol administered sublingually.

36b. For the medical management of incomplete abortion at ≥ 14 weeks uterine size: **Suggest** the use of repeat doses of 400 µg misoprostol administered sublingually, vaginally or buccally every 3 hours.*

Remarks:

- The decision about the mode of management of incomplete abortion should be based on the individual's clinical condition and preference for treatment.
- Expectant management of incomplete abortion can be as effective as misoprostol; it can be offered as an option on the condition that the woman, girl or other pregnant person is informed of the longer time for expulsion of the pregnancy tissue and the increased risk of incomplete emptying of the uterus.
- Recommendation 35 was extrapolated from research conducted in women with reported spontaneous abortion.

* Misoprostol can be repeated at the noted interval as needed to achieve success of the abortion process. At gestational ages ≥ 14 weeks, providers should use caution and clinical judgement to decide the maximum number of doses of misoprostol in pregnant individuals with prior uterine incision. Uterine rupture is a rare complication; clinical judgement and health system preparedness for emergency management of uterine rupture must be considered with advanced gestational age.

Source: Recommendation 35 carried forward from WHO (2012) where it was Recommendation 10 *(19)*. The wording has been revised to amend the gestational age from "13 weeks or less" to "before 14 weeks" (< 14 weeks). Recommendations 36a and 36b carried forward from WHO (2018) where they were Recommendations 1A and 1B *(120)*. The gestational ages have also been updated to change the cut-off point from 13 weeks to 14 weeks.

Who

SERVICE DELIVERY Recommendation 37: Medical management of uncomplicated incomplete abortion with misoprostol at gestational ages < 14 weeks

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Recommend**	No direct evidence was found for this option, but some indirect evidence was found that CHWs can use simple tools and checklists to determine gestational age (based on patient history), and to assess eligibility for and the outcome of medical abortion (low to moderate certainty). CHWs are often involved in advising women seeking abortion care (moderate-certainty evidence). In general, CHW interventions are acceptable and have proved feasible in many contexts. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a]
Pharmacy workers **Pharmacists**	**Recommend**	Although insufficient evidence was found for the safety and effectiveness of this option, the skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] In addition, the skills required for managing incomplete abortion with misoprostol are similar to those for provision of medical abortion at < 12 weeks, which is a recommended task for these health workers (see Recommendation 28).
Traditional and complementary medicine professionals	**Recommend**	Evidence was found for the safety and effectiveness of these professionals providing medical abortion at gestational ages < 12 weeks (low certainty), and the skills required for managing incomplete abortion with misoprostol are similar. In addition, the skills and knowledge for this task (according to the competency framework) align with the competencies of this type of health worker.[a]
Auxiliary nurses/ANMs	**Recommend**	Evidence was found for the safety and effectiveness of these health workers providing medical abortion at gestational ages < 12 weeks (moderate certainty), and the skills required for managing incomplete abortion with misoprostol are similar.
Nurses	**Recommend**	Indirect evidence was found for the safety, effectiveness and acceptability of nurses providing medical abortion (moderate certainty), and the skills required for managing incomplete abortion with misoprostol are similar. The option is feasible and has the potential to increase equitable access to quality abortion care.
Midwives	**Recommend**	Evidence was found from a low-resource setting for the safety and effectiveness of this option (moderate to high certainty). Women's overall satisfaction with the provider was high when midwives manage incomplete abortion (moderate-certainty evidence). This option is feasible and has the potential to increase equitable access to quality abortion care.
Associate/advanced associate clinicians	**Recommend**	Moderate-certainty indirect evidence was found for the safety and effectiveness of medical management of incomplete abortion by midwives, and moderate-certainty evidence was also found for the safety and effectiveness of medical abortion provision by health worker types with similar or less comprehensive basic training. Additionally, direct evidence was found that these clinicians can assess gestational age (by uterine size) as part of provision of manual vacuum aspiration. This option is feasible and the potential to increase equitable access to quality abortion care is high.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendations for which evidence relating to traditional and complementary medicine professionals (previously "suggest"), pharmacists and pharmacy workers (both previously "recommend against") and community health workers (previously "within the context of rigorous research") was reviewed using GRADE methodology, since the other health workers already had a strong recommendation for this task. After review, the recommendations were upgraded to "recommend" for all of the reviewed health worker categories. A summary of the evidence is presented in Supplementary material 3, EtD framework on Medical management of incomplete abortion.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

No requirement for location (on-site vs off-site).

How

Implementation considerations

- Restrictions on prescribing authority for some categories of providers may need to be modified or other mechanisms put in place for making the medicines available for these providers within the regulatory framework of the health system.
- The evacuation of retained products is a signal function of basic emergency obstetric care (EmOC); thus training and implementation of these tasks can be integrated with EmOC services.

Who

SERVICE DELIVERY Recommendation 38: Vacuum aspiration for management of uncomplicated incomplete abortion at gestational ages < 14 weeks

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Recommend**	Evidence was found for the effectiveness of these professionals carrying out components of the task, such as assessing uterine size with bimanual examination as part of medical abortion provision (very low certainty). The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] These professionals perform other transcervical procedures (e.g. IUD insertion) in some settings. This option has the potential to increase equitable access to quality abortion care in regions where these professionals constitute a significant proportion of the health workforce.
Auxiliary nurses/ANMs	**Suggest** Condition: In contexts where established health system mechanisms involve auxiliary nurses/ANMs in providing basic emergency obstetric care, and where referral and monitoring systems are strong.	Insufficient direct evidence was found for the safety and effectiveness of this option. However, the option of this type of health worker delivering emergency obstetric care (which includes removing retained products as a signal function) or post-abortion care using manual vacuum aspiration has been shown to be feasible in programmes in several low-resource settings.
Nurses	**Recommend**	Evidence was found for the safety and effectiveness of these health workers providing vacuum aspiration for induced abortion (low certainty), and the skills required for the management of uncomplicated incomplete abortion with vacuum aspiration are similar. The option is feasible, including in low-resource settings.
Midwives	**Recommend**	Indirect evidence was found for the safety and effectiveness of these health workers providing vacuum aspiration for induced abortion (moderate certainty), and the skills required for the management of uncomplicated incomplete abortion with vacuum aspiration are similar. The option is feasible, including in low-resource settings.

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Associate/advanced associate clinicians	**Recommend**	Indirect evidence was found for the safety and effectiveness of these clinicians providing of vacuum aspiration for induced abortion (moderate certainty), and the skills required for the management of uncomplicated incomplete abortion with vacuum aspiration are similar.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals and for auxiliary nurses and auxiliary nurse midwives was reviewed using GRADE methodology. After review, only the recommendation for traditional and complementary medicine professionals was upgraded from "suggest" to "recommend". For all the other health worker categories, the recommendations remain unchanged from the previous guidance. A summary of the evidence is presented in Supplementary material 3, EtD framework on Vacuum aspiration for management of incomplete abortion.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

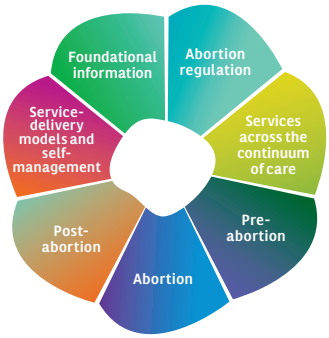
[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Where

In a health-care facility.

How

Implementation considerations



- The skills required for the provision of both MVA and EVA are similar, so the recommendations above apply to both. MVA is more commonly used and more likely to be used in primary care settings.
- Uncomplicated incomplete abortion can result after an induced or spontaneous abortion (i.e. miscarriage). The management is identical and the above recommendations apply to both.
- The evacuation of retained products is also a signal function of basic emergency obstetric care (EmOC) and training and implementation can be integrated with EmOC services.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO MANAGEMENT OF INCOMPLETE ABORTION

- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- Regardless of whether abortion is legal, States are required to ensure access to post-abortion care where it is needed.
- Post-abortion care must be available on a confidential basis, including in situations where abortion is illegal.
- Post-abortion care must be available without the threat of criminal prosecution or punitive measures. States must not require health workers to report persons suspected of undertaking unlawful abortion, or require them to provide any potentially incriminating information during or as a prerequisite to receiving post-abortion care.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Commodities (section 1.4.4)

3.5.3 Management of non-life-threatening complications: infection and haemorrhage

Initial and basic management includes recognizing the complication, stabilizing the woman, providing oral or parenteral antibiotics and intravenous fluids prior to referral to an appropriate health worker/facility.

Who

SERVICE DELIVERY Recommendation 39: Initial management of non-life-threatening post-abortion infection*

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Recommend**	Although no direct evidence was found for the management of post-abortion infection by these health workers, their basic training covers the skills required for this task. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] The expert panel affirmed that this option is feasible and that it has the potential to increase equitable access to post-abortion care.
Auxiliary nurses/ANMs **Nurses** **Midwives** **Associate/advanced associate clinicians**	**Recommend**	Although no direct evidence was found for the management of post-abortion infection by these health workers, the management of puerperal sepsis with intramuscular antibiotics, which requires similar skills, is within their typical scope of practice *(138)*.[b]
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals, pharmacists, pharmacy workers and community health workers was reviewed using GRADE methodology. After review, the recommendation was only upgraded for traditional and complementary medicine professionals, from "suggest" to "recommend." For all other health worker categories reviewed, the recommendations remain "recommend against" (not listed). A summary of the evidence is presented in Supplementary material 3, EtD framework on Diagnosis and management of abortion-related complications.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

* For the pharmacists, pharmacy workers and community health workers, it is important that they are equipped with the knowledge to recognize signs and symptoms of this complication.

Where

No requirement for location (on-site vs off-site).

How

Implementation considerations

- It is important that pharmacists, pharmacy workers and community health workers are equipped with the knowledge to recognize signs and symptoms of the complications of unsafe abortion and to know where to refer women in their communities.
- Restrictions on prescribing authority for some categories of providers may need to be modified or other mechanisms put in place for allowing such providers to administer the antibiotics within the regulatory framework of the health system.

Who

SERVICE DELIVERY Recommendation 40: Initial management of non-life-threatening post-abortion haemorrhage*

Type of health worker	Recommendation	Rationale[a]
Traditional and complementary medicine professionals	**Recommend**	No direct evidence was found for the management of post-abortion haemorrhage by these professionals, but their basic training covers the skills required for this task. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a]
Auxiliary nurses/ANMs	**Recommend**	Although no direct evidence was found for the management of post-abortion haemorrhage by these health workers, the initial management of post-partum haemorrhage with intravenous (IV) fluids, which requires similar skills, is a task that these health workers are recommended to do *(138)*.
Nurses **Midwives** **Associate/advanced associate clinicians**	**Recommend**	Although no direct evidence was found for the management of post-abortion haemorrhage by these health workers, the initial management of post-partum haemorrhage with IV fluids, which requires similar skills, is within their typical scope of practice *(138)*.
Generalist medical practitioners **Specialist medical practitioners**	**Recommend**	Within their typical scope of practice,[b] therefore no assessment of the evidence was conducted.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals, pharmacists, pharmacy workers and community health workers was reviewed using GRADE methodology. After review, the recommendation was only upgraded for traditional and complementary medicine professionals, from "suggest" to "recommend". For all other health worker categories reviewed, the recommendations remain "recommend against" (not listed). A summary of the evidence is presented in Supplementary material 3, EtD framework on Diagnosis and management of abortion-related complications.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

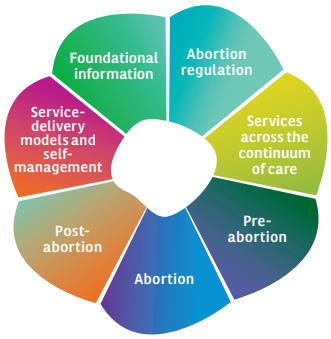
* For the pharmacists, pharmacy workers and community health workers, it is important that they are equipped with the knowledge to recognize signs and symptoms of this complication.

Where

No requirement for location (on-site vs off-site).

How

Implementation consideration



- Initial management of haemorrhage and infection is also a signal function of basic emergency obstetric care (EmOC) and training and implementation can be integrated with EmOC services.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO NON-LIFE-THREATENING COMPLICATIONS

- Regardless of whether abortion is legal, States are required to ensure access to post-abortion care where it is needed.
- Post-abortion care must be available on a confidential basis, including in situations where abortion is illegal.
- Post-abortion care must be available without the threat of criminal prosecution or punitive measures. States must not require health workers to report persons suspected of undertaking unlawful abortion, or require them to provide any potentially incriminating information during or as a prerequisite to receiving post-abortion care.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Links to related topics/recommendations

All recommendations relating to law and policy (Recommendations 1,2,3,6,7,21,22)

3.5.4 Post-abortion contraception

Following an induced or spontaneous abortion, ovulation can return as early as 8–10 days later and usually within one month, and thus contraception initiation as soon as possible within the first month is important for women who desire to delay or prevent a future pregnancy *(153, 154)*. All contraceptive options may be considered after an abortion. The client's wishes are paramount; if the individual wishes to start or resume a contraceptive method, then all contraceptive options may be considered at any point in care and some methods can be initiated at the time of the abortion *(155)*. States are required to ensure there is access to a wide range of modern, safe and affordable contraceptive methods *(36 [para. 8], 49 [para. 33])*. Criteria laid out in the WHO publications *Ensuring human rights in the provision of contraceptive information and services* and *Medical eligibility criteria for contraceptive use* should be adhered to *(156, 157)*. In-depth consideration of all methods of post-abortion contraception is outside the scope of this guideline.

This section addresses the timing of contraception and the health workers who can provide certain methods. The role of self-management approaches with post-abortion contraception will be discussed further in section 3.6.3.

CLINICAL SERVICES Recommendation 41: Medical eligibility criteria for post-abortion contraception

The following contraceptive methods may be started immediately (MEC Category 1 – no restrictions) after a surgical or medical abortion (first and second trimester, and also after a septic abortion): combined hormonal contraceptives (CHCs), progesterone-only contraceptives (POCs) and barrier methods (condoms, spermicide, diaphragm, cap – note: The diaphragm and cap are unsuitable until 6 weeks after second-trimester abortion)

Intrauterine devices (IUDs) may be started immediately after a first-trimester surgical or medical abortion (MEC Category 1 – no restrictions) or after second-trimester abortion (MEC Category 2 – the advantages generally outweigh the risks), but should not be started immediately after septic abortion (MEC Category 4 – insertion of an IUD may substantially worsen the condition).

Fertility-awareness-based (FAB) methods: Symptom-based methods should only be started after abortion with "caution" (special counselling may be needed to ensure correct use of the method in this circumstance) and the use of calendar-based methods should be delayed (until the condition is evaluated; alternative temporary methods of contraception should be offered).

Notes:

- Refer to the box below for an explanation of the MEC categories.
- CHCs include combined oral contraceptives (COCs), the contraceptive patch (P), the combined vaginal ring (CVR) and combined injectable contraceptives (CICs).
- POCs include progesterone-only pills (POPs), levonorgestrel (LNG) or etonogestrel (ETG) implants, depot medroxyprogesterone acetate (DMPA) injectables, and norethisterone enanthate (NET-EN) injectables.
- IUDs include copper-bearing IUDs (Cu-IUD) and levonorgestrel-releasing IUDs (LNG-IUD).
- Symptoms-based methods include the cervical mucus method (also called the ovulation method) and the TwoDay Method, which are both based on the evaluation of cervical mucus, and the sympto-thermal method, which is a double-check method based on evaluation of cervical mucus to determine the first fertile day and evaluation of cervical mucus and temperature to determine the last fertile day.
- Calendar-based methods include the Calendar Rhythm Method (avoiding unprotected intercourse from the first to the last estimated fertile days, after recording the length of several menstrual cycles as a basis for calculation) and the Standard Days Method (avoiding unprotected intercourse on cycle days 8–19, for people whose cycles are usually 26–32 days long).

Source: Recommendations brought in from WHO's *Medical eligibility criteria for contraceptive use* (2015) *(157)*. The wording has been revised to narrative format from the tables in the source guideline.

Key to MEC categories for contraceptive eligibility

- Category 1 – A condition for which there is no restriction for the use of the contraceptive method
- Category 2 – A condition where the advantages of using the method generally outweigh the theoretical or proven risks
- Category 3 – A condition where the theoretical or proven risks usually outweigh the advantages of using the method
- Category 4 – A condition which represents an unacceptable health risk if the contraceptive method is used.

CLINICAL SERVICES Recommendation 42: Timing of contraception and surgical abortion

For individuals undergoing surgical abortion and wishing to use contraception: **Recommend** the option of initiating the contraception at the time of surgical abortion.

Remark:

- The quality of evidence based on randomized controlled trials was very low.

Source: Part of Recommendation 13 carried forward from WHO (2012) *(19)*. Only the component of the existing recommendation that is relevant to surgical abortion has been retained, with the word "recommend" used to clarify that it is a strong recommendation and revisions made to include all contraceptive methods).

CLINICAL SERVICES Recommendation 43: Timing of contraception and medical abortion

For individuals undergoing medical abortion with the combination mifepristone and misoprostol regimen or with misoprostol alone:

a. For those who choose to use **hormonal contraception** (oral contraceptive pills, contraceptive patch, contraceptive ring, contraceptive implant or contraceptive injections): **Suggest** that they be given the option of starting hormonal contraception immediately after the first pill of the medical abortion regimen.

b. For those who choose to have an **IUD** inserted: **Suggest** IUD placement at the time that success of the abortion procedure is determined.

Remark (for Recommendations 43a and b):

- This recommendation applies to the combination mifepristone plus misoprostol regimen and the use of misoprostol alone. The letrozole plus misoprostol combination regimen is not mentioned here because the included studies informing these recommendations did not assess this regimen.

Remarks (for Recommendation 43a only):

- Immediate initiation of intramuscular depot medroxyprogesterone acetate (DMPA) is associated with a slight decrease in the effectiveness of medical abortion regimens *(158)*. However, immediate initiation of DMPA should still be offered as an available contraceptive method after an abortion.
- Indirect evidence was used as a basis for decision-making on initiation of hormonal contraception as an option for individuals undergoing medical abortion with misoprostol alone.
- No data were available on the use of combined hormonal contraception (pills or injections) by those undergoing medical abortion.
- Individuals who choose to initiate the contraceptive ring should be instructed to check for expulsion of the ring in the event of heavy bleeding during the medical abortion process.

Source: Recommendations 4a and 4b carried forward from WHO (2018) *(120)*.

Who

SERVICE DELIVERY Recommendation 44: Insertion and removal of intrauterine devices (IUDs)

Type of health worker	Recommendation	Rationale
Traditional and complementary medicine professionals	**Suggest** Condition: In contexts with established health system mechanisms for the participation of these professionals in other tasks related to maternal and reproductive health.	Their basic training generally covers the relevant skills needed for this task. This option is probably feasible and may promote continuity of care for women and increase access in regions where these professionals constitute a significant proportion of the health workforce.
Auxiliary nurses	**Suggest** Condition: In the context of rigorous research.	The recommendation comes originally from the *OptimizeMNH* guideline *(138).*
ANMs **Nurses** **Midwives**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138).*
Associate/advanced associate clinicians **Generalist medical practitioners** **Specialist medical practitioners**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138),* where this task was considered to be within their typical scope of practice.[a]

Source: Recommendation carried forward from WHO (2015) *(23).*

[a] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

Who

SERVICE DELIVERY Recommendation 45: Insertion and removal of implants

Type of health worker	Recommendation	Rationale
Community health workers	**Suggest** Condition: In the context of rigorous research.	The recommendation comes originally from the *OptimizeMNH* guideline *(138).*
Traditional and complementary medicine professionals	**Suggest** Condition: In contexts with established health system mechanisms for the participation of these professionals in other tasks related to maternal and reproductive health and where training in implant removal is given along with training in insertion.	Although insufficient direct evidence was found for the safety and effectiveness of this option, their basic training covers the relevant skills needed for this task. This option may promote continuity of care for women.
Auxiliary nurses/ANMs	**Suggest** Condition: In the context of targeted monitoring and evaluation.	The recommendation comes originally from the *OptimizeMNH* guideline *(138).*
Nurses **Midwives**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138).*
Associate/advanced associate clinicians **Generalist medical practitioners** **Specialist medical practitioners**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138),* where this task was considered to be within their typical scope of practice.[a]

Source: Recommendation carried forward from WHO (2015) *(23).*

[a] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

How

Implementation consideration

- The removal of implants can require greater skills than insertion; any health worker trained to independently insert implants should also be well trained on implant removal *(23)*.

Where

In a health-care facility or other setting with sterile conditions.

Who

SERVICE DELIVERY Recommendation 46: Administration of injectable contraceptives (initiation and continuation)

Type of health worker	Recommendation	Rationale[a]
Community health workers (CHWs)	**Recommend**	Limited evidence was found for the safety, effectiveness and feasibility of this option. The skills and knowledge for this task (according to the competency framework) align with the competencies for CHWs.[a] This option is feasible and acceptable given that CHWs provide other components of abortion care. In addition, this option has the potential to increase women's choices and reduce inequities in contraceptive access.
Pharmacy workers	**Recommend**	Although no evidence was found for the safety, effectiveness, acceptability or feasibility of this option, administering injections is within their typical scope of practice[b] and the additional training needs for this task would be minimal. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] This option has the potential to increase women's choices and reduce inequities in contraceptive access.
Pharmacists	**Recommend**	Although the available evidence for the safety and effectiveness of this option is of very low certainty, administering injections is within their typical scope of practice[b] and the additional training needs for this task would be minimal. This option has the potential to increase women's choices and reduce inequities in contraceptive access.
Traditional and complementary medicine professionals	**Recommend**	Their basic training covers the relevant skills needed for this task, hence additional training needs would be minimal. The skills and knowledge for this task (according to the competency framework) align with the competencies for this type of health worker.[a] This option is feasible and acceptable given that these professionals provide similar services in the existing health system, and thus it may promote continuity of care for women.
Auxiliary nurses/ANMs	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138)*.
Nurses **Midwives** **Associate/advanced associate clinicians** **Generalist medical practitioners** **Specialist medical practitioners**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138)*, where this task was considered to be within their typical scope of practice.[b]

Table Continues

Table Continued

Type of health worker	Recommendation	Rationale[a]
Individual/self		
Pregnant woman, girl or other pregnant person	**Recommend**	Refer to Recommendation 51 in section 3.6.2 for the rationale, remark, implementation considerations and further information about self-management approaches.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence relating to traditional and complementary medicine professionals, pharmacy workers, community health workers and individuals/self (self-administration) was reviewed using GRADE methodology. After review, recommendations for all three of those health worker categories were upgraded from "suggest" to "recommend". The recommendations for the other health worker categories were not reviewed and remain unchanged, such that all health worker categories and the individual/self now have a strong recommendation for this task. A summary of the evidence is presented in Supplementary material 3, EtD framework on Delivery of injectable contraceptives.

[a] For this and all health worker recommendations, given the limited evidence for many of the health worker–task combinations, the discussions of the expert panel focused on the competency framework in WHO's 2011 publication, *Sexual and reproductive health: core competencies in primary care (121)*, which provides information on the competencies (including skills and knowledge) required for each task, and also the WHO-INTEGRATE criteria, in particular on the feasibility, equity and acceptability of the intervention and women's values and preferences.

[b] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

No requirement for location (on-site vs off-site).

Implementation considerations

- The administration of an injectable contraceptive involves using a syringe and may be intramuscular or subcutaneous.
- It is important to have adequate mechanisms for the disposal of used sharps, syringes and needles.
- It is important to ensure a consistent supply of the injectables, especially at the point of sale for women to obtain and use on their own.
- The investment in initial training is a consideration where the health worker is not already certified to provide injections. It is important to have mechanisms to link the health worker to the health system and ensure a referral pathway.

SERVICE DELIVERY Recommendation 47: Tubal ligation

Type of health worker	Recommendation	Rationale
Nurses	**Suggest** Condition: In the context of rigorous research.	The recommendation comes originally from the *OptimizeMNH* guideline *(138)*.
Midwives	**Suggest** Condition: In the context of rigorous research.	The recommendation comes originally from the *OptimizeMNH* guideline *(138)*.
Associate/advanced associate clinicians **Generalist medical practitioners** **Specialist medical practitioners**	**Recommend**	The recommendation comes originally from the *OptimizeMNH* guideline *(138)*, where this task was considered to be within their typical scope of practice.[a]

[a] For typical scope of work/practice, please refer to Annex 5: Health worker categories and roles.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO POST-ABORTION CONTRACEPTION

- Contraception should be provided only where the person has given free and informed consent to receive it.
- States must ensure availability of the full range of contraceptive options, including a wide range of modern, safe and affordable methods.
- States must ensure adequate access to essential medicines, including contraceptives, in an affordable and non-discriminatory manner.
- Everyone has a right to evidence-based information on all aspects of SRH, including contraceptives.
- Contraceptive information and services must be provided without discrimination, coercion or violence.
- Everyone has a right to privacy and confidentiality in the receipt of contraceptive information and services.
- Post-abortion contraceptive information and services should be available and accessible to adolescents without requiring parental or guardian authorization.
- States must guarantee that practices of conscientious refusal/objection do not infringe on the right to contraceptive information and services.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

Commodities (section 1.4.4)

Information provision and counselling (sections 3.2.1 and 3.2.2)

3.6 Service-delivery options and self-management approaches

As indicated throughout this chapter so far, abortion care services can be provided by a range of health workers and some tasks can be managed by individuals themselves. Even for procedures that take place at a health-care facility, some elements of the care (e.g. pre-abortion information and counselling, cervical priming or post-abortion follow-up care) can take place in other locations.

Unlike surgical abortion, medical abortion is a process that takes place over a period of several hours or days rather than being a discrete procedure. The process as a whole or its components can take place at different locations including through self-management and/or with the support of different health workers at various stages of the process, making it possible – and in some cases desirable – to obtain care in a range of different settings, through a wide range of different options.

This section addresses supported service-delivery approaches (section 3.6.1) and self-management approaches. Self-management approaches addressed in this section include self-management of medical abortion (section 3.6.2), and self-management of post-abortion contraception (section 3.6.3).

3.6.1 Supported service-delivery approaches

Medical abortion services can be obtained from and provided or supported by a multitude of actors within the health system. Services may be delivered through a comprehensive model that addresses the full spectrum of abortion care or may include only specific components on the care pathway. Services could be delivered through the public or private sectors or nongovernmental organizations (NGOs), and may be received at a community-based, off-site location or even at home, and a variety of service-delivery models can co-exist at national, subnational and local levels.

Approaches to service delivery are not static and as the role of digital technologies grows and the science and evidence on effective interventions evolves, innovations will also continue to evolve. For this guideline, available evidence on various modalities of providing and/or supporting abortion care were reviewed. Examples of service-delivery approaches that were identified in the systematic reviews conducted for this guideline included:

- **Accompaniment models:** Where a community health worker provides support by accompanying the individual through the medical abortion process (by phone, secure technological platform, or in person), including providing information, counselling, emotional/moral support and/or logistical support (including referrals to and support interacting with local health-care facilities in the event that care is needed or desired).
- **Community outreach:** This includes health services that mobilize health workers to provide services to the population or to other health workers, away from the location where they usually work and live *(159)*. This is a strategy to mobilize health workers to remote or rural areas, such as mobile clinics. However, documented evidence on the use of this model for abortion care provision is limited.
- **Digital support tools:** These included apps providing information, text messaging reminders, and tools to assist in the assessment of pregnancy duration.
- **Harm reduction models:** Service models in the clinic setting, in which women are supported with pre-abortion information, are told where to find the medicines and how to use them and can return for post-abortion support if needed, but are not actually provided with the medicines to terminate the pregnancy.
- **Hotlines:** This typically refers to telephonic information services that can support women in accessing quality abortion care. Abortion hotlines may be limited to providing evidence-based information about services or may be linked to other service-delivery models that facilitate access to medicines and support women through the abortion process and after the abortion.
- **Social marketing:** Broadly defined as the application of marketing techniques to social problems and aims to persuade or motivate people to adopt specific sources of action or behaviour which are generally accepted as being beneficial. This approach to marketing has been well studied as a successful model for distribution of health interventions/commodities (e.g. condoms), however, documentation related to quality abortion care (i.e. abortion medicines and instructions) is more limited. It may be an option for increasing access and making care more affordable.

- **Social franchising:** This is described as a system of contractual relationships usually run by an NGO which uses the structure of a commercial franchise to achieve social goals. The overarching difference between social and commercial franchising is that social franchising seeks to fulfil a social benefit whereas commercial franchising is driven by profit. However, the limited evidence illustrates the potential inequities of such models *(160)*.
- **Telemedicine:** This is a mode of health service delivery where providers and clients, or providers and consultants, are separated by distance. The interaction may take place in real time (synchronously), using telephone or video link, or asynchronously using a store-and-forward method, when a query is submitted and an answer is provided later (e.g. by email, text or voice/audio message) *(161)*.

Across the range of service-delivery options, interactions between an abortion seeker and a health worker can take place in person or remotely. After review and assessment of the evidence by the expert panel, it was agreed that there was sufficient quantity and quality of evidence to support the formulation of a specific recommendation in relation to using telemedicine approaches as an alternative to in-person interactions for provision of medical abortion (see Recommendation 48).

The available evidence was inadequate to support the formulation of recommendations on any of the other service-delivery models. Instead, given the contextual nature of service-delivery approaches, the heterogeneity of the types of interventions and the overlaps between the approaches, a two-part best practice statement was developed to apply to all of them, with reference to service delivery in general, rather than any specific modality/model of service delivery (see Best Practice Statement 49).

What Who

SERVICE DELIVERY Recommendation 48 (NEW):
Telemedicine approaches to delivering medical abortion care

Recommend the option of telemedicine as an alternative to in-person interactions with the health worker to deliver medical abortion services in whole or in part.

Remarks:

- The above recommendation applies to assessment of eligibility for medical abortion, counselling and/or instruction relating to the abortion process, providing instruction for and active facilitation of the administration of medicines, and follow-up post-abortion care, all through telemedicine.
- Hotlines, digital apps or one-way modes of communication (e.g. reminder text messages) that simply provide information were not included in the review of evidence for this recommendation.

Rationale

A systematic review was undertaken to address this key question. Ten studies reporting on medical abortion provision through telemedicine were identified by the search strategy. Four randomized controlled trials were conducted in Bangladesh, Cambodia, Egypt and Indonesia, and six observational studies took place in Canada, Peru and the USA. In studies comparing telemedicine with in-person medical abortion care services, there was no difference between the two groups in rates of successful abortion or ongoing pregnancies (based on very low-certainty evidence). Referrals for surgical intervention were fewer among women who used telemedicine (based on low-certainty evidence). Satisfaction with telemedicine services was high and comparable to the usual clinical services (based on very low-certainty evidence). A summary of the evidence is presented in Supplementary material 3, EtD framework on Telemedicine.

How

Implementation consideration

- Telemedicine services should include referrals (based on the woman's location) for medicines (abortion and pain control medicines), any abortion care or post-abortion follow-up required (including for emergency care if needed), and for post-abortion contraceptive services, which may apply to both medical and surgical abortion.

What Who

SERVICE DELIVERY Best Practice Statement 49 (NEW)

Part 1: There is no single recommended approach to providing abortion services. The choice of specific health worker(s) (from among the recommended options) or management by the individual themself, and the location of service provision (from among the recommended options) will depend on the values and preferences of the woman, girl or other pregnant person, available resources, and the national and local context. A plurality of service-delivery approaches can co-exist within any given context.

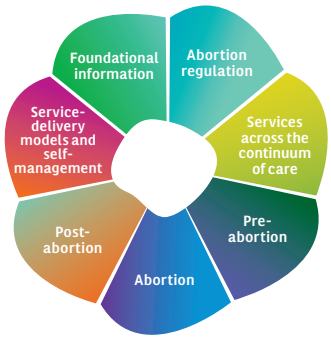
Part 2: Given that service-delivery approaches can be diverse, it is important to ensure that for the individual seeking care, the range of service-delivery options taken together will provide:

- access to scientifically accurate, understandable information at all stages;
- access to quality-assured medicines (including those for pain management);
- back-up referral support if desired or needed;
- linkages to an appropriate choice of contraceptive services for those who want post-abortion contraception.

A summary of the evidence is presented in Supplementary material 3, EtD framework on Medical abortion provided in different settings.

How

Implementation considerations



- Service-delivery approaches should, where feasible, be co-created with the people who will benefit from the intervention.
- All models should be tested and adapted for the local context in which they will operate.
- Not all service-delivery approaches may function at scale but for those that are being considered for national programmes, appropriate pilot testing is needed prior to scaling up.
- All service-delivery models should have mechanisms for monitoring quality and ensuring accountability.

KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO SERVICE-DELIVERY MODELS

- States should develop and enforce evidence-based standards and guidelines for the provision and delivery of sexual and reproductive health (SRH) services, and such guidance must be routinely updated to incorporate medical advancements. At the same time, States are required to provide age-appropriate, evidence-based, scientifically accurate comprehensive education for all on SRH.
- SRH services must be available, accessible, affordable, acceptable and of good quality. This means that delivery of services must be respectful of the culture of individuals, minorities, peoples and communities, and sensitive to gender, age, disability, sexual diversity and life-cycle requirements.
- States must take steps to reduce maternal mortality and morbidity.
- States must make accurate, evidence-based abortion information available to individuals on a confidential basis
- States must ensure delivery of services on the basis of non-discrimination and equality.
- States must ensure delivery of services in a way that respects the right to scientific progress, meaning that States should ensure access to modern and safe forms of contraception, including emergency contraception, abortion medicines, assisted reproductive technologies, and other SRH goods and services, on the basis of non-discrimination and equality.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

All recommendations related to law and policy (Recommendations 1,2,3,6,7,21,22)

3.6.2 Self-management approaches for medical abortion in whole or in part

Self-care, as defined in the Glossary, is a broad-based concept and can encompass numerous actions that are intended to empower the individual to enhance their own health. Self-management approaches are one component of self-care. Given the nature of the medical abortion process, it is possible for women to manage the process by themselves in whole or part. While individuals may conduct some or all elements related to the abortion process (self-assessment of eligibility, self-administration of medicines and self-assessment of the success of the abortion) entirely on their own, more typically, self-management co-exists with interactions with trained health workers or with a health-care facility and in conjunction with service-delivery approaches described in section 3.6.1. It is the individual (i.e. the "self") who drives the process of deciding which aspects of the abortion care will be self-managed and which aspects will be supported or provided by trained health workers or in a health-care facility.

Women may self-manage parts or all of the abortion process for a variety of reasons related to individual circumstances and preferences. For some women, this may be the only feasible option within their context and for others it may represent an active choice. However, from the perspective of the health system, self-management should not be considered a "last resort" option or a substitute for a non-functioning health system. Self-management must be recognized as a potentially empowering and active extension of the health system and task-sharing approaches. A supportive enabling environment as described in Chapter 1, section 1.3, is equally applicable to self-management approaches as it is to other elements of care provision.

SELF-MANAGEMENT Recommendation 50:
Self-management of medical abortion in whole or in part at gestational ages < 12 weeks

For medical abortion at < 12 weeks (using the combination of mifepristone plus misoprostol or using misoprostol alone): **Recommend** the option of self-management of the medical abortion process in whole or any of the three component parts of the process:

- self-assessment of eligibility (determining pregnancy duration; ruling out contraindications)
- self-administration of abortion medicines and management of the abortion proces outside of a health-care facility and without the direct supervision of a trained health worker
- self-assessment of the success of the abortion.

Remarks:

- There was more evidence for self-management of medical abortion (with either of the regimens) for pregnancies before 10 weeks of gestation.
- This recommendation applies to the combination regimen of mifepristone plus misoprostol, and the use of misoprostol alone. The included studies informing these recommendations did not assess the letrozole plus misoprostol regimen.
- All individuals engaging in self-management of medical abortion must also have access to accurate information, quality-assured medicines including for pain management, the support of trained health workers and access to a health-care facility and to referral services if they need or desire it.
- Restrictions on prescribing and dispensing authority for abortion medicines may need to be modified or other mechanisms put in place for self-management within the regulatory framework of the health system.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence for all of the subtasks was reviewed using GRADE methodology. After review, the recommendations for all subtasks were upgraded to "recommend" – from "suggest" for self-administration and self-assessment of outcome, and from "only in the context of rigorous research" for self-assessment of eligibility.

Where

No requirement for location (on-site vs off-site).

Rationale

Two systematic reviews were undertaken to address this key question. The first review focused on the self-assessment of eligibility and self-assessment of success. A total of 14 studies reporting on these two sub-tasks were identified by the search strategy. The four studies on self-assessment of eligibility took place in South Africa, the United Kingdom and the USA. Ten studies on self-assessment of success took place in Austria, Finland, India, Mexico, Nepal, Norway, South Africa, Sweden, Uzbekistan and Viet Nam. The second review was on the self-administration of medicines and included 18 studies, which took place in Albania, Bangladesh, China, France, India, Nigeria, Tunisia, Turkey and Viet Nam. A summary of the evidence is presented in Supplementary material 2, EtD framework on Self-management of medical abortion.

Self-assessment of eligibility: There is low-certainty evidence on the safety, effectiveness and acceptability of self-assessment of eligibility for a medical abortion, using the start date of last menstrual period (LMP) alone or in combination with other tools (e.g. checklists). The expert panel discussed the feasibility of this intervention in certain scenarios such as the woman having regular menses, a known LMP and the availability of validated tools. When they have the necessary information, women are able to determine their eligibility for medical abortion. Given this and taking into account the values and preferences and high acceptability of this approach, the panel determined that the intervention was favoured.

Self-administration of medicines: There is evidence that the option of self-administering medicines for medical abortion is effective (moderate certainty) and safe (low certainty). Women reported high satisfaction with taking their own medicines for the abortion (very low-certainty evidence). There was high adherence to the medical abortion regimen (low-certainty evidence). The high acceptability and feasibility favoured this intervention.

Self-assessment of success: There is high-certainty evidence that self-assessment of abortion outcome/success (using tools such as a low-sensitivity pregnant test or multi-level pregnancy test) is as effective as assessment by a trained health worker. Low-certainty evidence indicated that more women in the self-assessment group expressed satisfaction with the process.

How

Implementation considerations

- Every individual must have access to accurate information about the self-management process as well as other options available within their local context, to enable informed decision making on whether to self-manage all or parts of the process.
- Self-assessment of eligibility includes the assessment of pregnancy duration based on LMP. Paper or digital tools to assist recall and calculate duration or checklists may assist in the self-assessment of eligibility. When menstrual cycles are irregular or women have other concerns, she should be encouraged to seek support from a trained health worker where possible.
- Self-administration of medicines and management of the medical abortion process involves taking all or some of the abortion medicines without the direct supervision of a health worker. It is important that all sources from which medicines are procured provide quality-assured medicines.
- Women should also have information about pain during the process and should be able to obtain medicines for pain management.
- Women should also have information about the requirements of managing abortion-related bleeding at home, and should have access/referral to emergency care if this becomes necessary.

- Self-assessment of the success of abortion can be done using check lists of signs and symptoms. Other tools (e.g. low-sensitivity pregnancy tests), if available, may be used to assist the woman in self-assessing completion. Low-sensitivity urine pregnancy tests are different from ordinary pregnancy tests. The use of a high-sensitivity pregnancy test (a multi-level pregnancy test [MLPT]) alone or in conjunction with checklists has been shown to have a higher sensitivity for detecting successful abortion. Access should be available to a health worker or health-care facility to confirm the success of abortion or to manage side-effects or complications.
- As part of the enabling environment, health workers and managers should recognize self-management as a legitimate pathway to abortion care, and should work to adapt health systems to facilitate and support women in their self-management of abortion – for example, by adapting clinical protocols used at their facility.
- Mechanisms need to be established to ensure access or referrals to post-abortion contraception services and provision of contraception for women who want them.
- While self-management can support efficiencies within health systems in the long term, it should not mean that the burden of the cost of health services is simply transferred from the provider or facility to the woman herself.

3.6.3 Self-management approaches for post-abortion contraception

All contraceptive options may be considered after an abortion. For further information, refer to section 3.5.4: Post-abortion contraception. Many family planning methods are entirely self-managed (i.e. self-procured over the counter or online and self-administered) and generally available without a prescription, including barrier methods and some hormonal contraceptives, including some oral contraceptive pills (OCPs), and also emergency contraceptive pills. For methods that have traditionally required a prescription from a doctor and/or administration by a health worker, shifting to include the option of using self-management approaches, such as over-the counter OCPs and self-injection of hormonal contraceptives, may improve continuation of contraceptive use by removing barriers, such as the need to return to a health-care facility every three months for a repeat injection. These approaches could expand access to contraception for those facing challenges in accessing health-care settings regularly, and in places where there are shortages of health workers, thus potentially greatly reducing the incidence of unintended pregnancy.

What Who

SELF-MANAGEMENT Recommendation 51: Self-administration of injectable contraception (initiation and continuation)[17]

Recommend the option of self-administration of injectable contraception in the post-abortion period.

Remark:

- The administration of an injectable contraceptive involves using a syringe and may be intramuscular or subcutaneous. Compact pre-filled auto-disable devices have been developed to facilitate the self-administration process.

Source: Recommendation updated from WHO (2015) *(23)*.

Note on updating of the recommendation: This was an existing recommendation for which evidence was reviewed using GRADE methodology. After review, the recommendation was upgraded from "suggest" to "recommend".

Where

No requirement for location (on-site vs off-site).

17 Including a recommendation only on injectable contraception here does not imply that post-abortion contraceptive options for women should be limited to this method, or indeed to the methods covered by recommendations presented in section 3.5.4; all contraceptive methods can be considered after an abortion.

Rationale

A systematic review was undertaken to address this key question. Studies with indirect populations (i.e. women of reproductive age willing to initiate or continue with injectable contraceptive) were also considered for inclusion. Seven studies reporting on self-administered injectable contraceptives were identified by the search strategy and included in the reviewed evidence; three randomized controlled trials were conducted in Malawi and the USA and four observational studies were conducted in Senegal, Uganda, the United Kingdom and the USA. The evidence was considered indirect since none of the women included in the reviewed studies were described as seeking contraception post-abortion. A summary of the evidence is presented in Supplementary material 3, EtD framework on Self-administration of injectable contraception.

There is evidence that continuation rates for self-administered injectable contraceptives are higher compared with injectable contraceptives being provided by clinic-based providers (very low- to low-certainty evidence). Satisfaction was higher among the self-administration group (very low- to moderate-certainty evidence). The option may result in time and financial savings for women. In addition, this option may increase choice and autonomy in contraceptive use within a rights-based framework.

How

Implementation considerations

- There must be training in the technique for self-injection.
- There must be training in and the provision of mechanisms for the safe and secure storage and disposal of sharps (used injectable contraceptives), especially in settings with high HIV prevalence.
- The client must be able to procure injectable contraceptives on a regular basis without needing to repeatedly visit a health-care facility.

What Who

SELF-MANAGEMENT Recommendation 52: Over-the-counter oral contraceptive pills

Recommend that over-the-counter oral contraceptive pills (OCPs) should be made available without a prescription for individuals using OCPs.

SELF-MANAGEMENT Recommendation 53: Over-the-counter emergency contraceptive pills

Recommend making over-the-counter emergency contraceptive pills available without a prescription to individuals who wish to use emergency contraception.

SELF-MANAGEMENT Recommendation 54: Condom use

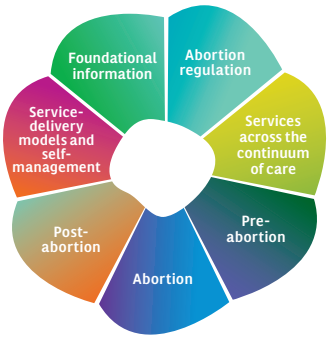
The consistent and correct use of male and female condoms is highly effective in preventing the sexual transmission of HIV; reducing the risk of HIV transmission both from men to women and women to men in serodiscordant couples; reducing the risk of acquiring other STIs and associated conditions, including genital warts and cervical cancer; and preventing unintended pregnancy.

Source: Recommendations 15, 16 and 18 brought in from WHO (2021) *(26)*.

No requirement for location (on-site vs off-site).

Implementation considerations for OCPs

- Provide up to one year's supply of pills, depending on the woman's preference and anticipated use.
- Programmes must balance the desirability of giving women maximum access to pills with concerns regarding contraceptive supply and logistics.
- The resupply system should be flexible, so that the woman can obtain pills easily in the amount and at the time she requires them.[18]



KEY HUMAN RIGHTS CONSIDERATIONS RELEVANT TO SELF-MANAGEMENT APPROACHES

- Sexual and reproductive health (SRH) care must be available, accessible, acceptable and of good quality.
- States must ensure availability of a wide range of modern, safe and affordable contraceptive methods.
- States must ensure adequate access to essential medicines in an affordable and non-discriminatory manner.
- States must respect autonomous decision-making, non-discrimination and equality. This means that States should repeal or reform laws and policies that nullify or impair the ability of certain individuals and groups to realize their right to SRH, including the criminalization of abortion or restrictive abortion laws.
- States must make accurate, evidence-based abortion information available to individuals on a confidential basis
- States must take steps to reduce maternal mortality and morbidity.
- In line with human rights requirements, self-management of abortion should not be criminalized. Criminalization of self-management of abortion may result in delays in or barriers to seeking assistance or post-abortion care where needed. Self-management of medical abortion should be available as an option on the basis of clinical appropriateness. It should not be restricted for non-clinical reasons such as age.

For further information and sources, please refer to Box 1.2 and Web annex A: Key international human rights standards on abortion.

18 These are Recommendations 20a, b and c from WHO (2021) *(26)*.

Chapter 4.

Dissemination, applicability, research gaps and future updates of the guideline and recommendations

4.1 Dissemination

This guideline will be published digitally (both an interactive web-based version and a traditional document available online for download) and in print; see further information in Annex 11.

Translation of the guideline into Spanish (in collaboration with the Pan American Health Organization [PAHO]), French and Portuguese is planned. Translations into other United Nations languages will be developed as needed.

Several derivative products will be developed based on this updated and consolidated guideline:*

- operational guidance containing details on implementation of the recommendations, including strategic considerations for improving access to quality abortion care for youth;
- informational materials, such as posters highlighting selected recommendations, which can be placed in health-care facilities and other appropriate places;
- pocket charts/cards for health workers, providing the updated recommendations for medical and surgical abortion and post-abortion contraception, and referral cards for referring individuals to other health-care services (adapted for use by different types of health workers and for different literacy levels);
- user-friendly decision-support tools for health workers and policy-makers, created with the input of end-users who will be engaged in the process of determining how best to translate the guidance for this purpose (the tools may include digital decision tools in the format of a mobile application [app]);
- case studies on quality abortion care in different humanitarian settings, to demonstrate and highlight the relevant considerations and requirements;
- operational guidance on medical management of select clinical indications, such as miscarriage.

* *Note:* Where applicable, WHO will collaborate with relevant United Nations agencies in the dissemination efforts. For example, WHO will collaborate with the Office of the United Nations High Commissioner for Human Rights (OHCHR) to disseminate guidance and tools to support application of a human rights-based approach to sexual and reproductive health, as well as respond to country requests for technical assistance to implement these approaches.

4.2 Implementation and impact evaluation of the guideline

Implementation of this guideline requires a multifaceted approach. After the initial publication, translation and dissemination efforts on regional, national and local levels (see Annex 11), it will be important to apply active techniques such as conducting workshops and training programmes to familiarize users with the guideline. Engagement by WHO team members with managers and staff of health-care facilities to build reminders about

the latest guidance into their clinical support systems will also be crucial. With regard to policy and programme planning, it will be important to work with policy-makers and national and local health officials to ensure implementation of the adopted recommendations at all levels of the health system. Engaging with national ministries and WHO country offices to contextualize the guidelines may facilitate adaptation of the guideline. It is anticipated that the main barrier to implementation of this guideline will be the subject matter – quality abortion care – which is a sensitive and stigmatized topic. This means that it is all the more important to work with stakeholders, including government, policy-makers and advocates for safe and legal abortion, to inform them about the guideline and facilitate open dialogue about the realities of abortion in their country. Using the Global Abortion Policies Database will facilitate these discussions *(116)*.

Process and impact evaluation will be ongoing during the first year of implementation of this guideline, focusing on the accessibility, acceptance, use, impact and generalizability of the guideline and its recommendations. As an assessment of document uptake, the engagement with the interactive online version of the guideline, the number of downloads of the document from the WHO website, and the number of hard copies of the guidance requested and distributed through the document centre will be monitored.

A year after publication, an evaluation of the immediate impact of the guidelines will be undertaken in the form of an online survey. This will be conducted through WHO regional and country offices and through selected respondents from other user groups (e.g. professional societies, NGOs) in order to gauge utilization in-country and whether and how any of the recommendations in the guideline have been implemented or have influenced policy decisions. This short-term impact evaluation will also include an assessment of barriers to effective implementation, which will be important feedback for derivative products and future modifications.

4.3 Research gaps/topics for further research

In the course of developing this guideline, during the meetings of the Evidence and Recommendation Review Groups (ERRGs) and the Guideline Development Group (GDG), several evidence gaps and areas for further research were identified.

Law and policy

- Impact of abortion laws and policies on people with disabilities and people with diminished capacity who seek abortion
- Impact of abortion laws and policies on groups in vulnerable situations and groups with marginalized identities, specifically adolescents and transgender individuals
- Impacts, effects and rights-related implications of procedural barriers to abortion in various contexts
- Impacts, effects and rights-related implications of making abortion available on the request of the woman, girl or other pregnant person, with no additional restrictions
- Impacts, effects, and rights-related implications of the decriminalization of self-management of abortion and of assistance with self-management of abortion

Clinical services

- Efficacy, safety and acceptability of the letrozole plus misoprostol combination regimen across gestational ages and compared with the mifepristone plus misoprostol combination regimen
- Effectiveness of using misoprostol alone (i.e. typical/real use outside of study conditions, optimal number of repeat doses)
- Efficacy, safety and acceptability of the use of misoprostol alone across gestational ages
- Effectiveness, safety and acceptability of outpatient medical abortion at gestational ages ≥ 12 weeks
- Safety, effectiveness and acceptability of anti-epileptics and anxiolytics for pain management for medical abortion at gestational ages ≥ 14 weeks
- Management of cervical priming prior to dilatation and evacuation (D&E) at gestational ages ≥ 18 weeks in settings where osmotic dilators are not available

- Optimal antibiotic regimens for post-abortion infection prophylaxis
- Effective methods for diagnosis and treatment of non-symptomatic ectopic pregnancy
- Safety and effectiveness of screening and antibiotic treatment for pelvic inflammatory disease before surgical abortion versus provision of pre- or perioperative prophylactic antibiotics without screening or risk assessment for pelvic inflammatory infection
- Effectiveness of telemedicine for medical abortion at gestational ages < 6 weeks
- Efficacy, safety and acceptability of all abortion methods and related clinical interventions across gestational ages in transgender, nonbinary and intersex individuals seeking abortion care
- Development and adaptation of validated materials to provide individuals engaging in self-management of abortion with the information they need to make informed decisions about the risks/benefits of and the alternatives to the use of different medical abortion regimens
- Development of effective and user-friendly information for abortion seekers, e.g. leaflets and web pages or information for use in the context of hotlines and telemedicine services
- Development and validation of quality training materials for use in training of providers on a range of abortion care services (e.g. to train pharmacists, pharmacy workers and community health workers to effectively provide – or support self-management of – all tasks involved in medical abortion at gestational ages < 12 weeks)
- Safety, convenience and acceptability of re-using manual vacuum aspiration (MVA) equipment

Service delivery

- Safety, effectiveness and feasibility of expansion of health worker roles for certain abortion care tasks in low- and middle-income settings (e.g. surgical abortion at gestational ages ≥ 12 weeks, vacuum aspiration for incomplete abortion)
- Feasibility of pharmacists administering injectable contraception in low- and middle-resource settings (implementation research)
- Impact of social marketing and social franchising approaches in abortion care assessed through evaluation research
- The most appropriate prescribing and dispensing authorities for abortion medicines, including comparison of self-sourced abortion medicines versus medicines prescribed and/or dispensed by trained health workers
- Mechanisms for ensuring individuals who manage medical abortion on their own have access to medicines for pain management and to contraceptive methods
- Acceptability of and satisfaction with a range of service-delivery approaches for quality abortion care for transgender, nonbinary and intersex individuals

Universal health coverage (UHC), health financing and commodities

- Impact of the WHO Model Lists of Essential Medicines changes to the mifepristone plus misoprostol combination regimen assessed through evaluation research

Indicators for use in monitoring and evaluation (M&E) of care

- Development and validation of indicators that include social and economic disability in addition to physical disability when calculating years living with abortion-related disability (in line with the growing focus on global burden of disease and disability estimation)
- Development and validation of standardized data-verification methods, so that abortion-related data can be presented with a verification score (as part of efforts to address the underreporting of abortion-related data as a result of abortion-related stigma)
- Development and increased use of qualitative methods for M&E of quality abortion care to assess barriers to progress and enablers for strengthening health system performance

Annexes

Annex 1. External experts and WHO staff involved in guideline development

Members of the Evidence and Recommendation Review Groups (ERRGs)

There were three ERRGs (expert panels), one for each domain of this guidance: Clinical services, Service delivery, Law and policy. Below each list of ERRG members, additional contributors to the pre-ERRG scoping meetings are listed per domain.

Clinical services domain ERRG members

Name	Affiliation City, country	WHO region of residence	Expertise	Declarations/ conflicts of interest
Laura Castleman	Planned Parenthood Michigan and University of Michigan Ann Arbor, MI, United States of America (USA)	Americas	Obstetrics and gynaecology	None
Suchitra Dalvie	Sexual and reproductive health programme consultant Mumbai, India	South-East Asia	Abortion, advocacy	None
Michalina Drejza	International Youth Alliance for Family Planning (IYAFP) Poznań, Poland	Europe	Obstetrics and gynaecology, youth	None
Kristina Gemzell Danielsson[a]	Department of Women's and Children's Health, Karolinska Institutet Stockholm, Sweden	Europe	Obstetrics and gynaecology, abortion research	None
Laura Gil[a]	Fundación Educación Para la Salud Reproductiva (ESAR) (Education Foundation for Reproductive Health) Bogotá, Colombia	Americas	Abortion, contraception	None
Selma Hajri[a]	TAWHIDA Group for Research and Action on Women's Health Tunis, Tunisia	Eastern Mediterranean	Abortion, contraception, research	None
Guyo Jaldesa	University of Nairobi Nairobi, Kenya	Africa	Obstetrics and gynaecology	None
Dhammika Perera[a]	Marie Stopes International London, United Kingdom of Great Britain and Northern Ireland	Europe	Abortion, contraception	None
Alongkone Phengsavanh	University of Health Sciences Vientiane, Lao People's Democratic Republic	Western Pacific	Obstetrics and gynaecology, abortion care	None
Judiac Ranape[a]	Department of Health Cape Town, South Africa	Africa	Nursing, nurse training, abortion care	None
Kitihoun Serge	Reproductive Health Unit, Alfred Comlan Quenum Regional Institute of Public Health Ouidah, Benin	Africa	Abortion, contraception	None
Human rights adviser				
Christina Zampas	Center for Reproductive Rights Geneva, Switzerland	Europe	Law, human rights, sex work, forced sterilization	None

[a] These members also contributed to the scoping meeting for this domain, in advance of the ERRG meetings, along with the following additional contributing experts: Abigail Aiken (University of Texas, USA), Rodica Comendant (Reproductive Health Training Center, Republic of Moldova), Debora Diniz (Instituto de Bioética, Brazil), Angel Foster (University of Ottawa, Canada), Daniel Grossman (University of California, San Francisco, USA), Kinga Jelinksa (Women Help Women, Netherlands), Munir Kassa (Center for International Reproductive Health Training, Ethiopia), Rasha Khoury (Médecins Sans Frontières, Afghanistan), Alice Mark (National Abortion Federation, USA), Mariana Romero (Center for the Study of State and Society, Argentina), Marion Stevens (Sexual and Reproductive Justice Coalition, South Africa), Nadira Sultana (Global Fund – United Nations Office for Projects Services, Bangladesh).

Service delivery domain ERRG members

Name	Affiliation City, country	WHO region of residence	Expertise	Declarations/ conflicts of interest
Fauzia Akhter Huda[a]	Maternal and Child Health Division, International Centre for Diarrhoeal Disease Research Bangladesh (ICDDRB) Dhaka, Bangladesh	South-East Asia	Public health, health systems, abortion	None
Nana Yaa Appiah	Women's Voices Foundation Accra, Ghana	Africa	Pharmacy, social marketing, professional development	None
Karla Berdichevsky	Gender Equity and Reproductive Health, Mexico Federal Ministry of Health Mexico City, Mexico	Americas	Sexual and reproductive health programming, policy and research	None
Jemima Araba Dennis-Antwi	Ghana College of Nurses and Midwives Accra, Ghana	Africa	Health systems strengthening, maternal health, midwifery, nursing training	None
Surendra Dhital	Independent Pharmacist Kathmandu, Nepal	South-East Asia	Pharmacy, counselling, safe abortion	None
Caitlin Gerdts[a]	Ibis Reproductive Health Oakland, CA, USA	Americas	Qualitative research, use of technology, access to abortion	None
Daniel Maceira	Economics Department, University of Buenos Aires Buenos Aires, Argentina	Americas	Health systems research, health programming and policy development	None
Vinoj Manning[a]	Ipas Development Foundation New Delhi, India	South-East Asia	Health systems, abortion care	None
Sybil Nkeiru	Generation Initiative for Women and Youth Network (GIWYN) Lagos, Nigeria	Africa	Human rights activist	None
Hiromi Obara[a]	Department of Health Planning and Management, Bureau of International Health Cooperation, National Center for Global Health and Medicine Tokyo, Japan	Western Pacific	Health planning and management, Maternal health and abortion policy	None
Karan Parikh	International Youth Alliance for Family Planning (IYAFP) Mumbai, India	South-East Asia	Clinician, youth	None
Michelle Remme	United Nations University's International Institute for Global Health (UNU-IIGH) Kuala Lumpur, Malaysia	Western Pacific	Research, gender, health system financing	None
Karthik Srinivasan[b]	International Planned Parenthood Federation (IPPF) London, United Kingdom	Europe	Commodities, health system	None
Human rights adviser				
Christina Zampas	Center for Reproductive Rights Geneva, Switzerland	Europe	Law, human rights, sex work, forced sterilization	None

[a] These members also contributed to the scoping meeting(s) for this domain, in advance of the ERRG meetings, along with the following additional contributing experts: Patrick Aboagye (Ghana Health Services, Ghana), Laura Castleman (Ipas, Planned Parenthood and University of Michigan, USA), Amanda Cleeve (Karolinksa Institutet, Sweden), Saida Chowdhury (Independent consultant, USA), Rodica Comendant (Reproductive Health Training Center, Republic of Moldova), Joanna Erdman (Dalhousie University, Canada), Rebecca Gomperts (Women on Waves, Netherlands), Chisale Mhango (University of Malawi, Malawi), Monica Oguttu (Kisumu Medical and Education Trust, Kenya), Paul Mandira (United Nations Population Fund, USA), Mariana Romero (Center for the Study of State and Society, Argentina), Sarmad Soomar (International Youth Alliance for Family Planning, Pakistan).

[b] This member began working for a funding agency before the final ERRG meeting and therefore his involvement in guideline development ended at that point.

Law and policy domain ERRG members

Name	Affiliation City, country	WHO region of residence	Expertise	Declarations/ conflicts of interest
Marge Berer	International Campaign for Women's Right to Safe Abortion London, United Kingdom	Europe	Social science, abortion policy	None
Joanna Erdman[a]	Schulich School of Law, Dalhousie University Halifax, Canada	Americas	Human rights, health law and policy	None
Godfrey Kangaude	University of Pretoria and University of Toronto Blantyre, Malawi	Africa	Sexual and reproductive health and rights law	None
Akila Radhakrishnan	Global Justice Center New York, NY, USA	Americas	Law and policy	None
Ruben Avila Reyna	International Youth Alliance for Family Planning (IYAFP) Youth Taskforce Nuevo León, Mexico	Americas	Human rights, advocacy, youth	None
Chi-Chi Undie	Population Council Nairobi, Kenya	Africa	Abortion and contraception, policy	None
Human rights advisers				
Abhijit Das	Centre for Health and Social Justice New Delhi, India	South-East Asia	Human rights	None
Sara Hossain	Bar of the Supreme Court of Bangladesh Dhaka, Bangladesh	South-East Asia	Law and policy, human rights	None
Karima Khalil	Maternal and Child Health Consultant New Delhi, India	South-East Asia	Law and policy, human rights	None
Primah Kwagala	Director, Women's Probono Initiative Kampala, Uganda	Africa	Law and policy, human rights	None
Monica Arango Olaya	Faculty of Law, University of Oxford Oxford, United Kingdom	Europe	Law and policy, human rights	None
Xian Warner	Research and Program Coordinator, The Equality Institute Dili, Timor-Leste	Western Pacific	Law and policy, human rights	None
Christina Zampas[a]	Center for Reproductive Rights Geneva, Switzerland	Europe	Law, human rights, sex work, forced sterilization	None

[a] These members also contributed to the scoping meeting(s) for this domain, in advance of the ERRG meetings, along with the following additional contributing experts: Paola Bergallo (University of Torcuato Di Tella, Argentina), Lucia Berro Pizzarossa (University of Groningen, Netherlands), Scott Burris (Temple University, USA), Fiona de Londras (Birmingham University, United Kingdom), Silvia de Zordo (University of Barcelona, Spain), Debora Diniz (Instituto de Bioética, Brazil), Heather Douglas (University of Queensland, Australia), Daniel Grossman (University of California, San Francisco, USA), Selma Hajri (TAWHIDA Group for Research and Action on Women's Health, Tunisia), Jihan Jacob, Center for Reproductive Rights, Philippines), Minzee Kim (Ewha Womans University, Republic of Korea), Chisale Mhango (University of Malawi, Malawi), Mahesh Puri (Centre for Research on Environment, Health and Population Activities, Nepal), Patricia Schulz (Committee on the Elimination of Discrimination against Women, Switzerland), Patty Skuster (Ipas, USA), Marion Stevens (Sexual and Reproductive Justice Coalition, South Africa), Maya Unnithan (University of Sussex, United Kingdom).

Members of the Guideline Development Group (GDG), and declarations of interests

Name	Job title, affiliation City, country	WHO region of residence	Expertise	Declarations/ conflicts of interest
Fauzia Akhter Huda	Project Coordinator, Maternal and Child Health Division, International Centre for Diarrhoeal Disease Research Bangladesh (ICDDRB) Dhaka, Bangladesh	South-East Asia	Public health, health systems, abortion	None
Karla Berdichevsky	Director, Gender Equity and Reproductive Health, Mexico Federal Ministry of Health Mexico City, Mexico	Americas	Sexual and reproductive health programming, policy and research	None
Marge Berer	Coordinator, International Campaign for Women's Right to Safe Abortion London, United Kingdom	Europe	Law and policy	None
Laura Castleman (CHAIR)	Associate Medical Director, Planned Parenthood of Michigan and Adjunct Clinical Assistant Professor, University of Michigan Ann Arbor, MI, USA	Americas	Obstetrics and gynaecology	None
Michalina Drejza	Director on Research and Development, International Youth Alliance for Family Planning (IYAFP) Poznań, Poland	Europe	Obstetrics and gynaecology, youth	None
Joanna Erdman	Associate Professor, Health Law and Policy, Schulich School of Law, Dalhousie University Halifax, Nova Scotia, Canada	Americas	Law and policy	None
Kristina Gemzell Danielsson	Head, Department of Women's and Children's Health, Karolinska Institutet Stockholm, Sweden	Europe	Obstetrics and gynaecology, abortion research	None
Caitlin Gerdts	Vice President for Research, Ibis Reproductive Health Oakland, CA, USA	Americas	Qualitative research	None
Laura Gil	Clinician Bogotá, Colombia	Americas	Clinical	None
Selma Hajri	Founder and President, TAWHIDA Group for Research and Action on Women's Health Tunis, Tunisia	Eastern Mediterranean	Abortion, contraception, research	None
Guyo Jaldesa	Associate Professor of Obstetrics and Gynaecology, University of Nairobi Nairobi, Kenya	Africa	Obstetrics and gynaecology	None
Godfrey Kangaude	Postdoctoral Researcher, University of Pretoria, and Reproductive and Sexual Health Law Fellow, University of Toronto Blantyre, Malawi	Africa	Sexual and reproductive health and rights law	None
Vinoj Manning	Chief Executive Officer Ipas Development Foundation New Delhi, India	South-East Asia	Health systems	None
Hiromi Obara	Medical Doctor, Deputy Director, Division of Global Health Policy and Research, Department of Health Planning and Management, Bureau of International Health Cooperation Japan, National Center for Global Health and Medicine, and Project Coordinator, Cambodia, Japan International Cooperation Agency (JICA) Tokyo, Japan	Western Pacific	Health systems	None
Alongkone Phengsavanh	Vice Dean, Faculty of Medicine, University of Health Sciences Vientiane, Lao People's Democratic Republic	Western Pacific	Obstetrics and gynaecology, abortion care	None
Akila Radhakrishnan	President, Global Justice Center New York, NY, USA	Americas	Law and policy	None

Continued on the next page

Continued

Name	Job title, affiliation City, country	WHO region of residence	Expertise	Declarations/ conflicts of interest
Michelle Remme	Research Lead, United Nations University's International Institute for Global Health (UNU-IIGH) Kuala Lumpur, Malaysia	Western Pacific	Research, gender, health system financing	None
Chi Chi Undie	Senior Associate, Population Council Nairobi, Kenya	Africa	Abortion and contraception, policy	None
Human rights adviser				
Christina Zampas	Associate Director of Global Advocacy, Center for Reproductive Rights Geneva, Switzerland	Europe	Human rights	None

GDG meeting observers:

- Patricia Lohr, Medical Director, British Pregnancy Advisory Service (BPAS), London, United Kingdom; also member of Royal College of Obstetricians and Gynaecologists (RCOG) Making Abortion Safe Programme Advisory Group
- Jaydeep Tank, Secretary General of the Federation of Obstetrics and Gynaecological Societies of India (FOGSI) and Chair, International Federation of Obstetrics and Gynaecology (FIGO) Working Group for safe abortion, Mumbai, India
- Francelle Toedtli, Consultant, United Nations Population Fund (UNFPA), New York, New York, USA
- Ann Yates, Lead Midwife Adviser, International Confederation of Midwives (ICM), Head Office, The Hague, the Netherlands

Guideline methodologist(s)

Clinical services domain: Jeppe Schroll, Consultant, Research Coordinator and Associate Professor, Department of Obstetrics and Gynaecology, Amager Hvidovre Hospital, Copenhagen, Denmark

Service delivery domain: Nicholas Henschke and Gemma Villanueva, Senior Systematic Reviewers, and Yanina Sguassero, Systematic Review, of Cochrane Response

Law and policy domain: Maria Rodriguez, Associate Professor, Obstetrics and Gynecology, Oregon Health & Science University (OHSU), Portland, Oregon, USA

Evidence Synthesis Team(s)

Clinical services domain:

- Cochrane Fertility Regulation (CFR) Group, at Oregon Health & Science University (OHSU)
  - Lead researchers: Alison Edelman, Maria Rodriguez, Makalapua Motu'apuaka, Taylor King
  - Search strategy support: Robyn Paynter
  - Team members/review authors: Jessica Atrio, Sharon Cameron, Justin T. Diedrich, Eleanor Drey, Alison Edelman, Katherine Gambir, Bela Ganatra, Jeffrey T.J. Jensen, Nathalie Kapp, Caron Kim, Patricia Lohr, Adrienne E. McKercher, Karen Meckstroth, Chelsea Morroni, Kelly Ann Necastro, Sara J. Newmann, Thoai D. Ngo, Antoinette Nguyen, Mark D.N. Nichols, Regina-Maria Renner, John J. Reynolds-Wright, Tesfaye Tufa, Mulat A. Woldetsadik
- WHO Department of Sexual and Reproductive Health and Research (SRH) staff, consultants and Family Planning fellows:
  - Michelle Chan, Family Planning fellow, University of British Columbia, Vancouver, British Columbia, Canada
  - Elizabeth Clark, Family Planning fellow, Emory University, Atlanta, Georgia, USA
  - Teresa DePiñeres, Lead Clinician, Medication Abortion Access Project, Essential Access Health

- Margit Endler, Obstetrician and Gynaecologist, Stockholm South Central Hospital, and Researcher, Karolinska Institutet, Stockholm, Sweden
- Roopan Gill, Consultant, Preventing Unsafe Abortion Unit, SRH Department, WHO, Geneva, Switzerland; Women's Health Advisor, Médecins Sans Frontières (MSF), Paris, France
- Yelena Korotkaya, Family Planning fellow, University of California, Los Angeles, California, USA
- Lemi Tolu, Family Planning fellow, Assistant Professor of Obstetrics and Gynaecology, Saint Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia

Service delivery domain:

- Cochrane Response
  - Lead researchers: Nicholas Henschke, Yanina Sguassero and Gemma Villanueva
  - Search strategy support: Elise Cogo
  - Team members/review authors: Hanna Bergman, Brian Buckley, Jennifer Petkovic, Chantelle Garritty, Candyce Hamel, Katrin Probyn
- WHO SRH staff, consultants and Family Planning fellows:
  - Ferid Abubeker, Family Planning fellow, Assistant Professor of Obstetrics and Gynaecology, Saint Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia
  - Mekdes Feyssa, Medical Officer, Preventing Unsafe Abortion (PUA) Unit, SRH Department, WHO, Geneva, Switzerland
  - Roopan Gill, Consultant, PUA Unit, SRH Department, WHO, Geneva, Switzerland; Women's Health Advisor, Médecins Sans Frontières (MSF), Paris, France
  - Caron Kim, Medical Officer, PUA Unit, SRH Department, WHO, Geneva, Switzerland
  - Bianca Stifani, Family Planning fellow, Obstetrician and Gynaecologist, Albert Einstein College of Medicine and Montefiore Medical Center, New York, New York, USA
  - Tesfaye Tufa, Family Planning fellow, Assistant Professor of Obstetrics and Gynaecology, Saint Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia
- Other contributors:
  - Ernestina Coast, Professor of Health and International Development, London School of Economics and Political Science, London, United Kingdom
  - Samantha Lattof, Visiting Fellow, Department of International Development, London School of Economics and Political Science, London, United Kingdom
  - Brittany Moore, Consultant, Scientific and Technical Division Advisor, Ipas, Chapel Hill, North Carolina, USA
  - Cheri Poss, Associate Director, Program Evidence, Ipas, Chapel Hill, North Carolina, USA
  - Yana Rodgers, Professor, Department of Women's, Gender, and Sexuality Studies, Director of the Center for Women and Work, Rutgers University, New Brunswick, New Jersey, USA

Law and policy domain:

- The Policy Surveillance Program at the Center for Public Health Law Research (CPHLR), Temple University, Philadelphia, Pennsylvania, USA
  - Lead researcher: Scott Burris
  - Team members/review authors: Lindsay Foster Cloud, Adrienne R. Ghorashi, Rachel Rebouché, Patty Skuster
- Birmingham Law School, University of Birmingham, Birmingham, United Kingdom
  - Lead researcher: Fiona de Londras, Chair of Global Legal Studies, Birmingham Law School
  - Team members/review authors: Alana Farrell, Magdalena Furgalska

- WHO SRH staff and consultants:
  - Amanda Cleeve, Consultant in sexual and reproductive health and preventing unsafe abortion, Stockholm, Sweden
  - Antonella Lavelanet, Medical Officer, PUA Unit, SRH Department, WHO, Geneva, Switzerland
  - Maria Rodriguez, Associate Professor, Obstetrics and Gynecology, Oregon Health & Science University (OHSU), Portland, Oregon, USA

External Review Group (ERG)

Name	Affiliation City, country	WHO region of residence	Expertise
Safia Ahsan	Reproductive Health Supplies Coalition, PATH Washington, DC, USA	Americas	Market development, supply chain management
Traci Baird	EngenderHealth Washington, DC, USA	Americas	Leadership, women's health, sexual and reproductive health
Sharon Cameron	Chalmers Hospital Edinburgh, United Kingdom	Europe	Obstetrics and gynaecology, abortion, contraception, genital tract infection
Jane Harries	Women's Health Research Unit, School of Public Health, University of Cape Town Cape Town, South Africa	Africa	Abortion, contraception, research
Thoai Ngo	Population Council New York, NY, USA	Americas	Research, health policy
Mariana Romero	Centre for the Study of State and Society (CEDES) Buenos Aires, Argentina	Americas	Maternal health, abortion, research
Rachel Simon-Kumar	School of Population Health, University of Auckland and Centre for Asian Health Research and Evaluation (CAHRE) Auckland, New Zealand	Europe	Social science, gender and economics
Beverly Winikoff	Gynuity Health Project New York, NY, USA	Americas	Reproductive choice, contraception, abortion, women's health

External partners (including implementing partner organizations) who provided feedback on the draft guideline

- Rasha Dabash, Ipas, Chapel Hill, North Carolina, USA
- Rebecca Wilkins, International Planned Parenthood Federation (IPPF), London, United Kingdom
- Bethan Cobley, MSI Reproductive Choices, London, United Kingdom
- Steve Luboya, Pathfinder, Watertown, Massachusetts, USA
- Eva Lathrop, Population Services International (PSI), Washington, DC, USA

Members of the WHO Steering Group

Name	Department and Unit	Expertise
Mekdes Daba Feyssa	Department of Sexual and Reproductive Health and Research (SRH), Preventing Unsafe Abortion (PUA) Unit, WHO headquarters	Abortion, contraception
Bela Ganatra	SRH, PUA, WHO headquarters	Abortion, social science
Roopan Gill (during first stages of guideline planning)	SRH, PUA, WHO headquarters (formerly)	Abortion, contraception, humanitarian settings
Heidi Johnston	SRH, PUA, WHO headquarters	Abortion, demography
Rajat Khosla (during first stages of guideline planning)	SRH, Director's Office, WHO headquarters (formerly)	Human rights adviser
Caron Kim[a]	SRH, PUA, WHO headquarters	Abortion, contraception, sexual and reproductive health and rights in health emergencies
Antonella Lavelanet	SRH, PUA, WHO headquarters	Abortion, contraception, law and policy, and human rights
Lemi Tolu (during the first stages of guideline planning)	SRH, PUA, WHO headquarters (formerly)	Abortion, contraception

[a] Responsible technical officer for development of this guideline

Members of the WHO Secretariat

Name	Department and Unit (and region if applicable)
Moazzam Ali	Department of Sexual and Reproductive Health and Research (SRH), Contraception and Fertility Care (CFC) Unit, WHO headquarters, Geneva, Switzerland
Ian Askew	SRH, WHO headquarters
Chilanga Asmani	Reproductive and Maternal Health (RMH) and Ageing, WHO Regional Office for Africa, Brazzaville, Congo
Laurence Codjia	Department of Health Work Force (HWF), Health Labour Market and Partnerships (HLM) Unit, WHO headquarters, Geneva, Switzerland
Ibadat Dhillon	Human Resources for Health and Fellowships (HRH), WHO Regional Office for South-East Asia, New Delhi, India
Carolin Ekman	SRH, Preventing Unsafe Abortion (PUA) Unit, WHO headquarters
Claire Garabedian	SRH, PUA, WHO headquarters
Rodolfo Gómez Ponce de León	Latin American Center for Perinatology, Women's Health and Reproductive Health (CLAP/WR), Pan American Health Organization (PAHO), Montevideo, Uruguay
Veloshnee Govender	SRH, SRH Integration in Health Systems (SHS) Unit, WHO headquarters
Hannah Hatch	SRH, PUA, WHO headquarters
Lisa Hedman	HIS, Essential Medicines and Health Products (EMP) Unit, WHO headquarters
Nilmini Hemachandra	Reproductive and Maternal Health (RMH), WHO Regional Office for the Eastern Mediterranean, Cairo, Egypt
Shogo Kubota	Lao People's Democratic Republic, WHO Country Office, Vientiane, Lao People's Democratic Republic
Laurence Läser	SRH, PUA, WHO headquarters
Ulrika Loi Rehnström	SRH, PUA, WHO headquarters
Bruno Meessen	Health Systems Governance and Financing (HGF), Health Financing (HEF), WHO headquarters
Fahdi Dkhimi	HGF, HEF, WHO headquarters
Marta Schaaf	SRH Director's Office, WHO headquarters
Patricia Titulaer	SRH, PUA, WHO headquarters

Annex 2. Selected human rights treaties and their treaty monitoring bodies

For more detailed information on the how international human rights standards apply to abortion, refer to Web annex A: Key international human rights standards on abortion, available at https://apps.who.int/iris/handle/10665/349317.

Treaty (in chronological order)	Abbreviation	Year of adoption	Year entered into force	Treaty monitoring body (TMB)[a]	Abbreviation
International Convention on the Elimination of All Forms of Racial Discrimination	ICERD	1965	1969	Committee on the Elimination of Racial Discrimination	CERD
International Covenant on Civil and Political Rights	ICCPR	1966	1976	Human Rights Committee	HRC
International Covenant on Economic, Social and Cultural Rights	ICESCR	1966	1976	Committee on Economic, Social and Cultural Rights	CESCR
Convention on the Elimination of All Forms of Discrimination against Women	CEDAW	1979	1981	Committee on the Elimination of Discrimination against Women	CEDAW
Convention against Torture and Other Cruel, Inhuman or Degrading Treatment or Punishment	CAT	1984	1987	Committee against Torture	CAT
Convention on the Rights of the Child	CRC	1989	1990	Committee on the Rights of the Child	CRC
International Convention on the Protection of the Rights of All Migrant Workers and Members of Their Families	ICMW	1990	2003	Committee on Migrant Workers	CMW
Convention on the Rights of Persons with Disabilities	CRPD	2006	2008	Committee on the Rights of Persons with Disabilities	CRPD

[a] Also sometimes referred to as "treaty bodies".

Further information on the Core International Human Rights Instruments and their TMBs is available at: https://www.ohchr.org/EN/ProfessionalInterest/Pages/CoreInstruments.aspx

Annex 4. Guideline development methods and process

A. Guideline development working groups

Please refer to Annex 1 for the names of members of each of the working groups (and declarations of interests). A summary of the key meetings held is provided at the end of this annex.

The WHO Guideline Steering Group

The WHO Guideline Steering Group led the guideline development process. Chaired by the WHO Department of Sexual and Reproductive Health and Research (SRH), it was composed of eight staff members from the Department, including seven from the Prevention of Unsafe Abortion (PUA) Unit and the Department's human rights adviser. Gender, ethics, social accountability and human rights expertise among the Steering Group members ensured that key underlying principles were adequately reflected. The Steering Group members drafted the initial scope of the guideline; identified and drafted the priority questions in "PICO" format (population, intervention, comparator, outcome); and identified individuals to be invited to participate as guideline methodologists and as members of the Evidence Synthesis Teams (ESTs), the Evidence and Recommendation Review Groups (ERRGs), the Guideline Development Group (GDG) and the External Review Group (ERG) (see below). The members of these groups and the participation of other external contributors were only confirmed after completion of a process of declaration and management of any conflicts of interest, which was managed by the Steering Group in consultation with the Office of Compliance, Risk Management and Ethics (see section B). The Steering Group identified the chair of the GDG, and this was confirmed by the other GDG members. The Steering Group oversaw the work of the ESTs, organized the ERRG and GDG meetings, and drafted the recommendations based on the decisions of the ERRGs and GDG. The Steering Group did not determine or agree on the final recommendations as this was the role of the GDG. The Steering Group was responsible for drafting, revising and finalizing the guideline in collaboration with the ERRG, GDG and ERG members and other contributors, and for overseeing the publication and dissemination of the guideline and the development of related implementation tools. Finally, the Steering Group is responsible for monitoring new information and user needs and for determining when the guideline may need to be updated. The WHO Steering Group was supported by the wider WHO Secretariat, which included 19 WHO staff members and consultants from the SRH Department and other departments at WHO headquarters and representatives from WHO regional offices.

Guideline methodologists

The guideline methodologists worked closely with the WHO Steering Group and members of the Evidence Synthesis Teams (ESTs) to appraise the evidence from systematic reviews using GRADE methodology (see section D). In addition, the guideline methodologists oversaw all methodological issues and were responsible for the GRADE assessments of the certainty of the evidence. One guideline methodologist was appointed for the Clinical services domain and one for the Law and policy domain, while a team from Cochrane Response served this role for the Service delivery domain.[1] Appreciating that the public health impact of laws and policies is complex, that evidence related to law and policy is not a research area that lends itself to randomized controlled trials or comparative observational studies, and that this evidence cannot be readily synthesized using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach, a pragmatic approach was applied (see details in section D).

Evidence Synthesis Teams (ESTs)

The ESTs planned and conducted the systematic reviews and prepared the GRADE Evidence-to-Decision (EtD) frameworks (which include evidence summaries, evidence profiles/tables and EtD tables). The ESTs comprised researchers from among WHO staff, consultants and fellows, as well as external collaborating research groups. For the **Clinical services domain**, the EST was formed of members of the Cochrane Fertility Regulation (CFR) Group, Family Planning fellows (WHO staff or interns), and the responsible technical officer from the Steering Group for this guideline. For the **Service delivery domain**, the EST comprised staff from Cochrane Response, Family Planning fellows (current and former WHO staff), and the responsible technical officer from the Steering Group. The CFR

1 Cochrane Response is an evidence consultancy business operated by the Cochrane Collaboration. It provides tailored and responsive evidence services, and accessible review formats.

Group and Cochrane Response have updated their systematic reviews to provide the evidence base for many of the recommendations in these two domains. For the **Law and policy domain**, the EST included WHO consultants as well as external teams based at two centres:

- The Policy Surveillance Program at the Center for Public Health Law Research (CPHLR), Temple University, Philadelphia, USA: Researchers within this programme created conceptual frameworks and legal mapping of the various interventions and the systems around them, and identified data for the empirical assessment of laws and policies.
- Birmingham Law School, University of Birmingham, United Kingdom: The team in Birmingham provided expertise in health law and policy, human rights, comparative law, and global legal studies. This team conducted systematic reviews to provide the evidence base for the law and policy recommendations.

The Evidence and Recommendation Review Groups (ERRGs) and the Guideline Development Group (GDG)

Rather than having one Guideline Development Group (GDG) from the start of the guideline development process, for the development of this wide-ranging consolidated guideline, three separate ERRGs were formed – one for each of the three domains: Clinical services, Service delivery and Law and policy. For the final stage of the process, one GDG was formed comprising 3–4 members from each of the three ERRGs. The three ERRGs had 6–13 members representing all regions and a range of expertise, including one youth representative from the International Youth Alliance for Family Planning (IYAFP). The ERRG members were identified and invited by the WHO Steering Group, as were the human rights advisers who also contributed to the meetings by ensuring consideration of relevant human rights during recommendation formulation. Each ERRG undertook a detailed review of the evidence, formulated and agreed on draft recommendations during a series of 4–5 online meetings between March 2020 and March 2021. Prior to each meeting, background documents – the EtD frameworks and draft recommendations – were shared with the ERRG members. Consultations via email, Skype, Microsoft Teams, GoToMeeting and Zoom were conducted as needed in between meetings to ensure input was received from each ERRG member for each area under review.

In early 2021, representatives from each ERRG were invited by the WHO Steering Group to join the GDG for the final meeting in late April 2021, during which the draft recommendations from all three ERRGs were presented for review and finalization. The confirmed members of the GDG in turn confirmed the WHO Steering Group's selection of a chair for the GDG. There were 18 GDG members (14 female, 4 male), representing all six WHO regions and a range of expertise, including a youth representative from IYAFP. A draft of the full guideline document, including the draft recommendations, was shared with all the GDG members to review in advance of the formal meeting, along with other relevant background documents (the EtD frameworks). During the meeting, the GDG reviewed and discussed the evidence and the draft recommendations, with the aim of reaching consensus on the certainty of the supporting evidence and the strength and direction of the new and updated recommendations (see Chapters 2 and 3). Subsequent to the GDG meeting, the members also had an opportunity to review the revised guideline document into which the decisions made during the GDG meeting had been integrated.

The External Review Group (ERG)

The WHO Steering Group, in consultation with the GDG, identified and confirmed nine technical experts and stakeholders with thematic area expertise relevant to the recommendations presented in this guideline to serve as members of the ERG. The ERG members were balanced in terms of geographic representation, and had no important conflicts of interest. Following the GDG meeting and the subsequent revisions to the draft guideline, the document was circulated to the ERG members. The role of the ERG members was to provide input regarding the accuracy, clarity of the language, implementation/adaptation considerations, and presentation of the guideline. The ERG also ensured that the GDG decision-making processes had considered and incorporated the contextual values and preferences of persons affected by the recommendations. Recommendations in the document, which had been finalized by the GDG, were not changed based on ERG input other than to improve clarity and readability, as needed. All comments from the ERG members were collated by the responsible technical officer and shared with the WHO Steering Group for review. No serious factual errors or concerns were identified that affected any of the recommendations or any major sections of the draft guideline.

Meeting observers and external partners

In accordance with guidance in the *WHO handbook for guideline development, second edition (2014),*[2] representatives from a range of relevant professional organizations and United Nations agencies were invited to attend the GDG meeting in April 2021 as observers with no role in determining the recommendations (see Annex 1). The invited observers included the United Nations Population Fund (UNFPA), the Royal College of Obstetricians and Gynaecologists (RCOG), the International Federation of Gynecology and Obstetrics (FIGO), the International Confederation of Midwives (ICM) and the International Council of Nurses (ICN), and representatives from all attended except for ICN. In addition, a range of WHO/HRP's implementing partner organizations were invited to review the draft guideline prior to submission to the GRC; these organizations included Ipas, the International Planned Parenthood Federation (IPPF), MSI Reproductive Choices, Pathfinder and Population Services International (PSI).

B. Management of declarations and conflicts of interests, and confidentiality

In accordance with the *WHO handbook for guideline development*, all invited members of the ERRGs, GDG, the ESTs, the ERG, and the GDG meeting observers, guideline reviewers representing implementing partner organizations, and other external contributors (e.g. consultants and collaborators) were asked to declare in writing any competing interests (academic, financial or other) at the time of invitation to participate in the guideline development or evidence review process. This was done by electronic submission of a signed WHO Declaration of Interests (DOI) form along with a copy of their curriculum vitae to the responsible technical officer prior to participation. In addition, internet searches were conducted on each invited member to assess any potential conflicts of interest that had not been disclosed. The management of conflicts of interest was explained to the invited participants, including the fact that no member would be allowed to participate in the meeting(s) if they failed to first complete and sign a DOI form.

The responsible technical officer assessed the DOI forms and CVs received with reference to the *WHO handbook for guideline development*, in consultation with the Director of the SRH Department and with the input of the WHO Steering Group, to determine the existence (and severity) of any conflict of interest, and agree upon a management plan. One conflict arose for one ERRG member during the course of guideline development, and this person thus did not attend any meetings thereafter. There were no other cases of any conflict of interest (this is also reported in the ERRG and GDG members lists in Annex 1).

Biographical information for all ERRG and GDG members deemed not to have significant conflicts of interest (i.e. conflicts that precluded their participation in the GDG) were posted on the WHO SRH Department's website for public comment for at least two weeks before the start of the respective meetings, with their consent (in 2020 for the ERRGs and in 2021 for the GDG). ERRG and GDG members were confirmed once this process was completed. On confirmation of their eligibility to participate, all ERRG, GDG and ERG experts were instructed to notify the responsible technical officer of any change in relevant interests during the course of their participation in the process. At the start of each meeting, all ERRG and GDG participants had the opportunity to verbally confirm, append or amend any declared interests so that all fellow GDG members and other attendees were made aware. They had a similar opportunity to do the same in writing before submitting comments on draft versions of the guideline.

Finally, it should be noted that each member of the ERRGs, GDG, ERG, ESTs and each guideline methodologist was asked to sign a confidentiality agreement relating to the guideline development process and outcomes. In addition, the responsible technical officer securely stored all received electronic and printed hard copies of the signed DOI forms and curriculum vitae to ensure that confidentiality was maintained.

C. Scope of the guidance: defining topic areas and outcomes of interest

In September 2018, an online survey was undertaken to initiate the process of updating WHO guidance on safe abortion. The objectives of this survey were (i) to identify relevant areas that require an update or new areas that need to be added to the guidance and (ii) to generate suggestions for making the guidelines more user-friendly. The survey was distributed within various networks in the sexual and reproductive health field and resulted in 122 responses.

2 WHO handbook for guideline development, second edition. Geneva: World Health Organization; 2014 (https://apps.who.int/iris/handle/10665/145714).

Thereafter, scoping meetings for each of the three domains (Clinical services, Service delivery, and Law and policy) were conducted with a range of experts, between November 2018 and June 2019. The purpose of these meetings was to determine the key topic areas that required formulation of key questions in the "PICO" format (population, intervention, comparator, outcomes) and to formulate and discuss these questions. The PICO questions were further reviewed, modified and finalized in the follow-up email exchanges between the WHO Steering Group and the ERRG members for each domain. The topic areas for the final PICOs of each domain, as determined during the scoping meetings, are provided in Box A below. The PICO questions for each domain are provided in Annexes 8, 9 and 10.

In addition to the scoping meetings, three technical meetings also focused on issues relating to abortion care in humanitarian settings (June 2019), values and preferences relating to abortion care (September 2019), and youth concerns relating to abortion care (April 2021) (further details on these meetings and issues are presented in Box B at the end of this annex and in the Web annex B: Technical meetings during guideline development).

BOX A: Topic areas per domain for development of PICOs for new and updated recommendations

Law and policy	Criminalization Grounds-based approaches Gestational age limits Mandatory waiting periods Third-party authorization Restrictions on abortion providers Conscientious objection by a health worker
Clinical services	Rh isoimmunization Pain management for medical and surgical abortion and for cervical priming Cervical priming prior to surgical abortion Self-management of medical abortion (all subtasks) Medical abortion using new methods (regimens including letrozole) Medical management of missed abortion Follow-up care or additional services after abortion
Service delivery	**Health workers providing services:** self, community health workers, pharmacy workers, pharmacists, traditional and complementary medicine professionals, auxiliary nurses, auxiliary nurse midwives, nurses, midwives, associate/advanced associate clinicians, generalist medical practitioners **Services:** • Provision of information on safe abortion • Counselling across the continuum of care • Cervical priming with medication and osmotic dilators prior to surgical abortion • Surgical abortion (vacuum aspiration [VA] and dilatation and evacuation [D&E]) • Medical management of induced abortion (all subtasks; including self-management) • Medical management of intrauterine fetal demise (IUFD) • Medical and surgical management of incomplete abortion • Initial management of non-life-threatening complications • Initiation and continuation of injectable contraceptives (including self-injection) **Service-delivery methods:** • Community-based outreach models for provision of abortion care • Medical abortion care provided through telemedicine • Harm-reduction counselling on abortion care • Social marketing methods for abortion services • Self-sourcing of abortion medications online

D. Review of the evidence and formulation of recommendations

Defining and reviewing priority questions

The full list of PICO questions was confirmed during follow-up communications among the WHO Steering Group and the ERRG members after the scoping meetings for each domain, which were described in the previous section. All the PICO questions and related details are provided in Annexes 8, 9 and 10.

Systematic review methods (evidence retrieval)

A list of all reviews conducted for the development of this guideline is presented in Annex 7. Refer to the published systematic reviews and to the packages of supplementary materials online for information about the specific methods used, including search strategies. Refer to beginning of this annex for information about the Evidence Synthesis Teams (ESTs).

Sources for evidence relating to the PICOs of interest for the Clinical services and Service delivery domains included randomized controlled trials (RCTs) as well as non-randomized controlled trials, controlled before-and-after studies, interrupted time series and cohort studies. The following databases were searched from inception to December 2020, without language filters:

- Global databases: ClinicalTrials.gov, Cochrane database, Cumulative Index to Nursing and Allied Health Literature (CINAHL), Excerpta Medica database (Embase), POPLINE, PubMed.
- Regional databases: African Index Medicus (AIM), Chinese Biomedical Literature Database, Global Index Medicus, Index Medicus for South-East Asia (IMSEAR), Index Medicus for WHO Eastern Mediterranean, Latin American and Caribbean Health Sciences Literature (LILACS), Western Pacific Regional Index Medicus.

In addition, a search of trial registry sites and organizational websites was conducted, and information from experts in the field was also used to identify any major ongoing or completed but unpublished trials that could be relevant to the guideline recommendations. Data from studies meeting the inclusion criteria were extracted using a standardized form and organized into Summary of Findings tables within the GRADE evidence summaries, using the online GRADE (Grading of Recommendations Assessment, Development and Evaluation) application.[3]

For the Law and policy domain, the primary databases searched included Google Scholar, JSTOR, Hein Online and PubMed, from 2010 to 2021. For this domain, in addition to RCTs and other types of studies, the reviews also included legal and policy analyses, regulatory documents, and legal and policy reviews.[4]

Assessment of the quality and certainty of the evidence for recommendations

In accordance with the WHO guideline development process, the GDG formulated the recommendations guided by the quality/certainty of the available evidence.[5] WHO has adopted the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach to recommendation development, which defines the quality/certainty of evidence as the extent to which one can be confident that the reported estimates of effect (desirable or undesirable) available from the evidence are close to the actual effects of interest.[6] The GRADE approach specifies four levels of certainty of evidence, which should be interpreted as follows:

- High – We are very confident that the true effect lies close to that of the estimate of the effect.
- Moderate – We are moderately confident in the effect estimate: the true effect is likely to be close to the estimate of the effect, but there is a possibility that it is substantially different.
- Low – Our confidence in the effect estimate is limited: the true effect may be substantially different from the estimate of the effect.
- Very low – We have very little confidence in the effect estimate: the true effect is likely to be substantially different from the estimate of the effect.

3 GRADEpro GDT. GRADEpro Guideline Development Tool [Software] (developed by Evidence Prime, Inc.). McMaster University; 2020 (https://gradepro.org/).
4 de Londras F, Cleeve A, Rodriguez M, Lavelanet A. Integrating rights and evidence: a technical advance in abortion guideline development. BMJ Glob Health. 2021;6(2):e004141.
5 WHO handbook for guideline development, 2014.
6 Schünemann H, Brożek J, Guyatt G, Oxman A, editors. GRADE handbook for grading the quality of evidence and the strength of recommendations. The GRADE Working Group; 2013 (https://gdt.gradepro.org/app/handbook/handbook.html).

As a baseline, RCTs provide "high-quality" evidence, while non-randomized trials and observational studies provide "low-quality" evidence. This baseline quality rating may be downgraded based on consideration of study design limitations (risk of bias – assessed using the criteria outlined in the *Cochrane handbook for systematic reviews of interventions* along six domains)[7], inconsistency, imprecision, indirectness and publication bias. For observational studies, other considerations, such as magnitude of effect, could lead to upgrading of the rating if there are no limitations that indicated a need for downgrading. The EST members and guideline methodologists, in accordance with standard operating procedures approved by the WHO Steering Group, performed the grading of review evidence.

The GRADE approach to appraising the quality of quantitative evidence was used for all the critical outcomes identified in the PICO questions,[8] and a GRADE evidence profile (GRADE table) was prepared for each quantitative outcome within each PICO; these are presented in the supplementary materials available online.

With regard to the Law and policy domain, there was an existing composite recommendation in the 2012 *Safe abortion* guidance, which spoke to these issues and related interventions; the topics identified during the scoping process for this updated guideline (see Box A) stemmed from there. However, there was no existing standardized approach for assessing the quality or certainty of the evidence relating to laws and policies on abortion using a rights-based analysis.[9] Therefore, an innovative approach was developed to evaluate the evidence that effectively integrated human rights protection and enjoyment as part of health outcomes and analysis, while considering several important factors and their potential interactions.[10] This is in line with WHO's norms and values, and thus underpins integrated evidence for application within an Evidence-to-Decision (EtD) framework.

The outcomes of interest for the Law and policy domain were informed by the conceptual frameworks and legal mapping initially performed by the EST team at Temple University (see section A), which mapped the various interventions and the systems around them and identified empirical research assessing the health effects of laws and policies. This mapping emphasized policy surveillance, advancing technology and methods for legal evaluation, teaching policy surveillance methods, and sharing credible scientific data with researchers, policy-makers and the public to make the case for laws that improve health. Next, the team developed causal logic models for the legal interventions on abortion to display plausible pathways from the implementation of the restriction to health and socioeconomic outcomes. The third step involved using the models as a guide to conduct a second rapid scan, in order to identify non-legal studies investigating whether the processes and outcomes posited in the models do, in fact, occur, and with what frequency and severity, and with what consequences. This evidence, in turn, supported plausible inferences of causality for practical policy and guideline development purposes. The Identifying Data for the Empirical Assessment of Law (IDEAL) method attempts to create an objective framework for crystallizing the various influences and consequences attributable to the impact of specific abortion restrictions, leading to the identification of untapped scientific evidence on plausible effects of the law.[11]

The quantitative evidence retrieved from all types of studies and documents was assessed for precision, directness and magnitude of effect, while the qualitative evidence was assessed for adequacy, and compiled in an EtD table. An overarching Rights Analysis Table, which identified human rights standards relevant to the specific interventions, was applied to the evidence table, leading to the development of a Human Rights to Evidence Table, organized by outcome of interest. The full methods are described in de Londras et al. (2021).[12]

Formulation of recommendations and determining the strength of recommendations

The WHO Steering Group supervised and finalized the preparation of evidence summaries, including GRADE tables and Summary of Findings tables, for each PICO question. For the Clinical services and Service delivery domains, the evidence summaries followed the new Evidence-to-Decision (EtD) framework, known as the WHO-INTEGRATE

7 Each included study is assessed and rated to be at low, high or unclear risk of bias for sequence generation, allocation concealment, blinding of study personnel and participants, attrition, selective reporting and other sources of bias (Higgins J, Thomas J, Chandler J, Cumpston M, Li T, Page M, Welch V, editors. Cochrane handbook for systematic reviews of interventions, Version 6.2. The Cochrane Collaboration; 2021 [https://training.cochrane.org/handbook/current]).

8 Schünemann et al., editors, GRADE Handbook, 2013.

9 Rehfuess E, Stratil JM, Portela A, Baltussen R, Scheel IB, Norris SL. The WHO-INTEGRATE evidence to decision framework version 1.0: integrating WHO norms and values and a complexity perspective. BMJ Glob Health. 2019;4:e000844.

10 de Londras et al., 2021.

11 Burris S, Ghorashi AR, Cloud LF, Rebouché R, Skuster P, Lavelanet A. Identifying data for the empirical assessment of law (IDEAL): a realist approach to research gaps on the health effects of abortion law. BMJ Glob Health. 2021;6:e005120.

12 de Londras et al., 2021.

framework. This new framework is broader and better suited to system-level interventions. The six substantive criteria of the WHO-INTEGRATE framework are the following: balance of health benefits and harms; human rights and sociocultural acceptability; health equity, non-discrimination and equality; societal implications; financial and economic considerations; and feasibility and health system considerations. The additional meta-criterion is quality of evidence (i.e. type, size and limitations of the available studies used as evidence). The WHO-INTEGRATE framework allows for the fact that some interventions are complex and have multiple components interacting synergistically or dissynergistically, may be non-linear in their effects, or may be context dependent. This framework is better able to accommodate recommendation formulation for the Law and policy domain, as well as the Clinical services and Service delivery domains, thus allowing guideline users to make informed decisions on all interventions. Also integral to the recommendation formulation process across all domains is the values placed on the outcomes and the preferences of the women affected by the recommendations. Taking this into account along with all the criteria of the WHO-INTEGRATE framework, as applied to each intervention for the specified population, new and updated recommendations were formulated by the ERRG and GDG members and qualified as either strong ("recommend") or weak ("suggest"; with specified conditions for application) recommendations in favour of the intervention, or as strong recommendations against the intervention/in favour of the comparator.

Recommendations were considered "new" (as labelled in the table at the end of the Executive Summary and in Chapter 3) if no recommendation existed in a previous WHO guideline on the specific topic or intervention in question for the specified population. In particular it should be noted that the 2012 *Safe abortion* guidance provided a composite recommendation related to law and policy; in this guideline, this was developed this into seven separate recommendations, but they are not considered to be "new" (i.e. Recommendations 1,2,3,6,7,21,22).

E. Decision-making by the GDG during guideline development

The GDG meeting took place in April 2021 to review, revise and finalize the draft recommendations from all three domains that had been prepared by the ERRGs, as described above. Decision-making was based on discussion of the synthesized evidence and the use of the DECIDE Framework[13] The final adoption of each recommendation was made by consensus, defined as full agreement among all GDG participants when at all possible – this is the preferred method. In one instance, voting was used since consensus could not be reached. The decision on how to present the medical abortion regimens was made based on the large majority voting in support of upholding the way it is described and presented in the previous guidelines. WHO staff attending the meeting, EST members, methodologists and meeting observers were not allowed to vote.

F. Compilation, review and presentation of the guideline content

The WHO responsible technical officer led the writing of the guideline with external/consultant writers, with significant input from the ESTs, the guideline methodologists and other members of the WHO Steering Group. In advance of the GDG meeting, an early draft of the full guideline document was prepared. The guideline methodologists drafted the GRADE evidence summaries and the WHO Steering Group members drafted corresponding Evidence-to-Decision (EtD) frameworks. The full draft and these supplementary materials were shared electronically with all GDG members (see Annex 1) two weeks before the GDG meeting, which was held during the last week of April 2021.

Following the GDG meeting, revisions were made to accurately reflect the deliberations and decisions of the GDG members on the recommendations and to incorporate their feedback on the draft. Subsequently, the revised draft guideline was shared electronically with all GDG members for two weeks for further comment. It was simultaneously shared for comment with all members of the External Review Group (ERG), the GDG meeting observers, and the representatives of implementing partner organizations (see section A and Annex 1), who were unconnected with the process of guideline development.

Next, the Steering Group carefully evaluated the written input of all the reviewers (via email and direct comments/edits on the draft document) for inclusion in the final guideline document and the revised version was reviewed by the director of the WHO SRH Department and edited for clarity. The final draft was submitted for review at a meeting of the WHO Guidelines Review Committee (GRC) and was fully approved by the GRC in August 2021 after some requested revisions had been completed.

13 Evidence to Decision frameworks (EtDs) for policy makers [website]. Cochrane Norway; 2021 (https://www.cochrane.no/decide-frameworks-policy-makers).

Evidence derived from the systematic reviews in support of the new and updated recommendations was summarized in EtD frameworks to provide the evidence base on effectiveness that informed the new recommendations in this guideline. These EtD frameworks are presented separately in the three packets of supplementary materials available online at https://www.who.int/publications/i/item/9789240039483:

- Supplementary material 1: Evidence-to-Decision frameworks for the law and policy recommendations
- Supplementary material 2: Evidence-to-Decision frameworks for the clinical service recommendations
- Supplementary material 3: Evidence-to-Decision frameworks for the service delivery recommendations and best practice statements

Scoping meetings: November 2018 – June 2019

BOX B: Key meetings during guideline development (in Geneva, Switzerland, or online)

Two-day scoping meetings were held for each of the three domains of this guideline, during which external experts on the subject areas and methodology (see Annex 1) identified the priority topics and the specific areas requiring new or updated recommendations or good practice statements.

- **Law and policy domain:** Geneva, November 2018. This meeting facilitated discussion and the development of new approaches to guideline development for (i) abortion law and policy, and (ii) integration of human rights.
- **Clinical services domain**: Virtual meeting, December 2018.
- **Service delivery domain**: Geneva, June 2019.

Technical meetings:

(i) Implementation considerations for abortion care in humanitarian settings: A two-day technical meeting was held in Geneva in June 2019. This meeting convened approximately 20 experts in the fields of humanitarian aid, conflict settings, abortion care and human rights (including three youth representatives) together with 20 representatives from the WHO Secretariat. The expert participants came from nine countries in the regions of Africa, the Eastern Mediterranean, Europe and North America. During the meeting participants identified specific barriers and facilitating factors for implementation of safe abortion in humanitarian/emergency settings. Common barriers that were identified included: stigma, the role of social norms and values, the lack of clinical skills and knowledge, and perceived legal barriers. Practices that facilitate implementation of quality abortion care in these settings are: engagement with key stakeholders (in particular with community and religious leaders), developing a concrete implementation strategy with identification of potential entry points, and ensuring data collection and monitoring. For further details, see Web annex B: Technical meetings during guideline development.

(ii) Global abortion values and preferences: An online survey was prepared and disseminated in October and November 2018. In September 2019, a two-day technical meeting was convened in Geneva with a diverse range of stakeholders, including 19 participants from 15 different organizations/countries (including three youth representatives) and 8 members of the WHO Secretariat. For the first time, this was a meeting focused solely on unpacking the meaning of "values and preferences" in relation to abortion. By the end of the meeting, the information generated from the rich discussions formed a basis for the guideline development discussions on the values and preferences of women, which was one of the key criteria in the recommendation formulation process. For further details, including a summary of the literature review findings, see Web annex B: Technical meetings during guideline development.

BOX B: *Continued*

(iii) Youth concerns relating to abortion care: For each of the scoping and technical meetings for this guideline, mentioned in this box, there were representatives from the International Youth Alliance for Family Planning (IYAFP) to provide a youth perspective, and one representative from IYAFP also served on each ERRG and one on the final GDG. In addition, a dedicated two-day technical meeting was held online in April 2021, bringing together 16 members of the IYAFP Youth for Abortion Taskforce which IYAFP had formed to support and inform the guideline development process, and 4 WHO staff members from the Preventing Unsafe Abortion (PUA) Unit of WHO's Department of Sexual and Reproductive Health and Research. Participants included youths (up to age 30) with demonstrated leadership skills in the field of adolescent sexual and reproductive health and rights, representing 13 countries across the WHO regions. The meeting discussions centred around three key themes: youth's values and preferences related to abortion services, addressing barriers and abortion stigma, and scaling up promising practices and interventions. Key issues discussed included the elements of an enabling environment and meaningful youth engagement. IYAFP members are developing a position paper as the main output of the meeting. For further details, see Web annex B: Technical meetings during guideline development.

Evidence and Recommendations Review Group (ERRG) meetings: March 2020 – March 2021

The ERRG meetings (4–5 meetings for each of the three domains) all occurred online, each one taking place across two days, facilitated by the WHO responsible technical officer and other members of the WHO Steering Group. At these meetings, members of the Evidence Synthesis Teams presented their systematic reviews of the evidence, and the ERRG members (see section A and Annex 1) discussed and reviewed the evidence and formulated draft recommendations, implementation considerations and good practice statements to be presented for further review, revision and finalization by the GDG.

- Clinical services domain: March 2020, May 2020, June 2020, September 2020, February 2021
- Service delivery domain: Pre-ERRG June 2020, October 2020, January 2021, early March 2021, late March 2021
- Law and policy domain: March-April 2020, June 2020, August–September 2020, March 2021.

Guideline Development Group (GDG) meeting

Online, 27–30 April 2021. During the GDG meeting, the GDG members reviewed, discussed, revised and finalized the draft recommendations, implementation considerations and good practice statements from all three domains.

WHO Guidelines Review Committee (GRC) meeting

7 July 2021.

Annex 5. Health worker categories and roles

The health worker types considered in the guideline are described in the table below. Descriptions have been adapted for the purpose of this guideline to be generic enough to apply across settings. They are indicative and illustrative and are not intended as a substitute for the formal definitions of professional bodies or titles used in specific countries.

Broad category	Description of qualifications and tasks, for the purpose of this guideline	Illustrative examples of other terms for these types of health workers (some examples may be specific to a country or regional context)
Community health worker (CHW)	A person who performs functions related to health-care delivery/information provision and has been trained in some way in the context of the task but has received no formal professional or paraprofessional certificate or tertiary education degree.	Lay health worker, village health worker, female community health volunteer, trained birth attendant, trained helpline worker, abortion accompanier, hotline counsellor
Pharmacy worker	Technicians and assistants who perform a variety of tasks associated with dispensing medicinal products under the guidance of a pharmacist. They inventory, prepare and store medications and other pharmaceutical compounds and supplies, and may dispense medicines and drugs to clients and instruct on their use as prescribed by health professionals. Technicians typically receive two or three years of training in a pharmaceutical school, with an award not equivalent to a university degree. Assistants have usually also been through two or three years of secondary school with a subsequent period of on-the-job training or apprenticeship.	Pharmacy assistant, pharmacy technician dispenser, pharmacist aide, dispensary assistant
Pharmacist	A health-care practitioner who dispenses medicinal products. A pharmacist can counsel on the proper use and adverse effects of drugs and medicines following prescriptions issued by medical doctors/health-care professionals. Education includes university-level training in theoretical and practical pharmacy, pharmaceutical chemistry or a related field.	Chemist, clinical pharmacist, community pharmacist
Traditional and complementary medicine professionals	A professional of traditional and complementary systems of medicine (non-allopathic physician) whose training includes a four- or five-year university degree that teaches human anatomy, physiology, management of normal labour and the pharmacology of modern medicines used in obstetrics and gynaecology, in addition to their systems of medicine. For the purpose of this guideline, these doctors are included with reference to the provision of elements of abortion-related care as per conventional medical practice.	Ayush doctor, Ayurvedic physician, doctor of complementary systems of medicine, non-allopathic physician
Auxiliary nurse midwife (ANM) and auxiliary nurse	An auxiliary nurse is someone trained in basic nursing skills but not in nursing decision-making. An ANM has basic nursing skills and some midwifery competencies but is not fully qualified as a midwife. The duration of training may vary from a few months up to three years. A period of on-the-job training may be included, and this is sometimes formalized in apprenticeships.	Auxiliary midwife, family welfare visitor
Nurse	A person who has been legally authorized (registered) to practise after examination by a state board of nurse examiners or similar regulatory authority. Education includes three or more years in nursing school, and leads to a university or postgraduate university degree or the equivalent.	Registered nurse, clinical nurse specialist, licensed nurse, BSc nurse
Midwife	A person who has been registered by a state midwifery or similar regulatory authority and has been trained in the essential competencies for midwifery practice. Training typically lasts three or more years in nursing or midwifery school and leads to a university degree or the equivalent. A registered midwife has the full range of midwifery skills, which include abortion.	Registered midwife, community midwife, nurse-midwife
Advanced associate clinician and associate clinician	A professional clinician with basic competencies to diagnose and manage common medical and surgical conditions and also to perform some types of surgery. Training generally requires three or four years post-secondary education in an established higher education institution. The clinician is registered and their practice is regulated by a national or subnational regulatory authority.	Assistant medical officer, clinical officer, medical licentiate practitioner, health officer, physician assistant, surgical technician, non-physician clinician, medical assistant, nurse practitioner
Generalist medical practitioner	A medical doctor who holds a university-level degree in basic medical education but does not have a specialization in obstetrics and gynaecology.	Family doctor, general practitioner, medical doctor, physician
Specialist medical practitioner	A medical doctor with postgraduate clinical training and specialization in obstetrics and gynaecology.	Gynaecologist, obstetrician

Source: adapted with minor revisions from WHO (2015) *(18)*, including updating some of the names of health worker categories to use current preferred WHO terminology, as presented in the International Standard Classification of Occupations (ISCO), Part III: Definitions of major groups, sub-major groups, minor groups and unit groups, updated 21 June 2016 (available at: https://www.ilo.org/public/english/bureau/stat/isco/isco08/index.htm).

Annex 6. Monitoring and evaluation of quality abortion care: identification of indicators

Methods and preliminary results

To achieve consensus on indicators that can be used to effectively document progress in quality abortion care at programmatic and country levels, a scoping review and multiple expert consultation processes have been conducted by scientists from the London School of Hygiene and Tropical Medicine (LSHTM) and WHO.

Scoping review: The scoping review yielded a summary of abortion measures and indicators reported over the 10-year period 2008–2018 in scientific literature and materials identified on major non-governmental organization websites. In total, 1999 abstracts and 7 additional relevant documents were screened for indicators, yielding 792 indicators identified from 142 documents. The findings of the scoping review were recently published in *BMJ Global Health* and the 792 indicators are available on a searchable spreadsheet among the supplementary materials for the publication.[1]

Consultation meeting: At an initial (virtual) consultation meeting in June 2020, multiple sets of indicators that could be used for global- and programme-level monitoring were presented. These included a sub-set of 17 core indicators that had been selected from among the indicators identified in the scoping review and from among indicators for monitoring abortion care based on measurement initiatives implemented variously by the UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), the WHO Regional Office for Africa, the Maternal Mortality Initiative (of the WHO Department for Sexual and Reproductive Health and Research) and Ibis Reproductive Health. In total, 52 unique indicators were proposed during the consultation meeting. The WHO health systems strengthening monitoring and evaluation framework was also presented as a potential structure for quality abortion monitoring and evaluation (M&E).

Consolidation: During a consolidation phase, a team of LSHTM and WHO scientists eliminated 29 out of the 52 indicators, removing indicators with duplication of information, using as main review criteria (i) relevance within the health systems strengthening monitoring and evaluation framework, and (ii) feasibility for M&E. Six indicators were added to represent categories in the health system strengthening monitoring and evaluation framework which previously had no associated proposed indicators (such as social protection and infrastructure) and in an effort to align with the Sustainable Development Goals (SDG) targets related to sexual and reproductive health and rights. These six additional indicators were sourced from the original scoping review list of indicators,[2] the Ibis Reproductive Health quality of care indicators,[3] and the WHO Department of maternal, newborn, child and adolescent health (MCA) indicators on respectful care.[4]

Online consultation: In an online consultation in March 2021, measurement and M&E experts in abortion care were invited to comment on (i) the relevance to abortion programmes of the WHO health systems strengthening monitoring and evaluation framework, (ii) the validity, feasibility, importance and sensitivity to change of each proposed indicator, and (iii) suggestions for alternative indicators. Twenty-two (out of 27) invited experts reviewed a total of 29 consolidated indicators during the online consultation. The 29 indicators were categorized in the health systems strengthening monitoring and evaluation framework areas of governance (5), financing (1), infrastructure (1), information system (1), health workforce (1), intervention access and services readiness (5), intervention quality and safety (5), coverage of interventions (1), prevalence of risk behaviours and risk factors (1), improved health outcomes and equity (4), responsiveness (2) and social protection (2).

Next steps

The core team from LSHTM and WHO is currently finalizing the indicator list following review of input gathered during the online consultation, recognizing that the indicator list will require periodic assessment for strengthening and maintaining utility and relevance. A report will be published in due course.

Annex 7. Systematic reviews and links to PICOs and recommendations

Topic area	Title and authors of review (and reference details, if published)	Related PICO numbers(s), as listed in annexes	Related recommendation number(s) as presented in the main document
Topics scoped for development of new or updated recommendations			
Law and policy topics **For the Evidence-to-Decision (EtD) frameworks, refer to Supplementary material 1[1]**	**All reviews conducted by the Law and Policy Evidence Synthesis Team for development of this guideline[2]**	**Refer to Annex 8**	
Criminalization[3]	Impact of criminalization on abortion-related outcomes	1	1
Grounds-based approaches	Impact of grounds on abortion-related outcomes	2	2
Gestational age limits	Impact of gestational limits on abortion-related outcomes	3	3
Mandatory waiting periods	Impact of mandatory waiting periods on abortion-related outcomes	4	6
Third-party authorization	Impact of third-party authorization on abortion-related outcomes	5,6,7,8,9	7
Abortion provider restrictions	Impact of provider restrictions on abortion-related outcomes	10	21
Conscientious objection	Impact of conscientious objection on abortion-related outcomes	11	22
Clinical service topics **For the Evidence-to-Decision (EtD) frameworks, refer to Supplementary material 2[4]**	**All reviews conducted by the Clinical services Evidence Synthesis Team for development of this guideline**	**Refer to Annex 9**	
Rh isoimmunization	New systematic review: Chan M, Gill R, Kim C. The effect of routine anti-D administration among unsensitized Rh negative individuals who have an abortion. BMJ Sex Reprod Health. 2021 (in press).	1	8
Pain management for surgical abortion	Updated review by Cochrane Fertility Regulation (CFR) Group: Renner R-M, Edelman A, McKercher AE, Jensen JTJ, Nichols MDN. Pain control in first trimester surgical abortion. 2020 *(forthcoming)* New systematic review: DePiñeres T. Pain management regimens for surgical abortion > 14 weeks gestation. 2020 *(unpublished)*	2, 3	11 & 12 13 & 14
Pain management for medical abortion	New review by CFR Group: Reynolds-Wright JJ, Woldetsadik MA, Morroni C, Cameron S. Pain management for medical abortion before 14 weeks' gestation. 2020 *(forthcoming)* New systematic review: Korotkaya Y, Kim C. Pain control in second-trimester medical termination of pregnancy: a systematic review. 2019 *(unpublished)*	4, 5	15 16
Cervical priming prior to surgical abortion < 12 weeks	Updated review by CFR Group: Kapp N, Nguyen A, Atrio J, Lohr P. Cervical preparation for surgical abortion less than 14 weeks. 2020 *(forthcoming)*	6a	17
Cervical priming prior to surgical abortion ≥ 12 weeks	Updated review by CFR Group: Newmann SJ, Tufa T, Drey E, Meckstroth K, Diedrich JT. Cervical preparation for second trimester dilation and evacuation. 2019 *(forthcoming)*	6b,7,8,9	18
Other medical methods to induce abortion	New systematic review: Tolu L, Kim C. The efficacy, safety, and acceptability of alternative methods of medication abortion to the routine mifepristone and/or misoprostol. 2020 *(manuscript in progress)*	10,11,12	27c
Missed abortion < 14 weeks	New systematic review: DePiñeres T. Management options for pregnant individuals with missed abortion < 14 weeks. 2020 *(unpublished)*	13,14,15	31

1 Supplementary material 1, available at: https://www.who.int/publications/i/item/9789240039483
2 Authors of all seven reviews include: Amanda Cleeve, Fiona de Londras, Alana Farrell, Magdalena Furgalska, Antonella Lavelanet, Maria Isabel Rodriguez.
3 These first three recommendations are presented in Chapter 2. The remainder are presented in Chapter 3.
4 Supplementary material 2, available at: https://www.who.int/publications/i/item/9789240039483

Topic area	Title and authors of review (and reference details, if published)	Related PICO numbers(s), as listed in annexes	Related recommendation number(s) as presented in the main document
Self-management of medical abortion (eligibility, administration of medications, assessment of outcome)	New systematic review: Clark E, Tolu L, Gill R, Kim C. Eligibility and outcome assessment. 2020 *(unpublished)* New review by CFR Group: Gambir K, Kim C, Necastro KA, Ganatra B, Ngo TD. Self-administered versus provider-administered medical abortion. Cochrane Database Syst Rev. 2020;(3):CD013181.	16	50 (Self-management)
Service delivery topics **For the Evidence-to-Decision (EtD) frameworks, refer to Supplementary material 3[5]**	**All reviews conducted by the Service delivery Evidence Synthesis Team for development of this guideline**	**Refer to Annex 10**	
Provision of information	Updated review by Cochrane Response (on pharmacy workers): Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: information provision by pharmacy workers. 2021 *(unpublished)*	1	4
Counselling	Updated review by Cochrane Response (on traditional and complementary medicine professionals, pharmacists, pharmacy workers and community health workers): Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: pre- and post-abortion counselling. 2021 *(unpublished)*	2	5
Cervical priming using osmotic dilators or medication prior to induced surgical abortion	Updated review by Cochrane Response (on traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives, nurses or auxiliary nurses/auxiliary nurse midwives): Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Cervical priming using osmotic dilators or medications. 2021 *(unpublished)*	3	19 & 20
Vacuum aspiration for all indications at < 14 weeks Vacuum aspiration for management of incomplete abortion	Updated Cochrane Review (on traditional and complementary medicine professionals, auxiliary nurse midwives, auxiliary nurses, nurses, midwives, associate/advanced associate clinicians): Kim C, Barnard S, Park MH, Ngo TD. Doctors or mid-level providers for abortion. Cochrane Database Syst Rev. 2021 *(forthcoming)*	4 & 10	24 & 38
Dilatation and evacuation (D&E) for surgical abortion at ≥ 14 weeks	New systematic review (on traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives): Feyssa M, Kim C. Systematic review on effectiveness, safety and acceptability of second trimester abortion by midlevel providers. 2021 *(unpublished)*	5	26
Medical abortion at < 12 weeks (eligibility, administration of medications, assessment of outcome)	Updated Cochrane Review (on traditional and complementary medicine professionals, auxiliary nurse midwives, auxiliary nurses, midwives, nurses, associate/advanced associate clinicians): Kim C, Barnard S, Park MH, Ngo TD. Doctors or mid-level providers for abortion. Cochrane Database Syst Rev. 2021 *(forthcoming)* New review by Cochrane Response (on pharmacists, pharmacy workers and community health workers): Villanueva G, Cogo E, Petkovic J, Bergman H, Probyn K, Buckley B, et al. Medical abortion facilitation. 2021 *(unpublished)*	6	28
Medical abortion at ≥ 12 weeks	New systematic review (on traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives, nurses, auxiliary nurses): Feyssa M, Kim C. Systematic review on effectiveness, safety and acceptability of second trimester abortion by midlevel providers. 2021 *(unpublished)*	7	30
Medical management of intrauterine fetal demise (IUFD)	New review by Cochrane Response: Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: medical management of intrauterine fetal demise (IUFD). 2020 *(unpublished)*	8	33
Medical management of incomplete abortion	Updated review by Cochrane Response: Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: medical management of incomplete abortion. 2020 *(unpublished)*	9	37

5 Supplementary material 3, available at: https://www.who.int/publications/i/item/9789240039483

Topic area	Title and authors of review (and reference details, if published)	Related PICO numbers(s), as listed in annexes	Related recommendation number(s) as presented in the main document
Diagnosis and management of abortion-related complications	Updated review by Cochrane Response (on traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives, nurses, auxiliary nurses/auxiliary nurse midwives): Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: diagnosis and management of abortion related complications. 2021 *(unpublished)*	11	39 & 40
Delivery of injectable contraceptives	Updated review by Cochrane Response (on traditional and complementary medicine professionals medicine, pharmacists, pharmacy workers) Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: injectable contraception. 2020 *(unpublished)*	12	46
Telemedicine for provision of medical abortion care (comprehensive abortion care or individual components)	Updated review by Cochrane Response: Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: telemedicine. 2020 *(unpublished)*	13	48
Community-based outreach models for provision of abortion care	New systematic review by Cochrane Response: Villanueva G, Probyn K, Bergman H, Petkovic J, Cogo E, Buckley B, et al. Health worker roles in providing safe abortion care and post-abortion contraception: Community outreach models. 2021 *(unpublished)*	14	49 (Best practice statement [BPS])
Harm-reduction counselling for persons seeking induced abortion	New systematic review: Stifani B, Gill R, Kim C. Harm-reduction counselling to reduce the harms of unsafe abortion: a systematic review. 2021 *(manuscript under review)*	15	49 (BPS)
Social marketing outreach for pregnant women seeking induced abortion	New systematic review: Abubeker F, Tufa T, Kim C. Impact of social marketing interventions on safe abortion services. 2021 *(unpublished)*	16	49 (BPS)
Self-sourcing of medications through online services for pregnant women seeking induced abortion	New systematic review: Abubeker F, Tufa T, Kim C. Safety, effectiveness, and acceptability of self-sourcing of medications for induced abortion. 2021 *(unpublished)*	17	49 (BPS)
Self-administration of injectable contraceptives in the post-abortion period	Updated review by Cochrane Response: Villanueva G, Bergman H, Cogo E, Petkovic J, Buckley B, Probyn K, et al. Health worker roles in providing safe abortion care and post-abortion contraception: self-administration of injectable contraceptives. 2020 *(unpublished)*	18	51 (Self-management)
II. Topics not scoped, but an updated evidence review was conducted			
Prophylactic antibiotics	Existing review: Low N, Mueller M, Van Vliet HAAM, Kapp N. Perioperative antibiotics to prevent infection after first-trimester abortion. Cochrane Database Syst Rev. 2012;(3):CD005217. *(Updated evidence review conducted in 2021)*	N/A	9
Pre-abortion ultrasound	Existing review: Kulier R, Kapp N. Comprehensive analysis of the use of pre-procedure ultrasound for first-and second-trimester abortion. Contraception, 2011;83(1):30-3. *(Updated evidence review conducted by Cochrane Response in April 2021)*	N/A	10
Surgical methods for first trimester abortion	Existing review: Kulier R, Cheng L, Fekih A, Hofmeyr GJ, Campana A. Surgical methods for first trimester termination of pregnancy. Cochrane Database Syst Rev. 2001;(4):CD002900. *(Updated evidence review conducted in April 2021)*	N/A	23
Medical management of induced abortion	Existing review: Abubeker FA, Lavelanet A, Rodriguez MI, Kim C. Medical termination for pregnancy in early first trimester (≤ 63 days) using combination of mifepristone and misoprostol or misoprostol alone: a systematic review. BMC Womens Health. 2020;20(1):142. Updated review: Whitehouse K, Brant A, Sporstol Fonhus M, Lavelanet A, Ganatra B, et al. Medical regimens for abortion at 12 weeks and above: a systematic review and meta-analysis. Contracept X. 2020;2:100037.	N/A	27 29

Topic area	Title and authors of review (and reference details, if published)	Related PICO numbers(s), as listed in annexes	Related recommendation number(s) as presented in the main document
Medical management of IUFD	Existing review: Cleeve A, Fønhus MS, Lavelanet A. A systematic review of the effectiveness, safety, and acceptability of medical management of intrauterine fetal death at 14–28 weeks of gestation. Int J Gynaecol Obstet. 2019;147(3):301-12.	N/A	32
Post-abortion follow-up	Existing reviews: Grossman D, Ellertson C, Grimes DA, Walker D. Routine follow-up visits after first-trimester induced abortion. Obstet Gynecol. 2004:103(4):738-45. Annex 8. Law and policy domain PICO questions

PICO: P = population; **I** = intervention; **C** = comparator (where applicable*); **O** = outcome(s)[1]

* Where a comparator is available, these data have been included, but very few studies that report on abortion-related policy interventions include a comparator of any kind.

Abortion regulation

Criminalization

PICO 1: The impact of criminalization (see Recommendation 1)

PICO question: For pregnant people seeking abortion and also for medical professionals providing abortion services, what is the impact of criminalization on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees), perceived impact on provider–client relationship, stigmatization of health-care providers (considering the application of the intervention), criminal justice procedures, harassment, anti-abortion sting operations, availability of trained providers, reporting of suspected unlawful abortion?

P: Pregnant people seeking abortion; medical professionals providing abortion services

I: Criminalization

C: None (studies do not need to specify comparator)

O:[2]

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (includes psychological opportunity costs)
- Unlawful abortion
- Self-managed abortion
- Referral to another provider
- Workload implications (including reassignment issues with organization of work, as well as increases or decreases in workload)
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Perceived impact on provider–client relationship
- Stigmatization of health-care providers (considering the application of the intervention)
- Criminal justice procedures
- Harassment
- Anti-abortion sting operations
- Availability of trained providers
- Reporting of suspected unlawful abortion.

1 For further information on the findings of the reviews based on the PICOs presented in this annex, refer to the EtD frameworks in Supplementary material 1.

2 For each of the PICOs in this annex, the outcomes for both populations (pregnant people seeking abortion and medical professionals providing abortion services) have been combined in one list; for more specific information about the outcomes of interest for each review, refer to the EtD frameworks in Supplementary material 1.

Grounds-based approaches

PICO 2: The impact of grounds-based approaches (see Recommendation 2)

PICO question: For pregnant people seeking abortion and also for medical professionals providing abortion services, what is the impact of grounds-based approaches (that limit access to and/or provision of abortion on "grounds" or that prohibit access to abortion) on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, disproportionate impact, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), perceived imposition on personal conscience or ethics, perceived impact on provider–client relationship, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees), stigmatization of health-care providers (considering the application of the intervention)?

P: Pregnant people seeking abortion; medical professionals providing abortion services

I: Grounds-based approaches (that limit access to and/or provision of abortion on "grounds" or that prohibit access to abortion)

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (includes psychological opportunity costs)
- Unlawful abortion
- Self-managed abortion
- Anticipated or experienced family disharmony
- Anticipated or experienced exposure to interpersonal violence or exploitation
- Anticipated or experienced reproductive coercion
- Disproportionate impact
- Referral to another provider
- Workload implications (including reassignment issues with organization of work, as well as increases or decreases in workload)
- Perceived imposition on personal conscience or ethics
- Perceived impact on provider–client relationship
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Stigmatization of health-care providers (considering the application of the intervention).

Gestational age limits

PICO 3: The impact of gestational age limits (see Recommendation 3)

PICO question: For pregnant people seeking abortion and also for medical professionals providing abortion services, what is the impact of gestational age limits on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, disqualification from unlawful abortion, disproportionate impact, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees), perceived impact on provider–client relationship, stigmatization of health-care providers (considering the application of the intervention)?

P: Pregnant people seeking abortion; medical professionals providing abortion services

I: Gestational age limits

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (including psychological opportunity costs)
- Unlawful abortion
- Self-managed abortion
- Disqualification from unlawful abortion
- Disproportionate impact
- Referral to another provider
- Workload implications (including reassignment issues with organization of work, as well as increases or decreases in workload)
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Perceived impact on provider–client relationship
- Stigmatization of health-care providers (considering the application of the intervention).

Pre-abortion

Mandatory waiting periods

PICO 4: The impact of mandatory waiting periods (see Recommendation 6)

PICO question: For pregnant people seeking abortion and also medical professional providing abortion services, what is the impact of mandatory waiting periods on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), disproportionate impact, unlawful abortion, self-managed abortion, disqualification from lawful abortion, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees), perceived impact on provider–client relationship, stigmatization of health-care providers (considering the application of the intervention)?

P: People seeking abortion services; medical professionals providing abortion services

I: Mandatory waiting periods

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy

- Opportunity costs (including abortion travel and psychological opportunity costs))
- Disproportionate impact
- Unlawful abortion
- Self-managed abortion
- Disqualification from lawful abortion
- Referral to another provider
- Workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload)
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Perceived impact on provider–client relationship
- Stigmatization of health-care providers (considering the application of the intervention).

Third-party authorization for abortion (see Recommendation 7)

PICO 5: Impact of judicial bypass

PICO question: For pregnant people seeking abortion, what is the impact of judicial bypass on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)?

P: Pregnant people seeking abortion

I: Judicial bypass

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (including abortion travel and psychological opportunity costs)
- Unlawful abortion
- Self-managed abortion
- Anticipated or experienced family disharmony
- Anticipated or experienced exposure to interpersonal violence or exploitation
- Anticipated or experienced reproductive coercion
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees).

PICO 6: Impact of judicial bypass versus parental consent

PICO question: For pregnant people seeking abortion, what is the impact of judicial bypass versus parental consent on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)?

[P-I-O same as PICO 5 but with a comparator (C) added: parental consent]

PICO 7: Impact of parental consent versus parental notification laws/requirements

PICO question: For pregnant people seeking abortion, what is the impact of parental consent versus parental notification laws/requirements on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)?

[P and O same as PICO 5; I = parental consent and C = parental notification laws/requirements]

PICO 8: Impact of authorization by parent through consent or notification

PICO question: For pregnant people seeking abortion, what is the impact of authorization by parent through consent or notification on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)?

[P-C-O same as PICO 5 but I = authorization by parent through consent or notification]

PICO 9: Impact of authorization by spousal consent

PICO question: For pregnant people seeking abortion, what is the impact of authorization by spousal consent on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, anticipated or experienced family disharmony, anticipated or experienced exposure to interpersonal violence or exploitation, anticipated or experienced reproductive coercion, system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)?

[P-C-O same as PICO 5 but I = authorization by spousal consent]

Abortion provider restrictions

PICO 10: Impact of provider restrictions (see Recommendation 21)

PICO question: For pregnant people seeking abortion and also for medical professionals providing abortion services, what is the impact of provider restrictions on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), disproportionate impact, unlawful abortion, self-managed abortion, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), system costs (including direct system costs, and "diversions" from public health systems to paid-for services/private fees), perceived imposition on personal conscience or ethics, perceived impact on provider–client relationship, stigmatization of health-care providers (considering the application of the intervention)?

P: Pregnant people seeking abortion; medical professionals providing abortion services

I: Provider restrictions

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (including abortion travel and stigmatization, and psychological opportunity costs)
- Disproportionate impact
- Unlawful abortion
- Self-managed abortion

- Referral to another provider
- Workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload)
- System costs (including direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Perceived imposition on personal conscience or ethics
- Perceived impact on provider–client relationship
- Stigmatization of health-care providers (considering the application of the intervention).

Conscientious objection

PICO 11: Impact of conscientious objection (see Recommendation 22)

PICO question: For pregnant people seeking abortion and also medical professionals providing abortion services, what is the impact of conscientious objection on delayed abortion, continuation of pregnancy, opportunity costs (including psychological opportunity costs), unlawful abortion, self-managed abortion, referral to another provider, workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload), system costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees), perceived imposition on personal conscience or ethics, perceived impact on provider–client relationship, stigmatization of health-care providers (considering the application of the intervention)?

P: Pregnant people seeking abortion; medical professionals providing abortion services

I: Conscientious objection/refusal

C: None (studies do not need to specify comparator)

O:

- Delayed abortion
- Continuation of pregnancy
- Opportunity costs (including abortion travel and stigmatization, and psychological opportunity costs)
- Unlawful abortion
- Self-managed abortion)
- Referral to another provider
- Workload implications (including reassignment, issues with organization of work, as well as increases or decreases in workload)
- System costs (includes direct system costs, and "diversions" from public health systems to paid-for services/private fees)
- Perceived imposition on personal conscience or ethics
- Perceived impact on provider–client relationship
- Stigmatization of health-care providers (considering the application of the intervention).

Annex 9. Clinical services domain PICO questions

PICO: P = population; **I** = intervention; **C** = comparator; **O** = outcome(s)[1]

Pre-abortion

Rh isoimmunization

PICO 1: No anti-D administration in unsensitized Rh-negative individuals seeking abortion (see Recommendation 8 [NEW])

PICO question: For an unsensitized Rh-negative individual seeking abortion at < 12 weeks of gestation, is no administration of anti-D a safe and effective alternative to routine anti-D administration?

P: Unsensitized Rh-negative individuals seeking abortion at < 12 weeks (undergoing either medical or surgical abortion)

I: No anti-D administration

C: Routine anti-D administration

O:

- Rate of isoimmunization in subsequent pregnancy
- Rate of antibody formation after initial pregnancy.

Pain management for surgical abortion

PICO 2: Pain control for surgical abortion at < 14 weeks of gestation (see Recommendations 11 and 12 [NEW])

PICO question: For a pregnant person seeking surgical abortion at < 14 weeks of gestation, is pain control with any particular method (I) safer, more effective and/or more satisfactory/acceptable compared with pain control with a different method or no pain control (C)?

P: Pregnant persons seeking surgical abortion at less than 14 weeks of gestation.

I:

i. Paracervical block (PCB) (this includes the different concentrations, type [lidocaine], carbonated vs not, depth of injection)

ii. PCB with premedication

iii. Intravenous (IV) conscious sedation plus PCB

iv. General anaesthesia

v. Topical anaesthesia (e.g. lidocaine)

vi. Non-pharmacological intervention (music, acupuncture, “verbicaine”, etc.)

C:

i. No PCB

ii. PCB alone

iii. PCB with premedication

iv. IV conscious sedation plus PCB

O:

- Effectiveness (maximum pain as measured by visual analogue scale; VAS)
- Anxiety scores using VAS
- Safety (complications related to pain control methods, use of supplemental narcotic, use of any additional analgesic medication, duration of recovery time, hospital admission), side-effects
- Satisfaction/acceptability.

1 For further information on the findings of the reviews based on the PICOs presented in this annex, refer to the EtD frameworks in Supplementary material 2.

PICO 3: Pain control for surgical abortion at ≥ 14 weeks of gestation (see Recommendations 11, 13 and 14 [NEW])

PICO question: For a pregnant person seeking surgical abortion at ≥ 14 weeks of gestation (including cervical priming prior to the procedure), is pain control with any particular method (I) safer, more effective and/or more satisfactory/acceptable compared with pain control with a different method or no pain control (C)?

P: Pregnant persons seeking surgical abortion at 14 weeks of gestation or above

I:

i. PCB (this includes the different concentrations, type [lidocaine], carbonated vs not, depth of injection)

ii. PCB with premedication

iii. IV conscious sedation plus PCB

iv. General anaesthesia

v. Topical anaesthesia (e.g. lidocaine)

vi. Non-pharmacological intervention (music, acupuncture, "verbicaine", etc.)

C:

i. No PCB

ii. PCB alone

iii. PCB with premedication

iv. IV conscious sedation plus PCB

O:

- Effectiveness (maximum pain as measured by VAS)
- Anxiety scores using VAS
- Safety (complications related to pain-control methods, use of supplemental narcotic, use of any additional analgesic medication, duration of recovery time, hospital admission), side-effects
- Satisfaction/acceptability.

Pain management for medical abortion

PICO 4: Pain control for medical abortion at < 14 weeks of gestation (see Recommendation 15)

PICO question: For a pregnant person seeking medical abortion at < 14 weeks of gestation, is pain control with any particular (i) pharmacological method (given prophylactically or after onset of pain) or (ii) non-pharmacological method safer, more effective and/or more satisfactory/acceptable compared with any other such method or no treatment/placebo?

P: Pregnant persons seeking medical abortion at < 14 weeks of gestation

I:

i. Pharmacological methods (Timing: prophylactic or after onset of pain)

- Ibuprofen
- Acetaminophen plus codeine
- Anti-emetics
- Loperamide
- Tramadol

ii. Non-pharmacological methods (music, acupuncture, "verbicaine", etc.)

C:

i. Pharmacological methods (Timing: prophylactic or after onset of pain)

- Ibuprofen
- Acetaminophen plus codeine
- Anti-emetics
- Loperamide
- Tramadol

ii. Non-pharmacological methods (music, acupuncture, “verbicaine”, etc.)

iii. No treatment/placebo

O:

- Effectiveness (maximum pain as measured by VAS)
- Safety (complications related to pain-control methods, use of any supplemental narcotic, use of any additional analgesic medication), side-effects
- Effectiveness of medical abortion regimen, defined as successful completion without additional surgical intervention
- Time to expulsion
- Satisfaction/acceptability.

PICO 5: Pain control for medical abortion at ≥ 14 weeks of gestation (see Recommendation 16 [NEW])

PICO question: For a pregnant person seeking medical abortion at ≥ 14 weeks of gestation, is pain control with any particular (i) pharmacological method (given prophylactically or after onset of pain) or (ii) non-pharmacological method safer, more effective and/or more satisfactory/acceptable compared with any other such methods or no treatment/placebo?

P: Pregnant persons seeking medical abortion at 14 weeks of gestation or above

I:

i. Pharmacological methods (Timing: prophylactic or after onset of pain)

- Pretreatment (ibuprofen, acetaminophen plus codeine, antiemetics, loperamide, tramadol)
- IV opiates
- PCB

ii. Non-pharmacological methods (music, acupuncture, “verbicaine”, etc.)

C:

i. Pharmacological methods (Timing: prophylactic or after onset of pain)

- Pretreatment (ibuprofen, acetaminophen plus codeine, antiemetics, loperamide, tramadol)
- IV opiates
- PCB

ii. Non-pharmacological methods (music, acupuncture, “verbicaine”, etc.)

iii. No treatment/placebo

O:

- Effectiveness (maximum pain as measured by VAS)
- Safety (complications, use of any supplemental narcotic, use of any additional analgesic medication), side-effects
- Effectiveness of medical abortion regimen, defined as successful completion without additional surgical intervention
- Time to expulsion
- Satisfaction/acceptability.

Cervical priming

PICO 6a: Cervical priming at < 12 weeks of gestation (see Recommendation 17)

PICO question: For a pregnant person seeking surgical abortion at < 12 weeks of gestation, is cervical priming effective, safe and acceptable?

P: Pregnant persons seeking surgical abortion < 12 weeks

I: Cervical priming with medication or mechanical methods

C: Cervical priming with placebo, with medication (using different routes, doses or treatment intervals) or with different mechanical methods

O:

- Effectiveness
- Satisfaction/acceptability
- Safety.

PICO 6b: Cervical priming at ≥ 12 weeks with medications (comparing different regimens) (see Recommendations 18b–d [NEW])

PICO question: For a pregnant person seeking surgical abortion at ≥ 12 weeks of gestation, is cervical priming with mifepristone plus misoprostol or with mifepristone alone a safe, effective and satisfactory/acceptable alternative to cervical preparation with misoprostol alone?

P: Pregnant persons seeking surgical abortion at ≥ 12 weeks

I: Cervical priming with

i. Mifepristone plus misoprostol [various routes, doses, intervals]

ii. Mifepristone alone [various routes, doses, intervals]

C: Cervical priming with misoprostol alone [various routes, doses, intervals]

O:

- Effectiveness (pre-procedure cervical dilatation, need for further dilatation, ease of procedure, time to complete procedure)
- Safety (complications, need for additional interventions, pre- and post-procedure pain), side-effects
- Satisfaction (client and provider)/acceptability
- Cost (comparative cost and cost to the client).

PICO 7: Cervical priming at ≥ 12 weeks with medications compared with mechanical methods (see Recommendation 18b [NEW])

PICO question: For a pregnant person seeking surgical abortion at ≥ 12 weeks of gestation, is cervical priming with medical methods (mifepristone, misoprostol, or both) a safe, effective and satisfactory/acceptable alternative to mechanical methods (laminaria, Foley bulb, Dilapan)?

P: Pregnant persons seeking surgical abortion at ≥ 12 weeks

I: Cervical priming with medical methods

i. Mifepristone alone

ii. Misoprostol plus mifepristone

iii. Misoprostol alone

C: Cervical priming with mechanical methods (i.e. laminaria, Foley bulb, Dilapan)

O:

- Effectiveness (pre-procedure cervical dilatation, need for further dilatation, ease of procedure, time to complete procedure)
- Safety (complications, need for additional interventions, pre- and post-procedure pain), side-effects

- Satisfaction (client and provider)/acceptability
- Cost (comparative cost and cost to the client).

PICO 8: Cervical priming at ≥ 12 weeks with medication(s) plus laminaria compared with laminaria alone (see Recommendation 18d [NEW])

PICO question: For a pregnant person seeking surgical abortion at ≥ 12 weeks of gestation, is cervical priming with medication(s) plus laminaria a safe, effective and satisfactory/acceptable alternative to cervical preparation with laminaria alone?

P: Pregnant persons seeking surgical abortion at ≥ 12 weeks

I: Cervical priming with medication(s) plus laminaria

i. Mifepristone plus misoprostol plus laminaria

ii. Misoprostol plus laminaria

iii. Mifepristone plus laminaria

C: Cervical priming with laminaria alone

O:

- Effectiveness (pre-procedure cervical dilatation, need for further dilatation, ease of procedure, time to complete procedure)
- Safety (complications, need for additional interventions, pre- and post-procedure pain), side-effects
- Satisfaction (client and provider)/acceptability
- Cost (comparative cost and cost to the client).

PICO 9: Cervical priming at ≥ 12 weeks by mechanical method(s) before dilatation and evacuation (D&E) (see Recommendation 18 [NEW])

PICO question: For a pregnant person seeking surgical abortion (D&E) at ≥ 12 weeks of gestation, is cervical priming with one mechanical method a safe, effective and satisfactory/acceptable alternative to cervical priming with a different mechanical method?

P: Pregnant person seeking surgical abortion at ≥ 12 weeks

I: Cervical priming with one mechanical method before D&E

C: Cervical priming with a different mechanical method before D&E

O:

- Effectiveness (pre-procedure cervical dilatation, need for further dilatation, ease of procedure, time to complete procedure)
- Safety (complications, need for additional interventions, pre- and post-procedure pain), side-effects
- Satisfaction (client and provider)/acceptability
- Cost (comparative cost and cost to the client).

Abortion

New medical methods for abortion

PICO 10: Medical abortion with letrozole plus misoprostol, compared with misoprostol alone (see Recommendation 27c [NEW])

PICO question: For a pregnant person seeking medical abortion, is medical abortion with letrozole plus misoprostol a safe, effective and satisfactory/acceptable alternative to medical abortion with misoprostol alone?

P: Pregnant persons seeking medical abortion (all gestational ages)

I: Medical abortion with letrozole plus misoprostol [various routes, doses, intervals]

C: Medical abortion with misoprostol alone [various routes, doses, intervals]

O:

- Effectiveness (ongoing pregnancy rate, procedure completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost (comparative and cost to the client).

PICO 11: Medical abortion with letrozole plus misoprostol, compared with mifepristone plus misoprostol

PICO question: For a pregnant person seeking medical abortion, is medical abortion with letrozole plus misoprostol a safe, effective and satisfactory alternative to medical abortion with mifepristone plus misoprostol?

P: Pregnant persons seeking medical abortion (all gestational ages)

I: Medical abortion with letrozole plus misoprostol [various routes, doses, intervals]

C: Medical abortion with mifepristone plus misoprostol [various routes, doses, intervals]

O:

- Effectiveness (ongoing pregnancy rate, completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost (comparative and cost to the client).

PICO 12: Medical abortion with mifepristone plus letrozole, compared with misoprostol alone

PICO question: For a pregnant person seeking medical abortion, is medical abortion with mifepristone plus letrozole a safe, effective and satisfactory alternative to medical abortion with misoprostol alone?

P: Pregnant person seeking medical abortion

I: Medical abortion with mifepristone plus letrozole [various routes, doses, intervals]

C: Medical abortion with misoprostol alone [various routes, doses, intervals]

O:

- Effectiveness (ongoing pregnancy rate, completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost (comparative and cost to the client).

Missed abortion at < 14 weeks of gestation

PICO 13: Medical management of missed abortion with mifepristone plus misoprostol (see Recommendation 31 [NEW])

PICO question: For a pregnant person with missed abortion at < 14 weeks of gestation, is medical management with mifepristone plus misoprostol a safe, effective and satisfactory/acceptable alternative to medical management with misoprostol alone?

P: Pregnant persons with missed abortion < 14 weeks

I: Medical management with mifepristone plus misoprostol [various routes, doses, intervals]

C: Medical management with misoprostol alone [routes, doses, intervals]

O:

- Effectiveness (failed expulsion/ongoing retained products, completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost of treatment.

PICO 14: Medical management of missed abortion with all regimens (see Recommendation 31 [NEW])

PICO question: For a pregnant person with missed abortion at < 14 weeks of gestation, is medical management (all regimens) a safe, effective and satisfactory/acceptable alternative to expectant management?

P: Pregnant persons with missed abortion < 14 weeks

I: Medical management (all regimens)

C: Expectant management

O:

- Effectiveness (failed expulsion/ongoing retained products, completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost of treatment.

PICO 15: Surgical management of missed abortion (see Recommendation 31 [NEW])

PICO question: For a pregnant person with missed abortion at < 14 weeks of gestation, is surgical management a safe, effective and satisfactory/acceptable alternative to medical or expectant management?

P: Pregnant persons with missed abortion < 14 weeks

I: Surgical management

C:

- Medical management
- Expectant management

O:

- Effectiveness (failed expulsion/ongoing retained products, completed without surgical intervention
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Satisfaction/acceptability
- Cost of treatment.

Self-management approaches

Self-management of medical abortion (see Recommendation 49)

PICO 16: Self-management of medical abortion

PICO question: For a pregnant person seeking medical abortion, is self-management of the process of medical abortion (assessing eligibility, administration of mifepristone and/or misoprostol, self-assessing outcome/success), without direct supervision of a trained health worker, a safe, effective and satisfactory/acceptable alternative to medical abortion managed by a trained health worker?

P: Pregnant persons seeking medical abortion at any gestational age

I: Pregnant persons self-managing the process of medical abortion (in whole) without direct supervision of a trained health worker

C: Medical abortion managed by a trained health worker (all medication abortion regimens)

O:

- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Safety (serious adverse events and complications)
- Satisfaction/acceptability
- Physical and emotional experience (side-effects, positive and negative emotions, internalized stigma), knowing when to seek medical care (unscheduled visits, phone calls to the clinic, emergency visits)
- Cost.

PICO 16a: Self-assessment of eligibility for MA

PICO question: For a pregnant person seeking medical abortion, is self-assessment of eligibility[2] for medical abortion a safe, effective and satisfactory/acceptable alternative to eligibility assessment by a physician or other trained health worker?

P: Pregnant persons seeking medical abortion at any gestational age

I: Pregnant persons self-managing the first part of the medical abortion process by self-assessing their eligibility for medical abortion without direct supervision of a health worker

C: Eligibility assessment performed by a trained health worker

O:

- Proportion of pregnant persons deemed eligible for medical abortion
  - Proportion of pregnant persons who were deemed ineligible due to gestational age
  - Proportion of pregnant persons who were deemed ineligible due to contraindications
- Accuracy of these assessments when measured against an independent verifier and/or diagnostic standard
- Ongoing pregnancy
- Completed without surgical intervention
- Safety (serious adverse events and complications)
- Satisfaction/acceptability
- Cost.

2 Eligibility criteria defined as: < 12 weeks; no contraindications; no signs or symptoms of ectopic pregnancy.

PICO 16b: Self-administering medications for medical abortion

PICO question: For a person seeking medical abortion, is self-administration of medications for medical abortion, when provided with instructions for their use from a reliable source, a safe, effective and satisfactory/acceptable alternative to administration of medications by a trained health worker?

P: Pregnant persons seeking medical abortion at any gestational ages

I: Pregnant persons self-administering the medications for medical abortion (as part of the medical abortion process) without direct supervision by a health worker (but with instructions from a reliable source of health care)

C: Administration of medications for medical abortion by a trained health worker

O:

- Pregnant persons' adherence to the recommended medical abortion regimen following instructions
- Effectiveness (ongoing pregnancy rate, completed without surgical intervention)
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment
- Physical and emotional experience (side-effects, positive and negative emotions, internalized stigma), knowing when to seek medical care (unscheduled visits, phone calls to the clinics, emergency visits)
- Satisfaction/acceptability
- Cost (comparative and cost to the client).

PICO 16C: Self-assessment of the outcome of the medical abortion process

PICO question: For an individual who has undergone medical abortion, is self-assessment of the outcome/success of medical abortion a safe, effective and satisfactory/acceptable alternative to assessment of the outcome/success by a trained health worker?

P: Individuals who have undergone medical abortion

I: Pregnant persons self-managing the last part of the medical abortion process by self-assessing the outcome/success of the abortion without direct supervision by a trained health worker

C: Assessment of outcome/success of abortion by a trained health worker

O:

- Effectiveness (proportion of pregnant persons assessed to have successful abortion, accuracy of these assessments when measured against an independent verifier and/or diagnostic standard)
- Ongoing pregnancy rate
- Completed without surgical intervention
- Safety (serious adverse events and complications), side-effects
- Expulsion time from initiation of treatment;
- Physical and emotional experience (side-effects, positive and negative emotions, internalized stigma), knowing when to seek medical care (unscheduled visits; phone calls to the clinics, emergency visits)
- Satisfaction/acceptability
- Cost (comparative and cost to the client).

Annex 10. Service delivery domain PICO questions

PICO: P = population; **I** = intervention; **C** = comparator; **O** = outcome(s)[1]

Note: For a description of all the health worker categories mentioned in this annex, please refer to Annex 5.

Services applicable across the continuum of care

Provision of information

PICO 1: Pharmacy workers to provide accurate information (see Recommendation 4)

PICO question: For a person seeking information about abortion care (before or after treatment/abortion), is information on the availability of safe providers for abortion care (abortion provision, care for complications of abortion, care for incomplete abortion) provided by a pharmacy worker a safe, effective and satisfactory/acceptable alternative to no provision of information (usual practice)?

P: Person seeking information about abortion care before their treatment, or following an incomplete abortion or complications of abortion (including medical or surgical, at any gestational age)

I: Information and linkage to abortion services, in the community or in other locations, by pharmacy workers

C: No information (usual practice)

O:

- Effectiveness (pharmacy workers' correct knowledge of safe abortion and possible complications, of safe post-abortion care, and of indications for referral)
- Privacy and confidentiality in provision of information
- Accessibility of the services for the person who requires them
- Satisfaction with/acceptability of the information and services provided.

Counselling

PICO 2: Pre- and post-abortion counselling (see Recommendation 5)

PICO question: For a pregnant person having an abortion, is pre- and post-abortion counselling provided by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to counselling provided by in-clinic staff?

P: Pregnant persons having an abortion

I: Pre- and post-abortion counselling by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Counselling provided by in-clinic staff (i.e. generalist or specialist medical practitioners, nurses or midwives)

O:

- Effectiveness (health workers' and clients' correct knowledge of contraceptive options, of safe and appropriate abortion services, and of safe post-abortion care)
- Satisfaction with/acceptability of the contraception advice provided, and the counselling and services provided
- Availability of contraceptive counselling and services
- Accessibility of information and method of choice
- Privacy and confidentiality of client respected during provision of counselling and services
- Participation in provision of counselling and services
- Quality of counselling and services
- Informed decision-making after provision of counselling and services
- Accountability in the provision of counselling and services
- Mix in types of contraception offered in the counselling.

1 For further information on the findings of the reviews based on the PICOs presented in this annex, refer to the EtD frameworks in Supplementary material 3.

Pre-abortion

Cervical priming prior to surgical abortion

PICO 3: Cervical priming using osmotic dilators or medication (see Recommendations 19 and 20)

PICO question: For a pregnant person having an induced surgical abortion, is provision of cervical priming using osmotic dilators or medication by a traditional and complementary medicine professional, associate/advanced associate clinician, midwife, nurse or auxiliary nurse/auxiliary nurse midwife a safe, effective and satisfactory/acceptable alternative to provision of cervical priming by a physician?

P: Pregnant persons having an induced abortion with vacuum aspiration or D&E

I: Cervical priming with

i. osmotic dilators provided by traditional and complementary medicine professionals, associate/advanced associated clinicians, midwives, nurses or auxiliary nurse/auxiliary nurse midwives

ii. medications provided by traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives, nurses, auxiliary nurse/auxiliary nurse midwives, pharmacists or pharmacy workers

C: Cervical priming performed by physicians with (i) osmotic dilators or (ii) medications

O:

- Safety (serious adverse events and complications)
- Effectiveness (degree of dilatation and provider's perception of ease of procedure)
- Satisfaction/acceptability.

Abortion

Surgical abortion at gestational ages < 14 weeks

PICO 4: Vacuum aspiration for all indications at gestational ages < 14 weeks (see Recommendation 24)

PICO question: For a pregnant person seeking induced abortion or treatment for incomplete abortion or miscarriage (i.e. all indications for vacuum aspiration), is provision of vacuum aspiration by a traditional and complementary medicine professional, auxiliary nurse midwife or auxiliary nurse a safe, effective and satisfactory/acceptable alternative to provision of vacuum aspiration by a physician?

P: Pregnant persons seeking an induced abortion or treatment for incomplete abortion or miscarriage

I: Vacuum aspiration provided by traditional and complementary medicine professional, auxiliary nurse midwives or auxiliary nurses

C: Vacuum aspiration provided by generalist or specialist medical practitioners (obstetricians/gynaecologists)

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion following the procedure
- Satisfaction/acceptability.

Surgical abortion at later gestational ages

PICO 5: Dilatation and evacuation (D&E) for surgical abortion at ≥ 14 weeks (see Recommendation 26)

PICO question: For a pregnant person having a surgical abortion (D&E), is provision by a traditional and complementary medicine professional, associate/advanced associate clinician, midwife a safe, effective or satisfactory/acceptable alternative to provision of care by a doctor?

P: Pregnant women seeking surgical abortion at ≥ 14 weeks of gestation

I: D&E provided by traditional and complementary medicine professionals, associate/advanced associate

clinicians, midwives

C: Surgical abortion provided by generalist and specialist medical practitioners

O:

- Effectiveness (success of abortion following the procedure)
- Safety (serious adverse events and complications)
- Satisfaction/acceptability.

Medical abortion for gestational ages < 12 weeks and its component tasks (see Recommendation 28)

PICO 6: Provision of medical abortion care at < 12 weeks

PICO question: For a pregnant person seeking medical abortion at < 12 weeks, is provision of medical abortion (i.e. assessment of eligibility, administering quality assured medications, assessment of outcome/success) by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker, a safe, effective and satisfactory/acceptable alternative to provision of medical abortion by a physician?

P: Pregnant persons seeking medical abortion

I: Medical abortion provided by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Medical abortion provided by generalist or specialist medical practitioners (obstetrician/gynaecologists)

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the treatment)
- Satisfaction/acceptability.

PICO 6a: Assessment of eligibility for MA

PICO question: For a pregnant person seeking medical abortion, is assessment of eligibility for medical abortion by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to – and as accurate as – assessment by a physician?

P: Pregnant persons seeking medical abortion

I: Eligibility assessment by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Eligibility assessment by generalist or specialist medical practitioners (obstetrician/gynaecologists)

O:

- Effectiveness (proportion of pregnant persons deemed eligible for medical abortion by provider type and accuracy of these assessments when measured against an independent verifier and/or diagnostic standard)
- Safety (serious adverse events, excluding treatment for incomplete abortion or ongoing pregnancy)
- Effectiveness (success of abortion following the procedure)
- Satisfaction.

PICO 6b: Administration of medications for MA

PICO question: For a pregnant person seeking medical abortion, is administration of medications for medical abortion (i.e. information provision, dispensing of quality assured medications, referral to a reputable source for medications) with instructions for their use by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to administration by a physician?

P: Pregnant persons seeking medical abortion

I: Administration of medications (i.e. information provision, dispensing of quality assured medications, referral to a reputable source for medications) with instructions for their use by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Administration of medications (i.e. information provision, dispensing of quality assured medications, referral to a reputable source for medications) by generalist or specialist medical practitioners

O:

- Participants understanding of the protocol, as shown by taking the correct regimen
- Safety (serious adverse events, excluding treatment for incomplete abortion or ongoing pregnancy)
- Effectiveness (success of abortion following the procedure)
- Satisfaction.

PICO 6C: Accurate assessment of success of the MA process

PICO question: For a pregnant person seeking medical abortion, is assessment of the success of the medical abortion process by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to – and as accurate as – assessment by a physician?

P: Pregnant persons seeking medical abortion

I: Assessment of success of abortion by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Assessment of success of abortion by generalist or specialist medical practitioners

O:

- Effectiveness of the assessment of the outcome (proportion of pregnant persons assessed for success of abortion by provider type and accuracy of these assessments when measured against an independent verifier and/or diagnostic standard)
- Effectiveness (success of abortion following the procedure)
- Safety (serious adverse events, excluding treatment for incomplete abortion or ongoing pregnancy, ectopic pregnancy)
- Satisfaction.

Management of induced abortion at gestational ages ≥ 12 weeks

PICO 7: Provision of abortion care at ≥ 12 weeks (see Recommendation 30)

PICO question: For a pregnant person seeking induced abortion, is medical or surgical abortion by a traditional and complementary medicine professional, associate clinician, midwife, nurse, auxiliary nurse, pharmacist, pharmacy worker or community health worker a safe, effective or satisfactory alternative to provision of abortion care by doctors?

P: Pregnant women seeking medical or surgical abortion after 12 weeks of gestation

I: Medical abortion or surgical abortion provided by traditional and complementary medicine professionals, associate clinicians, midwives, nurses, auxiliary nurses, pharmacists, pharmacy workers or community health workers

C: Medical abortion or surgical abortion provided by generalist and specialist medical practitioners

O:

- Effectiveness (success of abortion without need for further medical or surgical intervention)
- Safety (serious adverse events and complications)
- Satisfaction.

Intrauterine fetal demise (IUFD)

PICO 8: Medical management of intrauterine fetal demise (IUFD) (see Recommendation 33 [NEW])

PICO question: For a pregnant person diagnosed with intrauterine fetal demise (IUFD), is medical management of IUFD (with mifepristone and misoprostol, or misoprostol alone) provided by a traditional and complementary medicine professional, associate/advanced associate clinician, midwife, nurse, auxiliary nurse/auxiliary nurse midwife, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory alternative to medical management by a physician?

P: Pregnant persons diagnosed with IUFD

I: Medical management with mifepristone and misoprostol or misoprostol alone provided by traditional and complementary medicine professionals, associate/advanced associate clinicians, midwives, nurses, auxiliary nurses/auxiliary nurse midwives, pharmacists, pharmacy workers or community health workers

C: Medical management with mifepristone and misoprostol or misoprostol alone provided by generalist or specialist medical practitioners

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Satisfaction/acceptability.

Post-abortion

Incomplete abortion at gestational ages < 14 weeks

PICO 9: Management of incomplete abortion with misoprostol (see Recommendation 37)

PICO question: For a pregnant person with incomplete abortion, is management of incomplete abortion with misoprostol provided by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to management with misoprostol provided by a physician?

P: Pregnant persons with incomplete abortion

I: Medical management with misoprostol provided by traditional and complementary medicine professionals, pharmacists, pharmacy workers or community health workers

C: Medical management with misoprostol provided by generalist or specialist medical practitioners

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Satisfaction/acceptability.

PICO 10: Vacuum aspiration for management of uncomplicated incomplete abortion (see Recommendation 38)

PICO question: For a pregnant person seeking an induced abortion, is provision of vacuum aspiration for induced abortion/incomplete abortion/miscarriage (all indications) by traditional and complementary medicine professionals, auxiliary nurses or auxiliary nurse midwives a safe, effective or satisfactory option to provision of vacuum aspiration by physicians?

P: Pregnant persons seeking induced abortion

I: Vacuum aspiration provided by traditional and complementary medicine professionals, auxiliary nurses or auxiliary nurse midwives

C: Vacuum aspiration provided by generalist or specialist medical practitioners (obstetrician/gynaecologists)

O:

- Effectiveness (success of abortion following the procedure)
- Safety (serious adverse events and complications)
- Satisfaction/acceptability.

Recognizing and managing complications (see Recommendations 39 and 40)

PICO 11: Diagnosis and management of abortion-related complications

PICO question: For a person presenting with complication(s) of an induced abortion and in a stable condition, is diagnosis and management of abortion-related complications by a traditional and complementary medicine professional, pharmacist, pharmacy worker or community health worker a safe, effective and satisfactory/acceptable alternative to – and as accurate as – diagnosis and management by a physician?

P: Women presenting with complication(s) of an induced abortion and in a stable condition

I: Diagnosis and management of complications by traditional and complementary medicine professional, pharmacists, pharmacy workers or community health workers

i. Diagnosis and management of infection by traditional and complementary medicine professionals, pharmacists, pharmacy workers, community health workers

ii. Diagnosis and management of haemorrhage by traditional and complementary medicine professionals, pharmacists, pharmacy workers, community health workers

C: Diagnosis and management of infection and heavy bleeding by generalist and specialist medical practitioners

O:

- Effectiveness (accurate determination of a complication followed by an offer of correct treatment or referral depending on professional capacity and clinical setting)
- Safety (serious adverse events)
- Satisfaction/acceptability.

Post-abortion contraception

PICO 12: Post-abortion provision of injectable contraceptives (see Recommendation 46)

PICO question: For a person in the post-abortion period needing contraception, is provision of injectable contraceptives (initiation or continuation) by a traditional and complementary medicine professional, pharmacy worker or community health worker, a safe, effective and satisfactory/acceptable alternative to provision by a trained health worker?

P: Women in the post-abortion period needing contraception

I: Delivery of injectable contraceptives, by traditional and complementary medicine professionals, pharmacy workers or community health workers

C: Delivery of injectable contraceptives by trained health workers

O:

- Contraceptive uptake and continuation

- Safety (serious adverse events and complications related to provision of the method)
- Effectiveness (method failure)
- Satisfaction/acceptability.

Service delivery considerations

Non-facility-based/outpatient/home-based care

PICO 13: Telemedicine (see Recommendation 48)

PICO question: For a pregnant person seeking medical abortion, is medical abortion care provided through telemedicine (comprehensive care or individual components) a safe, effective and satisfactory/acceptable alternative to in-person medical abortion care?

P: Pregnant persons seeking medical abortion

I: Medical abortion care provided through telemedicine, including comprehensive medical abortion care, or any number of the following individual components:

- Eligibility assessment for medical abortion through telemedicine
- Counselling and/or instructions for medical abortion through telemedicine
- Instructions for and active facilitation of medical abortion through telemedicine
- Follow-up of medical abortion through telemedicine

C: In-person medical abortion care

O:

- Effectiveness (rates of ongoing pregnancy, success of abortion without need for surgical intervention following the procedure, and of surgical evacuation post abortion)
- Safety (serious adverse events and complications)
- Satisfaction/acceptability
- Rate of adherence to recommended dose regimen (self-reported)
- Reported cost of services.

PICO 14: Community-based outreach (see Best Practice Statement 49)

PICO question: For a pregnant person seeking induced abortion, are community-based outreach models for provision of abortion care safe, effective and satisfactory/acceptable alternatives to provision of abortion care in a health-care facility by a trained health worker?

P: Pregnant persons seeking induced abortion

I: Outreach involving health workers

C: Provision of care in a health-care facility by trained health workers

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Cost-effectiveness
- Increased health seeking behaviours
- Satisfaction/acceptability.

Setting:

- Weak infrastructure
- Legally restrictive.

PICO 15: Harm-reduction counselling (see Best Practice Statement 49)

PICO question: For a pregnant person seeking an induced abortion, is harm-reduction counselling on abortion care a safe, effective and satisfactory/acceptable alternative to routine in-clinic service delivery?

P: Pregnant persons seeking an induced abortion

I: Harm-reduction counselling

C: Routine in-clinic service delivery

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Satisfaction/acceptability.

Setting:

- Humanitarian settings
- Non-humanitarian settings.

PICO 16: Social marketing outreach/communicating safe abortion (see Best Practice Statement 49)

PICO question: For a pregnant person seeking an induced abortion, can social marketing outreach provide improved access to safe, effective and satisfactory/acceptable induced abortion services compared with provision of abortion care in a health-care facility by a trained health worker?

P: Pregnant persons seeking an induced abortion

I: Social marketing methods for induced abortion services

C: In-clinic abortion service provision

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)
- Access (affordability, utilization, client volume, attendance and coverage per population)
- Quality of care (abortion methods of choice, quality of information given to pregnant person, provider competence, pregnant person/provider relationship)
- Adverse effects (undesirable impacts on existing public or private services, inappropriate use of services)
- Equitable access or utilization (distribution of access across sociodemographic characteristics)
- Cost/service (from a societal perspective or perspective of marketer/franchiser, franchisee or pregnant person/client)
- Satisfaction/acceptability.

PICO 17: Self-sourcing medications for induced abortion (see Best Practice Statement 49)

PICO question: For a pregnant person seeking induced abortion, is self-sourcing of medications through online sources a safe, effective and satisfactory/acceptable alternative to obtaining a prescription and/or medications from a trained health worker?

P: Pregnant persons seeking induced abortion

I: Pregnant persons self-sourcing medications for an abortion through an online source without a prescription

C: Pregnant persons obtain a prescription and/or medications from a health worker (specialist or generalist medical practitioner, traditional and complementary medicine professional, midwife, nurse, auxiliary nurse, auxiliary nurse midwife, pharmacist, pharmacy workers, community health worker)

O:

- Safety (serious adverse events and complications)
- Effectiveness (success of abortion without need for surgical intervention following the procedure)

- Quality of medications
- Satisfaction/acceptability.

Self-management approaches

Self-management approaches for post-abortion contraception

PICO 18: Post-abortion self-administration of injectable contraceptives (see Recommendation 50)

PICO question: For a person in the post-abortion period needing contraception, is self-administration of injectable contraceptives (initiation or continuation) a safe, effective and satisfactory/acceptable alternative to provision by a trained health worker?

P: Women in the post-abortion period needing contraception

I: Self-administration of injectable contraceptives (initiation or continuation)

C: Delivery of injectable contraceptives by trained health workers

O:

- Contraceptive uptake and continuation
- Safety (serious adverse events and complications related to provision of the method)
- Effectiveness (method failure)
- Satisfaction/acceptability.

Annex 11. Details about guideline dissemination and updating

Dissemination

The full guideline will be published digitally (both an interactive web-based version and a PDF document available online for download) and in print. The recommendations from this guideline will also feature in the annually updated compendium of recommendations approved by the WHO Guidelines Review Committee (GRC), which will be produced by the WHO Department of Sexual and Reproductive Health and Research (SRH) across all thematic areas. The digital versions of the guideline will be available via the WHO website.[1] The links to the digital versions will be disseminated through nongovernmental organization (NGO) partners, the websites of professional associations, and social media platforms. Supplementary materials including the corresponding GRADE Evidence-to-Decision (EtD) frameworks for each of the recommendations are also available online.[2] Print versions of the guideline will be distributed to WHO regional and country offices, NGO partners and professional associations.

Translation of the guideline into Spanish (in collaboration with the Pan American Health Organization [PAHO]), French and Portuguese is planned. Translations into other United Nations languages will be developed as needed. Third-party translations into additional languages will be encouraged, provided they comply with WHO guidance on such translations.

The guideline will be launched through dissemination meetings in each WHO region, and specific knowledge transfer and adaptation activities and implementation research will take place in select countries based on need and expressed interest to move ahead with implementation of the recommendations. Additional products will support the launch of the guideline to allow for regional colleagues to disseminate the key information widely. Such products include:

- a PowerPoint presentation that summarizes the key messages and new elements to the guideline;
- a PowerPoint presentation on the evidence behind selected recommendations;
- social media tiles.

WHO regional offices and a number of interested agencies and NGO partners are expected to be active partners in the regional, national and local dissemination and adaptation of this guideline and in developing derivative informational materials.

Updating

This guideline will be presented online in an interactive web-based format soon after publication of the standard format version, which will be available for download. The web-based format will allow the guideline to be a "living guideline", facilitating review of new research evidence to ensure that it can be brought to the GDG for review and then updated as appropriate in the guideline on an ongoing basis. This consolidated guideline currently combines and updates recommendations from three former WHO guidelines on abortion care,[3] and future updates will also cover new related topics, as needed.

The rapidly evolving nature of the interventions and approaches for quality abortion care, especially those for self-management of abortion, calls for a continuous review of the literature. The WHO Guideline Steering Group (see Annex 1) is in the process of developing a database system that will allow for continuous search and review of the evidence. This in turn will help with future updates of the recommendations and will inform any areas that may potentially require a new recommendation. There are many areas for which no evidence was found or which are only supported by low-certainty evidence (see Chapter 4, section 4.3), and in these cases new recommendations or a change in the published recommendation, respectively, may be warranted. Any concern about the validity of an existing recommendation can be communicated promptly to the Prevention of Unsafe Abortion (PUA) Unit at WHO's Department of Sexual and Reproductive Health and Research (email: srhpua@who.int), after which the PUA

2 Available at: https://www.who.int/publications/i/item/9789240039483
3 Safe abortion: technical and policy guidance for health systems, second edition. Geneva: World Health Organization; 2012 (https://www.who.int/publications/i/item/9789241548434).
Health worker roles in providing safe abortion care and post-abortion contraception. Geneva: World Health Organization; 2015 (https://www.who.int/reproductivehealth/publications/unsafe_abortion/abortion-task-shifting/en/).
Medical management of abortion. Geneva: World Health Organization; 2018 (https://www.who.int/reproductivehealth/publications/medical-management-abortion/en/).

Unit will seek approval from the WHO GRC to undergo the process for a "rapid guidance", and plans will be made to update the recommendation as needed.

All technical products developed during the process of developing this guideline – including full reports of systematic reviews, corresponding search strategies and dates of searches – will be archived for future reference and use. Where there are concerns about the validity of a recommendation based on new evidence, the systematic review addressing the primary question will be updated. To update the review, the search strategy used for the initial review will be re-applied. Any new questions identified following the original scoping exercise for the guideline will undergo a similar process of evidence retrieval, synthesis and application of the GRADE approach in accordance with the standards in the *WHO handbook for guideline development*.[4] For further information on the "living guidelines" process, refer to recent publications by Vergara-Merino et al. (2020)[5] and Vogel et al. (2019).[6]

Re: Docket No. FDA-2025-P-3288

Dear Drs. Francis, Artigues, Chupp, and Stanford:

This letter responds to the citizen petition received by the Food and Drug Administration (FDA or Agency) on August 20, 2025 (Petition). The Petition requests that FDA: (1) deny approval of an application for mifepristone[1] for miscarriage management "due to lack of sufficiently rigorous safety studies under conditions of real-world use"; [2] (2) "deny approval for any use of mifepristone for miscarriage management or for other new drug indications"; (3) quantify "the risk of hemorrhage, sepsis, retained tissue and need for surgical completion" before approving any new indication; (4) require "that additional safety studies be conducted, under conditions of anticipated use, prior to consideration of approval of mifepristone for use in miscarriage management," (5) prohibit dispensing of mifepristone for any use via "telehealth visit" or by "interactive computer service, mail, or common carrier," and (6) "acknowledge the political

[1] Korlym and a generic version of Korlym (Mifepristone Tablets, 300 mg) contain the active ingredient mifepristone and are approved for the control of hyperglycemia (high blood sugar levels) due to hypercortisolism in adult patients with endogenous Cushing's syndrome who have type 2 diabetes or glucose intolerance and have failed surgery or are not candidates for surgery. We interpret your Petition as not making any requests related to those products and, accordingly, references in this response to "mifepristone" do not apply to them.

[2] Your August 2025 Petition states that you are resubmitting your January 7, 2025, citizen petition in which you "request[ed] that [FDA] deny the currently supplemental application for . . . use of mifepristone in miscarriage management due to lack of sufficiently rigorous safety studies under conditions of real-world use." We therefore interpret your August 2025 Petition to make the same request (Petition at 1).

pretext that has steered [FDA's] mifepristone regulations."[3]

The Petition also requests that: "[f]or any use of mifepristone, FDA should (a) at a minimum retain the current REMS [(risk evaluation and mitigation strategy)], (b) better yet strengthen the REMS, as described below or by "restoring the REMS in place before 2016, and (c) ideally revoke FDA's approval of mifepristone for abortion."[4]

With respect to the REMS, the Petition states that such "strengthened REMS" would require, at minimum, the following:

1. Ultrasound confirmation of fetal or embryonic demise (if being used for treatment of miscarriage) according to the criteria published by the Society of Radiologists in Ultrasound Multispecialty Panel on Early First Trimester Miscarriage and Exclusion of a Viable Intrauterine Pregnancy, which includes:

    - Crown-rump length of 7 mm (millimeters) or greater and no heartbeat;
    - Mean sac diameter of 25 mm or greater and no embryo;
    - Absence of embryo with heartbeat 2 weeks or more after a scan that showed a gestational sac without a yolk sac; or
    - Absence of an embryo with a heartbeat 11 days or more after a scan that showed a gestational sac with a yolk sac.

2. That all patients have an in-person follow-up to confirm that no tissue remains after the use of mifepristone.

3. That all adverse events which occur after the use of mifepristone are reported to FDA by any prescriber or health care professional treating any subsequent adverse event via a user- friendly FDA-maintained online adverse event reporting portal.

4. That all [licensed] health care professionals receive information from FDA about the need for a high index of suspicion for *Clostridium sordellii (aka Paraclostridium sordellii)* sepsis when a woman presents after mifepristone use with malaise and/or nausea and vomiting, along with a high white blood count. This information, which is currently contained in the black box warning, must be distributed by letter to all licensed health care professionals.

5. That all women who are given mifepristone must receive a copy of the currently existing black box warnings. Further, prescribing information must include at least the boxed warning that is currently included in the prescribing information for mifepristone for pregnancy termination.

6. That all women who are given mifepristone be made aware that it is critically important for the treating healthcare professional to be aware of her use of mifepristone in order to appropriately treat any adverse event she experiences after mifepristone use.[5]

[3] Petition at 1-5.
[4] Petition at 5.
[5] Petition at 2–4.

The Petition also requests that dispensing of mifepristone via telehealth visit, "let alone by interactive computer service, mail, or common carrier," be prohibited.[6]

We have carefully considered the information submitted in the Petition. For the reasons set forth below, we deny without comment your specific requests in the Petition regarding the approvability of any potential pending application for a drug product containing mifepristone that would fall within the scope of your Petition. In addition, we deny your Petition insofar as the Agency continues to consider the complex scientific and legal issues you raise and is unable to resolve them within the 150-day time frame set forth in section 505(q) of the Federal Food, Drug, and Cosmetic Act (FD&C Act) (21 U.S.C. 355(q)).

I. BACKGROUND

A. Summary of Drug Product History

On September 28, 2000, FDA approved Mifeprex (mifepristone) Tablets, 200 milligrams (mg) for the "medical termination of intrauterine pregnancy through 49 days' pregnancy" (new drug application (NDA) 020687).[7] The application was approved under title 21, part 314, subpart H of the Code of Federal Regulations (CFR); specifically, 21 CFR 314.520 of subpart H provides for approval with restrictions that are needed to assure the safe use of the drug product. In accordance with 21 CFR 314.520, FDA restricted the distribution of Mifeprex as specified in the September 2000 approval letter.[8] Those restrictions included, among other things, a requirement that mifepristone be dispensed to patients only in certain healthcare settings, specifically clinics, medical offices, and hospitals (commonly referred to as the in-person dispensing requirement).

Subsequently, Mifeprex was identified as one of the products that was deemed to have in effect an approved REMS under the Food and Drug Administration Amendments Act of 2007 (FDAAA) because on the effective date of Title IX, subtitle A of FDAAA (March 28, 2008), Mifeprex had in effect elements to assure safe use.[9] On June 8, 2011, FDA approved a REMS for Mifeprex, consisting of a Medication Guide, elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS.

On March 29, 2016, FDA approved an efficacy supplement (S-020) to NDA 020687 for Mifeprex. The supplement included, among other things, expanding the gestational age up to which Mifeprex has been shown to be safe and effective (through 70 days gestation).[10]

---

[6] Petition at 4.
[7] Mifeprex labeling (NDA 020687) approved Sep. 28, 2000, "Indication and Usage," available at https://www.accessdata.fda.gov/drugsatfda_docs/label/2000/20687lbl.pdf.
[8] See FDA approval letter for Mifeprex (NDA 020687), dated Sep. 28, 2000, available at https://www.accessdata.fda.gov/drugsatfda_docs/appletter/2000/20687appltr.pdf.
[9] 73 FR 16313 (Mar. 27, 2008).
[10] Mifeprex labeling (NDA 020687) approved Mar. 29, 2016, section 1, available at https://www.accessdata.fda.gov/drugsatfda_docs/label/2016/020687s020lbl.pdf.

On April 11, 2019, FDA approved a generic version of Mifeprex, Mifepristone Tablets, 200 mg (abbreviated new drug application (ANDA) 091178). At the same time that FDA approved the generic version of Mifeprex in 2019, FDA approved a modification to the REMS for Mifeprex to establish a single, shared system REMS for mifepristone products for the medical termination of intrauterine pregnancy through 70 days gestation (referred to as the Mifepristone REMS Program). On January 3, 2023, FDA approved a modification to the Mifepristone REMS Program to remove the in-person dispensing requirement and to add a pharmacy certification requirement. On September 30, 2025, FDA approved a second generic version of Mifeprex, Mifepristone Tablets, 200 mg (ANDA 216616).

B. Section 505(q) of the FD&C Act

Section 505(q) of the FD&C Act (21 U.S.C. 355(q)) was added by section 914 of FDAAA (Public Law 110-85, 121 Stat. 823) and was amended by the Food and Drug Administration Safety and Innovation Act (Public Law 112-144, 126 Stat. 993). Section 505(q), as originally added by FDAAA, applies to certain citizen petitions and petitions for stay of agency action that request that FDA take any form of action relating to a pending application submitted under section 505(b)(2) or (j) of the FD&C Act and governs the manner in which these petitions are treated. Among other things, section 505(q)(1)(F) of the FD&C Act governs the time frame for final agency action on a petition subject to section 505(q). Under this provision, FDA must take final agency action on such a petition no later than 150 days after the date on which the petition is submitted.

II. DISCUSSION

The contentions in your Petition, described below, focus on three areas: (1) safety studies of mifepristone for termination of pregnancy or miscarriage management,[11] (2) "proper safeguards"[12] for the use of drug products containing mifepristone, and (3) "evidence-based medical standards"[13] for FDA's regulation of drug products containing mifepristone. Your Petition makes requests regarding the approvability of any potential pending application for a drug product containing mifepristone. We do not interpret section 505(q) of the FD&C Act to require that the Agency render a final Agency decision within the 150-day statutory deadline on the approvability of a potential pending application when a final decision on the approvability of any such application has not yet been made. Your Petition also requests FDA change the approved conditions of use, including by "strengthen[ing] the REMS," for the currently approved applications for drug products containing mifepristone. Accordingly, as explained below, we deny your Petition without comment on whether we would take the specific actions you request.

A. Petition's Contentions

1. *Safety Data Associated with the Use of Mifepristone for Termination of Pregnancy, Miscarriage Management, or Any Other New Indication*

[11] Petition at 1-2.
[12] Petition at 2.
[13] Petition at 5.

In your Petition, you refer to "new information about increasing risks of real-world mifepristone use" that, you assert, "call[s] into question the safety data which FDA previously reported for mifepristone use for termination of pregnancy."[14] You contend that post marketing surveillance is needed "because the clinical trials which supported the initial approval of mifepristone were neither blinded, controlled nor randomized."[15] You assert that "Danco [the application holder for Mifeprex (NDA 020687)] did not fulfill the requirements for post marketing surveillance required by FDA at approval."[16] You contend that changes to adverse event reporting requirements under the Mifepristone REMS Program have rendered this requirement "inadequate for tracking mifepristone related complications and deaths," and accordingly, "[FDA's Adverse Event Reporting System (FAERS)] data cannot be relied upon."[17] You also assert that "current real-world data indicates that mifepristone use in induced abortion is associated with significantly more adverse events than FDA was aware of." [18]

Regarding clinical trials, you assert that "the clinical trials which supported the initial approval of mifepristone were neither blinded, controlled nor randomized."[19] You contend that "during clinical trials it is impossible for sponsors to ascertain every possible adverse event that patients may experience when taking a new drug or an existing drug for a new indication."[20] You assert that "[g]iven the paucity of information gathered in studies to date on the safety of mifepristone for miscarriage management, " before any approval for this indication, "it is necessary that further robust studies of the safety of mifepristone for miscarriage management be conducted focusing on the rates of hemorrhage, serious and fatal infections and deaths which are known to occur during the use of mifepristone for termination of pregnancies."[21] You assert that it is "critically important that the conditions under which the drug is administered during these safety studies mirror the conditions of use expected in the real world."[22]

Regarding adverse event reporting, you contend that the "current REMS for mifepristone when prescribed for induced abortion is completely inadequate to track or prevent serious complications."[23] You state that "FAERS data cannot be relied upon to demonstrate that [mifepristone] is safe for miscarriage management" because FDA does not obtain "comprehensive information about adverse events following mifepristone use for induced abortion."[24] You assert that the absence of a "requirement or mechanism for abortion provider tracking of complications and deaths, or any requirement that the treating physician report those deaths and complications to FDA, guarantees that these deaths and complications will be vastly underreported" in FAERS.[25] You state that the "system" for reporting adverse events for mifepristone "need[s] to be overhaul[ed]" because of the "reliance solely on interested parties to

[25] Petition at 9–10.

report, the large percentage of uncodable events, the redaction of critical clinical information unrelated to personally identifiable information, and the inadequacy of the reports."[26]

You contend that the 2016 REMS modification that removed the REMS requirement for "mandatory reporting of serious adverse events by certified prescribers of mifepristone for induced abortion, except for death," which occurred at the same time as "removal of other patient protections from the mifepristone REMS," "decreased the already limited effectiveness of FAERS."[27] You assert that the Prescriber Agreement Form "only requires that a prescriber 'provide [or refer] for surgical intervention' if necessary, and…report any deaths following mifepristone use," and that this requirement is "currently grossly inadequate for tracking mifepristone-related complications and deaths."[28] You assert that because FAERS reports reveal that in over half of the cases, someone other than the abortion provider managed the patient's complications," this "means that complications and deaths will often be missed by the abortion provider."[29] You assert that States cannot "fill in missing information on adverse events following the use of mifepristone" because although "some states collect adverse event data following abortion and share that information with the Centers for Disease Control and Prevention (CDC)," there is "extremely limited" value in the CDC's Abortion Surveillance Findings and Reports. You further note that there are "four nonreporting states . . . that account for a quarter of all abortions."[30]

You assert that "[w]ithout knowing the actual number of deaths and complications resulting from the real-world use of mifepristone for induced abortion, it is impossible for FDA to assess the current safety of mifepristone for use to induce abortion."[31] You contend that any "new indication for mifepristone will rely heavily on the perception of safety of mifepristone in induced abortion" and that such a "perception . . . lacks scientific support in real world use."[32] You state that there are "[n]o high-quality studies [that] clearly delineate the risks of mifepristone use under current real-world conditions," and that therefore no new indication "for extending the use of mifepristone should be considered, nor should mifepristone be approved for a new indication for use in miscarriage management."[33] To support your contention, you assert that "no meaningful safety information can be gleaned" from a 2021 meta-analysis by Jay Ghosh, et al, (2021 meta-analysis) of "all randomized controlled trials assessing the effectiveness or safety of methods for miscarriage management" that "would sufficiently support" the "current" new indication for miscarriage management.[34] You state that 2021 meta-analysis calls into question the utility of the available data due to limitations in that data, including "low" or

[34] Petition at 13–17 (quoting Ghosh J, Papadopoulou A, Devall AJ, Jeffery HC, Beeson LE, Do V, Price MJ, Tobias A, Tunçalp Ö, Lavelanet A, Gülmezoglu AM, Coomarasamy A, Gallos ID. Methods for managing miscarriage: a network meta-analysis. Cochrane Database Syst Rev. 2021 Jun 1;6(6):CD012602. doi: 10.1002/14651858.CD012602.pub2..

"very low" certainty in the findings.[35]

You also assert that the "efficacy numbers . . . may be inaccurate." You refer to Chu et al., Schreiber et al, and Trinder et al to support your position that there "may be little to no benefit to adding mifepristone in cases of incomplete miscarriage," which you state can be "effectively managed using misoprostol alone."[36] You characterize the 2021 meta-analysis as finding that medical management of miscarriage, including with mifepristone, was more effective than expectant management or placebo, but less effective than surgical methods, and that expectant management or placebo had higher chance of serious complications. However, you refer to limitations in the data, including "inconsistency and heterogeneity" with respect to "type of miscarriage (missed and incomplete)."[37]

2. "Proper Safeguards" for Drug Products Containing Mifepristone

In your Petition, you contend that FDA should deny approval of drug products containing mifepristone for any new indication because of "the need to ensure that proper safeguards are on these drugs."[38] Specifically, you state that "[p]rior to even considering any [new indication] for additional uses of mifepristone, FDA must significantly strengthen the [REMS] with [ETASU] for the current uses of mifepristone and demonstrate that the proposed strengthened REMS is able to account for and mitigate the known safety risks of hemorrhage, sepsis, retained tissue and need for surgical completion which exist for the current use of mifepristone for pregnancy termination."[39]

You contend that "[f]or any use of mifepristone, FDA should (a) at a minimum retain the current REMS, (b) better yet strengthen the REMS, as described [in the Petition] or by restoring the REMS in place before 2016, and (c) ideally revoke FDA's approval of mifepristone for abortion."[40]

As noted above, you assert that "the current REMS for mifepristone when prescribed for induced abortion is completely inadequate to track or prevent serious complications."[41] You also assert that without your requested "safeguards in place for all uses of mifepristone for abortion and for miscarriage management, no use of mifepristone can possibly be safe and no true informed consent for the use of mifepristone can be possible."[42] In support of these assertions, you state that there are serious and potentially fatal complications associated with medical abortion, including missed ectopic pregnancy and heavy bleeding from incomplete abortion, which necessitate a REMS.[43] You state that "the risks of hemorrhage, retained tissue, and ongoing

[35] Petition at 17.
[36] Petition at 14–15.
[37] *See id*. You quote the authors as suggesting that this inconsistency and heterogeneity is important because, according to a subgroup analysis, "surgical and medical methods may be more beneficial in women with missed miscarriage compared to women with incomplete miscarriage." *Id*.

pregnancy increase with increasing gestational age" when mifepristone is used for medical abortion and "appears to be true for mifepristone use in missed miscarriage as well."[44] You also state that the "alternative [to medical abortion], surgical evacuation, is associated with less complications."[45]

You raise concerns with the Prescriber Agreement Form required by the approved REMS. You assert that the Prescriber Agreement Form requires that prescribers can accurately assess duration of pregnancy and diagnose ectopic pregnancies, but that there is no requirement for the prescriber to actually do either.[46] You also assert that the requirement in the Prescriber Agreement Form for the prescriber to agree to provide or refer a patient for surgical intervention if needed and report any deaths following use of mifepristone "is currently grossly inadequate" due to the limitations in FAERS discussed above.[47]

In addition, you assert that FDA should not approve any drug product containing mifepristone for any indication without a "significantly strengthen[ed] REMS," with at least seven elements.[48] In support of this assertion, you say that "[w]ithout these safeguards in place for all uses of mifepristone for abortion and for miscarriage management, no use of mifepristone can possibly be safe and no "true informed consent for the use of mifepristone can be possible."[49]

First, you contend that a REMS for mifepristone use for any indication should require "[u]ltrasound confirmation of fetal or embryonic demise (if being used for the treatment of miscarriage) according to the criteria published by the Society of Radiologists in Ultrasound Multispecialty Panel on Early First Trimester Miscarriage and Exclusion of a Viable Intrauterine Pregnancy."[50] In support of this assertion, you assert that an ultrasound "is the standard of care for dating first trimester pregnancies" and the American College of Obstetricians and Gynecologists (ACOG) "recognizes that a pregnancy which does not have an early ultrasound is inadequately dated."[51] You also assert that the "standard of care for diagnosis of ectopic pregnancy is . . . an ultrasound" and, "[w]ithout an ultrasound, it is not possible to ensure than an early pregnancy is located within the uterine cavity."[52] You state that the "risks for mifepristone use in abortion are gestational age dependent and require an ultrasound for accurate gestational age determination and determination if a pregnancy is ectopic."[53] You also state that "[w]ithout [a] precise diagnosis of gestational age, it is not possible to give an accurate picture of the risks of the [abortion] procedure, since the risks of hemorrhage, retained tissue, and ongoing pregnancy increase with increasing gestational age."[54] You state that this "appears to be true for mifepristone use in missed miscarriage as well."[55]

[55] Petition at 8.

Second, you contend that a REMS for mifepristone use for any indication should require that "all patients have an in-person follow-up to confirm that no tissue remains after the use of mifepristone."[56] In support of this assertion, you state that the studies included in the 2021 meta-analysis "scheduled follow-up appointments for participants that usually included ultrasonography."[57,58] Citing Chu et al, you state that "[w]omen who have not completed their miscarriages may need further medical or surgical treatment," and you cite ACOG to support your contention that patients should have an in-person follow-up appointment, to include an ultrasound, within one to two weeks after the procedure.[59]

Third, you contend that a REMS for mifepristone use for any indication should require "all adverse events which occur after the use of mifepristone [to be] reported to FDA by any prescriber or health care professional treating any subsequent adverse event via a user-friendly FDA-maintained online adverse event reporting portal.[60] In support of this assertion, you state that the reports from the current sponsors of mifepristone for medical abortion "provide a very limited picture of the dangers posed by mifepristone."[61] You state that the "already limited effectiveness of FAERS" decreased in 2016 when the REMS requirement for certified prescribers to report serious adverse events to the sponsors was narrowed to only require reporting deaths to the sponsors.[62] You also state that the REMS requirement for certified prescribers to report certain adverse events to the drug sponsor and the drug sponsor to report to FDA leaves the drug sponsors to act as "the screening agents as to which complications are reported to FDA."[63] You state that the adverse event reporting requirement for certified prescribers under the REMS is insufficient because emergency care providers, who "are more likely than prescribers to treat the adverse events," are not required to report adverse events.[64] You state that there have been discrepancies in the number of adverse events, referencing a paper by Cirucci et al "comparing adverse events claimed to have been reported by Planned Parenthood, but never appearing in the FAER[S] database."[65]

Fourth, you assert that a REMS for mifepristone use for any indication must require that all licensed health care professionals receive information from FDA, in the form of a letter, containing information from the boxed warning about the need for a high index of suspicion for *Clostridium sordellii* (aka *Paraclostridium sordellii*) sepsis when a woman presents after mifepristone use with malaise and/or nausea and vomiting, along with a high white blood count."[66] In support of this assertion, you state that there have been deaths associated with

[65] Petition at 23.
[66] Petition at 3.

Clostridium sordelli sepsis following use of mifepristone for the medical termination of intrauterine pregnancy.[67] You also state that the Centers for Disease Control and Prevention and FDA convened "an emergency meeting in Atlanta in 2006 during which mifepristone was clearly demonstrated to affect innate immunity."[68] You state that one presenter recommended "that the use of mifepristone be reduced or eliminated."[69]

Fifth, you assert that a REMS for mifepristone use for any indication should require "that all women who are given mifepristone . . . receive a copy of the currently existing black box warnings" and that prescribing information for any newly approved mifepristone product "must include at least the boxed warning that is currently included in the prescribing information for mifepristone for pregnancy termination."[70]

Sixth, you assert that a REMS for mifepristone use for any indication should require that "all women who are given mifepristone be made aware that it is critically important for the treating healthcare professional to be aware of her use of mifepristone in order to appropriately treat any adverse event she experiences after mifepristone use."[71] In support of this assertion, you state that if patients do not make treating healthcare professionals aware of mifepristone use, healthcare professionals are less likely to recognize adverse events following mifepristone use and this would "hinder[ ] patient care and FDA's post marketing surveillance of the drug."[72]

Seventh, you assert that mifepristone for any indication should "never be provided in a [telehealth] visit" or "dispensed via interactive computer service, mail, or common carrier."[73] In support of this assertion, you state that it is "not possible to provide the necessary safety screening nor to make a definitive diagnosis of miscarriage or the viability or duration of the pregnancy via telehealth visit."[74] You state that "Federal law prohibits dispensing abortion drugs by interactive computer service, mail, or common carrier."[75] You state that "[a]nytime an abortion drug is approved for any indication, a strong likelihood exists that, whether on-label or off-label, the drug will be used in practice for abortion," and thus, FDA should "ensure that any approval of mifepristone comes with a REMS that ensures that it not be dispensed by interactive computer service, mail, or common carrier."[76]

3. Evidence-Based Medical Standards for FDA's Regulation of Drug Products Containing Mifepristone

In your Petition, you contend that FDA should "acknowledge the political pretext that has steered [FDA's] mifepristone regulations since the beginning" and FDA should "commit to

[67] Petition at 10–12.
[68] Petition at 10.
[69] Petition at 10.

[72] Petition at 26.
[73] Petition at 4 (emphasis omitted). Your Petition states that mifepristone "should never be provided via health visit." We understand "health" in this statement to refer to "telehealth."
[74] Petition at 4 and 30.
[75] Petition at 31.
[76] Petition at 31.

evidence-based medical standards in the future."[77] You contend that "FDA never had evidence that mifepristone was safe and effective" because "FDA's action rested on pretext from the start."[78] You state that "FDA's actions approving and deregulating mifepristone have always been an unlawful pretext for expanding abortion access and undermining state pro-life laws."[79]

In support of these assertions, you provide quoted language from 2021 through 2024 from a variety of Federal government sources including the White House, U.S. Department of Health and Human Services, and U.S. Department of Justice, which include statements by the then-President and then-Vice President, press briefings, press releases, and fact sheets.[80] You also provide quoted language from a vacated court opinion and an FDA oral history interview from 2019.[81,82] You contend that "[e]ven FDA's label admits that these drugs are not safe."[83] You point to the approved drug product's labeling that contains a warning that serious and sometimes fatal infections and bleeding can occur, direction to exclude ectopic pregnancies, and notation of possible need for treatment at an emergency room or surgical intervention.[84]

You further assert that "FDA's removal of safeguards on mifepristone in 2016 lacked sufficient evidence to support the changes."[85] In support of this assertion, you state that "FDA did not rely on any study that evaluated the changes as a whole" and that FDA "relied on studies that included safety measures omitted under the labeled conditions of use."[86] You also assert that "FDA lacked appropriate evidence" for the removal of the in-person dispensing requirement from the REMS.[87] In support of this assertion, you state that "FDA based its decision . . . on (1) adverse event reports and (2) published literature that the agency conceded was not adequate."[88]

B. FDA's Response

As described above, section 505(q)(1)(F) of the FD&C Act requires FDA to take final agency action on the Petition within 150 days of submission. Therefore, we must take action on the Petition at this time. For the reasons explained below, we deny without comment the specific requests in the Petition regarding the approvability of any potential pending application for a drug product containing mifepristone or change to the approved conditions of use for any currently approved application for a drug product containing mifepristone that would fall within the scope of your Petition.

Any FDA decision to approve or not approve a specific application is based on the particular

[87] Petition at 40.
[88] Petition at 40.

facts that are applicable to that application at the time of the decision, including whether the data and information submitted in the application are sufficient to support approval. To the extent that there is any pending application for a drug product containing mifepristone that would fall within the scope of your Petition, FDA has not made a final determination to approve it.[89] Further, if there were such a pending application, addressing the issues raised in the Petition could necessitate taking final agency action regarding the approvability of certain aspects of that pending application before taking final agency action on the approvability of the application as a whole. In light of this, we believe it is appropriate to evaluate the statutory and regulatory provisions governing the content and review of NDAs and ANDAs in connection with the statutory provision of section 505(q) of the FD&C Act governing the time frame for action on the Petition.

The FD&C Act and FDA regulations establish procedural protections for applicants in the context of application review. Section 505 of the FD&C Act and FDA regulations 21 CFR part 314 describe certain procedures by which the Agency reviews an NDA or ANDA and notifies an applicant if it determines that an application is approved or may not be approved, or identifies the deficiencies in the application and the steps an applicant may take to respond to the deficiencies.[90] In addition, the statute and regulations describe a specific process through which an applicant whose application the Agency has found does not meet the requirements for approval may challenge the Agency's determination.[91] Under this process, the Agency will give the applicant notice of an opportunity for a hearing on whether the application is approvable in its present form, with a specific time frame and process should the applicant request such a hearing.[92] These procedures ensure that applicants have an adequate opportunity to challenge a finding by the Agency that a product does not meet the requirements for approval.

There is no evidence that in enacting section 505(q) of the FD&C Act, Congress intended to bypass the application review process or to lessen an applicant's procedural rights by requiring that the Agency make decisions that constitute final agency action regarding the approvability of certain aspects of pending applications on a piecemeal basis outside of the process established under the FD&C Act and FDA regulations.[93] Therefore, we do not interpret section 505(q) of

[89] Under 21 CFR 314.430, we are generally prohibited from disclosing the existence of an application unless the applicant has publicly disclosed or acknowledged the existence; further, even if an applicant has publicly disclosed or acknowledged the existence of an application, no information regarding that application is generally publicly available prior to its approval.

[90] See section 505(c) and (j) of the FD&C Act; and 21 CFR 314.105(a) and (d) (FDA will approve an NDA or ANDA and send the applicant an approval letter if none of the reasons in 21 CFR 314.125 or 314.127 for refusing to approve the NDA or ANDA applies). See also section 505(c), (d), and (j) of the FD&C Act; 21 CFR 314.125 and 314.127 (listing reasons that FDA may refuse to approve an NDA or ANDA); and 21 CFR 314.110 (setting forth the requirements for a complete response letter).

[91] See section 505(c)(1)(B) and (d) of the FD&C Act; and 21 CFR 314.200.

[92] Id.

[93] In other citizen petition responses, we have responded to requests related to general standards for approval (e.g., bioequivalence criteria for generic drug products) that may pertain to one or more pending drug product applications without commenting on the approvability of any particular aspect of a specific pending application. We believe that this approach of describing our general policies or standards for approval of a drug application (beyond that described in this response) would not be appropriate in this case because, as stated, FDA's review of a given application would inform our decisions regarding the sufficiency of the specific data and information needed for

the FD&C Act to require that the Agency render a final Agency decision within the 150-day statutory deadline on the approvability of a specific aspect of an application when a final decision on the approvability of any such application has not yet been made.

Accordingly, we deny without comment the specific requests in the Petition regarding the approvability of any potential pending application for a drug product containing mifepristone that would fall within the scope of your Petition. Your Petition also requests FDA modify currently approved applications for drug products containing mifepristone to ensure (1) "proper safeguards"[94] for these products and (2) "evidence-based medical standards"[95] underpin FDA's regulations of these products as with any other drug product regulated by FDA. Your requests raise complex scientific and policy issues that FDA cannot resolve within the 150-day time frame set forth in section 505(q) of the FD&C Act, and we deny your Petition without comment on whether we would take the specific actions you request. FDA will consider the issues raised by your Petition, as appropriate, when making determinations regarding currently marketed drug products containing mifepristone as part of FDA's ongoing regulation of these products. We will continue to evaluate data and information to ensure appropriate regulatory decisions are made using the same standards that are applied to all drug product applications under section 505 of the FD&C Act.

III. CONCLUSION

For the reasons discussed in this response, your Petition is denied.

Sincerely,

TRACY B. HOEG -S

December 17, 2025

Re: Docket No. FDA-2025-P-2162

Dear Mr. Masingill:

I am writing to inform you that the Food and Drug Administration (FDA or Agency) has not yet resolved the issues raised in the citizen petition submitted by GenBioPro, Inc. on July 3, 2025. The petition requests that the Agency: "(1) refrain from taking any action that would reduce patient access to the drug mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone, absent new robust scientific or clinical evidence that meets applicable statutory standards warranting such a change; and (2) confirm that any steps that may be taken to modify, suspend, or withdraw FDA approval for mifepristone, including in response to any court order, will follow all applicable rules and procedures for any withdrawal or suspension required under the Administrative Procedure Act ("APA"), the FDCA, and implementing regulations, and that Petitioner will be permitted to continue to market and sell mifepristone in the United States until all such procedures have been completed."

FDA has been unable to reach a decision on your petition because it raises complex issues requiring extensive review and analysis by Agency officials. This interim response is provided in accordance with FDA regulations on citizen petitions (21 CFR 10.30(e)(2)). We will respond to your petition as soon as we have reached a decision on your requests.

Sincerely,

Carol Bennett -S

The US Food and Drug Administration's Regulation of Mifepristone

Sophie Dilek, MPH; Joanne Rosen, JD, MA; Anna Levashkevich, MSPH; Joshua M. Sharfstein, MD; G. Caleb Alexander, MD, MS

IMPORTANCE Mifepristone, used with misoprostol, is the most common abortion regimen in the US. It is also a focal point of reproductive health policy and politics, with controversy over its legal status and regulation by the US Food and Drug Administration (FDA).

OBJECTIVE To characterize the FDA's decision-making with respect to the regulation of mifepristone, with a particular interest in the agency's rationale for establishing, maintaining, or modifying key components of its regulatory approach over time.

EVIDENCE REVIEW Qualitative analysis of 5239 pages of FDA documents obtained through a Freedom of Information Act request, including sponsors' Risk Evaluation and Mitigation Strategy (REMS) assessment reports, FDA review of these reports, internal memos, and regulatory correspondence (2011-2023), supplemented by a review of publicly available information. Review focused on FDA justifications for implementing, maintaining, or modifying postapproval safety measures and the supporting evidence cited.

FINDINGS Five key moments in the FDA's regulation of mifepristone that have led to the current state of oversight were identified: (1) conversion to the REMS framework in June 2011; (2) reevaluation of REMS necessity in October 2013; (3) a sponsor-requested label change in May 2015; (4) the response to the COVID-19 pandemic in 2020 and 2021; and (5) a comprehensive reassessment of the REMS in November 2021. Key themes across this period were consistent findings on safety, lack of ideological bias in staff scientists' recommendations, and the limited impact of political interference—to date—on the agency's oversight. Even as litigation, the COVID-19 public health emergency, and evolving practice standards changed the context of mifepristone regulation, the agency generally followed the policy approach favored by scientists at the agency.

CONCLUSIONS AND RELEVANCE FDA oversight of mifepristone, developed during key moments from 2011 to 2023, has been shaped by scientific evidence and a cautious regulatory approach led by scientists at the agency.

Mifepristone is a progesterone receptor antagonist with antiglucocorticoid activity. In combination with misoprostol, it is the most widely used abortion regimen in the US.[1] Mifepristone is also approved by the US Food and Drug Administration (FDA) for the control of hyperglycemia in adults with endogenous Cushing syndrome who are not candidates for curative surgery. First approved by the FDA in 2000 for pregnancy termination through 49 days' gestation, mifepristone had already been subject to controversy for more than a decade and has remained under intense scrutiny by parties across the spectrum of the abortion debate. There is consensus among leading US and international professional associations and regulatory authorities that mifepristone is effective for pregnancy termination and that serious complications, such as heavy bleeding or sepsis, are very rare.[2,3]

The FDA has imposed special restrictions on mifepristone to support its safe use. Initially, these conditions were part of 21 CFR Part 314 Subpart H, a regulatory pathway that permitted the FDA to require specific safety-related measures for drugs with serious safety concerns or potential for significant risk.[4] The final plan accompanying the 2000 FDA approval of mifepristone included prescriber qualifications, dispensation limited to certain settings, signed patient agreement forms, provision of a patient medication guide, and mandatory reporting of adverse events.[5]

With the passage of the Food and Drug Administration Amendments Act (FDAAA) in 2007, oversight transitioned to a new statutory framework. Under the FDAAA, the agency was authorized to require a formal program known as a Risk Evaluation and Mitigation Strategy (REMS) for both newly approved drugs and previously approved drugs with known serious risks. REMS could include specific measures, known as Elements to Assure Safe Use (ETASU), for products whose safety varies markedly depending on the context of their use. Per the FDAAA, ETASUs must be commensurate with specific serious risks listed in the labeling of the drug and

Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 02/02/2026

should not be unduly burdensome on patient access. Additionally, the FDA is required to periodically review and reassess whether regulatory elements continue to be necessary to assure safe use. Mifepristone was among the drugs the FDA deemed to require a REMS based on existing restrictions governing its use. The official REMS for mifepristone was formally approved in 2011.

Substantial debate has surrounded the mifepristone REMS program. Some organizations and politicians, including those opposed to abortion, have argued that availability of the drug should be restricted fully or substantially to avoid adverse events.[6] Others, including researchers and professional associations, have argued that the continuation of additional safety precautions is unnecessary.[7] This debate surfaced again on October 1, 2025, when the FDA approved a new generic version of mifepristone.[8]

These competing perspectives are also reflected in litigation. In cases such as *US Food and Drug Administration v Alliance for Hippocratic Medicine*, parties have argued that the FDA improperly applied the US Food, Drug, and Cosmetic Act in its initial approval of and subsequent decisions regarding mifepristone.[9] Conversely, in cases such as *Purcell v Kennedy* (formerly *Chelius v Becerra*), parties have argued that the continuation of the mifepristone REMS program is unnecessary.[10] These cases, together with the *Dobbs v Jackson Women's Health Organization* decision overturning *Roe v Wade*, have set the stage for renewed federal review of mifepristone, as well as state-level efforts to limit, ban, or protect access to mifepristone.

Despite extensive public discussion and litigation, to date, there has been no review of FDA documents to shed light on how regulatory decisions about mifepristone have been made.

Document Review and Analysis

Study Design and FOIA History

In May 2019, we submitted a Freedom of Information Act (FOIA) request to the FDA regarding the design, conduct, and evaluation of FDA postapproval safety programs for 6 products, including mifepristone.[11] Based on similar prior work examining postapproval opioid regulation,[12,13] we requested a variety of documents relevant to each program, including the sponsors' REMS assessment reports, FDA reviews of these reports, internal memos, and regulatory correspondence.

Over 4 productions between March and September 2023, the FDA provided 1977 pages of documents regarding mifepristone. We reviewed and indexed these documents and then used the peer-reviewed literature on mifepristone safety and effectiveness, publicly available policy briefs, FDA-published archives, and the initially provided documents to identify additional documents of interest. We requested these documents from the FDA, yielding an additional 3262 pages of materials. The FDA redacted some documents based on exceptions for "confidential commercial information" (5 USC §552 [b][4]) and/or "personal privacy" (5 USC §552 [b][6]).[14] We appealed some redactions, resulting in the deredaction of 1 document. Our final analysis included 264 documents representing 5239 pages covering the FDA's safety program for mifepristone from June 2011 to January 2023 (eTable in the Supplement).

Document Coding and Analysis

Two authors (A.L., S.D.) performed primary document review, with oversight from a third (G.C.A.), followed by primary analysis and discussion among all authors. Each source document was reviewed and indexed to track the document subject, document type, creation date, length, and the presence of redacted material. Our primary focus was the FDA's rationale for the initial establishment of the mifepristone safety program and the agency's subsequent decisions to maintain, modify, or remove specific regulatory elements over time. We sought to identify key moments in this regulatory history, as well as key themes of the FDA's actions. Our analytic approach centered on a close reading of internal FDA review documents and other materials relevant to the agency's oversight of the mifepristone REMS program. Within each REMS review document, we extracted content related to the agency's stated rationale for maintaining or modifying specific ETASUs and evidence cited in support of regulatory decisions.

History of the FDA's Mifepristone REMS Program

Our review of documents identified 5 key moments related to the regulation of mifepristone over time: (1) conversion to the REMS framework in June 2011; (2) reevaluation of REMS necessity in October 2013; (3) a sponsor-requested label change in May 2015; (4) response to the COVID-19 pandemic in 2020 and 2021; and (5) a comprehensive reassessment of the REMS in November 2021 (**Table**).

Key Moment 1: Conversion to REMS Framework (June 2011)

The sunsetting of Subpart H following the passage of the FDAAA presented the FDA with a key opportunity to consider whether to require a formal REMS for mifepristone and to make substantive changes to its postapproval regulation.

Documents suggest there was substantial communication between the FDA and sponsor Danco over the initial use of the REMS authority for mifepristone. However, the FDA extensively redacted documents describing the agency's internal deliberations regarding specific regulatory requirements under the REMS, and the details of this exchange are not available.

The final approved REMS closely mirrored the Subpart H requirements. Under the REMS, these restrictions were formalized as ETASUs: certification of prescribers with specialized training or experience; restricted distribution to clinics, medical offices, and hospitals under the supervision of a certified prescriber; and documentation of safe-use conditions (FDA Review of Risk Evaluation and Mitigation Strategy for Mifepristone, June 2011 [Reference ID FDACDER006118-FDACDER006144]).

The FDA adopted an implementation system to monitor adherence and required the manufacturer to submit assessment reports to the FDA 1 year following approval and every 3 years thereafter, as well as in response to specific regulatory events, such as safety-related label changes (FDA Review of Risk Evaluation and Mitigation Strategy for Mifepristone, June 2011 [Reference ID FDACDER006118-FDACDER006144]).

Key Moment 2: Reevaluation of the Need for the REMS (October 2013)

In October 2012, the director of the Center for Drug Evaluation and Research (CDER), Janet Woodcock, requested a reevaluation

Table. Evolution of Mifepristone Regulatory Elements Over Time

Requirement	Pre-REMS, Sept 2000-June 2011	Key moment 1: Conversion to REMS Framework, June 2011	2: Reevaluation of REMS necessity, October 2013	3: Sponsor-requested label change, March 2016	4: COVID-19 pandemic, July 2020-April 2021	5: Comprehensive reassessment of REMS, November 2021
Certification of prescribers: Prescribers required to have specific training or experience	Prescribers required to meet specific qualifications as part of approval under 21 CFR Part 314 Subpart H	Requirement maintained under the REMS framework as ETASU	No change	No change	No change	No change
Certification of dispensing setting: Dispensing health care settings, such as pharmacies, must be specially certified	No requirement for pharmacy certification as part of approval under 21 CFR Part 314 Subpart H	No change	No change	No change	No change	Pharmacy certification was recommended for approval in November 2021 as ETASU B but change not formally implemented until January 2023 following approval of regulatory materials reflecting updated REMS elements
Restricted distribution: Dispensing restricted to certain health care settings	Distribution limited to clinics, medical offices, and hospitals under supervision of a certified prescriber as part of approval under 21 CFR Part 314 Subpart H	Requirement maintained under REMS framework as ETASU	No change	No change	In response to litigation, enforcement discretion exercised with respect to this requirement between July 2020 and January 2021 In April 2021, agency announced formal policy of enforcement discretion	In-person dispensation requirement recommended for removal in November 2021 but change not formally implemented until January 2023 following approval of regulatory materials reflecting updated REMS elements
Documentation of safe use conditions: Drug can only be dispensed to patients with documentation of safe-use conditions	Prescribers required to provide the patient agreement form and Medication guide, obtain patient signature on agreement form, and place in medical record as part of approval under 21 CFR Part 314 Subpart H	Requirement maintained under REMS framework as ETASU	No change	Patient agreement form recommended for removal by staff scientists, though maintained per commissioner's request Medication guide was removed from the REMS but maintained under labeling requirements	No change	No change

Abbreviations: CFR, Code of Federal Regulations; ETASU, Elements to Assure Safe Use; REMS, Risk Evaluation and Mitigation Strategies.

of mifepristone to determine whether the REMS continued to be necessary, prompting a review that was completed the following year (Key Document 1 in the Supplement). As part of this assessment, FDA staff scientists reviewed safety data and reported that the "overall safety profile of Mifeprex has not changed over the last 6-7 years and is consistent with current product labeling."

The scientists reviewed each ETASU in turn. After assessing the impact of removing or retaining each element, the scientists explicitly outlined the pros and cons of maintaining the REMS. In support of REMS elimination, they cited the stable safety profile and data indicating that safe-use practices were already embedded in most sites. In support of REMS maintenance, they argued that there was a relative lack of familiarity with medical abortion among clinicians given limited training opportunities. Scientists also noted controversies over the medication in considering changes to restricted distribution, writing "Concerns regarding protests or targeting may deter retail pharmacies from stocking Mifeprex." Ultimately, they concluded that the REMS should be maintained.

Key Moment 3: Sponsor-Requested Label Change (May 2015)

In May 2015, mifepristone's sponsor submitted an efficacy supplement proposing substantial changes to the drug's labeling, including extending the approved gestational age from 49 days to 70 days; reducing the dose of mifepristone; modifying the dosing regimen and the interval between mifepristone and misoprostol; changing the route of misoprostol administration; and broadening the qualifications for certified prescribers. Because these labeling changes affected the conditions for safe use, they triggered the need for a formal REMS modification. Consequently, the FDA reviewed the efficacy supplement and the REMS in parallel, issuing coordinated decisions on March 29, 2016 (Key Document 2 in the Supplement).[15]

In undertaking this review, the FDA conducted a comprehensive assessment of available evidence, including published studies reflecting clinical practice, 16 years of accumulated postmarketing safety data, and the most recent sponsor-submitted

© 2026 American Medical Association. All rights reserved, including those for text and data mining, AI training, and similar technologies.
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 02/02/2026

REMS assessment report. Collectively, these sources demonstrated that the revised dosing regimen, route of administration, and expanded clinician qualifications were appropriate.[15] Consistent with these findings, the FDA concluded that "Overall, the rate of deaths and SARs [Serious Adverse Reactions] is acceptably low and data for the proposed regimen do not suggest a safety profile that deviates from that of the originally approved regimen."[15] The agency also revised the assessment plan by eliminating certain adverse event metrics from the sponsor's required reports because this information was already being provided to the FDA through other pathways, including spontaneous adverse event reporting (Key Document 2 in the Supplement).

Two additional considerations arose during this regulatory review that do not appear to have been raised by the company. The first related to the medication guide, a handout given to all patients with information about mifepristone. Because of a broader shift in REMS regulation, the FDA removed the medication guide from the REMS program but still required its distribution to patients under patient labeling provisions.

The second consideration was the patient agreement form, which patients were required to sign under the existing REMS. In the review document, FDA scientists argued that this form was "duplicative of the informed consent and counseling processes that take place in the US, consistent with medical standard of care and current clinical practice guidelines for abortion providers," as well as the medication guide (Key Document 2 in the Supplement).

The FDA commissioner at the time, Dr Robert Califf, overrode this decision. In a memo, CDER director Janet Woodcock wrote, "After being briefed on the planned changes to the [New Drug Application] that the Center was considering, the Commissioner concluded that continuing the REMS requirement for a signed patient agreement form would not interfere with access and would provide additional assurance that the patient is aware of the nature of the procedure, its risks, and the need for appropriate follow-up care" (Key Document 3 in the Supplement).

Key Moment 4: The COVID-19 Pandemic (2020-2021)

The COVID-19 pandemic created a challenging moment for mifepristone regulation. The FDA faced the key question of whether to modify REMS provisions governing the medication, as the FDA had done with 2 other drugs that were under an in-person dispensation requirement.[16]

In May 2020, the American College of Obstetricians and Gynecologists (ACOG) sued the FDA to challenge the enforcement of the in-person dispensation and signature requirements for mifepristone during the pandemic. The FDA opposed this action, arguing that these requirements were necessary to mitigate serious risks associated with the medication.[16] The court found that ACOG's action was likely to succeed and issued a preliminary injunction in July 2020 enjoining the FDA from enforcing these requirements while the litigation continued.

Our review of documents found that the FDA's position in the ACOG litigation was contrary to the views of scientists in the FDA's review division. On June 10, 2020—the same day that the FDA filed its brief in the litigation—an office within CDER wrote a memo to the center director reviewing the various mifepristone REMS requirements (Key Document 4 in the Supplement). The staff scientists acknowledged that "the public, including patients seeking medical abortion, have been advised to practice social distancing and avoidance of public places, to minimize their risk of exposure to the novel coronavirus." They highlighted the intended purpose of the in-person dispensing requirement—to ensure that patients receive counseling at the time of dispensation and to facilitate completion of the patient agreement form—before stating that these benefits could be achieved through telemedicine. The scientists concluded that if other REMS requirements were met, then "the in-person dispensing of mifepristone for medical termination of early pregnancy may present additional COVID-related risks to patients and healthcare personnel…Accordingly, it would be appropriate to exercise enforcement discretion with respect to this element of the Mifepristone REMS Program during the COVID-19 [public health emergency]." This internal memo, however, did not change the FDA's position in the litigation.

In January 2021, the Supreme Court reinstated the in-person requirements. Soon after, the FDA initiated a new review of these requirements. In an April 2021 memo from FDA staff to the CDER director, scientists cited 4 published studies finding no evidence of an increase in serious safety concerns occurring with medical abortion as a result of modifying the in-person dispensation requirement between June 2020 and January 2021 (Key Document 5 in the Supplement). The CDER director endorsed this conclusion (Memorandum to Acting Commissioner Regarding In-Person Dispensing Requirement in Mifepristone REMS Program During the COVID-19 Public Health Emergency, April 2021 [Reference ID FDACDER006897-FDACDER006898]). Later that month, the FDA adopted a formal policy of enforcement discretion, meaning it would not enforce the in-person dispensation requirement.

Key Moment 5: Comprehensive Reassessment of the REMS (November 2021)

In November 2021, the FDA undertook a comprehensive reassessment of the REMS program, creating another opportunity for significant changes to mifepristone's postapproval regulation. The agency considered a range of options, from resuming enforcement of the in-person dispensation requirement to eliminating the REMS program altogether.

The comprehensive reassessment was conducted by an internal FDA team. Findings were shared at a meeting in November 2021 (Key Document 6 in the Supplement). The team relied primarily on a scoping literature review spanning 2016-2021 and safety data collected since the initiation of the COVID-19 public health emergency. Evidence was evaluated in relation to the necessity of each ETASU. FDA scientists once again affirmed the safety of the medication, writing that the agency "routinely monitors adverse events reported to FAERS [FDA Adverse Event Reporting System] and published in the medical literature with mifepristone for medical termination of pregnancy…to date, no new safety concerns have been identified."

On prescriber certification, agency scientists identified no new data demonstrating a continued need for certification; however, in the view of agency scientists, the literature also did not support removing the certification. On the patient agreement form, the team referenced 2 studies indicating a potential increase in the number of new prescribers, which they argued warranted a greater need for standardized patient education (Key Document 6 in the Supplement).

© 2026 American Medical Association. All rights reserved, including those for text and data mining, AI training, and similar technologies.
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 02/02/2026

On the in-person dispensation requirement, the FDA team cited results from 16 publications documenting the absence of significant concerns associated with various mifepristone delivery models. They also referenced as supporting evidence the absence of new safety concerns during the public health emergency when enforcement discretion was exercised and mifepristone was available without in-person dispensation (Key Document 6 in the Supplement).

To meet the agency's obligation to ensure REMS are not unduly burdensome, the reviewers concluded that the in-person dispensation requirement should be removed and replaced with a pharmacy certification system (Review of the One Year [1st] Single Shared System REMS Assessment Report for Mifepristone, December 2021 [Reference ID FDACDER006331-FDACDER006354]). Under this approach, pharmacies would be required to obtain certification, which typically involves agreeing to specified dispensing and recordkeeping requirements. Documents detailing the specific operationalization of the pharmacy certification system were not included in our analysis. The final recommendations from the internal FDA team also included retaining the patient agreement form. The agency announced these changes in December 2021 but did not formally implement them until January 2023, following the sponsors' submission and the FDA's approval of regulatory materials reflecting the updated REMS elements.

Key Themes

Internal FDA documents offer a rare opportunity to examine how the agency made decisions over time about mifepristone, a medicine that has been the subject of intense debate. At key moments, agency scientists reviewed extensive evidence about the agency's controls on mifepristone access and made decisions regarding whether to maintain stricter requirements for mifepristone than for most other medicines, whether to expand the condition of use, whether to adapt to the pandemic, and whether to lift certain provisions as clinical experience accumulated. Three key themes emerged from our analysis.

Consistent Findings on Safety

The FDA has monitored mifepristone's safety through multiple complementary mechanisms, including spontaneous adverse event reports, clinical studies, published literature, and information submitted by professional organizations and advocacy groups (Letter from Select Health Care Practitioners, March 2021 [Reference ID FDACDER006463-FDACDER006750]; Letter from the American College of Obstetricians and Gynecologists and Society for Maternal Fetal Medicine, April 2020 [Reference ID FDACDER006391-FDACDER006445]). From the drug's original approval in 2000 through 2016, the REMS assessment plan required the sponsor to provide summaries of spontaneous adverse event reports and updates on any postapproval studies. In 2016, the agency continued to obtain these data through annual reports, routine pharmacovigilance, and other mechanisms.

The documents we examined underscore the repeated regulatory finding by FDA scientists that mifepristone's safety is well-characterized, serious adverse events have rarely occurred, and best-practice guidelines address major risks.

Lack of Ideological Bias in Staff Scientists' Recommendations

Staff scientists at the FDA based their recommendations on comprehensive reviews of evidence, making decisions that were not consistently on one side or the other of the debate taking place outside the agency regarding mifepristone regulation.

For example, FDA scientists supported removing the in-person dispensation requirement, first in June 2020 during the pandemic, then again in April 2021, and again, following a comprehensive review, in November 2021. These decisions have drawn criticism from abortion opponents, who have pressed for a return to more restrictive regulation.

At the same time, FDA scientists continued to endorse multiple elements to support safe use, including provisions requiring prescriber certification and completion of the patient agreement form. In each case, the agency cited the need for additional data to justify any reconsideration of these provisions. These determinations have been criticized by ACOG and other professional groups, who have called for them to sunset.

The Question of Political Interference

In our document review, we identified 2 moments of potential intervention from FDA political appointees on decisions that ran contrary to the perspective of agency scientists on appropriate evidence-based regulation. In 2016, the FDA commissioner decided, over the apparent objections of the review division, to maintain a requirement for a patient agreement form. The commissioner justified this decision on the grounds that it would promote understanding without interfering with access. Several years later, FDA scientists would endorse continuing with this requirement to best ensure patient understanding of the risks of the product.

In June 2020, the scientific team's conclusion that in-person dispensation was not required during the COVID-19 pandemic was not adopted as the agency's position in response to a court challenge by ACOG against the continuation of this requirement during the pandemic. On the same day that a memo from the scientific team concluded that the in-person dispensation requirement was not needed, the agency filed a brief opposing the challenge. We did not identify documents to explain the timing of these decisions or their provenance.

What might have been a moment of interference with the scientific team's approach was forestalled by the court's action to block the in-person requirement from July 2020 to January 2021. With the exception of the period from January 2021, when the Supreme Court reinstated the in-person requirement, until April 2021, when the FDA chose not to enforce it, we found no documentary evidence of political intervention that substantially affected access to the medication.

Looking Ahead

Litigation on mifepristone access continues to generate uncertainty. Several active cases seek the removal of the REMS requirements altogether. Other cases have been directed at restricting or revoking FDA approval of the drug—most notably, *Alliance for Hippocratic Medicine v FDA*.[17] Although the Supreme Court unanimously dismissed the case in June 2024 on procedural grounds, its decision left the door open for future plaintiffs to revisit similar arguments. Three states are currently challenging the FDA's approval

© 2026 American Medical Association. All rights reserved, including those for text and data mining, AI training, and similar technologies.
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 02/02/2026

of mifepristone.[18] These cases are occurring alongside broader campaigns targeting abortion providers and access, state efforts to restrict mifepristone availability, mounting pressures on the health care system, and deepening disparities in reproductive care.[19]

On September 19, 2025, Department of Health and Human Services Secretary Robert F. Kennedy Jr and FDA Commissioner Martin Makary indicated that the FDA is undertaking a new evaluation of mifepristone's safety and effectiveness.[20] Kennedy has said that key decisions would be up to the president himself.[21] A reversal of FDA policy on mifepristone by political leaders or appointees would represent a significant break from the last quarter century of mifepristone oversight.

Limitations

Our analysis has several limitations. Documents that we received through our FOIA request included redactions that limited our ability to fully understand the factors the FDA considered and its internal deliberations with regard to those factors. In some instances, entire pages were redacted, preventing us from understanding regulatory decision-making and presenting gaps in our review. Additionally, there may be documents that were not provided to us or internal discussion related to mifepristone regulation that was not captured in the written documents. Our interpretation of the documents necessarily reflects judgments about the weight and meaning of regulatory actions over time. Consequently, our analysis may not fully capture the complexity of agency decision-making or the influence of external pressures, including political or legal considerations, that are not explicitly documented. Moreover, our study was not designed to be comparative, and we did not evaluate how the mifepristone REMS compares with REMS programs for other drugs.

Conclusions

Mifepristone's regulatory trajectory offers an instructive case study of how the FDA has conducted drug safety oversight in a politicized environment: cautiously and with the support of evidence and regulatory judgment. Our analysis of internal agency documents spanning more than a decade shows that while the FDA has consistently affirmed mifepristone's safety, changes to its REMS were often made conservatively, incrementally, and in response to external events such as the COVID-19 pandemic. While the FDA considered more radical changes at several key moments, it opted against them to better balance various considerations. As the FDA prepares to review the safety data again, as legal challenges are expected to continue, and as state policies diverge, mifepristone will likely remain a flashpoint in reproductive health policy. Maintaining integrity in this process will require a continued commitment to scientific evidence and an avoidance of political interference.[22]

Rockville, MD 20852

Reproductive Health Researchers' Comment

The UCLA Law Center for Reproductive Health, Law, and Policy and UCSF Advancing New Standards in Reproductive Health submit this comment on behalf of the below signed 263 reproductive health researchers trained and experienced in conducting or evaluating clinical and social science studies on reproductive health issues, including studies on the safety and effectiveness of mifepristone.[1] Signatories share a commitment to evidence-based reproductive health care and FDA decision-making based on sound and transparent science. Signatories submit this comment in support of pending citizen petitions (FDA-2025-P-0377-0001; FDA-2025-P-1576-0001; FDA-2025-P-2162-0001) that, among other steps to ensure medication abortion remains accessible, ask the FDA to refrain from imposing additional or increased restrictions on mifepristone. Specifically, signatories submit this comment to contextualize the relevant research and to explain the flaws in recent reports on mifepristone that are not grounded in gold standard science or transparent and reliable data and analysis.

I. Decades of Voluminous Gold Standard Science Support the Safety and Effectiveness of Mifepristone, Including Through Telehealth

Decades of conclusive scientific evidence amassed through more than one hundred rigorous studies based on hundreds of thousands of patient outcomes have overwhelmingly established the safety and effectiveness of mifepristone for medication abortion and management of early pregnancy loss. The FDA has reviewed that large and sound body of science at many junctures over the past 25 years and, at each moment,

[1] The institutional affiliations of signatories are for identification purposes only and the views expressed in this letter do not necessarily reflect the views of signatories' affiliated institutions.

confirmed the safety and effectiveness of mifepristone generally[2] and, time and time again, the FDA has found complications and serious adverse events associated with mifepristone extremely rare.[3] Based on this body of evidence, the FDA has modified mifepristone labeling, and eased specific REMS restrictions when science proved they were unnecessary to protect patient safety and unduly restricted access.[4]

The evidence supporting the safety and effectiveness of telehealth provision of medication abortion is part of this body of sound, gold standard science.[5] The FDA has reviewed the safety of telehealth provision of mifepristone multiple times, each time reaffirming the safety and effectiveness. In April 2021, the FDA reviewed clinical outcome data for over 50,000 instances of medication abortion provision in rigorous studies that evaluated the safety and effectiveness of care delivered in-person, via telehealth, with pharmacist dispensing of mifepristone, and through hybrid options both before and during the COVID-19 public health emergency. In that review, the FDA concluded that studies of telehealth provision and real world postmarketing adverse event data did not show increases in safety concerns.[6] Again in December 2021, the FDA further reviewed some of the studies it

A., Collins, A., Hannum, C., Ho, S., Seibold-Simpson, S. M., Sobota, M., Tocce, K., Schwarz, E. B., & Gold, M. (2024). Mail-Order Pharmacy Dispensing of Mifepristone for Medication Abortion After In-Person Screening. *JAMA Internal Medicine*, *184*(8), 873–881. https://doi.org/10.1001/jamainternmed.2024.1476 (among 510 medication abortions where eligibility was assessed in an in-person visit but patients received medication through a mail-order pharmacy rather than in-clinic, finding 97.8% effectiveness and only three serious adverse events (0.6%)).

more recent non-comparative studies," and that "serious adverse events are rare."[9] Telehealth for medication abortion is an accepted, standard method of abortion provision in the United States and around the world.[10]

The White House has recently directed that agencies must produce and act upon sound, gold standard science. A recent Executive Order defines gold standard science as science with data and methods that are, among other criteria, "reproducible," "transparent," "communicative of error and uncertainty," "skeptical of its findings and assumptions," and "subject to unbiased peer review," so that federal decisions can be "informed by the most credible, reliable, and impartial scientific evidence available.[11] An Office of Science and Technology Policy Memorandum further directs agencies to use gold standard science as defined by nine tenets that include reproducibility, transparency, and unbiased peer review.[12] Moreover, when federal agencies use scientific information to inform agency decision-making, federal employees are directed to apply a "'weight of scientific evidence' approach."[13] FDA Commissioner Makary recently declared his pride in the FDA taking action grounded in "transparency [and] gold-standard science."[14]

[14] *See* FDA. (2025, July 10). *A Statement from FDA Commissioner Marty Makary, M.D., M.P.H: 100 Days of Embracing Gold-Standard Science, Transparency and Common Sense*.

We strongly believe that the lynchpin of sound science is whether the data and methods are transparent, the work is reproducible by other scientists, and the work has been subject to the rigors of unbiased peer review. We are extremely concerned that the FDA may be considering significant action to reverse previous mifepristone REMS and label updates based on unverified and unreliable reports and studies that do not satisfy gold science standards. For the reasons discussed below, significant federal action based on these recent reports, or others that similarly lack scientific rigor and reliability, would be inappropriate and unsound federal agency decision-making.

II. New Research That is Not Reproducible, is Methodologically Flawed, or Both, Does Not Outweigh the Overwhelming Body of Rigorous Evidence on Mifepristone's Safety and Effectiveness

A. The Self-Published Analysis of Unknown Data by the Ethics and Public Policy Center is Not Verifiable or Reproducible and Suffers Multiple Methodological Flaws

In support of its recommendation that the FDA reinstate a regulatory protocol from when mifepristone was first approved over 20 years ago, the Ethics and Public Policy Center (EPPC)[15] has self-published two position papers on medication abortion – one on occurrences of serious adverse events[16] and one on the occurrence of failure.[17] In these papers, EPPC presents its findings and conclusions as the product of the "largest-known study of the abortion pill" derived from its "analysis of data from an all-payer insurance

---

https://www.fda.gov/news-events/press-announcements/statement-fda-commissioner-marty-makary-md-mph-100-days-embracing-gold-standard-science-transparency.

[15] According to EPPC, its mission is "to apply the riches of the Jewish and Christian traditions to contemporary questions of law, culture, and politics" in America. *See* Ethics & Public Policy Center (n.d.). *Our Mission*. Retrieved August 25, 2025, from https://eppc.org/about/. EPPC's "The Life and Family Initiative," which produced the recent reports on mifepristone, is "committed both to ensuring the equal protection of unborn children in law and to providing concrete support to families by advancing a pro-life, pro-family agenda that takes our duties in justice to the unborn and to families seriously." *See* Ethics & Public Policy Center (n.d.). *Life and Family Initiative*. The Abortion Pill Harms Women: Insurance Data Reveals One in Ten Patients Experiences a Serious Adverse Event. *Ethics & Public Policy Center*. https://eppc.org/publication/insurance-data-reveals-one-in-ten-patients-experiences-a-serious-adverse-event/ (hereinafter "EPPC Report on Serious Adverse Event").

[17] Hall, J. B., & Anderson, R. T. (2025). The Abortion Pill Harms Women: Insurance Data Reveals Repeated Abortion Attempts Due to High Failure Rate. *Ethics & Public Policy Center*. https://eppc.org/publication/the-abortion-pill-harms-womeninsurance-data-reveals-repeated-abortionattempts-due-to-high-failure-rate/ (hereinafter "EPPC Report on Failure Rate").

claims database."[18] However, as discussed below, these reports lack basic information and disclosures that reputable studies provide for transparency and reproducibility. Moreover, several claimed findings and conclusions appear to be based on errors and/or flawed assumptions drawn from the undisclosed data source and guided by an unnamed research team. Given these serious deficiencies, EPPCs position papers do not credibly call into question, let alone outweigh, the consistent findings from an overwhelming body of rigorous scientific studies and methodologically transparent data demonstrating that mifepristone, including when provided through telehealth, is safe and effective.

Below we summarize some of the most serious concerns and questions about the underlying data and analysis from which these position papers draw their conclusions and upon which they base sweeping recommendations to more heavily regulate mifepristone.

1. **The Data and Analyses Used by EPPC are Not Disclosed and Cannot be Verified or Reproduced**

In its first self-published report of insurance data for medication abortion prescriptions, EPPC claims that its analysis shows 10.93% of patients experienced "a serious adverse event" after a mifepristone abortion.[19] This purported finding is the foundation of their claim that the "real-world rate of serious adverse events following mifepristone abortions is at least 22 times as high as reported on the drug label."[20] But the report does not provide reliable evidence to support this claim, nor does any published literature.

In describing their data and methodology, the authors assert the data came from an "all-payer insurance claims database," from which they analyzed data of 865,727 "prescribed mifepristone abortions from 2017-2023," and that their analysis was "conducted and validated" by a research team of "data scientists, analysts, and engineers, with assistance from our clinical team of board-certified obstetricians and gynecologists."[21] However, the EPPC report authors do not identify the name of the database or the researchers and their affiliations, nor do they share the coding they used to generate the study cohort and analyze the data. Likewise, two follow-on explainers[22] and the second report on emergency

visits following failed medication abortion[23] do not share any of this information and thus offer no greater transparency or ability to verify and reproduce the data and analysis.

One of the most problematic aspects of representing their analysis as a scientifically validated large-scale study is that they do not provide the source of the all-payer insurance claims database, precluding the ability of other researchers and scientists to independently verify their analysis and results. Despite a statement in the Frequently Asked Questions ("FAQ") release that: "We have made our study fully replicable for anyone who wants to analyze the insurance claims data" and the "dataset is available for purchase and our methodology is public,"[24] the information simply is not provided in any of these reports and explainers. Additionally, EPPC has stated publicly that it will not reveal the dataset used to identify patient outcomes.[25]

And while EPPC suggests this singular database is readily identifiable, to the best of our knowledge that is not the case. Signatories to this letter, which includes numerous researchers who regularly analyze insurance and medical claims data in their work, do not know of a single "commercially available all-payer health insurance claims database" that includes both private and public health insurance "data for all U.S. patients"[26] as described by EPPC.

Assuming the EPPC research team did acquire data from a commercial compilation of Medicaid and several private insurance claim datasets or databases, it is crucial to know which ones were relied upon and included in the study. There are known methodological

[24] EPPC FAQ, *supra* note 22, at pp. 3-4.

[25] EPPC repeatedly told journalists it could not reveal the dataset or even its source. *See, e.g.,* Glenn Kessler, *Digging Into the Math of a Study Attacking the Safety of the Abortion Pill*, WASH. POST (May 12, 2025), https://www.washingtonpost.com/politics/2025/05/12/abortion-pill-medication-abortion-study-mifepristone ("[EPPC's spokesperson] cited a confidentiality agreement with the vendor. . . . 'we do not view the confidentiality of our specific dataset as a barrier for others interested in obtaining similar data and replicating or extending this research.'"); Keren Landman, *A Convenient Piece of Junk Science,* ATLANTIC, (May 24, 2025), https://www.theatlantic.com/health/archive/2025/05/mifepristone-abortion-rfk-fda/682939/ ("In an email, Hunter Estes, EPPC's communications director, told [the Atlantic] that the center's contract with their data vendor prevents EPPC from sharing the name of the database or even of the vendor."). And at least one signatory to this comment directly contacted the authors asking for information on the database but received no answer.

[26] EPPC Serious Adverse Event, *supra* note 16, at p. 5.

limitations of some databases for analyzing abortion claims data. For example, some commercially available sources of Medicaid claims data are over-representative of "Hyde exceptions" because many states only provide Medicaid coverage for abortions in situations of rape, incest, or life endangerment.[27] Medicaid claims data thus overrepresent abortions to prevent life-threatening health risks and are not representative of abortion cases overall. Likewise, patients covered by Medicaid often present with more complex needs and additional health conditions that can contribute to a higher risk of complications as compared to the general population. Thus, for patients with Medicaid coverage, abortions – like any healthcare – can result in a greater need for follow-up care. Accordingly, in a retrospective review of insurance or medical claims, it is standard to disclose the different payer and billing sources and to identify and address any inherent limitations in the data such as over- or under-representation of certain populations or regions of the country, or potential for claims misclassifications in particular datasets.

Additionally, it is highly problematic that EPPC does not disclose the full list of diagnosis and procedure codes used in its analyses, nor many other standard disclosures like the coding they used to analyze data, information about their study cohort (such as comorbidities), or how that cohort was created. Full disclosure of methods for creating the study cohort and lists of the diagnoses and procedure codes for measuring both exposures and outcomes is standard practice in analyses of insurance claims data. But EPPC simply states that it "identified relevant ICD-10 diagnoses codes and CPT/HCPCS procedures codes from multiple sources," (including from CDC, CMS, FDA and "codes suggested by our doctors")[28] without listing each diagnosis and procedure code used or saying more about its study cohort.

In standard studies of medication abortion safety, researchers use treatment codes to identify serious adverse events, given that diagnosis codes alone may not indicate the degree of seriousness of an event.[29] A lack of treatment indicates the encounter did not

[29] Taylor, D., Upadhyay, U. D., Fjerstad, M., Battistelli, M. F., Weitz, T. A., & Paul, M. E. (2017). Standardizing the classification of abortion incidents: The Procedural Abortion Incident Reporting and Surveillance (PAIRS) Framework. *Contraception*, *96*(1), 1–13. https://doi.org/10.1016/j.contraception.2017.05.004. The full list of diagnosis and procedure codes is also important to verify if the medications or procedures provided to a patient were in fact related to an abortion. Some medications and procedures commonly used in abortion are also commonly

involve a serious adverse event. For example, given the variety of definitions of hemorrhage, it would be inaccurate to consider a hemorrhage diagnosis a serious adverse event if it did not require any treatment. Thus, when classifying adverse events, it is critical to examine treatment/procedure codes, not only diagnosis codes. While EPPC's subsequent FAQ claims its analysis was based on "diagnosis and procedure codes" and only counted "treatment for a serious complication,"[30] it never identifies a single treatment code that was used as part of that methodology, let alone discloses all the treatment codes considered under each category it counts as a serious adverse event.

Finally, contrary to standards for transparency in scientific studies, the EPPC report has no discussion of the limitations of its analysis. For example, EPPC does not address how the serious adverse event rate they report is impacted by exclusion of certain populations from an insurance claims database, such as patients who pay out of pocket.[31] Some public and private insurance plans cover abortions only in limited circumstances, such as when continuing the pregnancy poses a serious health risk. Pregnant people who do not qualify will be among those who pay out of pocket for abortion. Thus, people more likely to have pregnancy complications or require more complex abortion treatment are overrepresented in insurance claims data.

2. EPPC's Findings and Conclusions, to the Extent Explained, are Inconsistent and Unsound

To the extent possible given the summary description of the data purchased, and the piecemeal explanations of the methodology used, we outline several additional concerns related to specific unexplained variables, assumptions, findings, and conclusions made by EPPC in its reports:

Lack of definitions and methodology to identify hemorrhage: The authors do not sufficiently define hemorrhage. This category accounts for 28,658 of the 94,605 "serious adverse events," which is one of the three largest categories of serious adverse events in their report.[32]

---

used for other indications unrelated to pregnancy. For example, a uterine aspiration may be performed to evaluate and treat heavy menstrual bleeding when a patient is not pregnant.

[30] EPPC FAQ, *supra* note 22, at p. 1.

[31] The authors state that the data excludes "cash pay transactions (which are disproportionately common for abortion)." EPPC Report on Serious Adverse Event, *supra* note 16, at p. 5. But there is no discussion of how that, or other excluded populations, impacts their findings.

[32] EPPC Report on Serious Adverse Event, *supra* note 16, at Fig. 1.

A successful medication abortion always involves some bleeding. When a patient presents with complaints of bleeding, it could be excessive bleeding or it could be the expected amount.[33] Without a standardized definition,[34] EPPC is likely misclassifying many cases of normal bleeding that occur with a medication abortion. Indeed, the FDA has previously addressed the problem of mischaracterizing or misclassifying treatment for heavy bleeding after medication abortion as a serious adverse event: "Heavy bleeding or hemorrhage after medical abortion is a small subset of bleeding and can require a surgical procedure due to ongoing pregnancy or incomplete expulsion; these are considered failed treatment rather than adverse events and are not characterized using the [Council for International Organizations of Medical Sciences'] definitions. Even if heavy, bleeding after medical abortion may not be considered a serious adverse event unless clinically diagnosed as hemorrhage or requiring a transfusion."[35]

EPPC's Fact Sheet claims that they "excluded non-serious bleeding" such as "typical expected bleeding," [36] but does not confirm how their methodology ensured this was done reliably. For example, relying only on diagnostic codes – as they seem to have done – could erroneously elevate the hemorrhage category numbers. For example, a patient could present after an episode of heavy bleeding after using medication abortion. A clinician may use the diagnosis code of "hemorrhage" to justify checking the patient's blood count. But if the patient is clinically stable, bleeding resolves, blood count is normal, and no treatment for hemorrhage is provided, this would not be a serious adverse event. Again, this is why it

(2023). *What is a Serious Adverse Event?* https://www.fda.gov/safety/reporting-serious-problems-fda/what-serious-adverse-event.

is imperative to look at diagnosis and treatment codes together to ensure proper classification.

Likely inclusion of emergency room visits unrelated to serious adverse events: Abortion-related emergency room (ER) visits were counted as serious adverse events. At a count of 40,960, this is the second largest category included in their report.[37]

While the FDA collects, reviews, and includes on the mifepristone labeling information about ER visits related to medication abortion, when evaluating real-world safety and effectiveness it considers whether those visits are accompanied by other serious adverse events.[38] FDA guidance states: "Emergency room visits that do not result in admission to the hospital should be evaluated for one of the other serious outcomes (e.g., life-threatening; required intervention to prevent permanent impairment or damage; other serious medically important event)."[39]

Research shows that many people go to an emergency room after a medication abortion to get immediate care for symptoms, or to ask questions, or to confirm they are no longer pregnant, without receiving any treatment.[40] This is more common when the patient lives far from the abortion provider.[41] ER visits are more common among people with Medicaid coverage, as many do not have a primary healthcare provider.[42] Additionally, the time period of the data analyzed, 2017-2023, overlaps with the height of the COVID pandemic,

during which the implementation of social distancing policies created barriers for in-office primary care visits,[43] which could have led to an increase in ER visits for routine follow-up care.

While EPPC later states in its Fact Sheet that it excluded ER visits that did not include serious adverse events,[44] for reasons addressed above, it is impossible to verify how this was done. For example, as already explained, their definition of hemorrhage remains unclear and unreliable. Thus, it is possible that billing for an ER visit with an initial diagnosis of hemorrhage, but which self-resolved and did not require treatment, was included. Likewise, infection is another category that requires more explanation to determine the extent to which the EPPC reporting of a 1.34% rate of infection might be inflated by inclusion of non-serious conditions like yeast vaginitis and urinary tract infections.[45] Further, their decision to rely on NIH's Common Terminology Criteria for Adverse Events raises further questions about the reliability of their coding analysis. Those codes originated in connection with cancer treatment and research and are not commonly used in connection with ER care.

"Other abortion-specific complications" are not clearly defined: There is a need for greater transparency around this "other" category. This is likely where EPPC included the unidentified "codes suggested by our doctors," contributing to greater confusion and obscurity around the methods used. This is the largest category of serious adverse events, accounting for 49,169 of the 94,605 serious adverse events counted by EPPC.[46]

Because no information about the researchers or doctors who did this coding was offered, we are unable to evaluate their expertise in abortion care or what they relied upon to designate abortion-specific complications for this category. Relatedly, and deeply problematic, they included diagnosis codes for homicidal and suicidal ideation as two of

[45] *See* EPPC Report on Serious Adverse Event, *supra* note 16, at Fig. 1. While neither the initial EPPC report, the EPPC Fact Sheet, nor the EPPC FAQ say anything about what types of infections were excluded, an EPPC spokesperson answering questions about the possible inclusion of yeast or urinary tract infections identified only one such diagnosis – vaginitis – that was excluded. *See* Kessler, *supra* note 25.

[46] EPPC Report on Serious Adverse Event, *supra* note 16, at Fig. 1.

the diagnosis codes qualifying as abortion-specific complications.[47] By including these codes, the EPPC team either misrepresents, or misunderstands, the evidence on abortion and the types of serious adverse events that relate to abortion. Rigorous published research overwhelmingly establishes that serious mental health crises are not a complication of abortion.[48] Thus, there is no basis for suggesting such events are related to an abortion because it was diagnosed within 45 days of an abortion, and it is irresponsible and misleading to suggest it does.[49]

Mischaracterizing subsequent treatment to complete a medication abortion as a serious adverse event and/or "repeated abortion": EPPC alternately counts any procedural abortion within 45 days following a medication abortion as a serious adverse event or as evidence that an initial medication abortion failed. But characterizing follow-up treatment for an incomplete or failed medication abortion as a serious adverse event is inconsistent with published literature and FDA guidance.

In their first report, EPPC counted "Repeated (surgical) abortion" after a medication abortion as a serious adverse event. Specifically, they assert procedural abortions account for 24,563 of the 94,605 serious adverse events in their findings.[50] Subsequently, in their second report claiming to identify the "real-world failure rate," of mifepristone abortion, they present this number differently. In the second report, EPPC claims "5.26 percent of women undergo a second abortion attempt within 45 days of the first," (this includes a

[49] Notably, a spokesperson for the authors admitted "there were zero instances of patients with those two SAE mental health diagnosis codes" within their data analysis. Kessler, *supra* note 25. This, however, does not minimize the harm of suggesting it is a risk related to medication abortion.

[50] EPPC Report on Serious Adverse Event, *supra* note 16, Fig. 1.

second abortion by either mifepristone and/or surgical procedure).[51] They then conclude that: "13.51 percent of women – roughly one in seven – experience at least one serious adverse event or repeated abortion attempt within 45 days of first attempting a mifepristone abortion."[52] While this new presentation of the data seems to acknowledge not all treatments to complete an abortion are serious adverse events, in their conclusion they once again assert, as they do in their first report, that the "real-world rate of serious adverse events following mifepristone abortions is at least 22 times as high as reported on the drug label."

It is known and expected that about 3-5% of patients will need additional medications or a procedure to complete the abortion.[53] And while EPPC's report of a five percent real-world failure rate is within the range of some prior clinical studies on effectiveness, it cannot be evaluated or verified for the reasons already explained regarding the unknown dataset and methodologies for data analysis.

Whether wrongly counting treatment for completing a medication abortion as a "serious adverse event," using that data to suggest mifepristone is not effective, or combining and presenting the data in a conflicting and inconsistent way, the EPPC's interpretation of insurance claims regarding treatment for incomplete abortions and ongoing pregnancy is misleading.

Problems identifying miscarriage treatment and other uses of mifepristone: One of the three ways EPPC says they identified medication abortions was a prescription for mifepristone with or without misoprostol within the next 3 days.[54] But mifepristone is used for other indications, including for miscarriage management and induction termination, along with misoprostol.[55] Additionally, mifepristone is frequently used for cervical priming

before procedural abortion in the second trimester.[56] Any of these uses could have been captured in this study. In general, miscarriage and treatment for miscarriage are associated with slightly higher complication rates than for abortion,[57] which would erroneously inflate the "serious adverse event" rate reported by the study.

EPPCs follow-up explanations only add to the confusion and further highlight potential problems in their analysis. In the subsequent FAQ, EPPC states it "was very careful to exclude miscarriage care in our report by requiring any mifepristone only prescription was accompanied by a Z332 code (encounter for elective termination of pregnancy) or Z640 (problems related to unwanted pregnancy)."[58] But mifepristone along with misoprostol is a recommended standard of care for miscarriage management,[59] which means patients experiencing a miscarriage will commonly be prescribed both medications. Yet, EPPC does not say it ensured there was an accompanying Z332 or Z640 code when a patient was prescribed both medications. Thus, it seems, EPPC has not excluded cases of standard

miscarriage treatment, or the corresponding problem of an erroneously inflated rate of serious adverse events.

"Other life-threatening adverse events" are not necessarily abortion related: This category accounts for 1,956 of the 94,605 "serious adverse events" in the report.[60] The analysis captures chronic issues, including cardiac and pulmonary events, as "serious adverse events," but there is no indication that they are abortion related. In fact, patients with these conditions may be more likely to have an abortion to avoid exacerbating their chronic condition, and thus, the direction of causality between the abortion experience and the serious adverse event is ambiguous. As explained above, it is quite likely these types of cases are over-represented in the database because many public and private insurance plans cover abortions only if a pregnancy is causing or exacerbating serious health issues. Again, without a clear list of each specific diagnosis and the corresponding treatment for claims included in this category, or description of the study cohort's characteristics, including existing comorbidities, it is impossible to determine if these are appropriately categorized as abortion-related complications simply by virtue of occurring within 45 days of an abortion.

EPPC makes sweeping conclusions and recommendations not supported by their stated evidence: The policy implications stated do not follow from the authors' own analyses, even if one were to take the reported findings at face value.

For instance, they find no evidence to support that a return to in-person dispensing of mifepristone for a medication abortion would reduce adverse events; the analysis does not stratify by the location of mifepristone dispensing so there is no evidence that adverse events would be different based on in-person versus remote dispensing of mifepristone. Likewise, they do not report serious adverse events by year, so there is no support for their conclusion that removing restrictions on mifepristone has resulted in increased adverse event rates. They also have no findings to support the recommendation that only physicians should provide mifepristone. The analysis does not look at or address whether a medication abortion was provided by a physician or an advanced practice clinician. Similarly, their analysis does not examine adverse events by pregnancy duration, and thus, their recommendation that medication abortion be restricted to the first seven weeks is unsupported by the analysis conducted.

[60] EPPC Report on Serious Adverse Event, *supra* note 16, at Fig. 1.

Finally, as EPPC itself acknowledges, ectopic pregnancy is not caused by or a complication of medication abortion,[61] and evidence establishes that abortion medications do not create harm if taken by someone with an ectopic pregnancy.[62] Yet EPPC makes the baseless claim that "use of mifepristone by a woman with an ectopic pregnancy poses extraordinary, heightened risk to her health."[63]

B. One New Study that Evaluates Emergency Department Visits Related to Abortion is Deeply Flawed

We are also aware of one new study published this year which sought to identify the prevalence and severity of emergency department ("ED") visits by patients who have taken mifepristone for medication abortion: *Determining the Period Prevalence and Acuity of Emergency Department Visits Following Induced Abortion Mistakenly Identified as Spontaneous Abortions: An Analytical Observational Prospective Cohort Study*.[64] In this paper, lead author James Studnicki and co-authors, all affiliated with the Charlotte Lozier Institute (the research and education institute of Susan B. Anthony Pro-Life America), conclude that ED visits following induced abortion have high severity, and that rates of such outcomes are being deflated and concealed due to high rates of miscoding and misattributing these visits as related to a spontaneous abortion (miscarriage). But the authors' interpretation of the data and findings rest on serious methodological flaws and

[64] Studnicki, J., Fisher, J. W., Cox, T. L., Cirucci, C. A., Reardon, D. C., Skop, I., Louttit, C., Harrison, D. J., & Craver, C. (2025). Determining the Period Prevalence and Acuity of Emergency Department Visits Following Induced Abortion Mistakenly Identified as Spontaneous Abortion: An Analytic Observational Prospective Cohort Study. *Family Medicine and Primary Care: Open Access,* *9*(282). https://doi.org/10.29011/2688-7460.100282. The authors of this study are largely the same authors of prior studies attempting to show a higher rate of emergency department visits related to medication abortion that were retracted because of fundamental problems with the study design and methodology. Retraction Notice. (2024). *Health Services Research and Managerial Epidemiology*, *11*, 23333928231216699. https://doi.org/10.1177/23333928231216699. Moreover, in this newest study, they again use the same methods as used in one of the studies that was retracted. Studnicki, J., Longbons, T., Harrison, D. J., Skop, I., Cirucci, C., Reardon, D. C., Craver, C., Fisher, J. W., & Tsulukidze, M. (2022). A Post Hoc Exploratory Analysis: Induced Abortion Complications Mistaken for Miscarriage in the Emergency Room are a Risk Factor for Hospitalization. *Health Services Research and Managerial Epidemiology*, *9*, 23333928221103107. https://doi.org/10.1177/23333928221103107 (Retraction published 2024, *Health Services Research and Managerial Epidemiology, 11*).

unreliable data that undermine their conclusions. As a result, the study does not credibly support their conclusion that use of mifepristone for induced abortion represents a "serious risk factor," and does not undermine the overwhelming body of scientific evidence demonstrating the safety of medication abortion with mifepristone.

1. **The Methodology Used by the Authors to Code for Acuity of Emergency Department Visits is Gravely Inaccurate**

The authors of this study are misclassifying acuity of patient outcomes and interventions to draw sweeping conclusions. Core to the conclusions of the paper are its determinations of acuity, or severity level, of patient emergency department visits following an induced abortion (as determined by the study authors, although this categorization is also flawed, see below). However, the study methodology misclassifies acuity based on use of Current Procedural Terminology (CPT) codes that do not support their determinations.

The study methodology classifies CPT codes 99284 and 99285 as "severe" or "critical" and thus labels any visit with one of these acuity codes as having high acuity.[65] However, these codes do not always support such categorization. CPT codes are used to describe emergency department visits for the evaluation and treatment of a patient, and the specific code is primarily determined on initial presentation of the patient and reflects the amount of cognitive work required for the ED clinician to evaluate the patient and make a diagnosis, not the severity of the overall visit once treatment is provided. These CPT codes have nothing to do with the seriousness of the final diagnosis and treatment. For example, an ED visit where detailed history, examination, urine and blood testing, and moderately complex medical decision making is required can push the CPT code to 99284 or 99285, but it does not necessarily indicate a serious adverse event or severe medical condition experienced by the patient. Additionally, the study does not disaggregate among all visits it categorizes as "high acuity," to show how many were put in that category because of CPT code 99284 versus CPT code 99285.

More generally, it is imprecise to use any single CPT code to determine the severity or acuity of an emergency department visit. It is critical to look at all treatment codes that patients receive in an emergency department to determine severity and acuity as accurately as possible. Comprehensively looking at multiple codes is also important to

[65] Studnicki et al., 2025, *supra* note 64, at p. 3.

mitigate the possibility that some higher acuity codes are inaccurate. Research shows that there is a growing trend of providers and hospitals using higher acuity codes.[66]

Despite the ability to conduct a comprehensive review of all treatment codes, the authors of this study did not. The authors pulled data from the Centers for Medicare and Medicaid Services (CMS),[67] which is a data source that includes access to all billing information for included visits. Thus, the researchers could and should have used this data source to determine the nature of each adverse event, rather than relying on CPT codes that do not accurately or sufficiently describe acuity level. The failure to do so, in combination with the authors' misclassification of at least some CPT codes, render the authors' findings that most emergency department visits after abortion were high acuity unsupported by the study itself and inconsistent with methodology and conclusions in previous research.

2. The Determination of What Counts as a "Miscode," Relies on Flawed Methodology and Bad Faith Assumptions About Patients and Providers

The authors' methodology for classifying a "miscode" is flawed and undermines the credibility and reliability of the authors' staggering claim that 18% of all ED visits following medication abortion were miscoded.[68] The study authors identify a cohort of patients who had a medication abortion using a single Healthcare Common Procedure Coding System (HCPCS) code (HCPCS code S0190, which is the code for mifepristone).[69] However, mifepristone is not exclusively used to induce abortion, it is also increasingly used to treat miscarriages.[70] As a result, many of the uses of that code may in fact be actual miscarriages. But the authors only make the miscoding assumption in one direction – a direction that necessarily inflates the prevalence of ED visits related to induced abortion.

One major error is the authors' failure to account for the complexity of billing data and coding. Billing data for a single emergency department visit contains multiple claims, sometimes even hundreds of rows of claims for different tests, medications, IV fluids, etc., each of which will have a different claim and diagnosis or treatment code. In practice, this means that there may be some discrepancy between each claim for an emergency

---

[69] *Id.* at p. 2.

[70] *See supra* note 59 (citing multiple studies documenting increased use of mifepristone for miscarriage care).

department visit due to the number of claims related to each visit. For example, if a patient's urine goes to the emergency department lab for pregnancy testing, it is possible that the wrong diagnosis code could be used in that single claim, but that does not mean that the entire visit was miscoded. Nonetheless, in this study, the presence of a single code for miscarriage alongside a single code for induced abortion led authors to classify the entire visit as a "miscode." This methodological error undergirds a misunderstanding of the fundamental coding processes as used in the emergency department context.

The presence of codes for both induced abortion and miscarriage does not mean that the entire visit was miscoded, particularly in the emergency department context. Emergency department visits with severe acuity – which can include miscarriages – will have many, many claims, and thus an even greater likelihood of at least one claim being attributed to an induced abortion rather than a miscarriage, particularly given that the two conditions present very similarly. For the same reason, visits the authors consider to have been "miscoded" are also likely to be ones that present with higher acuity codes and have more claims associated with them.

Additionally unfounded, and especially concerning, is the authors' underlying assumption and premise that miscodes result from intentional deception for "concealment of the abortion."[71] Foundational to the study's results and recommendations is the authors' postulation that these miscodes result from patients lying to the emergency department doctors and/or health care workers lying in their coding in order to attribute visits to miscarriages rather than induced abortions. The authors inappropriately assume bad faith of patients and providers[72] and fail to adequately consider the likelihood of human error, given how easy it is to code incorrectly in one of the many claims associated with an ED visit (as described above). By way of example, even if ten codes are used and nine signal miscarriage, if one signals induced abortion, it appears as if the study authors consider the entire visit as purposeful lying or attempts to hide an abortion.

---

[71] Studnicki et al., 2025, *supra* note 64, at p. 6. Relatedly, the authors assert that miscoding has created a problem for reliably researching prevalence rates of abortion complications, stating: "miscoded abortion complications remain invisible to research scientists resulting in large underestimation of actual abortion complications." *Id.* But, as described above, many researchers have used more rigorous methods to assess abortion complications. These researchers have examined actual treatment codes and reviewed comprehensive claims data to see whether an ED visit led to a hospital admission in order to accurately determine complications. *See, e.g.,* FDA/CDER 2016, *supra* note 3; FDA 2024, *supra* note 3; Kulier et al., 2011, *supra* note 2; GenBioPro Petition, *supra* note 2, at pp. 12-14.

[72] Studnicki et al., 2025, *supra* note 64, at p. 6.

3. The Study Lacks Reliable Data to Reproduce or Verify its Results

In addition to the above ways in which the study methodology is obscure and flawed, the study's reliance only on Medicaid administrative data for abortion is unreliable. The study draws data from the CMS Transformed Medicaid Statistical Information System Analytical Files (TAF) for 2016-2021 and from the discontinued Medicaid Analytic eXtract (MAX) files for 2004-2015.[73] However, the use of Medicaid administrative data for abortion rates has been shown to be inaccurate. Research has shown that this dataset is unreliable for abortion-related studies.[74] In a recent study, researchers compared the number of abortions counted in the MAX and TAF datasets to the number of expected abortions covered by Medicaid nationwide and by state. The study found that MAX identified only 11% of expected Medicaid-covered abortions in 2009 and 13% in 2010, while TAF identified 25% of expected Medicaid-covered abortions in 2020, which constituted only 7% of total abortions in the United States for that year.[75] Thus the study authors concluded that these databases significantly undercount abortion covered by Medicaid and cautioned against use of MAX or TAF data for abortion-related research. Given that the Studnicki study relies solely on these databases, both the numerator and denominator used for their article are likely wrong.

CONCLUSION

Standard practices in epidemiology emphasize the importance of transparency in methodological approaches to ensure the reliability, reproducibility, and credibility of research findings.[76]

The issues discussed above reflect just some of the most serious transparency, reproducibility, and methodology problems that make any reliance on the recent EPPC papers, Studnicki study, or other research with similar flaws wholly inconsistent with FDA standards and obligation to rely on sound, gold standard science in its decision-making.

These shortcomings are even more problematic where, as here, claimed findings contradict consistent and overwhelming findings of decades of rigorous, transparent, and

EXHIBIT G

IN THE SUPREME COURT OF THE UNITED STATES

U.S. Food and Drug Administration, *et al.*, *Applicants*	
v.	No. 22A-
Alliance for Hippocratic Medicine, *et al.*, *Respondents*	

DECLARATION OF JANET WOODCOCK, M.D.

I, Janet Woodcock, M.D., of the U.S. Food and Drug Administration (FDA), pursuant to 28 U.S.C. § 1746, declare under penalty of perjury that the following is true and correct to the best of my knowledge:

1. I am the Principal Deputy Commissioner of FDA. I began working at FDA in 1986 in FDA's Center for Biologics Evaluation and Research ("CBER"). From 1994 to 2004 and 2007 to 2020, I served as the Director of FDA's Center for Drug Evaluation and Research ("CDER"). I served as the Acting Commissioner of Food and Drugs from January 20, 2021 to February 17, 2022. During my tenure at FDA, I have also held the positions of Deputy Commissioner, Chief Medical Officer, and Director of the Office of Therapeutics Research and Review in CBER.

2. I received my medical degree from Northwestern University Medical School, and my undergraduate degree from Bucknell University. I have held teaching appointments at Pennsylvania State University and the University of California at San Francisco.

3. CDER regulates over-the-counter and prescription drugs by, among other things, overseeing the development of new and generic medications, evaluating applications for FDA approval, and monitoring drugs' safety once they are marketed.

4. In my role as the Director of CDER, I provided overall direction to all CDER activities to help ensure that safe and effective drug products are available to improve the health of consumers, and that prescription and over-the-counter drug products, both brand name and generic, work effectively and that the health benefits of these products outweigh the known risks.

5. As a result of my experience, particularly through my official duties at FDA, I am familiar with FDA's drug approval process generally and with FDA's ongoing efforts to monitor the safety and efficacy of approved drugs. I am also familiar with Risk Evaluation and Mitigation Strategies, also known as REMS. *See* 21 U.S.C. § 355-1.

6. I am familiar with the new drug application ("NDA") for Mifeprex (mifepristone) Tablets, 200 mg, including the supplemental NDA ("sNDA") approved in 2016, and the abbreviated new drug application ("ANDA") for Mifepristone Tablets, 200 mg approved in 2019.

7. I submit this declaration in support of FDA's Application for a Stay in the above-captioned matter. This declaration is based on my personal knowledge, my background, training, and experience, and my review and consideration of information available to me in my official capacity, including information furnished by FDA personnel in the course of their official duties.

8. FDA-approved drug applications include specified conditions of use that define the scope of the approval. Changing the approved conditions of use of a drug product requires action by both the sponsor and FDA; neither party can make such changes unilaterally. The sponsor must propose the changes in a supplemental application, and FDA must then review and approve the proposed changes. See, e.g., 21 U.S.C. §§ 355, 355-1; 21 C.F.R. § 314.70. FDA may notify the sponsor that changes are required and direct the sponsor to submit them. 21 U.S.C. §§ 355-1(g)(4)(B) and 355(o)(4).

9. Mifeprex has been subject to restrictions on its use since approval in 2000, initially under 21 C.F.R. § 314.520 and later under a REMS under 21 U.S.C. § 355-1. The sNDA that FDA approved in 2016 modified the conditions of use, including the REMS. Those modifications included: changing the dose and dosing regimen for Mifeprex and the second drug in the approved regimen (misoprostol), changing the gestational age for which the product is approved (from through 49 days gestation to through 70 days gestation), requiring only one clinic or office visit rather than three, removing a requirement to administer mifepristone and misoprostol in the office or clinic, providing greater flexibility on the timing and method of follow up care, and allowing any healthcare provider licensed to prescribe medications under state law (rather than just physicians) to become certified to prescribe mifepristone.

10. The Memorandum Opinion and Order issued by the United States District Court for the Northern District of Texas on April 7, 2023 stated, "the Court hereby STAYS the effective date of FDA's September 28, 2000, Approval of mifepristone and all subsequent challenged actions related to that approval – i.e., the 2016 Changes, the 2019 Generic Approval, and the 2021 Actions." Mem. Op. at 67. The District Court stayed its Order until April 15 at 12:01 am, Central Time. I understand that the U.S. Court of Appeals for the Fifth Circuit stayed the District Court's order regarding the 2000 approval of mifepristone, but allowed the District Court's order to go into effect in all other respects. I am informed that this means that FDA's 2016 and subsequent modifications to the conditions of use, including the REMS, will be stayed, absent intervention from this Court. I understand that if the District Court and Fifth Circuit orders go into effect, FDA's approval of Mifepristone Tablets, 200 mg, will be stayed, and FDA's approval of Mifeprex will cover only the conditions of use, including the REMS, that were in place prior to FDA's approval of the 2016 Mifeprex sNDA.

11. I have been informed that the Fifth Circuit's Order assumes that the conditions of use for Mifeprex, including the REMS, could simply snap back to what they were prior to FDA's 2016 approval of labeling changes (including dose and dosing regimen changes) and REMS modification ("2016 action"). The reality is far more disruptive, given the interrelatedness of the REMS and FDA-approved product labeling, among other factors. In this Declaration, I describe the practical consequences and disruption of requiring the conditions of use (including the REMS) to revert to those in place prior to FDA's approval of the sNDA in 2016.

12. Although the 2019 Citizen Petition submitted to FDA by the American Association of Pro-Life Obstetricians and Gynecologists and the American College of Pediatricians did not question the change in the dose and dosing regimen approved in 2016 (*see* Citizen Petition at 1-2, reciting requested actions), and neither court concluded that FDA erred in changing the dose and dosing regimen, based on the Fifth Circuit panel's partial stay opinion, FDA's understanding is that the labeling for Mifeprex would need to be revised to reflect the dose and dosing regimen in place pre-2016. Specifically, reverting to the pre-2016 conditions of use would require the Mifeprex labeling to be changed to reflect that a patient be given a substantially higher dose of mifepristone, and to reflect a different overall dosing regimen for mifepristone and misoprostol (the second drug in the approved dosing regimen) and a lower dose of misoprostol, administered by a different route. Prior to the 2016 supplement approval, the approved Mifeprex labeling included the following approved conditions of use: a 600 mg. dose of mifepristone, followed 48 hours later by a 400 mcg dose of misoprostol, both taken orally. In 2016, the labeling for Mifeprex was revised to reflect the following revised conditions of use: a 200 mg. oral dose of mifepristone, followed 24-48 hours later by a 800 mcg dose of misoprostol administered buccally (dissolved in the cheek pouch). In the absence of a stay, the prescribing

information for medical providers would need to be revised to reflect a dose and a dosing regimen that have not been in place for years and that will be unfamiliar to many certified prescribers today. This also would result in the drug's prescribing information providing for higher doses of mifepristone than what we now know are needed for the intended use.

13. The conditions for use (including the REMS) are reflected in multiple documents: the FDA-approved prescribing information, the Medication Guide, the REMS Document (which sets out the REMS requirements), the Prescriber Agreement Form, and the Patient Agreement Form. In the absence of a stay, the sponsor would be required to submit a supplement to revise all these documents and obtain FDA approval in order to distribute a product whose labeling conforms with the pre-2016 conditions of approval (including the REMS) and the District Court's and Fifth Circuit's orders.

14. The Prescriber Agreement Form, which is part of the REMS, would need to be changed, because the current Prescriber Agreement Form imposes different requirements from the Prescriber Agreement Form pre-2016. For example, the pre-2016 prescribing guidelines describe the need for a follow-up visit at approximately 14 days after treatment, and a requirement for prescribers to report any serious adverse events to the sponsor. By signing the Prescriber Agreement Form, a prescriber agrees to follow those guidelines. At least some current prescribers likely never completed the Prescriber Agreement Form that was approved pre-2016, because they did not become certified prescribers until 2016 or later, or even if they did, they would have subsequently signed the newer Prescriber Agreement Form, thereby agreeing to different terms. The combination of the District Court's and Fifth Circuit's orders thus arguably requires all current prescribers to be re-certified. And if the scope of the stay pending appeal is later revised, they may need to become recertified again.

15. There are significant practical consequences for the sponsor to change the above-described documents. In the absence of a stay, when the administrative stay expires, the sponsors' drug products immediately would become misbranded and thus unlawful to introduce in interstate commerce. The FDCA requires that drugs bear labeling containing adequate directions for use. 21 U.S.C. § 352(f)(1); 21 C.F.R. 201.5 (defining "adequate directions for use" as "directions under which the layman can use a drug safely and for the purposes for which it is intended"). For prescription drugs, like mifepristone, adequate directions for use cannot be written for a layperson. *See* 21 U.S.C. § 353(b)(1). Thus, all prescription drugs are misbranded under 21 U.S.C. § 352(f)(1) unless they fall within one of the exemptions from the requirement for adequate directions for use, *see, e.g.*, 21 C.F.R. § 201.100(c)(2). As a result of the courts' orders, Mifepristone Tablets, 200 mg, will be misbranded because FDA's approval of the generic application will be stayed. A new approval would be required unless the District Court's stay of the approval is lifted. And as a result of the courts' orders, Mifeprex also will be misbranded until the sponsor submits a supplemental application proposing changes to the conditions of use consistent with the courts' orders, FDA reviews and approves that supplement, and the sponsor incorporates those changes into the labeling and packaging for the product. The sponsor would also need to post and disseminate new Prescriber and Patient Agreement Forms and, as noted above, most prescribers would need to become recertified. Difficult and novel questions would need to be resolved, such as whether the combination of the courts' orders compels reversion to the pre-2016 labeling for Mifeprex even though it contains information that is now scientifically out-of-date, for example, by failing to reflect current scientific data on the safety and efficacy of the drug. It would also require FDA to reinstate a superseded dosing regimen, requiring a substantially *higher* dose of the drug than FDA has deemed necessary. We estimate that this

process would take months, at minimum, due to the logistics of effectuating such changes, including Danco's printing of new drug labels and labeling. And if a later court order reinstates the scope and conditions of FDA's Mifeprex approval as of 2023, the sponsor and FDA would need to start this process over again, with the sponsor crafting and submitting a new sNDA and, once approved, printing new labels and labeling once again while prescribers adjust again to changes in the approved dosing regimen.

16. The Fifth Circuit's partial stay order also will, if allowed to remain in place, create significant chaos for patients, prescribers, and the health care delivery system. As noted above, I have been informed that the order will result in Mifeprex being misbranded overnight and will stay the approval of the generic product (issued in 2019) altogether, leaving prescribers, patients, and the health care delivery system to face substantial uncertainty as to the legal status and appropriate options with regard to existing stores of the drug.

Dated: April 14, 2023

Janet Woodcock, M.D.
Principal Deputy Commissioner
United States Food and Drug Administration

EXHIBIT H

January 31, 3025

CITIZEN PETITION

Pursuant to 21 C.F.R. § 10.30, the American College of Obstetricians and Gynecologists, Society of Family Planning, and Society for Maternal-Fetal Medicine submit this petition, together with an appendix of supporting studies and documents, to request that the Food and Drug Administration ("FDA"): (1) remove the Mifepristone Shared System Risk Evaluation and Mitigation Strategy ("REMS"), including all of its Elements to Assure Safe Use ("ETASU"); or (2) in the alternative, at a minimum, refrain from taking any action that would further reduce patient access to mifepristone[1] and/or increase the burdens associated with prescribing or dispensing mifepristone.

Over more than two decades, hundreds of medical studies and vast amounts of data have confirmed that mifepristone, in combination with misoprostol, is a safe and effective way to terminate an early pregnancy. The scientific evidence is overwhelming: major adverse events occur in ***less than 0.32%*** of patients.[1] The risk of death is almost non-existent. Few drugs have been so extensively studied after their approval by FDA and few can boast such a clear and compelling record of safe use. Access to mifepristone enables practitioners to provide safe, medically-appropriate, evidence-based, and effective care. Indeed, mifepristone, in combination with misoprostol, constitutes the most common form of abortion in the United States, accounting for nearly two out of every three abortions.

[1] Petitioners use "mifepristone" herein to refer to both Mifeprex (NDA 020687) and its generic (ANDA 091178).

FDA itself determined in 2016, based on more than 2.5 million uses, that the drug's "efficacy and safety have become well established by both research and experience, and serious complications have proven to be extremely rare."[2] Yet, despite this record, FDA continues to subject mifepristone to unique regulatory requirements that impose burdens on health care providers and hamper patients' access to this medication. Particularly in light of rising maternal mortality across the country, access to mifepristone is a crucial component of comprehensive reproductive health care. Leading medical associations agree that, given mifepristone's outstanding safety record and its critical importance for reproductive health care, it is past time for FDA to fully lift the mifepristone REMS.[3] Consistent with this medical community consensus, Petitioners respectfully request that FDA eliminate its existing medically unnecessary barriers to mifepristone, or at minimum, take no further steps that would reduce access to this safe, essential medication.

ACTION REQUESTED

Petitioners request that FDA remove the Mifepristone Shared System REMS Program, including but not limited to the three ETASU requiring prescriber certification, pharmacy certification, and a patient agreement form. In the alternative, Petitioners request that FDA, at a minimum, take no action imposing greater burdens on patient access to mifepristone, and no action increasing burdens on the health care system relating to the provision of mifepristone, including but not limited to (a) adding new ETASU, (b) reinstating former mifepristone ETASU that are not currently part of the January 2023 REMS, (c) making the existing ETASU more onerous, or (d) modifying the REMS or labeling for mifepristone in a manner inconsistent with prevailing standards of evidence-based care.

STATEMENT OF GROUNDS

A. Mifepristone is extremely safe

Twenty-five years ago, FDA approved mifepristone (under the brand name Mifeprex) as part of a two-drug regimen for medication abortion.[4] In that regimen, which now is FDA-approved through ten weeks of pregnancy, mifepristone blocks a hormone necessary to sustain pregnancy, and misoprostol causes contractions and bleeding that empty the uterus.[5] As of December 31, 2024, approximately 7.5 million U.S. patients had used this regimen for medication abortion.[6] High-quality studies also support the use of mifepristone with misoprostol specifically for managing early pregnancy loss.[7]

While all abortion is very safe, FDA acknowledges that medication abortion with mifepristone provides a "meaningful therapeutic benefit" to some patients and may be "preferable and safer in [a patient's] particular situation."[8] Some patients, for instance, who have been the victims of rape or sexual assault may prefer to avoid the use of medical instruments in a procedural abortion; others may have uterine abnormalities that are contraindications for procedural abortion; still others may use medication abortion to avoid the risks of any anesthesia or sedation associated with abortion procedures.

As is the case for all drugs sold in the United States, the FDA-approved labeling for mifepristone warns of the drug's risks.[9] For mifepristone, the boxed warning in the labeling lists: "serious and sometimes fatal infections or bleeding," both of which FDA accurately described in 2016 as "exceedingly rare, generally far below 0.1% for any individual adverse event."[10] As the labeling makes plain, these risks arise whenever the pregnant uterus is evacuated, whether by "miscarriage, surgical abortion, medical abortion, or childbirth."[11] The labeling confirms: "[n]o causal relationship between the use of [Mifepristone tablets 200mg] and misoprostol and [serious infections and bleeding] has been established."[12] Indeed, FDA concluded in 2016 that the "critical

risk factor" for certain rare serious infections following mifepristone use "[wa]s pregnancy itself," not the medication.[13] After nearly 25 years of mandatory reporting of deaths potentially associated with mifepristone, the associated fatality rate is 0.00048%—and not one of the infinitesimally small number of deaths can be "causal[ly]" attributed to mifepristone.[14]

Mifepristone is as safe or safer than common drugs like Tylenol, Viagra, and penicillin—some of which are sold without a prescription and none of which has a REMS.[15] And mifepristone is far safer than hundreds of opioid analgesics that are subject to *less stringent* ETASU than mifepristone, even as opioids claim lives at such "a staggering rate" that they are "reducing life expectancy in the United States."[16]

B. Mifepristone's safety profile has remained strong and stable even after FDA removed certain medically unnecessary restrictions

Mifepristone's safety record has remained remarkably stable since FDA's original approval in 2000, including after FDA lifted some of its initial restrictions on the drug.

Since acknowledging in 2016 that mifepristone's safety profile is "well-characterized" and "has not changed over the period of surveillance,"[17] FDA has made three principal changes to the mifepristone REMS: (1) in 2016, FDA allowed all health care professionals with prescriptive authority under state law to become certified prescribers; (2) that same year, FDA eliminated the requirement that prescribers report serious adverse events potentially associated with mifepristone other than death; and (3) in 2021, FDA suspended and then, in 2023, permanently lifted the requirement that mifepristone be dispensed to patients only in person at a hospital, clinic, or medical office. In addition, in 2016, FDA made numerous changes to mifepristone's labeling, including updating the dosing and the route of misoprostol administration, removing the indication for multiple follow-up visits, and changing the gestational age indication from 49 days to 70 days.

There is no evidence that eliminating any of the former REMS restrictions (or changing

the label indications) reduced mifepristone's safety.[18] To the contrary, and as further detailed below, high-quality research and real-world data from both the United States and globally confirm that mifepristone remains one of the safest medications used in medical practice.[19]

1. Mifepristone is safe when prescribed and dispensed by qualified advanced practice clinicians

In 2016, FDA correctly concluded that advanced practice clinicians ("APCs") with prescriptive authority under state law could safely prescribe and dispense mifepristone. When FDA implemented this change, it relied upon three randomized controlled studies[20] and one comparative study[21] to support the conclusion that medication abortion is safe and effective when provided by APCs.[22] The success rates for medication abortions provided by APCs were greater than 96% across all the studies, and were similar to the success rates for physician-prescribed abortions.[23]

Since then, additional high-quality, peer reviewed studies further confirm FDA's 2016 finding that mifepristone remains safe and effective when prescribed and dispensed by qualified nonphysicians. A comprehensive, peer-reviewed review of the safety and effectiveness of medication abortion, conducted by the National Academies of Science, Engineering, and Medicine—an independent organization dedicated to providing objective expert advice on scientific, engineering and medical issues to inform public policy—concluded that "both trained physicians (OB/GYNs, family medicine physicians, and other physicians) and advanced practice clinicians (APCs) (physician assistants, certified nurse-midwives, and nurse practitioners) can provide medication and aspiration abortions safely and effectively."[24] A retrospective observational cohort study of medication abortion between 2009 to 2018 concluded that the safety and effectiveness of APC-provided medication abortion are within the established medical benchmarks.[25] And in the event that uterine aspiration is needed to complete the evacuation of a patient's uterus, studies show that the very low complication rate for aspiration procedures is "not

significantly different" whether performed by an APC or by a doctor.[26] The latter finding is consistent with research comparing the safety of aspiration abortion procedures when performed by physicians and APCs.[27]

Moreover, rescinding the ability of APCs to prescribe mifepristone would burden patient access by reducing the number of certified prescribers without increasing safety or efficacy.[28] And the burden would fall most heavily on underserved rural and remote populations.[29] Given the significant data showing that APCs offer improved access without compromising safety or efficacy, there is no reason for FDA to restrict the ability of APCs to provide medication abortions where permitted by state law.

2. The elimination of the in-person dispensing ETASU did not impact the safety of mifepristone

Telehealth for medication abortion is now a standard method of providing abortion care in the United States and around the world.[30] As in other areas of medicine provided by telehealth, reproductive health clinics and providers have developed specific protocols and technologies for telehealth care to ensure adequate patient contact and monitoring, such as health questionnaires, specialized patient platforms (*e.g.*, a patient "portal"), messaging and chat functions, and phone or video calls, all of which enable care to be provided with fewer or no in-person visits.

Critically, telehealth protocols for medication abortion offer the same patient protections as in-person dispensing and provide an equivalent level of patient care. Just as would happen during in-person care, patients are evaluated by a clinician who screens the patient to confirm pregnancy (relying on, *e.g.*, medical history, self-reported symptoms, and results of an at-home pregnancy test), assesses the duration of pregnancy, and identifies contraindications such as a potential ectopic pregnancy or other medical conditions or drug allergies.[31] Where clinically appropriate, the patient is advised to obtain in-person testing before proceeding.[32]

After the patient's eligibility for medication abortion has been confirmed and the patient has provided informed consent, the clinician either sends the appropriate medications to the patient directly or transmits a prescription to a mail-order or retail pharmacy.[33] And just as would happen during in-person care, the clinician advises the patient about follow-up care, including instructions for confirming that the pregnancy has terminated and what to do if they experience signs and symptoms of complications.[34] The percentage of patients that visit an emergency room for *any* abortion-related reason is exceedingly small,[35] and, as detailed below, the manner in which mifepristone is prescribed or dispensed does not alter its safety profile.

a. *Telehealth medication abortion is safe and effective*

After reviewing (a) REMS assessment data, (b) data from FDA's Adverse Event Reporting System ("FAERS") during the period when the in-person dispensing ETASU was not being enforced during the COVID-19 pandemic, and (c) numerous published studies, FDA concluded in December 2021 that "mifepristone will remain safe and effective for medication abortion if the in-person dispensing requirement is removed."[36] Specifically, FDA's analysis relied upon six studies that "generally support a conclusion that dispensing by mail is safe."[37] FDA stated that it would permanently remove the in-person dispensing requirement to "render the REMS less burdensome to healthcare providers and patients," enabling prescribers to provide medication abortion by telehealth where permitted by state law.[38] FDA formalized that change when it published the updated REMS in January 2023.

FDA's decision to eliminate this ETASU was strongly supported by the scientific evidence available as of December 2021. Research published since then further confirms that direct-to-patient telemedicine for medication abortion is safe and effective.[39]

For instance, a peer-reviewed study of over 6,000 telehealth patients in 20 states and Washington DC treated by three different online clinics between April 2021 and January 2022 found that "telehealth for abortion is effective and safe, with [safety and efficacy] rates similar to in-person care."[40] This study evaluated both "synchronous" telehealth care (where the provider communicates with the patient either by video or phone call) and "asynchronous" telehealth care (where the communication is by text message),[41] and further found that both "synchronous and asynchronous care are comparably effective and safe."[42] Specifically, the rates for both serious adverse events (0.25%) and ectopic pregnancy (0.14%) were "similar to previous studies of in-person medication abortion care," published in 2013 to 2015, which had found adverse event rates of 0.2–0.5%, and ectopic pregnancy rates of 0.2%.[43]

Other high-quality studies have come to similar conclusions. For instance, one study that compared in-person medication abortion care with telehealth care without in-person diagnostic or screening tests concluded that "medication abortion [performed through] telehealth screening and mail-order pharmacy dispensing of medications was associated with similar rates of complete abortion as in-person care with ultrasonography, met the prespecified threshold for noninferiority, and had low rates of [adverse events] overall."[44] A smaller study of medication abortion in primary care settings found that medication abortion provided by telehealth was "as effective, timelier and potentially more accessible than in-clinic care."[45] Another study comparing abortion outcomes between screening approaches across five telehealth sites showed no difference in serious adverse events between patients who received pre-abortion ultrasound or pelvic exams and those who did not.[46] And a systematic review and meta-analysis of the literature on medication abortion by telehealth confirms that telehealth abortion care is as safe and effective as in-person care, with a "shorter waiting time for medication delivery."[47]

All of these studies confirm that FDA was correct in determining that removal of the in-person dispensing requirement did not impact the safety and effectiveness of medication abortion.

b. *Telehealth for medication abortion improves access to care with high patient satisfaction*

At the same time, research also confirms that the availability of medication abortion by telehealth improves patient access to mifepristone and reduces burdens on the health care delivery system while maintaining or improving patient satisfaction. Accordingly, any reversion to an in-person dispensing requirement would burden patient access and the health care system, contrary to the statutory standards that govern FDA's imposition of ETASU. *See* 21 U.S.C. § 355-1(f)(2).

Telehealth increases access to abortion care by eliminating the need to travel to a health care provider. Thus, it offers a particular benefit for patients living in rural and medically underserved areas where there is no access to in-person abortion care,[48] as well as for patients who find it challenging to take time off from work or arrange for childcare in order to travel for abortion care.[49] Without associated travel, patients do not have to incur any expenses for transportation, gas, and lodging, incur fewer expenses for child care, and lose fewer wages.[50] In other words, telehealth eliminates or mitigates many of the burdens that can deter and delay abortion access for the low-income populations that comprise a majority of abortion seekers.[51] Telehealth also reduces delays in obtaining care because it enables patients to avoid long wait times at physical clinics[52]—a particularly urgent concern since *Dobbs v. Jackson Women's Health Organization*, as state abortion bans have increased demand for abortion care in many states where abortion remains lawful.[53] Reinstating in-person dispensing—which would lead to even more in-person visits at brick-and-mortar clinics already stretched thin—would increase burdens on the health care system and impede patient access.

Docusign Envelope ID: 46AF7693-3C4C-4C75-B832-DB4C87E29467

Even without considering the time and expense of having to travel for abortion care, medication abortion care is typically more affordable for patients when provided through telehealth than through in-person care.[54] In 2023, pricing data collected from brick-and-mortar clinics that offered both in-person and telehealth care revealed that they were able to offer telehealth abortion services at a lower rate than in-person medication abortion services.[55] Given the longstanding prohibition on using federal funds to pay for abortion, managing the cost of abortion care is essential to ensure that patients with fewer resources are able to access the care they need.

In general, telehealth offers many opportunities for patients and providers to build trust and rapport—and that observation holds true in the context of medication abortion. In a qualitative study of 1,600 patients who received abortion care through telemedicine, "nearly all participants were very satisfied with telehealth abortion," with 98% of those surveyed reporting that they trusted their provider.[56] Patients further reported that choosing telehealth not only made abortion care more accessible, but also allowed them to receive care more quickly and with greater privacy in the comfort of their own home.[57]

Studies also show that telehealth abortion care offers patients other significant advantages. In a survey of medication abortion patients, those who received services by telehealth felt that the option "allowed them to talk more freely and openly, and feel more confident about the privacy of their abortion decision."[58] Indeed, a recent qualitative study of telehealth patients found that telehealth mitigates some manifestations of abortion stigma by eliminating the need to visit a physical clinic and thus reducing the visibility of one's abortion decision.[59] This benefit is all the more essential given increased rates of anti-abortion violence and harassment at brick-and-mortar clinics—violence and harassment specifically designed to deter or prevent access to reproductive

Docusign Envelope ID: 46AF7693-3C4C-4C75-B832-DB4C87E29467

care.[60] In short, depriving mifepristone patients of the telehealth option would impede patient access in violation of FDA's congressional mandate not to impede access.

3. Evidence supports FDA's elimination of non-fatal mandatory adverse event reporting for mifepristone

FDA determined in 2016 that it was unnecessary to require prescribers of mifepristone to report non-fatal adverse events following the use of mifepristone given mifepristone's stable risk profile reflected in 15 years of mandatory serious-adverse-event reporting.[61] Since then, multiple data sources confirm that mifepristone continues to be extremely safe. FDA correctly lifted the broad adverse-event reporting requirement in 2016, and the ongoing requirement that mifepristone prescribers report the miniscule number of deaths following mifepristone use is extraneous.

First, FDA continues to collect data on adverse events for mifepristone through multiple data sources, including FAERS and case reports in published medical literature, just as it does for other drugs. *See* 21 U.S.C. § 355(k); 21 C.F.R. §§ 314.80, 314.81. FDA regularly relies upon stable FAERS data in determining whether a REMS may be removed.[62] Second, the medical literature shows an adverse event rate for mifepristone when prescribed pursuant to updated standards of evidence-based care, and in the absence of prior REMS requirements, that is comparable to the real-world clinical data reported to FDA prior to 2016. For example, a recent large prospective cohort study of over 6,000 patients who obtained medication abortion by telehealth had a serious adverse event rate of only 0.25%, comparable to the rate for in-person care included in the mifepristone labeling based on pre-2016 studies.[63] In other words, there is no reason to believe that the complication rate materially changed following the elimination of the pre-2016 adverse event reporting requirement. And, given the infinitesimal death rate associated with (and not proven to be caused by) mifepristone after millions of uses and decades of mandatory reporting, there is likewise no reason to maintain this special REMS reporting requirement.

C. A REMS is not necessary to ensure that mifepristone's benefits outweigh its risks, and the mifepristone ETASU do not fit the statutory profile

Given mifepristone's safety, FDA has not gone far enough in eliminating burdensome, medically unnecessary restrictions on this safe medication. As detailed below, the prescriber certification, patient agreement, and pharmacy certification ETASUs do not enhance safety—but *do* impede patient access and burden the health care delivery system. Indeed, FDA still regulates mifepristone more stringently than nearly any other of the 20,000 drugs it regulates. Unlike the 97% of prescription drugs without a REMS—including, to take just two examples, Viagra (with a fatality rate six-times that of mifepristone) and Jeuveau (a drug that temporarily improves the appearance of wrinkles and whose labeling features a black-box warning of "life threatening" breathing difficulties)—mifepristone is among the tiny fraction of medications subject to such regulation, alongside highly addictive and dangerous opioids.

A REMS is not necessary for mifepristone under the statutory scheme Congress has mandated to guide FDA's balancing of a medication's risks and benefits. Specifically, a REMS is permitted only if "necessary to ensure that the benefits of [a] drug outweigh [its] risks…." 21 U.S.C. § 355-1(a)(1); *accord id.* § 355-1(g)(4)(B)(i). Among other factors, Congress directed FDA to consider the "seriousness of any known or potential adverse events" and "the background incidence of such events in the population likely to use the drug, *id*.—a particularly meaningful consideration here since the serious adverse events associated with mifepristone are risks of "pregnancy itself."[64] Congress further limited FDA's authority to impose ETASU, permitting them only where "necessary to assure safe use of the drug, because of its inherent toxicity or potential harmfulness," and only where "required as part of [a] strategy to mitigate a specific serious risk listed in the labeling of the drug." 21 U.S.C. §355-1(f)(1). Moreover, ETASU may be imposed only when they are "commensurate with the specific serious risk[s] listed in the labeling"; must,

"to the extent practicable," "conform with [ETASU] for other drugs with similar, serious risks"; and may "not be unduly burdensome on patient access," "considering in particular … patients who have difficulty accessing health care (such as patients in rural or medically underserved areas)." *Id.* §355-1(f)(1)-(2). Petitioners respectfully submit that the mifepristone REMS and ETASU do not meet these statutory requirements.

1. Prescriber Certification

The Prescriber Certification ETASU requires would-be prescribers to fax a form to the drug distributor attesting that they can date a pregnancy and diagnose an ectopic pregnancy; can ensure patient access to a uterine evacuation procedure in cases of incomplete abortion or severe bleeding and to medical facilities equipped to provide blood transfusions and resuscitation if necessary; and have read and understood the prescribing information. Clinicians also agree to review the Patient Agreement with the patient, answer the patient's questions, obtain a signature, retain the signed form, and provide the patient a copy; and (as discussed in Section B.3, above), to report any patient deaths to the drug sponsor. As of 2023, this ETASU also requires clinicians to fulfill certain obligations if a pharmacy will dispense the mifepristone, including providing the pharmacy with their signed Prescriber Certification form and communicating directly with the pharmacy if the pharmacy cannot ensure delivery within four calendar days.

For 99.5% of the over 20,000 prescription drugs it regulates, FDA does not impose a prescriber certification ETASU.[65] This is true even for drugs that, unlike mifepristone, require diagnostic tests or special screening before they can be safely prescribed. FDA has retained the Prescriber Certification ETASU because it assumes that certification is necessary to assure that only qualified providers will prescribe mifepristone.[66] The facts, however, show otherwise. For instance, in 2017, Canada removed its REMS-like requirements, which included a prescriber certification requirement. While eliminating those restrictions significantly increased access to

Docusign Envelope ID: 46AF7693-3C4C-4C75-B832-DB4C87E29467

mifepristone, it had no negative impact on mifepristone's safety or efficacy.[67]

Contrary to FDA's assumption, the Prescriber Certification ETASU is unnecessary to assure that health care professionals prescribe mifepristone only when competent to do so because *all* clinicians are ethically obligated to provide only medically necessary and appropriate care within the scope of their training and competence.[68] There are countless medications not subject to a Prescriber Certification ETASU that can be safely prescribed only when the clinician makes a proper diagnosis, screens for contraindications, and provides instructions for any necessary follow-up or emergency care—and there is nothing unique about prescribing mifepristone that makes this burdensome ETASU necessary. To the contrary, as Petitioner ACOG noted in a letter to FDA nearly a decade ago, "[a] standard clinical license should be sufficient to ensure that a practitioner meets qualifications for prescribing mifepristone."[69] Nor is it necessary to assure that a health care professional will obtain a patient's informed consent for mifepristone when medical ethics and professional guidelines already require informed consent as an essential practice across all areas of medicine, including abortion care.[70] Indeed, FDA has recognized that there is "strong adherence to evidence-based guidelines" by clinicians who provide abortion care.[71]

The Prescriber Certification ETASU also impedes patient access to mifepristone by chilling a health care provider's decision to offer this medication. Nearly one in ten OBGYNs responding to a survey of Petitioner ACOG's members were deterred from prescribing mifepristone because of the requirement that they register with the drug sponsor.[72] A qualitative survey of family practitioners concluded that removal of the in-person dispensing requirement would not eliminate the distinct deterrent effect of prescriber certification on would-be prescribers.[73]

It is well-documented that many would-be prescribers do not register to prescribe mifepristone because they fear anti-abortion threats and violence if their registrations became

public.[74] Moreover, the Pharmacy Certification ETASU requires prescribers to send their certification form to every pharmacy that will dispense mifepristone to their patients and requires the pharmacy to keep that form on file. Notwithstanding the important confidentiality safeguards contained in the Pharmacy Certification's ETASU requirement, this protocol multiplies the possibility of a data breach and amplifies providers' concerns for their safety and the safety of their families. In the aftermath of the *Dobbs* decision, acts of anti-abortion violence and harassment have increased dramatically in states where abortion access is protected by state law.[75] The Prescriber Certification ETASU persists in deterring providers from prescribing mifepristone and impeding patient access.

2. Pharmacy Certification

The Pharmacy Certification ETASU is largely a means of enforcing the Prescriber Certification requirement by "ensur[ing] that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers."[76] As detailed above, there is no valid reason for maintaining Prescriber Certification, undermining any justification for this derivative ETASU. Meanwhile, the Pharmacy Certification ETASU compounds the burdens on providers and the health care delivery system. As Petitioners and other commenters have previously warned, the extra costs and administrative burdens that this ETASU imposes on pharmacies disincentivizes pharmacies from dispensing mifepristone—an assessment that FDA seemingly shared when it found that the Pharmacy Certification would "likely limit" "pharmacies choosing to certify."[77]

Critically, FDA has not reckoned with the significant burdens the Pharmacy Certification ETASU imposes on patients—particularly those who already face significant obstacles in obtaining needed health care—despite a statutory requirement to assess those burdens. *See* 21 U.S.C. §355-1(f)(2)(C)(ii). First, the strong disincentivizing effect of the ETASU on brick-and-mortar pharmacies leaves telehealth patients dependent on mail-order (*i.e.*, online) pharmacies to

Docusign Envelope ID: 46AF7693-3C4C-4C75-B832-DB4C87E29467

access mifepristone. While it is critical that patients retain the option to have their mifepristone mailed to them, this model does not work for everyone, as Petitioners' members see in their practices. Individuals who lack stable housing may not have a physical address to which a package can be securely and confidentially mailed. Patients experiencing abuse in their household may not be able to rely on mail delivery if they need to keep their pregnancy and abortion decision confidential for their own safety. Patients who lack facility with computers[78] or who lack reliable internet access, such as those living in rural areas, are more likely to depend on neighborhood retail pharmacies to access mifepristone. In such situations, the inability to use an online pharmacy may impede access altogether.

Moreover, the Pharmacy Certification ETASU places significant burdens on the health care delivery system by, for example, mandating that pharmacies either ensure delivery to the patient within four days of receiving the prescription or contact the prescriber to confirm that later delivery is acceptable. In their discussions with FDA, the drug sponsors noted that this means a default of "two-day or next day shipping," and noted concerns about the resulting "affordability of shipping services."[79] Indeed, this four-day requirement makes expedited delivery the default option—effectively increasing shipping costs for all patients—even when delivery on a longer timeline is clinically appropriate. To be sure, Petitioners are deeply invested in ensuring timely access to health care. But mifepristone is no different from the countless other time-sensitive medications dispensed through pharmacies without a Pharmacy Certification ETASU mandating such deadlines.[80] As the sponsors made clear, "the professional practice of pharmacy requires that pharmacies promptly dispense products to patients upon receiving the prescription or swiftly communicate with the patient and prescriber if that is not possible within the appropriate clinical window."[81] And FDA found no increase in adverse events when mail-order pharmacies dispensed

mifepristone during the COVID-19 pandemic with no delivery-date mandate.[82] At bottom, while timely access to health care is certainly critical, it is not in mifepristone patients' best interests for FDA to impose delivery restrictions that needlessly increase the cost of abortion care and deter pharmacies from dispensing this medication.

Additionally, the Pharmacy Certification ETASU means that prescribers cannot simply issue a prescription to the patient's preferred pharmacy location, as they do with virtually all other medications (including other time-sensitive medications). Instead, they have to contact any pharmacy their patients may seek to use in order to identify one that is certified to dispense mifepristone. As a practical matter, since so few pharmacies are certified, the Pharmacy Certification ETASU results in additional burdens and delay.

3. Patient Agreement

The Patient Agreement ETASU requires the patient to sign an FDA-approved form stating that they are taking mifepristone because they have "decided ... to end [their] pregnancy," that they will follow a particular clinical protocol, and that they understand when and how to seek follow-up or emergency care. Notably, in 2016, FDA's own scientific review team determined that this ETASU was "duplicative" of the Medication Guide that every patient receives and "does not add to safe use conditions" and, accordingly, recommended its elimination.[83] However, FDA's Commissioner at the time overrode the review team's recommendation, leading FDA to maintain this ETASU.[84]

In choosing to again retain this requirement in 2023, FDA speculated that *new* mifepristone prescribers might not provide appropriate counseling and obtain informed consent absent the Patient Agreement ETASU.[85] FDA's speculation, however, cannot be reconciled with the Agency's recognition that, in general, "informed consent in medicine is an established practice."[86] As noted above in Section C.1, informed consent is part of the professional guidelines governing abortion

care.[87] And, as FDA recognizes, the "same risk information" contained in the Patient Agreement is contained in the Medication Guide that all patients receive.[88] FDA did not identify any evidence suggesting that new prescribers of mifepristone would shirk these professional norms; in fact, the Agency routinely approves entirely new drugs without a patient agreement ETASU, even though every prescriber will be unfamiliar with that new medication. This evidence justifies "remov[ing] this REMS requirement[] . . . based on the integration of the REMS safe use condition into clinical practice,[89] as the Agency has done for other drugs.

FDA acknowledged in 2016 that the Patient Agreement ETASU "is a burden for patients."[90] It can also be a burden for qualified health care providers who seek to prescribe mifepristone, since they often must struggle with administrative complexities associated with integrating the Patient Agreement form into existing clinical record systems.[91] In the course of its reviews of the mifepristone REMS, the Agency has never explained why it believes this ETASU's burdens are essential to ensure that mifepristone's benefits outweigh its risks.

D. FDA should have reviewed *all* relevant data in its most recent REMS review

During FDA's most recent REMS review, FDA excluded from consideration information that was directly relevant to the Agency's statutory obligation to ensure that an ETASU is "not … unduly burdensome on patient access" (especially for those patients in "rural or medically underserved areas"), as well as the requirement that FDA "minimize the burden on the health care delivery system" when imposing ETASU. 21 U.S.C. §§ 355-1(f)(2)(C), (D).[92] That information included input from Petitioners and other associations of health care professionals on the burdens imposed by the REMS, as well as "[d]ata on the logistics of accessing abortion care in general, such as time to appointment or the distance traveled to obtain care."[93]

These exclusions prevented FDA from accurately assessing the burdens that the mifepristone ETASU impose on patient access and the health care system. Petitioners respectfully

Docusign Envelope ID: 46AF7693-3C4C-4C75-B832-DB4C87E29467

submit that this was a significant misstep, which deprived FDA of information directly relevant to the applicable statutory requirements. Petitioners therefore urge FDA to revisit this highly relevant evidence from 2022 or earlier as well as the more recent evidence cited above confirming that mifepristone remains extremely safe and effective after FDA's 2016 and 2023 changes to the REMS and mifepristone label and that those regulatory updates reduced needless burdens.

E. In the alternative, and at an absolute minimum, FDA must maintain the status quo with respect to mifepristone

At the very minimum, based on the evidence detailed above of mifepristone's ongoing safety and efficacy, there is no medical basis to further restrict access beyond the status quo as of January 2023 by, for instance, reinstating any previously withdrawn ETASU; increasing the burdens of the existing ETASU; imposing a new ETASU; or modifying the mifepristone labeling to be inconsistent with prevailing standards of evidence-based care. As discussed in Section B, numerous high-quality studies show that mifepristone's safety profile remained strong and stable even after FDA removed the special non-fatal adverse-event reporting requirement, permitted APCs to independently prescribe mifepristone where permitted by state law, and eliminated the in-person dispensing requirement. To be sure, anti-abortion activists have pointed to other publications in support of their efforts to reinstate previous, superseded ETASU, such as the five articles attached to the complaint in *Alliance v. Hippocratic Medicine*, No. 2:22-cv-00223-Z (N.D. Tex.). But as FDA recognized at the time, none of these articles contains "safety data relevant to" the removal of the in-person dispensing requirement.[94]

Conversely, the evidence is clear that reinstating the prior ETASU would impede patient access. For example, one recent study found that telehealth plays an "instrumental role in obtaining an abortion among patient populations who are known to face the most structural barriers to abortion care," particularly "those residing in rural areas, and those who resided far from an

abortion facility."[95] Reinstating the prior ETASU would demonstrably impede patient access, particularly for "patients who have difficulty accessing health care," in violation of the statutory command of 21 U.S.C. § 355-1(f)(2).

ENVIRONMENTAL IMPACT

Petitioners' proposal is categorically exempt from the requirement of an environmental impact statement under 21 C.F.R. § 25.31(a) or 21 C.F.R. § 25.31(b).

ECONOMIC IMPACT

No information required at this time.

CERTIFICATION

Petitioners certify that, to the best of our knowledge and belief, this petition includes all information and views on which the petition relies, and that it includes representative data and information known to the petitioners which are unfavorable to the petition.

EXHIBIT I

October 6, 2025

Martin Makary, MD, MPH
U.S. Food and Drug Administration
10903 New Hampshire Ave.
Silver Spring, MD 20993-002

Dear Commissioner Makary,

We submit this comment in support of pending citizen petitions (FDA2025-P-0377-0001; FDA-2025-P-1576-0001; FDA-2025-P-2162-0001) regarding FDA regulation of mifepristone. We support Petitioners' request that the Food and Drug Administration (FDA): (1) remove the Mifepristone Shared System Risk Evaluation and Mitigation Strategy (REMS), or (2) in the alternative, at a minimum, refrain from taking any action that would further reduce patient access to mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone.

We conduct research on access to mifepristone as part of the Reproductive Health Outcomes and Disparities (RHOADs) Research Lab at the University of Chicago, which works to generate new knowledge to improve reproductive health care and outcomes and reduce racial and socioeconomic disparities. As part of this work, we have researched the use of a learning collaborative to support evidence-based use of mifepristone for early pregnancy loss and abortion in primary care and have conducted research to explore the provision of mifepristone across other settings. We have expertise in providing mifepristone, training others to provide it, and researching barriers and facilitators to access in diverse settings, including telehealth, pharmacy, and primary care.(1–6)

Mifepristone is among the most thoroughly studied medications approved by the FDA, with a strong scientific consensus affirming its safety and effectiveness, as outlined in Citizen Petition FDA-2025-P-0377-0001. Beyond the safety and efficacy of mifepristone, its availability, along with the drug misoprostol, has expanded access to abortion; the most recent research suggests that medication abortion makes up more than 60% of abortions in the U.S.(7) Additional regulations on mifepristone or removal of FDA approval could dramatically reduce access to abortion, delaying care, or preventing access entirely.

Our research and that of others has found that prior ETASU requiring in-person dispensing created barriers to access, including reducing the number of qualified mifepristone providers.(1,5,8–11) For instance, a national study of ob-gyns conducted before the in-person dispensing requirement was lifted found that among those not providing medication abortion, 28% said they would if they could write a prescription for mifepristone.(8) Similarly, interviews with ob-gyns in Massachusetts found that the most common barriers to using mifepristone to manage early pregnancy loss were barriers related to the REMS program.(9,12)

Among primary care providers, the REMS requirements have also been cited as barriers to integrating mifepristone into regular care. One 2019 study among primary care providers interested in reproductive health care found only one-third stocked mifepristone and a key barrier identified was the in-person dispensing requirement. Providers in this study also believed that lack of mifepristone access resulted in negative patient experiences, including disrupted continuity of care, medically-unnecessary appointments, and undesired aspiration procedures.(10) Another study involving interviews with family physicians across the U.S. found that 41% raised the REMS criteria as a barrier to providing medication abortion in primary care by adding administrative burdens and bureaucratic complexity that discouraged uptake.(11)

The FDA is authorized to impose a risk evaluation and mitigation strategy (REMS) program when it determines that restrictions are necessary, including additional regulations known as Elements to Assure Safe Use (ETASU). 21 U.S.C. § 355-1(a) and 21 U.S.C. § 355-1(f)(1)(A). However, any ETASU must "not be unduly burdensome on patient access to the drug, considering in particular…patients who have difficulty accessing health care (such as patients in rural or medically underserved areas)." 21 U.S.C. § 355-1(f)(2)(C)(ii) (cite) In the case of mifepristone, the FDA must consider whether ETASU unduly burden patient access to medication abortion, particularly among those patients who have difficulty accessing care. And as explained in detail below, further restrictions on medication abortion, including but not limited to restrictions on access to telehealth, could unduly burden patient access.

Extensive research has demonstrated the significant burdens for patients and their families when abortion access is restricted, including access to medication abortion with mifepristone. Such research has identified the burdens to pregnant people, their children, and families in terms of maternal and child health, emotional well-being, physical safety, socio-economic security, and educational opportunities.

Abortion restrictions lead to abortion delays and denial. Years of research demonstrate that restrictions on abortion access—including restrictions on medication abortion, gestational limits, waiting periods, restrictions on facilities providing abortion, limits for minors, and outright bans—lead to people experiencing delays or denied access to desired abortion care. For example, one study demonstrated that states with regulations targeting abortion facilities saw the largest declines in number of available clinics.(13) Research in states with laws requiring two-trip mandatory waiting periods found that restrictions delay and prevent abortions and increase births, with one national study finding an increase in second-trimester abortions by 18%, reduction in abortions by 9-11%, and an increase in births by 2%.(14–19) Furthermore, increases in births were larger in counties further away from clinics or that had lower socioeconomic status, suggesting that the greater the financial and logistical barriers, the more likely that abortion care was denied.(19) Similarly, a study in Texas found that an increase in travel distance from 0–50 miles to 50–100 miles reduced abortion rates by 16%.(20–22) Recent research on the effects of state abortion bans post-*Dobbs* also suggest such bans lead to increases in births, from 1-3.2% depending on distance and appointment availability.(23)

Similarly, FDA restrictions that interfere with access to mifepristone and medication abortion, or make it unavailable altogether, risk the same delays and denials of abortion care and the same range of harmful consequences for patients, as outlined below.

Abortion restrictions lead to increases in live births and infant deaths. In the U.S., infant mortality (i.e., death before age 1 year) has generally been declining, with 5.6 infant deaths per 1000 live births in 2022 (down from 6.9 in 2000).(24) Abortion restrictions, however, can lead to increased infant deaths through the continuation of pregnancies with congenital malformations, the leading cause of infant mortality in the U.S.(25,26) Restrictions may also limit access to high-risk pregnancy care, which could result in maternal health complications linked to adverse infant outcomes.(27–30) Further, restrictions on abortion access may exacerbate disparities in infant mortality because individuals who are unable to overcome barriers to abortion access are often from the same groups that experience higher rates of infant mortality, including racially minoritized individuals, those without a college degree, and individuals using public health insurance.(25,31–35) In fact, research following abortion restrictions in Texas prior to the *Dobbs* decision estimated a 6% to 13% increase in infant mortality above expectation while another study showed a 7% increase in infant mortality nationwide following the *Dobbs* decision, with the predominant cause from all three studies being death associated with congenital malformations.(36–38) This research has been affirmed by recent national findings: researchers analyzing birth certificate data between 2012-2023 estimate that abortion bans in 14 states resulted in 22,180 additional live births and 478 additional infant deaths above what would have been expected.(39) The impacts were greater in certain populations; Black infants died at a rate 11% higher than would have been expected.(40)

Denying access to abortion also contributes to worsening maternal health outcomes. Numerous studies have demonstrated how the inability to access abortion can affect maternal mortality and morbidity, as well as longer-term physical and mental health outcomes. For instance, results from the seminal Turnaway Study[1] indicate that people who were denied an abortion and gave birth reported more life-threatening complications like eclampsia and postpartum hemorrhage and more chronic headaches or migraines, joint pain, and gestational hypertension.(41,42) Similarly, an analysis of Vital Statistics Natality data up through 2017 found that laws targeting abortion providers increased rates of adverse cardiovascular health outcomes among birthing people by 11–16%.(43)

Additional analysis of national statistical data find associations between abortion restrictions and maternal mortality. Results from a study using 2007–2015 National Vital Statistics System microdata mortality files from 38 states and DC found states that enacted legislation to restrict

[1] The Turnaway Study followed 1,000 women for five years and compared outcomes of individuals seeking abortions who either received or were denied care. This rigorous study provides critical data on the long-term adverse effects of abortion denial, including serious physical and mental health challenges as well as economic hardship and insecurity.

abortion based on gestational age increased the maternal mortality rate by 38%.(44) Another study using 2015-2018 National Center for Health Statistics maternal mortality data examined the associations between the state abortion policy context and maternal death and found that states with a higher number of abortion-restricting policies had a 7% increase in total maternal mortality (defined as a death while pregnant or within 1 year following the end of a pregnancy, from any cause related to or aggravated by the pregnancy or its management).(45) At the same time research has shown that expanded access to abortion results in lower maternal mortality and morbidity.(46,47)

Research has also identified adverse mental health outcomes for people denied abortion access. A recent review of the literature suggested that women who obtain abortions do not have worse mental health outcomes related directly to abortion and that those denied access to abortion have worse initial adverse psychological outcomes.(48) Research on outcomes following denial of abortion come largely from the Turnaway Study. Findings suggest that women denied abortion showed a less steep decline in baseline depression or anxiety symptoms and also faced greater initial levels of anxiety, lower self-esteem, and lower life satisfaction.(49–54) Research also found that women who were denied abortion initially reported more negative emotions.(55)

Denying abortion access contributes to adverse outcomes for children. Researchers compared children born after an abortion denial to children born later from subsequent pregnancies to women who received an abortion. Children born after a denial were more likely to experience poor maternal bonding (9% vs 3%) and have more reported injuries in early life (6% vs 3%).(56) They were also more likely to live in households unable to cover basic living expenses. Abortion restrictions have also been shown to increase racial disparities in infant health outcomes at birth – increasing gaps in premature birth and low birthweight between Black and white infants by 3–6 %.(43) Other research confirms that children from unintended pregnancies face additional challenges and disadvantages: they are more likely to be reported in less than excellent health, have extreme activity levels (either too active or too inactive), which is associated with behavioral and developmental challenges, and they also have higher odds of scorning below the median on standardized developmental assessments.(57)

Denying abortion access can increase poverty and developmental delays for existing children. The majority of abortion patients are already parents.(58) Studies show that when women are denied an abortion, their existing children have more economic insecurity and are more likely to be living below the federal poverty line compared to the children of women who received a desired abortion.(59) Likely due to financial and emotional stress, these children also have comparatively more challenges meeting developmental milestones.(59)

Denying abortion access can result in system-level impacts on children and families. Beyond harms to individual households, abortion restrictions have been associated with greater family instability and added strain on child welfare systems, while also exacerbating inequities across communities. A recent national cohort study found that the enactment of TRAP laws—state restrictions on abortion providers—was associated with an 11% increase in foster care

placements, often due to housing inadequacy, with more significant effects for Black and other racial and ethnic minority children.(60) Restrictions have also been linked to child maltreatment, where longer travel distances to abortion facilities have been associated with increases in reports of neglect and physical abuse, especially for infants and non-white children.(61) Research has also suggested associations between state abortion restrictions and increased homicide deaths among children age 0-5.(62) In contrast, legalization of abortion has historically been associated with about a 10% decline in reported child abuse and neglect.(63)

Restricted access to abortion and increase risks of intimate partner violence.
Homicide is already a leading cause of death during pregnancy and the postpartum period in the United States. Pregnancy and the postpartum period are times of elevated risk for homicide among all females of reproductive age; one study examining homicide rates during and following pregnancy found that the majority occurred in the home, implicating involvement by known persons.(64) For women who give birth after being denied an abortion, ongoing contact with the man involved in the pregnancy results in continued exposure to violence. Research found that having an abortion was associated with a reduction over time in physical violence from the man involved in the pregnancy, while giving birth was not, suggesting that having a baby from an unwanted pregnancy appears to result in sustained violence.(65) Along the same lines, research found that women denied abortions were slower to end their romantic relationships than women having abortions.(66) Conversely, women who receive wanted abortions are more likely to describe themselves as being in very good relationships years later compared to women who are denied an abortion.(65–67) Access to abortion care is particularly important for survivors of intimate partner violence, especially those whose unintended pregnancies resulted from reproductive coercion or rape. In cases where a survivor needs privacy around her abortion decision out of fear of abuse, mifepristone offers a safe and private abortion option. As set forth in greater detail in the Comment in Support of Citizen Petition No. FDA-2025-P-0377-0001from Legal Voice, women are more likely to experience intimate partner violence during pregnancy and access to abortion can play a critical role in escaping the harms of such violence.

Research identifies numerous socio-economic costs of abortion delay and denial. Being denied a wanted abortion can significantly curtail educational attainment, labor force participation, and achievement of aspirational life goals.(68–72) The Turnaway Study found that women denied an abortion who gave birth experienced an increase in household poverty lasting at least four years, were more likely to not have enough money to cover basic living expenses, and were more likely to have a lower credit score.(70,73,74) Researchers also found that being denied an abortion increased a woman's amount of debt and increased the number of their negative public financial records, such as bankruptcies and evictions.(74) After being denied an abortion, women had more than three times greater odds of being unemployed and were more likely to be enrolled in public safety net programs.(70)

Restrictions on abortion access can also derail educational opportunities. One study found that regulations on abortion providers, which often lead to clinic closures, increased births among teens

by more than 3%. The same study reported that living in states with such laws before age 18 reduced college initiation by 2.1%, and college completion by 5.8% among Black women in particular.(75)

In addition to the socio-economic costs when abortion is denied, barriers to access caused by abortion restrictions can increase burdens for those who still ultimately obtain abortions. Restrictions can result in delays to care and associated costs, including possibly pushing a person beyond the gestation eligible for a medication abortion, requiring more expensive procedures or greater travel to an appropriate clinic setting. Regulations that would remove access to mifepristone via telehealth services could also cause delay and require people to travel to an in-person clinic site, increasing burdens and costs. Research on the burdensome consequences of additional costs in seeking abortion care are detailed further below.

Access to mifepristone through telehealth abortion services alleviates burdens; if access is removed, burdens will increase. The use of telehealth for abortion care has been demonstrated as safe and effective.(76) It has also become a common way to access abortion. The number of abortions delivered via telehealth has increased since April 2022; by the end of 2024, 1 in 4 abortions was provided via telehealth. In states where abortion and telehealth were permitted, on average, 15% of abortions were provided via telehealth each month.(77) If the FDA imposes REMS or ETASU such that mifepristone can no longer be accessed via telehealth, this will have a burdensome impact on patients in states where abortion remains legal, but access to in-person services can prove difficult due to cost, geography, or other logistical barriers. In states with few abortion providers or large rural areas like Colorado, Minnesota, Alaska, Wisconsin, Hawaii, Ohio, Pennsylvania, Utah, and Virginia, telehealth abortion numbers have steadily increased over time, suggesting increasing reliance on this service.(77)

Research has proven that cost poses a barrier to abortion; restrictions that would limit access to telehealth abortion and require more travel could increase costs, resulting in delays and denials of care and the harmful consequences described above. Abortion is often not covered by insurance, and, for many, the out-of-pocket cost of an abortion can be considered a catastrophic health expenditure (CHE), according to one study that looked at whether abortion costs exceeded 40% of average monthly income. (78) One cross-sectional study of U.S. patients seeking abortion found that 42% of individuals were estimated to incur CHEs as part of care-seeking.(79) Findings from a systematic review by Barr-Walker et al (2019) describe the range of financial and logistical burdens of abortion travel pre-*Dobbs*, including planning and paying for accommodations, transit, and childcare along with compensating from time away from work.(80) Financial obstacles can result in delays, affect method choice, lead to financial stress, and result in inability to obtain care altogether.(78,81–84) Delay and denial of abortion care resulting from financial obstacles result in the same harmful consequences of delayed and denied access described above.

In conclusion, decades of research demonstrate the harmful impacts for patients when abortion access is restricted. Additional regulations that make mifepristone more difficult or impossible to

obtain will unduly burden patients, especially those who already face difficulty in accessing care. We urge the Department to consider the evidence presented in this comment and incorporate it when analyzing the petition. Should you wish to discuss their contents with us further, please reach out to Lee Hasselbacher at lhasselbacher@uchicago.edu.[2]

Re: Supplemental Comment in Support of Citizen Petition FDA-2025-P-0377-0001

Acting Commissioner Brenner,

The Boston University School of Law's Program on Reproductive Justice (BUPRJ), Immigrants' Rights and Human Trafficking Program (IRHTP), and the Racial Justice and Movement Lawyering Clinic (RJMLC) jointly submit this public comment regarding the pending Citizen Petitions, FDA-2025-P-0377-0001; FDA-2025-P-1576-0001; FDA-2025-P-2162-0001; and FDA-2025-P-3287-0001 ("Petitions"). We previously submitted Public Comment FDA-2025-P-0377-0242 on October 11, 2025.

We now submit this supplemental comment to provide additional analysis and information in light of new research highlighting the connection between intimate partner violence (IPV) and access to reproductive healthcare. We join the aforementioned petitions insofar as they advise the U.S. Food and Drug Administration (FDA) to: (1) eliminate the Mifepristone Shared System Risk Evaluation and Mitigation Strategy (REMS); or (2) at minimum, refrain from imposing additional restrictions on mifepristone.

For the reasons set forth in our prior comment and below, we urge the FDA to swiftly expand access to mifepristone and reproductive healthcare via telehealth and other evidence-based measures, rather than imposing unduly burdensome requirements making it harder for patients to access care.

This supplemental comment highlights recent findings by the National Bureau of Economic Research (NBER) demonstrating that limiting access to reproductive healthcare increases IPV against women. This NBER working paper provides the first comprehensive, causal analysis of how post-*Dobbs* abortion restrictions have affected IPV, the most common form of violence

against women.[1] The NBER study demonstrates that between 2017 and 2023, restrictive abortion policies led to a 7-10% increase of IPV incidents for reproductive-age women.[2] This equates to approximately 9,000 IPV cases, where the abuse rose directly from or correlated with inaccessibility of abortion services.[3] According to the paper, non-Hispanic Black women experienced the highest increase in IPV incidents under these circumstances, reflecting broader disparities to access along lines of race and ethnicity.[4] These findings suggest that barriers to reproductive healthcare access, created by the REMS and other abortion restrictions, likely contribute to violence against pregnant people, with especially stark impacts on historically marginalized communities.

The connection between restricted abortion access and increased IPV, as substantiated in the NBER paper, furthers existing public health research and illustrates the tangible consequences of limiting reproductive healthcare. Abortion restrictions can intensify financial strain, prolong exposure to abuse, and reduce individuals' ability to exit unsafe relationships.[5] The NBER study found that almost 80% of women who were forced to carry a pregnancy to term due to abortion restrictions experienced IPV, highlighting the widespread harm these restrictions can cause.[6] The study also found that abortion restrictions can increase the likelihood of IPV even when they do not ultimately result in a birth.[7] Factors such as stress, prolonged interactions with violent partners, and other burdens imposed by restrictions can also elevate the likelihood of IPV while pregnant.[8] This is particularly alarming given that more than half of all homicides against women are committed by a former or current intimate partner.[9] By creating additional barriers to timely abortion care, policies that restrict access to mifepristone may increase the likelihood that pregnant people remain in dangerous, and even life-threatening, circumstances for longer. These restrictions can essentially confine individuals within unsafe situations by limiting the care they need.

The rise in IPV due to abortion restrictions imposes substantial burdens to the government, as well as disproportionate economic burdens on individuals. Increased IPV imposes sizable fiscal costs on society as a whole. According to the NBER study, restrictions linked to IPV impose approximately $1.24-$1.87 billion in added social costs.[10] Adjusted to the value of the dollar in

2023, the lifetime economic burden amounts to over $4.5 trillion.[11] These costs encompass increased healthcare expenditures, lost productivity and earnings, and significant burdens on public systems such as law enforcement and social services.[12] While these figures highlight strain on public infrastructure, the NBER study also reveals how limited access directly harms individuals. Notably, the financial and social burdens of both IPV and abortion inaccessibility fall disproportionately on low-income individuals, who are more likely to already face barriers to healthcare and lack the resources to travel for care or recover from economic harm.[13] Restricting access to safe, effective, evidence-based reproductive healthcare, thus, risks avoidable economic harm, while undermining patient health and safety.

The FDA should remove unnecessary restrictions on mifepristone to reduce preventable harm and support patient safety. In light of this new research, we reiterate our support for lifting unnecessary REMS requirements and expanding access to medication abortion via telehealth and other equitable, evidence-based mechanisms. Given the growing body of evidence linking abortion restrictions to increased rates of IPV, we strongly urge the FDA to refrain from imposing such restrictions. The FDA should swiftly remove all unwarranted barriers to mifepristone, affirm its safety and efficacy, and promote policies that protect patient health and safety.

Sincerely,

Georgia Aguilar

RE: Comment in Support of Citizen Petition No. FDA-2025-P-0377-0001

Submitted electronically via regulations.gov

Commissioner Makary,

Pursuant to 21 C.F.R. § 10.30, Legal Voice, Family Violence Appellate Project, Sexual Violence Law Center, and Washington State Coalition Against Domestic Violence, submit this comment in support of the Citizen Petition filed by the American College of Obstetricians and Gynecologists, Society of Family Planning, and Society for Maternal-Fetal Medicine, Petition No. FDA-2025-P-0377-0001. We strongly support Petitioners' request that the Food and Drug Administration (FDA): (1) remove the Mifepristone Shared System Risk Evaluation and Mitigation Strategy (REMS), or (2) in the alternative, at a minimum, refrain from taking any action that would further reduce patient access to mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone.

Legal Voice advances gender equity throughout the Pacific Northwest through litigation, administrative and legislative advocacy, and public education. Legal Voice advocates and works in Alaska, Idaho, Montana, Oregon, and Washington, all of which have different levels of access barriers to abortion services. Reproductive freedom is fundamental and essential, particularly for Black, Indigenous, and People of Color (BIPOC) women, LGBTQIA+ people, survivors of intimate partner violence (IPV), and those living at the intersection of multiple marginalized identities. Legal Voice is familiar with the challenges that IPV survivors face in exercising their autonomy and understands the barriers that make it especially difficult for IPV survivors to access reproductive health care, including abortion medication.

Family Violence Appellate Project is the only nonprofit organization in California dedicated to representing survivors of domestic violence and other forms of gender-based abuse in civil appeals for free. FVAP is devoted to ensuring domestic violence survivors can live in healthy safe environments, free from abuse. Abuse through reproductive coercion is widespread, and safe access to medication abortion is paramount to survivor safety and health.

Sexual Violence Law Center attorneys represent survivors of sexual violence, domestic violence, and gender-based violence in court on multiple issues, including healthcare autonomy and privacy.

Washington State Coalition Against Domestic Violence (WSCADV) is a statewide network of domestic violence programs, that works to end domestic violence by providing supports to our member programs and engaging in advocacy. Through WSCADV's work with domestic

violence (DV) survivors and their advocates, WSCADV knows that decisions about birth control, pregnancy, and parenting are deeply personal and can be challenging. For survivors of domestic violence, these choices are often taken away, with pregnancy used as a means of control. WSCADV's advocates have seen how non-consensual pregnancies can trap survivors in abusive relationships, making it even harder to escape. Sexual abuse within the relationship can lead to pregnancies, forcing survivors to confront the painful reality that their abuser might have legal rights to visitation or custody. Based on WSCADV's experience working with survivors across Washington, WSCADV believes that access to mifepristone offers hope and vital options for DV survivors, empowering them to make decisions about their reproductive health, access to healthcare, and safety for themselves and their families.

In recent years, the Food and Drug Administration has implemented changes to the Risk Evaluation and Mitigation Strategy for mifepristone, a medication used for medical termination of pregnancy. These changes have eased mifepristone access by allowing direct-to-patient telehealth and pharmacy certification, without compromising patient safety. Interfering with access to mifepristone and reinstating needlessly burdensome, medically unnecessary requirements for in-person dispensing of this safe and effective medication used by millions of American women would have one clear and certain effect: reducing access to medication abortion across the United States.

Restricting access to mifepristone will cause particularly grave harm to IPV survivors by limiting their ability to access abortion care, thus increasing their risk of health complications, violence, and homicide. Abusers often control their partners' reproductive choices by forcing pregnancy and restricting prenatal care. The consequences of such entrapment range from heightened abuse during pregnancy to death. As difficult as it is for all survivors of IPV to escape abusive relationships and exercise their reproductive autonomy, IPV survivors of color—who already experience disproportionately high rates of unintended pregnancy and increased health risks— face systemic inequities that make doing so even harder. Changes in the availability of mifepristone will curtail access to medication abortion with serious consequences for the health and lives of many survivors of IPV.

Intimate Partner Violence Survivors Face Higher Risk of Unintended Pregnancy, Threatening Health and Safety

Intimate partner violence is widespread, leads to increased risk of unintended pregnancy, and results in adverse health outcomes for millions of survivors. Nearly half of women in the United States have been affected by IPV, which the World Health Organization defines as "behaviour by an intimate partner or ex-partner that causes physical, sexual or psychological harm, including physical aggression, sexual coercion, psychological abuse and controlling behaviours."[1] Almost *60 million* American women[2] report that they have experienced sexual violence, physical violence, and/or stalking by an intimate partner

[2] People of many gender identities experience IPV. This brief specifically references "women" where the underlying research or quoted material focuses on women.

during their lifetimes.[3] Women of color face disproportionately high IPV rates, with over half of multiracial, Native, and Black individuals affected.[4] Noncitizens face added barriers like language, immigration status, and limited legal resources.[5]

In addition to physical abuse, IPV abusers exert "coercive control" over survivors by isolating them from family and friends, monitoring their whereabouts, and restricting their access to money[6] and transportation.[7] Survivors from marginalized communities face systemic inequities that exacerbate the conditions for coercive control.[8] This coercion limits survivors' access to resources needed to escape the abusive relationship.

Poverty and lack of resources make it even more difficult for survivors to escape IPV and women living in poverty are twice as likely to experience IPV.[9] People of color are even more likely to live in poverty if they also are LGTBQ+, disabled, or non-citizens.[10] It takes money to flee an abusive relationship—for hotel rooms, gas, food, and childcare, among other needs.[11] Longer-term costs include mental and physical health care needs, stable housing, legal representation, and finding flexible employers who will accommodate time-off requests for court appearances.[12]

Women living in rural areas experience more frequent and severe rates of IPV than women in urban areas, often making it more difficult for rural survivors to receive needed care.[13] Rural areas also have fewer health care providers and reproductive heath care services tend to be limited for people in rurual areas, even within states that protect abortion access.[14] Additionally rural emergency departments have fewer resources in place to address IPV.[15] These barriers further isolate survivors from necessary resources and highlight the importance of measures, like direct-to-patient telehealth, that reduce barriers to accessing reproductive health care, including medication abortion care.

Survivors of IPV face higher risks of unintended pregnancy due to "reproductive coercion", including birth control sabotage and forced pregnancies by abusive partners. Research from the Centers for Disease Control and Prevention (CDC) shows that nearly 10.3 million women have experienced a partner trying to force pregnancy or refusing to use contraception.[16] Studies have also found that IPV survivors are nearly three times more likely to conceal an abortion from their partners due to safety concerns. Again, systemic inequities further compound the risks. Marginalized communities already experience disproportionately high rates of unintended pregnancy,[17] largely due to a lack of access to sexual health information,[18] health insurance,[19] and affordable contraceptives,[20] as well as a history of coercion by and mistrust of state and medical institutions.[21]

Intimate Partner Violence Survivors Need Abortion Access but Face Major Barriers

Meaningful access to abortion care, while important to all women, is particularly critical for IPV survivors, and especially those whose unintended pregnancies resulted from reproductive coercion or rape. Because pregnancy termination undermines abusers' control, survivors face increased barriers to obtaining abortion care when they need to hide their abortion from their abuser. Mifepristone provides a safe and private abortion option for many people, such that maintaining access to mifepristone is critical for survivors of IPV.

Indeed, many survivors have children whom they already struggle to protect.[22] Among other risks, having a child, or another child, with an abusive partner exacerbates challenges survivors face in finding housing upon leaving the abuser, as they would be limited to shelters which permit children.[23]

It is common for abusers to control prenatal care, which can result in increased complications and adverse health outcomes. Survivors of IPV are at a high risk of depression and post-traumatic stress disorder and at increased risk of having babies preterm and babies with low birth weight.[24] While the United States has a maternal mortality rate over three times that of other developed nations,[25] BIPOC women are disproportionately affected with a higher maternal mortality rate and lower-quality

[25] Munira Z. Gunja et al., The Commonwealth Fund, *The U.S. Maternal Mortality Crisis Continues to Worsen: An International Comparison* (Dec. 1, 2022),

reproductive care due to systemic racism in healthcare.[26] Immigrant women are at higher risk because they tend to receive less prenatal care than non-immigrant women, in part due to exclusionary health insurance laws and policies.[27]

Not only do people in abusive relationships face increased health risks associated with pregnancy, IPV is common and often escalates during pregnancy. [28] Approximately 324,000 pregnant women are abused in the United States each year[29] and homicide is the leading cause of death among pregnant women, with Black and Native women at the highest risk.[30]

The ability to access mifepristone through telehealth services and mail delivery plays a crucial role in providing a safe and private abortion option and has been on the rise since 2022.[31] It is particularly important for survivors who cannot safely visit clinics due to the controlling nature of their partners.[32] Indeed, IPV survivors are nearly three times as likely to conceal their abortion from their partner.[33] Without these options, IPV survivors may be forced to travel long distances, an impossible burden for many facing abusive financial control or childcare responsibilities. Many IPV survivors have children and need to arrange childcare to go to medical appointments. Childcare options are limited for people who lack funds, want to keep their abortion private, or are isolated from friends and family, and leaving children alone with an abuser may not be an option. Further, the cost of travel, including gas—assuming a survivor has access to a car—and lodging, is a significant barrier. These costs will be prohibitive for many survivors of IPV, who disproportionately face economic hardship and financial control by their partners. Marginalized communities, including BIPOC people and immigrants, face additional obstacles like limited transportation, low wages, and lack of insurance, making abortion care even less accessible.[34]

Restricting Mifepristone Puts Intimate Partner Violence Survivors at Risk

The current REMS and ETASU requirements limit access to mifepristone, harming IPV survivors by making it difficult for them to access needed care. The patient agreement form is stigmatizing, and certification requirements make it more burdensome for providers to prescribe and dispense mifepristone, deterring some providers from providing medication abortion.[35] These unnecessary administrative requirements cause real harm to IPV survivors by reducing the number of providers they can go to to get care.

Any changes that the FDA makes to reinstate previous REMS and ETASU requirements would be even more harmful. Requiring in-person dispensing of mifepristone by providers would reduce the number of providers that IPV survivors can turn to for medication abortion due to the additional burdensome administrative steps.[36] When there are fewer providers available and direct-to-patient telehealth is not an option, people who want a medication abortion will be forced to travel long distances for care, and others will need to travel farther to reach a clinic that offers procedural abortions and that has available appointments.[37] For survivors of color and immigrants, discrimination and structural oppression exacerbate the barriers to abortion when mifepristone is more difficult to access.

In 2023, medication abortion made up 63% of all abortions in the United States.[38] Medication abortion is a particularly important option for survivors of IPV because they are subject to coercive control.[39] Disrupting the distribution of mifepristone and reinstating medically unnecessary, burdensome restrictions on its dispensing would irreparably harm IPV survivors by rendering abortion care inaccessible to many and consequently exposing them to a higher likelihood of significant health risks and further violence, including homicide. Simply put, changes in the availability of mifepristone will have life and death consequences for many survivors of IPV.

We urge the Department to consider the issues raised in this comment and incorporate them when analyzing the petition. Thank you for the opportunity to submit these comments. Should you wish to discuss their contents with us further, please reach out to Kelly O'Neill at koneill@legalvoice.org and Julia Marks at jmarks@legalvoice.org.

UNITED STATES DISTRICT COURT
FOR THE WESTERN DISTRICT OF LOUISIANA
LAFAYETTE DIVISION

THE STATE OF LOUISIANA, by and through its Attorney General, LIZ MURRILL, and ROSALIE MARKEZICH, *Plaintiffs*, v. U.S. FOOD AND DRUG ADMINISTRATION, *et al.*, *Defendants*.	Civil Action No. 6:25-cv-01491 Judge: David C. Joseph Mag. Judge: David J. Ayo

PROPOSED INTERVENOR-DEFENDANT GENBIOPRO, INC.'S CONDITIONAL MOTION TO DISMISS

Proposed Intervenor-Defendant GenBioPro, Inc. ("GenBioPro") hereby conditionally moves to dismiss this action pursuant to Federal Rules of Civil Procedure 12(b)(1) and 12(b)(6). In its position as a proposed Intervenor-Defendant (pending adjudication of its Motion to Intervene), GenBioPro respectfully submits that Plaintiffs lack Article III standing; that they have not exhausted their claims; and that Count Two of the Complaint fails as a matter of law, as described below and detailed in GenBioPro's Conditional Memorandum in Opposition to Plaintiffs' Motion for Preliminary Relief ("GenBioPro's Opposition") filed herewith.

First, Plaintiffs' Complaint should be dismissed under Rule 12(b)(1) because Plaintiffs lack Article III standing, depriving the Court of subject matter jurisdiction. As explained in Section I of GenBioPro's Opposition, neither Plaintiff has alleged a cognizable injury-in-fact traceable to FDA's 2023 REMS and redressable through the relief sought. Those deficiencies not only preclude the preliminary relief plaintiffs seek, but also require dismissal of the case. Article III standing is an "essential" and "core component" of the Court's subject matter jurisdiction. *Lujan v. Defs. of*

Wildlife, 504 U.S. 555, 560 (1992). "Without jurisdiction the court cannot proceed at all in any cause," and "the only function remaining to the court is that of announcing the fact and dismissing the cause." *Steel Co. v. Citizens for a Better Env't*, 523 U.S. 83, 94 (1998) (quoting *Ex parte McCardle*, 7 Wall. 506, 514 (1868)); *see also FDA v. All. for Hippocratic Med.*, 602 U.S. 367, 380 (2024) (directing dismissal of challenge to mifepristone regulations for lack of standing).

Second, since Plaintiffs failed to exhaust their claims, they breached a binding FDA requirement for filing suit. *See* 21 C.F.R. § 10.45(b). When an "agency rule" requires a party to first pursue administrative remedies as a "prerequisite to judicial review," as FDA regulations do, the party's failure to exhaust those remedies bars the claim from proceeding. *Darby v. Cisneros*, 509 U.S. 137, 153 (1993). As detailed in Section II of GenBioPro's Opposition, Plaintiffs failed to present their claims to the FDA before bringing suit and they offer no legally sufficient basis to excuse their lack of exhaustion. Accordingly, their claims should be dismissed under Rule 12(b)(6) for failure to exhaust, *see Bunker v. Dow Chem. Co.*, 111 F.4th 683 (5th Cir. 2024), or alternatively as unripe in light of FDA's ongoing reconsideration of the challenged actions, *see, e.g.*, *Huawei Techs. USA, Inc. v. FCC*, 2 F.4th 421, 434 (5th Cir. 2021) ("The ripeness doctrine prevents the courts, through avoidance of premature adjudication, from entangling themselves in abstract disagreements over administrative policies." (cleaned up)).

Third, Count Two of the Complaint fails to state a claim upon which relief may be granted because Plaintiffs have not plausibly pleaded that FDA's adoption of the 2023 REMS violated the Comstock Act. As detailed in Section III.B of GenBioPro's Opposition, Plaintiffs have not plausibly pleaded that the FDA engaged in conduct proscribed by the Comstock Act and nor have they plausibly pleaded that the FDA's determination in the 2023 REMS—that in-person dispensing of mifepristone is unnecessary for safety—compelled or permitted anyone else to

violate the Comstock Act. Because the issues raised by Plaintiffs in Count Two are purely legal, the administrative record is unnecessary for resolution of this claim.

For the foregoing reasons, and those set forth in GenBioPro's Opposition, the Court should dismiss Plaintiffs' Complaint under Rules 12(b)(1) and 12(b)(6).

Dated: February 3, 2026

Respectfully submitted,
