> Not having any other option made me trust the service. There were times I doubted it could possibly be this easy or straightforward without there being some horrible catch. –Age 36 years, New Jersey, synchronous care

Overall, 20% reported no drawbacks. About one fifth cited not having screening (20%) and follow-up (23%) tests as drawbacks of their telehealth abortion experience. One participant stated,

> I would have liked confirmation that it was complete via ultrasound. –Age 29 years, New York, asynchronous care

TABLE 2— Associations Between Patient and Abortion Characteristic and Acceptability Indicators: United States, 2021–2022

	Very Satisfied, PPR (95% CI)	Right Decision, PPR (95% CI)	Trust Provider, PPR (95% CI)	Cared for, PPR (95% CI)
Overall	89.7 (88.0, 91.4)	95.6 (94.4, 96.7)	98.0 (97.1, 98.8)	91.9 (90.4, 93.4)
Model of care				
Synchronous (n = 476; Ref)	90.4 (87.7, 93.2)	97.1 (95.6, 98.6)	97.3 (95.8, 98.8)	88.5 (85.5, 91.4)
Asynchronous (n = 836)	88.7 (86.5, 90.9)	94.7 (93.1, 96.2)	98.3 (97.5, 99.2)	93.4 (91.7, 95.1)**
Race or ethnicity				
Non-Hispanic White (n = 689; Ref)	89.5 (87.2, 91.8)	95.4 (93.7, 97.0)	97.9 (96.7, 99.1)	92.7 (90.7, 94.6)
Non-Hispanic Black or African American (n = 121)	91.4 (86.3, 96.5)	95.1 (91.3, 99.0)	97.9 (95.4, 100.0)	88.6 (83.0, 94.3)
Hispanic or Latinx[a] (n = 166)	90.7 (86.1, 95.2)	97.3 (94.9, 99.7)	98.8 (97.5, 100.0)	95.1 (91.5, 98.7)
American Indian, Alaska Native, Middle Eastern, North African, or multiracial (n = 194)	91.1 (87.2, 95.0)	97.1 (94.8, 99.4)	96.8 (94.3, 99.3)	89.6 (85.4, 93.9)
Asian, Native Hawaiian, or Pacific Islander[a] (n = 87)	78.5 (69.0, 87.9)**	91.5 (85.4, 97.7)	98.8 (97.5, 100.0)	87.7 (79.9, 95.6)

Note. CI = confidence interval; PPR = predicted prevalence rate. The sample size was n = 1312. Estimates are PPRs that draw from marginal estimates of multivariable logistic regression models. *P* values compare each category to the reference group in the multivariable logistic regression models. Multivariable models are adjusted for synchronous versus asynchronous care, patient age at abortion intake, pregnancy duration at abortion intake, food insecurity in the past month, race or ethnicity, previous medication abortion, education level, health insurance coverage, US nativity, and urban residence.

[a]Variable for race or ethnicity combined Hispanic or Latinx with Asian, Native Hawaiian, or Pacific Islander for the "trust provider" model.
*$P < .05$; **$P < .01$; ***$P < .001$.

A smaller proportion (12%) listed not seeing a provider in person as a drawback of the telehealth model. In the open-ended responses, some participants also described being unable to reach the virtual clinic at times:

> I took my pills on the weekend, so I had nobody to contact, which was unfortunate because I really wasn't sure if the severity of what I was experiencing was normal. –Age 24 years, California, asynchronous care

Overall Rates of Acceptability Indicators

We next examined the adjusted proportion of participants who reported each of the 4 patient acceptability indicators of interest: trust, right decision, cared for, and satisfied (Table 2). Overall, 98% trusted the virtual clinic, 96% felt telehealth was the right decision, 92% felt cared for, and 90% of participants were very satisfied with the telehealth model of care. Full regression output is presented in Table B (available as a supplement to the online version of this article at https://ajph.org).

Differences in Patient Acceptability by Participant Characteristics

Finally, we assessed differences in adjusted prevalence rates of each patient acceptability indicator by participant characteristics (Table 2). Asian, Native Hawaiian, and Pacific Islander participants were less likely than White participants to be very satisfied (79% vs 90%; $P = .008$). Similar proportions of patients who received synchronous and asynchronous care were very satisfied, felt telehealth was the right decision, and felt cared for by the telehealth provider. However, participants who had asynchronous care were slightly more likely to feel cared for (93% vs 89%; $P = .004$).

In the open-ended responses, we found that some participants stated clear preferences for synchronous care, while others clearly preferred asynchronous care. One participant explained their preference for asynchronous care because it facilitated anonymity:

> Everything was very professional and never pressed for any information. There was no pressure to do an appointment showing who I was. Privacy was well respected, and the ball was in my court to decide how much care I wish to receive (ex. seeing the doctor or nurse). –Age 29 years, California, asynchronous care

GBP-PET00411

However, some participants who received asynchronous care described how asynchronous communication could feel impersonal. One participant wrote,

> Since I talked to a nurse through chat, it didn't feel personable, and I wasn't sure if I was getting an automated message or if I was chatting with an actual person. –Age 27 years, California, asynchronous care

Another participant described how their synchronous care facilitated trust in the virtual clinic, despite initial reluctance about a video call:

> It was the video call! It proved it was a real service and that it was their focus at [the virtual clinic]. As much as I didn't want to do a video call, it helped solidify the legitimacy of the service. –Age 41 years, California, asynchronous care

One participant explained how being offered options for both synchronous and asynchronous services was important to their care:

> I knew it was legitimate because they were considering all the right things: the 24/7 hotline, video calls if we want but also that they aren't necessary. You can make it into the right abortion care for you. I personally didn't make any calls or message much, but I trust the service because I know I can get whatever help I need. –Age 23 years, Washington, asynchronous care

Another participant stated,

> They gave me a number to call if I needed, texted multiple times, and always said to text (which I love because I hate talking on the phone), or to call if I needed anything or had questions. –Age 43 years, California, asynchronous care

DISCUSSION

In this study, we found high acceptability of telehealth for abortion, whether it involved synchronous or asynchronous services. Nearly all participants were very satisfied with telehealth abortion. Telehealth abortion care is a new service and, thus, it was previously unknown whether this less medicalized model that eliminates in-person patient–provider interaction would negatively impact patient acceptability. Of course, telehealth abortion care is not for everyone, including individuals who are seeking abortion care later in pregnancy, those who prefer procedural abortions, and those who prefer to have screening and follow-up tests as a part of their medication abortion care. Thus, while access to in-person abortion care remains critical, this study indicates that telehealth is an important addition to the abortion landscape and offers substantial benefits over in-person care for some patients.

The most common reason for choosing telehealth was that patients felt more comfortable at home. Most patients also reported choosing telehealth for greater privacy, lower cost, expediency, and more agency in managing their abortion care. Thus, telehealth abortion appears to help mitigate some barriers patients face in accessing care from an abortion clinic. Beyond its role in increasing access to abortion care and addressing the surges abortion facilities face as patients travel in wake of *Dobbs*, telehealth can promote patient-centered care for some people seeking an abortion.[18,21]

We found few differences in acceptability between synchronous or asynchronous telehealth abortion care: patients were equally likely to be highly satisfied, trust the virtual clinic, and feel telehealth was the right decision. These findings suggest that both synchronous and asynchronous models are highly acceptable to patients. We found slightly higher rates of feeling cared for among participants who received asynchronous services. When patients from one clinic were offered asynchronous telehealth abortion services by default with an additional option for synchronous communication, almost no patients opted for synchronous care. While our results were largely similar for the 2 models, there may be different benefits and drawbacks of synchronous and asynchronous care with implications for providers and administrators. Services without real-time communication are presumed to feel less personable, but messaging can facilitate more frequent and responsive communication, which may contribute to patients feeling cared for. In addition, asynchronous models can require less time to provide, making them more cost-effective.[22,23] Our results demonstrate that asynchronous services can be provided while maintaining high levels of patient acceptability.

Nearly 40% of the sample was initially uncertain whether the virtual clinic services were safe or legitimate. At the time of the study, telehealth abortion services and virtual clinics were newly available within the formal US health care system. We expect that skepticism about legitimacy will decrease over time as public awareness about the safety and effectiveness of telehealth abortion increases. While these data draw from a time when interest in telehealth was very high because of the COVID-19 pandemic, use of telehealth abortion has continued to expand as barriers to access abortion care mount.[2]

GBP-PET00412

We found few differences in acceptability of telehealth abortion care by race or ethnicity in this sample, apart from finding lower rates of satisfaction among Asian versus White participants. Asian Americans are underrepresented among abortion patients, which could contribute to stigma and help to explain these findings.[24] Research has found lower levels of broader telehealth adoption among Asian individuals despite high levels of digital connectedness, which may be explained by discrimination in medical settings.[25]

Limitations

This analysis has several limitations. First, all participants self-selected into telehealth care. Participants in our study were disproportionately older, White, and more financially secure than the national population of abortion patients,[24] although our sample may be more representative of the 24 states where telehealth abortion is legal. In addition, virtual clinic abortion services were available only in English and required a credit or debit card. These factors may limit the generalizability of our findings, leading us to find higher acceptability than we would have seen if patients had been more representative of the general abortion patient population. While our follow-up rate was high compared with other medication abortion studies, 18% of the sample was lost to follow-up, which may have introduced selection bias. This could have overestimated patient acceptability if those less satisfied dropped out of the study at higher rates or underestimated acceptability if participants for whom privacy was very important were more likely to be lost to follow-up. Finally, our study had limited variation in synchronous and asynchronous care among the 3 included clinics and an insufficient number of clusters to calculate clustered standard errors within each virtual clinic. Therefore, our study may have overestimated differences in acceptability of care if the observed differences between synchronous and asynchronous are truly attributable to differences in acceptability across the virtual clinics. However, each virtual clinic had multiple clinicians, bolstering the validity of the differences we detected.

Public Health Implications

In a post-Roe world, telehealth is taking on a greater role in the US abortion care landscape. Therefore, medication abortion, and telehealth medication abortion specifically, has become a focus of abortion restrictions. The high patient satisfaction with telehealth abortion found in this study combined with documentation of the safety and effectiveness of this service delivery modality[8,26] supports its continued availability.

Although this study found very high patient satisfaction with telehealth abortion, it is critical to understand abortion service delivery preferences and lower levels of acceptability among Asian patients. Our data suggest that telehealth is disproportionately accessible to patient populations who face fewer barriers to in-clinic abortion care. Policy and service changes that facilitate patients' use of Medicaid and insurance to pay for the abortion, offer services in multiple languages, and increase minors' access to care are critical to ensuring a range of accessible and acceptable telehealth abortion models.[21] Given increasing barriers to abortion across the United States, it is essential to further develop innovative models of care and ensure that all people who need abortion care will have access to a service delivery model that is right for them. Abstract

Background: Even preceding the Supreme Court's 2022 *Dobbs v. Jackson Women's Health Organization* decision, patients in the United States faced exceptional barriers to reach abortion providers. Abortion restrictions disproportionately limited abortion access among people of color, young people, and those living on low incomes. Presently, clinics in states where abortion remains legal are experiencing an influx of out-of-state patients and wait times for in-person appointments are increasing. Direct-to-patient telehealth for abortion care has expanded since its introduction in the United States in 2020. However, the role of this telehealth model in addressing geographic barriers to and inequities in abortion access remains unclear.

Objective: We sought to examine the amount of travel that patients averted by using telehealth for abortion care, and the role of telehealth in mitigating inequities in abortion access by race or ethnicity, age, pregnancy duration, socioeconomic status, rural residence, and distance to a facility.

Methods: We used geospatial analyses and data from patients in the California Home Abortion by Telehealth Study, residing in 31 states and Washington DC, who obtained telehealth abortion care at 1 of 3 virtual abortion clinics. We used patients' residential ZIP code data and data from US abortion facility locations to document the round-trip driving distance in miles, driving time, and public transit time to the nearest abortion facility that patients averted by using telehealth abortion services from April 2021 to January 2022, before the *Dobbs* decision. We used binomial regression to assess whether patients reported that telehealth was more likely to make it possible to access a timely abortion among patients of color, those experiencing food insecurity, younger patients, those with longer pregnancy durations, rural patients, and those residing further from their closest abortion facility.

Results: The 6027 patients averted a median of 10 (IQR 5-26) miles and 25 (IQR 14-46) minutes of round-trip driving, and 1 hour 25 minutes (IQR 46 minutes to 2 hours 30 minutes) of round-trip public transit time. Among a subsample of 1586 patients surveyed, 43% (n=683) reported that telehealth made it possible to obtain timely abortion care. Telehealth was most likely to make it possible to have a timely abortion for younger patients (prevalence ratio [PR] 1.4, 95% CI 1.2-1.6) for patients younger than 25 years of age compared to those 35 years of age or older), rural patients (PR 1.4, 95% CI 1.2-1.6), those experiencing food insecurity (PR 1.3, 95% CI 1.1-1.4), and those who averted over 100 miles of driving to their closest abortion facility (PR 1.6, 95% CI 1.3-1.9).

Conclusions: These findings support the role of telehealth in reducing abortion-related travel barriers in states where abortion remains legal, especially among patient populations who already face structural barriers to abortion care. Restrictions on telehealth abortion threaten health equity.

Introduction

Distance has long been understood to be a key barrier to abortion access in the United States. The distance that patients must travel to the nearest abortion provider has increased substantially in the wake of the July 2022 US Supreme Court's *Dobbs v. Jackson Women's Health Services* decision, which has led to abortion being banned in at least 14 states [1,2]. As a result, providers in protected access states—states where abortion care remains legally available—have experienced an influx of out-of-state patients, which is increasing wait times to care, and may force abortion seekers to travel farther than they would if they could obtain care at the facility closest to their home [3].

Prior studies have found that the further a patient must travel to a provider, the less likely they are to obtain a desired abortion [4,5]. National data indicate that longer travel distances to care due to a spike in antiabortion restrictions in the United States in recent years have contributed to the decreased abortion rate [6]. As of 2019, 20% of people who can get pregnant in the United States lived 43 or more miles from an abortion provider [7] and as of 2018, the United States had 27 "abortion deserts," that is, major cities with no abortion provider within 100 miles [8]. These geographic barriers to abortion facilities exist even within states where abortion is legal [9].

Research has also demonstrated that the impacts of state abortion bans are experienced unequally. Increased distance poses particular challenges for low-income patients due to the lower likelihood of car ownership, loss of wages from the time needed off work, transportation costs for gas or transit fare, as well as the cost of lodging and childcare [10]. People living in rural areas, the South, Midwest, and Mountain West; Black and Hispanic individuals; and minors face greater distances to reach an abortion provider [11,12]. Since the *Dobbs* decision, travel times to abortion facilities have increased disproportionately for Black and Indigenous populations [2].

However, direct-to-patient telehealth abortion may greatly mitigate existing geospatial inequities in abortion access [10,13], despite only being legal in 24 states and Washington, DC as of September 2023 (although more states permit abortion care but prohibit telehealth) [14,15]. In direct-to-patient telehealth abortion, a clinician can interact with patients remotely through videoconferencing or secure messaging and dispense abortion medications via mail-order pharmacies. Prior to 2020, telehealth for abortion was limited to clinic-to-clinic models with remote patient-provider interactions that took place at medical facilities with ultrasonography and other in-person tests [16-20]. Early in the COVID-19 pandemic, professional organizations including The American College of Obstetricians and Gynecologists endorsed a telehealth abortion model [21]. Recent studies have demonstrated the safety and effectiveness of this model of abortion care that can take place without any visits to a clinic or medical facility [22-25]. However, existing research has not captured the travel averted due to telehealth access.

In addition to the potential benefits of direct-to-patient telehealth (subsequently referred to as telehealth) in reducing abortion-related travel, the role of these models in enabling people to obtain a wanted, timely abortion is not well understood. A study conducted in the Pacific Northwest found that patients who used telehealth abortion services resided further from an abortion facility than those who accessed in-clinic care and that some patients chose telehealth even when a clinic is geographically convenient, indicating a preference for telehealth among some patients who obtained an abortion [26]. It is critical to understand who benefits most from abortion models that allow patients to carry out the entire abortion process from home. Few studies have examined the extent to which patients choose telehealth abortion when they have access to in-clinic abortion or whether telehealth is making an otherwise inaccessible abortion possible, therefore reducing barriers to access.

Therefore, we aimed to estimate the amount of travel patients avert by using a telehealth service for medication abortion among a sample of patients who obtained abortions who overwhelmingly resided in states that allow telehealth for abortion care. We also aimed to understand the role that telehealth plays in enabling people to obtain a timely abortion, especially for those who face the greatest barriers to in-clinic care.

Methods

Overview

We used data from the California Home Abortion by Telehealth (CHAT) Study, a study that examines medication abortions provided via telehealth from 3 US virtual clinics, defined as telehealth abortion clinics without brick-and-mortar facilities: Choix, Hey Jane, and Abortion on Demand. While the study was initiated in California, it expanded as the virtual clinics expanded their services to 20 states and Washington, DC. We obtained anonymized clinical chart data from patients who obtained abortion care from these clinics for a defined period between April 2021 and January 2022. At the time of consent to care with the virtual clinic, patients provided permission for the telehealth provider to share their anonymized clinical records with researchers in accordance with each clinic's privacy policy. All clinical data received were deidentified apart from ZIP code (United States postal codes) and dates of service.

In addition, each virtual clinic invited patients who were approved for abortion care during a defined period between June 2021 and January 2022 to participate in a series of 3 surveys on the abortion provider's telehealth platform. Directly following the abortion intake, patients were directed to a page containing detailed information about the study and, if interested, patients provided electronic informed consent prior

XSL•FO
RenderX

GBP-PET00416

to their participation. The first survey was administered directly following abortion intake, after obtaining informed consent. Two follow-up surveys were administered within 4 weeks after abortion intake. All surveys were completed on the virtual clinics' telehealth platforms to maximize continuity and survey completion and minimize disruption for participants. Virtual clinics continued to invite patients to complete surveys until approximately 400 patients from each completed all 3 surveys. These participant surveys were linked with their clinical records, and all data were standardized and stored on a secure Research Electronic Data Capture (REDCap; Vanderbilt University) server [27]. We excluded records for abortions where the patient did not take the abortion medications, surveys that were not matched to a clinical chart, and patients with invalid ZIP codes.

Measures

Our key independent variables of interest reflected the amount of travel to the nearest abortion provider averted by using telehealth abortion services. Patient's ZIP codes were recorded in both the clinical chart data and in the surveys. For cases where the clinical chart ZIP code (used for mailing the medications) differed from the ZIP code reported in the survey, we retained the survey ZIP codes with the rationale that some patients may use addresses besides their home addresses for medication delivery. Using ArcGIS (Esri), we first calculated the centroid—the center point of all coordinate points inside the ZIP code polygon—of each unique ZIP code of patients' residences. Next, we used the Advancing New Standards in Reproductive Health 2021 Abortion Facility Database to establish the coordinates of publicly advertising US abortion facilities [28]. We used the ArcGIS Find Nearest feature to calculate the driving distance between the coordinates of the centroid of each patient's ZIP code and the coordinates of the closest abortion facility in miles. We doubled the calculation of 1-way driving distance in miles to calculate the total round-trip driving distance averted in miles. This ArcGIS calculation also generated 1-way travel time in minutes without traffic, which we doubled to develop estimates of round-trip travel time averted and converted to hours. We calculated public transit travel time in hours between patients' ZIP codes and abortion providers' geographic coordinates using the gmapsdistance package in R (R Core Team) [29].

Our outcome of interest was a measure that reflected whether telehealth made it possible to access an abortion in a timely manner (Multimedia Appendix 1). The original item was phrased: "If you didn't have an abortion through telehealth, what would have happened?" Response options were: "I would have gotten an abortion at a clinic soon;" "I would have gotten an abortion at a clinic, but it would have been a while;" "I would have continued the pregnancy;" "I don't know what would have happened;" or "something else." If the patient responded with "something else," they could provide free-text responses. These free-text responses included the following themes: patients would have attempted to self-manage their abortion (primarily seeking abortion pills through other channels), traveled out of state, or sought abortion care at a clinic without a specified time frame. We dichotomized this variable to reflect whether the patient perceived that telehealth made it possible to have an abortion in a timely manner ("I would have gotten an abortion at a clinic, but it would have been a while;" "I would have continued the pregnancy;" "I don't know what would have happened;" or "something else"), versus not ("I would have gotten an abortion at a clinic soon").

We also examined patient characteristics including: patient age at the time of abortion screening (younger than 18, 18-24, 25-29, 30-34, and ≥35 years); pregnancy duration (<35, 35-49, 50-62, and ≥63 days); self-reported race or ethnicity (Asian, Native Hawaiian, or Pacific Islander; Black; Hispanic or Latinx; White; multiracial, Native American, American Indian, or Alaska Native; Middle Eastern or North African; or unknown); urban versus suburban or rural residence based on the rural-urban commuting area codes corresponding to the patient's ZIP code [30]; and the round-trip driving distance to the nearest abortion facility (<5, 5-24, 25-49, 50-99, and ≥100 miles). In regression analyses, we collapsed patient age (younger than 24, 25-29, 30-34, ≥35 years) due to small cell sizes.

Data Analysis

We first described the median, IQR, and total amounts of round-trip driving distance, driving time, and public transit time averted using telehealth for abortion across the clinical chart sample. Next, we calculated median driving distances by the patient characteristic examined and tested for differences in driving distances by each characteristic using Kruskal-Wallis tests.

We used bivariate binomial regression to estimate prevalence ratios (PRs). We then calculated marginal estimates from these binomial regression models to estimate the proportion of participants within each category for whom telehealth made it possible to have an abortion in a timely manner as prevalence percentages (PPs). Analyses were conducted using ArcGIS Online, Stata (version 17.0; StataCorp), and RStudio (version 2022.10.0; Posit, PBC).

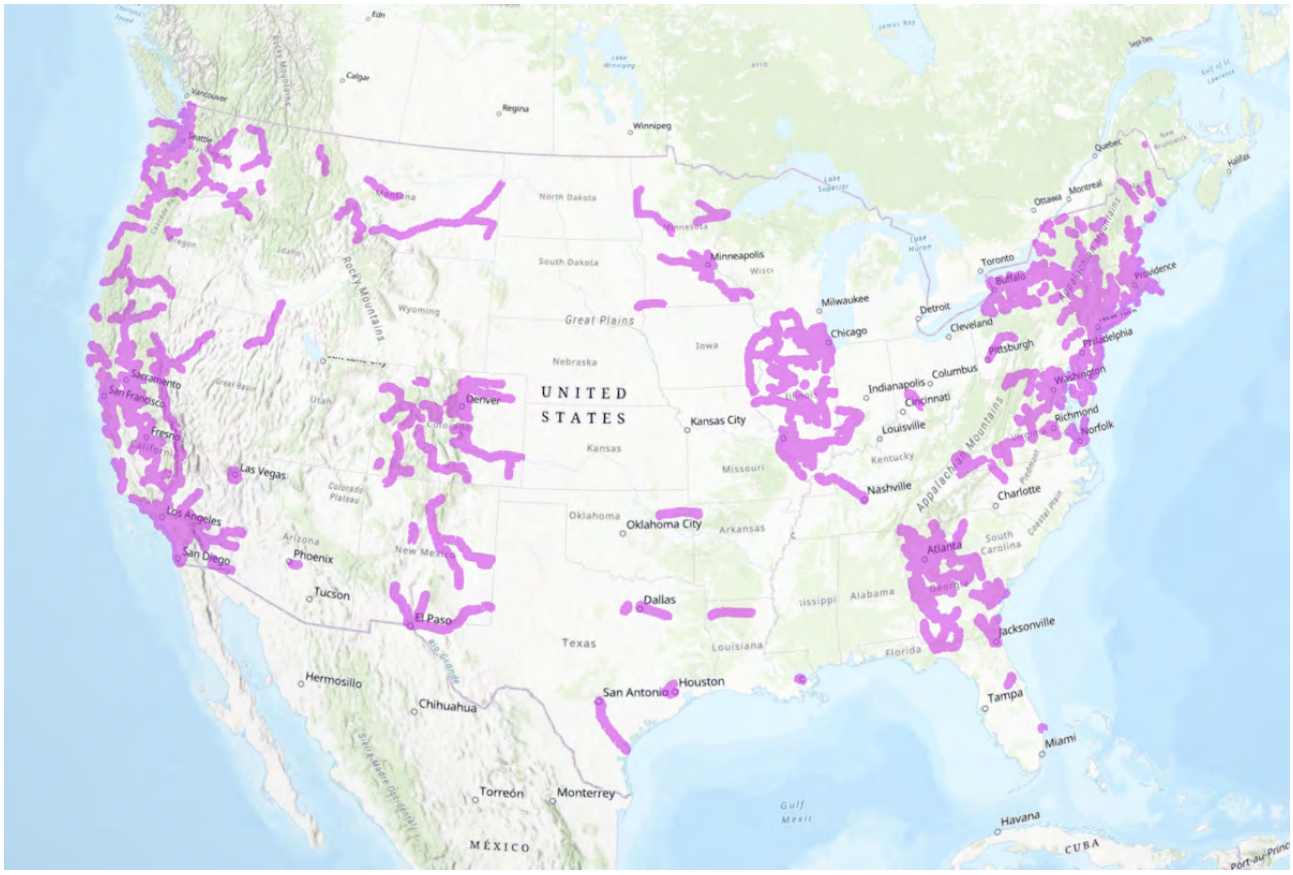
Ethical Considerations

This study was approved by the University of California, San Francisco institutional review board (20-32951). Clinical chart data that were deidentified except for patients' ZIP codes and dates of service were obtained from participating virtual clinics in accordance with their privacy policies. The subsample of patients who participated in detailed surveys provided electronic informed consent for their participation and were remunerated with a US $50 electronic debit card after the completion of the final survey. Clinical chart and survey data from participating virtual clinics were standardized and stored on a secure REDCap server [27].

Results

Overview

We obtained records for 6154 abortions provided by the virtual clinics between April 2021 and January 2022. Of those, 120 did not take medications, and 7 patients listed ZIP codes from which driving and transit distances could not be calculated, leaving 6027 records included overall. Among these, 1600 patients also participated in CHAT Study baseline surveys. The



XSL•FO
RenderX

ZIP codes in the dataset corresponded to 31 states and Washington, DC.

Travel Averted

The 6027 patients in this analysis averted a median of 10 (IQR 4.5-26.0, range 0.13-566) miles of round-trip driving travel and 25 minutes (IQR 14.1-46.1 minutes, range <1 minute-9 hours) of driving time each. Driving routes averted are depicted in Figure 1 and illustrate the vast distances averted and the distribution of these routes by region. This corresponded to a total of 162,663 miles and 4195 hours of driving averted across the sample (Multimedia Appendix 2). Next, we examined the total public transit time averted for the 5116 (85%) patients for whom public transit routes were available between patients' home ZIP codes and the nearest abortion facility. Patients in the sample averted a median of 1 hour 25 minutes (IQR 45.6 minutes-2 hours 30 minutes, range 2 minutes-48 hours) and a total of 11,720 hours of public transit time. Among the subsample of 1600 patients who completed surveys, patients averted a median of 10 (IQR 4.5-24.6) miles and 25 (IQR 14.3-44.1) minutes of driving, and 1 hour 26 minutes (IQR 46.5 minutes-2 hours 26 minutes) of public transit time. In total, this group of survey participants averted 41,746 miles and 1096 hours of driving, and 3070 hours of public transit time.

Figure 1. Driving routes to the closest abortion facility averted through telehealth (N=6027).

Sample Description

Characteristics of the clinical chart sample and of the survey participants are presented in Table 1. Among the survey subsample, most patients were 25-34 (51%, n=823) years of age and had pregnancy durations between 5 and 7 weeks (55%, n=885). Over half (53%, n=841) identified as White and in the remaining sample 13% (n=203) identified as Hispanic or Latinx; 9% (n=148) identified as Black; 7% (n=105) as Asian, Native Hawaiian, or Pacific Islander; and 19% (n=303) reported more than 1 race or ethnicity, another race or ethnicity, or their race or ethnicity was unknown. In total, 91% (n=1454) of the sample resided in an urban area.

Next, we examined whether patients perceived that telehealth made it possible to have an abortion in a timely manner. Approximately one-fourth (23%, n=371) thought they would have had an abortion at a clinic, but it would have taken some time. Meanwhile, 17% (n=268) did not know what would have happened, and 2% (n=29) said they would have continued the pregnancy. The other 57% (n=903) of the sample thought they would have gotten an abortion at a clinic soon.

We then evaluated differences in travel averted by patient characteristics (Table 2). White patients averted the most driving to the nearest abortion facility (median 12, IQR 5-30 miles), while Asian, Native Hawaiian, or Pacific Islander patients averted the least (median 8, IQR 3-16 miles). Urban residents averted a median of 9 (IQR 4-19) miles of driving time, while those living in rural areas averted a median of 83 (IQR 47-141) miles. The driving miles patients averted did not differ by age, pregnancy duration, or food insecurity.

The Role of Telehealth in Abortion Access

Next, we examined the differences in whether telehealth made it possible to obtain an abortion in a timely manner by patient characteristics and by the amount of travel averted (Table 3 and Figure 2). Compared to patients who were 35 years of age or older (PP 35.2%), telehealth was more likely to make abortion possible for patients 24 years of age or younger (PP 48.3%, PR 1.4, 95% CI 1.2-1.6) and for those of 25-29 years of age (PP 47.6%, PR 1.4, 95% CI 1.1-1.6). Patients who experienced food insecurity in the past month were more likely than those who had not experienced food insecurity to have reported that telehealth made a timely abortion possible (PP 51.2% vs 40.2%, PR 1.3, 95% CI 1.1-1.4). When we examined differences by race or ethnicity, patients who were Asian, Native Hawaiian, or Pacific Islander were less likely to report that telehealth made it possible to obtain a timely abortion than White patients (PP 30.5% vs 41.5%, PR 0.7, 95% CI 0.5-1.0). For patients who lived in rural areas, telehealth was more likely to make timely abortion care possible than those who resided in urban areas (PP 56.9% vs 41.7%, PR 1.4, 95% CI 1.2-1.6). Compared to those who averted 5-25 miles of driving to reach an abortion provider (PP 39.3%), those who averted less than 5 miles of round-trip driving (PP 47.7%, PR 1.2, 95% CI 1.1-1.4) or more than 100 miles of round-trip driving (PP 62.4%, PR 1.6, 95% CI 1.3-1.9) were more likely to perceive that telehealth made a timely abortion possible than those that averted less travel. The proportion of patients for whom telehealth made it possible to have an abortion soon was similar across pregnancy duration categories.

Discussion

Principal Findings

In this study, we found that direct-to-patient telehealth can be an important tool to overcome disparities in abortion access. While the expansion of telehealth is key to improving health equity broadly, abortion care is largely siloed to abortion facilities, which are few and far between and are now closing in record numbers [31]. Therefore, the impact of telehealth on improving equitable abortion access is even greater than for other health care services.

We found that using a telehealth abortion model can avert substantial driving distance and time for those with access to a car and travel time for those who would have used public transit. Our sample drew overwhelmingly from urban areas and from protected access states. Even so, while most of our sample resided close to an abortion facility, 15% lived 25 miles or further, and 7% lived 50 miles or further. Therefore, telehealth can expand the geographic reach of abortion services in states where abortion remains legal.

Telehealth abortion fits within an environmental justice framework, which views telehealth as a means of reducing the carbon footprint of health care services and space as a key component of health disparities [32,33]. Marginalized communities disproportionately bear the brunt of both unequal health policies and the unequal impacts of climate change. This analysis elucidates the connection between environmental justice and reproductive justice by examining abortion access within this framework of geospatial and environmental inequality.

These results suggest that telehealth abortion is poised to address health equity concerns across age, socioeconomic status, and geospatial location. Young people face unique logistical and privacy challenges, many of which can be alleviated by using telehealth, which allows patients to maintain privacy and avoid travel [34]. For low-income patients, the cost of abortion is often a substantial barrier to care, which is only exacerbated when coupled with the costs of associated travel [35]. Telehealth abortion has the potential to address geographic inequities in access to care for those living in abortion deserts or rural areas within protected access states. These findings on telehealth abortion fit within a broader literature that views telehealth as beneficial for reducing health care costs [36], serving underserved and rural patients [37,38], and easing the convenience and comfort of health care provision [39,40].

Compared to the national population of patients who obtained abortions during the same time period, patients in our sample who obtained abortions by telehealth were more likely to be older, White, and have higher socioeconomic statuses [41]. Thus, telehealth abortion may be reaching a subset of patients who are more resourced or have higher technology literacy. However, when patients were asked what would have happened had they not obtained the telehealth abortion, we found that for nearly half, telehealth made it possible to obtain timely abortion care. Telehealth was more likely to play this instrumental role in obtaining an abortion among patient populations who are known to face the most structural barriers to abortion care, such

XSL•FO
RenderX

as younger people, those experiencing food insecurity, those residing in rural areas, and those who resided far from an abortion facility [2,42]. Telehealth was less likely to make timely abortion care possible for Asian patients than White patients, perhaps due to urban residence and proximity to abortion providers. Given that telehealth abortion care is situated within a highly unequal health care landscape, there is interest in its role in mitigating inequities in abortion access [43,44]. Our results suggest that telehealth is playing different roles among different demographic groups within our sample. More specifically, while currently, White, urban patients might prefer telehealth due to its convenience or privacy, many patients from groups facing structural barriers to abortion care, such as people of color, those living on lower incomes, those who are younger, and those residing in rural areas, face greater distances to abortion facilities and thus may rely on telehealth for abortion access. These findings suggest that telehealth is key to promoting equitable access to abortion care in the United States, and expanding access to telehealth would be key for these groups.

We found that for patients who resided more than 100 miles from an abortion facility, telehealth was more likely to make it possible to access timely abortion care. This finding echoes prior research that has documented that geospatial barriers can determine whether patients obtain wanted abortions [4,5]. These results bolster the need for alternatives to in-clinic abortion care, especially as geographic access to abortion facilities grows increasingly unequal.

Limitations

This paper has several limitations. Our use of ZIP codes as the location of patient residences reduces the accuracy of the travel distances and travel times we calculated. This likely resulted in overestimated distances and times for some patients and underestimated distances and times for others; however, the net misclassification remains unknown [45]. Only one-fourth of patients elected to participate in the surveys, which may have introduced selection bias and limited the generalizability of these findings to the broader population of virtual clinic patients. Some patients from restricted access states who traveled for abortion care or used various mail-forwarding techniques may have chosen not to disclose their true home ZIP codes. Further, this analysis was conducted on data collected prior to the *Dobbs* decision in June 2022, after which 14 states have banned abortion care. Given the increased wait times for abortion care that have resulted from widespread abortion restrictions, many patients who seek in-person abortion care may need to travel further than their closest abortion facility. Therefore, our analysis may have underestimated the travel averted that we documented in this study. The overwhelming majority of patients in our sample resided in states that allow telehealth for abortion care. Most other states have laws that prohibit telehealth for abortion [15]. Our analysis, therefore, does not capture the full range of travel that could be averted if telehealth abortion care were available across the country. While we did not find that telehealth was more likely to make a critical difference in obtaining an abortion for people of color, this finding may be limited by the racial composition of our sample, in which Black and Hispanic patients, who face the greatest barriers to abortion care, were greatly underrepresented compared to the population of US patients who obtained abortions [41]. Despite these limitations, this study highlights the benefits of telehealth services by being among the first to use geospatial analysis to examine the travel averted, across both driving and public transit transportation, from using a telehealth model for abortion care.

Conclusions

This paper makes important contributions to a growing body of work on telehealth abortion and the broader literature on telehealth. Our findings support the role of telehealth abortion in reducing travel distance, time, and costs, which in turn mitigates the inequities embedded in abortion provision based on geospatial location, socioeconomic status, and local abortion policy. We found that telehealth can play a key role in accessing an otherwise unobtainable or delayed abortion, especially for marginalized patient populations. Future research should examine how telehealth abortion services can be tailored to improve health equity and digital inclusion. These findings may help direct future policy on expanding access to telehealth abortion, especially in the wake of the *Dobbs* decision, which is continuing to exacerbate longstanding inequities in abortion access. While states that ban abortion are unlikely to support telehealth for abortion, there are 6 states that permit abortion but restrict telehealth abortion care [14]. States invested in health equity that want to safeguard access in an increasingly restricted abortion landscape should legalize telehealth abortion. There is a need for federal actions to protect patients who seek and providers who dispense telehealth abortion care across state lines.

*Gynuity Health Projects, New York, NY, USA, †Gynuity Health Projects, Tbilisi, Georgia, and ‡Scientific Research Institute of Obstetrics and Gynaecology, Baku, Azerbaijan

ABSTRACT

Objective To examine the acceptability and feasibility of early medical abortion using mifepristone and misoprostol in Azerbaijan.

Methods A total of 863 women in Baku and two regions of Azerbaijan who sought termination of gestations up to 63 days were enrolled in the study. In the capital, women swallowed 200 mg mifepristone in the clinic and were given the option of taking 800 μg misoprostol buccally either at the clinic or at home 24–48 hours later. In the regions, women were given the option of taking both drugs at home. Follow-up visits were to take place two weeks after mifepristone administration to determine abortion status.

Results Seventy-four percent of women in the regions chose home administration of mifepristone, and 92% of women from all locations selected misoprostol home administration. Ninety-seven percent of women had complete abortions, and 97% were satisfied or very satisfied with the method. The vast majority of participants preferred medical abortion for a future procedure (96%). Nearly all women (98%) would recommend medical abortion for pregnancy termination to a friend.

Conclusion Mifepristone-misoprostol medical abortion with the option of home administration of both drugs is an acceptable and feasible option for women in Azerbaijan.

KEYWORDS Azerbaijan; First trimester pregnancy; Medical abortion; Mifepristone; Misoprostol

INTRODUCTION

The Republic of Azerbaijan, with a population of 9.4 million, is the largest country in the Caucasus region. Like in many of its neighbouring countries, abortion is a major and often resorted to method of fertility regulation[1,2]. The 2006 Demographic and Health Survey (DHS) reported a total abortion rate of 0.77 per woman year for the three-year period preceding the survey, with no difference between urban or rural residence[3]. The proportion of pregnancies that end in induced abortions increases dramatically with pregnancy order. The desire for small-sized families, early completion of childbearing, and continued reliance on traditional methods of contraception, contribute to persistently high rates of unwanted pregnancy and abortion[3,4].

Abortion has been legal for more than 50 years in Azerbaijan and, under the current law, abortion services

are available without restriction during the first 12 weeks of gestation. From 13 to 22 weeks of pregnancy, abortion is available only on select socioeconomic and broad medical grounds. Induced abortion can be performed by obstetrician/gynaecologists by either vacuum aspiration or sharp curettage under local or general anaesthesia depending on the woman's choice. Abortion procedures are permitted in private and public medical facilities. Women's consultation clinics can perform induced abortion only by electric or manual vacuum aspiration for pregnancies up to 6 weeks' gestation[5]. At the time these studies were conducted, mifepristone was not registered, and formal medical abortion services were not available in Azerbaijan.

Establishing mifepristone-misoprostol medical abortion in Azerbaijan would provide women with an alternative to surgical abortion and potentially increase access to safe abortion services. The World Health Organization recommends the use of 800 μg vaginal, buccal or sublingual misoprostol following 200 mg oral mifepristone for early medical abortion through 63 days since the last menstrual period (LMP)[6]. All three routes of misoprostol administration are highly effective, though some women prefer non-vaginal routes of administration and find in-the-mouth routes more private, comfortable and easy to administer[7–10]. This clinical trial examines the acceptability and feasibility of introducing the medical abortion regimen of 800 μg buccal misoprostol after 200 mg mifepristone up to 63 days' LMP in Azerbaijan. The study regimen also gave women the option to take the mifepristone at home, in addition to the misoprostol, which would afford them greater privacy, and allow them to schedule their bleeding around their other responsibilities.

METHODS

The first round of the study was conducted from October 2008 through March 2010 at two clinical sites in the capital city of Baku (Scientific Research Institute of Obstetrics and Gynaecology, and Family Planning Centre). The second round was conducted from November 2010 through November 2011 at three clinical sites in two north-western regions of Azerbaijan (Antenatal Clinic, Ganja; Family Planning Centre, Ganja; and Central Regional Hospital, Zakatala). All clinics provided surgical abortion services prior to this study. Clinicians at all five sites were trained in mifepristone-misoprostol medical abortion provision as well as in the study procedures. The Allendale Investigational Review Board reviewed and approved the study protocol. All participants gave written informed consent to participate in the study.

Women who presented for termination of a gestation up to 63 days' LMP were recruited to participate in the study. Exclusion criteria were suspicion of ectopic pregnancy, concurrent anticoagulant therapy, history of haemorrhagic disorders, concurrent long-term corticosteroid therapy, adrenal insufficiency, inherited porphyria, and known allergy to mifepristone or misoprostol. Gestational age was determined using one or more standard methods, including: menstrual history, physical examination, and ultrasound. In addition, women had to be 18 years or older, were expected to live or work within one hour of the study site, and had to be willing to return for a follow-up visit two weeks later.

In the first round of the study, women swallowed one 200 mg mifepristone pill (Pencrofton®; Pencroft Pharma, Russia) in the clinic and were given the option of taking misoprostol (Cytotec®; Pfizer, USA) either at the clinic or at home. During the second round of the study, women were given the option to take both the mifepristone and the misoprostol at home. For both rounds, women were instructed to take the misoprostol 24 to 48 hours after they had ingested the mifepristone.

Women opting for home administration of misoprostol were given four 200 μg pills of misoprostol to take at home. They were informed that they could return to the clinic to take the pills if they changed their minds. Participants were instructed to place two tablets of misoprostol between their cheek and gums on each side and to hold them there, letting the pills dissolve for 30 minutes, after which they were to swallow any remaining fragments. Participants choosing in-clinic misoprostol administration were given an appointment one to two days later to take the second set of pills in the presence of study staff. Women were given pain medication to use at their discretion. All participants were given a home study card with detailed instructions on misoprostol administration. Women in the capital were asked to note the date and time of misoprostol administration, the level of bleeding and any side effects experienced in the two weeks following mifepristone administration. Women in the region were asked to note the date and time of mifepristone

and misoprostol administration, and the number of missed days of work and/or school and hours of childcare needed due to the abortion. Participants were instructed to call the clinic if they had any questions and advised to return to the clinic if heavy or prolonged bleeding occurred, or if they experienced fever lasting six hours or more.

At the follow-up visit two weeks after mifepristone administration, providers used clinical examination and ultrasound as needed to determine the status of the abortion. Women with ongoing, viable pregnancies were offered a surgical abortion; those with incomplete abortions were given the option of a surgical completion or waiting another week, with or without an additional dose of 800 μg buccal misoprostol. If symptoms of incomplete abortion persisted after the additional week, a surgical completion was scheduled. Participants could request a surgical completion at any time during the study. If the abortion was determined to be complete, women were interviewed and discharged from the study.

This study assessed the acceptability and feasibility of mifepristone-misoprostol medical abortion, a new method of abortion in the country. The sample size (500 in the first round and 363 in the second) was selected to allow staff to gain expertise in this new method. Based on previous reports[11], we expected an efficacy rate of about 96%. All data were entered into SPSS version 13.0 at Gynuity Health Projects in Tbilisi and sent to Gynuity Health Projects in New York for analysis in SPSS version 15.0, using descriptive statistics. Analyses included all women who enrolled and provided any follow-up data.

RESULTS

Between October 2008 and November 2011, the study sites enrolled 863 women in total, 500 (58%) in the capital and 363 (42%) in the regions. None were lost to follow-up. Aside from one woman who did not take misoprostol after ingesting mifepristone and opted for surgical completion of the abortion instead, all participants followed the medical abortion protocol.

The median age of the women was 29 years, and more than half had completed a university education (Table 1). Nearly all participants were married and 90% had at least one live birth. More than two-thirds of them reported having had a previous abortion. Demographic characteristics were similar across the study sites, except that women from Baku were more educated than those from the regions.

Table 1 Characteristics of study participants ($N = 863$).

Age, years; median (range)	29 (17–48)
Highest level of education completed, %*	
High school or less	39
University	61
Married, %**	93
Gravidity; median (range)	4.0 (1–22)
Nulliparity, %	10
Previous abortion, %	70
Gestational age, days; median (range)	45.0 (30–63)

*$n = 858$; five women did not answer the question
**$n = 860$; three women did not answer the question

Ninety-seven percent of cases were successful (95% confidence interval [CI]: 96.2%, 98.4%), defined as complete abortions that did not require surgical completion at any point (Table 2). At the initial follow-up visit, 28 women presented with incomplete abortions with ten electing to have a surgical completion. The 16 subjects who received an additional dose of misoprostol and the two who chose expectant management all had complete abortions by their extended follow-up visit. There was no significant difference in success rates between participants who took the mifepristone at home and those who took it in the clinic. Success rates remained high as gestational age increased, with 96% of women with pregnancies of 57 to 63 days' LMP having a successful abortion. Twenty-three women received a surgical intervention to complete the abortion, seven of whom were diagnosed with

Table 2 Outcome of medical abortion ($N = 863$).

Success, %*	97
Success by gestational age category, % (*n*)*	
up to 49 days' LMP	97 (608/627)
50–56 days' LMP	99 (152/153)
57–63 days' LMP	96 (80/83)
Failure, % (*n*)	3 (23)
Ongoing pregnancy	0.8 (7)
Incomplete abortion	0.6 (5)
Surgery due to heavy bleeding	0.5 (4)
Surgery at patient request	0.8 (7)

*Success defined as complete abortion without recourse to surgical evacuation at any point during the study period.

Table 3 Top reasons for choice of mifepristone location among women in the region, % (*n*)*.

	Home administration (n = 267)		*Clinic administration (n = 96)*	
1	Presence of partner	49 (130)	Like staff presence	82 (74)
2	More private experience	35 (94)	Less anxiety	72 (65)
3	Compatible with duties	32 (84)	More comfortable	21 (19)
4	More comfortable	32 (84)	More private experience	14 (13)
5	Easier to plan childcare	27 (73)	Flexibility with schedule	11 (10)

*Women were allowed to choose more than one answer.

ongoing pregnancies. Ultrasound was used at the follow-up visit to determine abortion status for one-third of participants in the region and 86% of participants in Baku.

Overall, three quarters (74%) of women given the option chose to take the mifepristone at home rather than in the clinic. Almost half made this choice because they wanted their partner present, and more than one-third wanted a more private experience (Table 3). Of women who chose to take the mifepristone in the clinic, 82% liked the presence of clinic staff, and many stated that being in the clinic would make them less anxious about the procedure. All of the women in the home user group took mifepristone at the scheduled time (defined as within a window of ± 6 hours of the time they had selected with the provider) (Table 4). Only two of the 267 women selecting home mifepristone chose to take the pill a day or more after their initial visit with the doctor.

Home administration of misoprostol was offered to all participants, both in the capital and in the regions, and over 90% of them selected this option. All home mifepristone users and 88% of clinic mifepristone users chose to take the misoprostol at home. Among home misoprostol users, 96% took the drug within the therapeutic range of 24 to 48 hours after mifepristone. Only one woman deviated from her scheduled time of administration (defined as within a window of ± 6 hours of the selected time), taking the misoprostol 13 hours earlier than planned.

Participants in both groups were asked about the side effects they experienced during the abortion (Table 5). Women from the capital were instructed to document them daily on the home study card, while those from the region were asked to recall side effects at their follow-up visit. More than half of the subjects from Baku reported nausea, which was also the most frequently reported side effect among women from Zakatala and Ganja. Other commonly reported side effects included fever/chills and vomiting. Eighty-five percent of participants found the side effects acceptable or very acceptable.

Table 4 Timing of mifepristone and misoprostol administration.

Mifepristone administration among women in the region, % (n)		
Chose home mifepristone	74 (267/363)

Took home misoprostol at scheduled time, % (*n*)*	99.6 (266)	100 (525)
Median mifepristone-misoprostol interval, h (range)	48 (25–52)	47 (26–54)

*Women who took the drug ± 6 hours of the scheduled time were considered to have taken the drug on time.

Table 5 Reported side effects of medical abortion, %.

	*Capital (n = 500)**	*Region (n = 360)***
Nausea	53	38
Fever/chills	23	15
Diarrhoea	1	3
Vomiting	25	13
Other***	1	0.3

*Women from the capital reported side effects on the home study card.
**Women in the regions reported side effects at their exit interview.
***Other reported side effects included weakness, drowsiness, headache, syncope.

For the most part, women in the regions did not report that the abortion interfered with their work responsibilities. A little more than one third of the participants worked outside of the home, and only three reported that the medical abortion caused them to miss work. Additionally, the medical abortion interfered with the ability to fulfil childcare responsibilities for only less than 1% of participants.

At the follow-up exit interview, participants were asked about their experience and acceptability of the medical abortion (Table 6). Nearly all (96%) were satisfied or very satisfied with the method. Ninety-six percent of them would prefer medical over surgical abortion in the future, and 98% would recommend the medical method to a friend. Almost all women were satisfied with the counselling they received from their provider, reporting that they felt prepared for the amount of bleeding and pain, and the duration of the entire medical abortion procedure. In the regions, almost all participants (99%) who chose home administration for mifepristone would prefer home use again, while a third of clinic mifepristone users would switch to home use in the future. Women at all sites were very satisfied with taking the misoprostol at home, with 93% preferring home use in the future.

Women were asked to report the best and worst features of the abortion. The most commonly cited best feature was avoiding surgery and anaesthesia, followed by having a successful abortion without complications. More than half of participants felt that pain/cramps were the worst feature, with those from the capital reporting it with much higher frequency than regional residents (83% vs. 28%). Few women reported that there were no best or worst features of the abortion, 2% and 5%, respectively.

Table 6 Women's reported experience with and acceptability of medical abortion, % (*n*).

Very satisfied/satisfied with method	97 (828/858)
Side effects very acceptable/acceptable	85 (723/855)
Prefer medical abortion as method of next abortion	96 (820/859)
Prefer home as next place of misoprostol administration	93 (794/856)
Would recommend to a friend	98 (839/859)
Best features*	
Avoided surgery/anaesthesia	66 (569/859)
Successful, no complications	57 (485/859)
Home administration of misoprostol	28 (242/859)
Easy, quick, simple treatment	21 (179/859)
Private, confidential	13 (114/859)
No best feature	2 (19/859)
Worst features*	
Pain, cramps	60 (517/860)
Anxiety	39 (334/860)
Bleeding	33 (287/860)
Nausea, vomiting	29 (246/860)
Duration of procedure	18 (153/860)
No worst feature	5 (43/860)

*Women could choose more than one answer.

Providers at all sites were satisfied with the method; overall, only 6% of women made an unscheduled visit or call to the clinic with concerns about the abortion. Regardless of where participants chose to take the mifepristone, the providers in the region would recommend home administration of mifepristone for almost every patient if she was to have another abortion in the future.

DISCUSSION

Findings and interpretation

The study shows that medical abortion is highly feasible and acceptable in Azerbaijan. High success rates were achieved in the capital city, Baku, as well as in the regions. Almost all women enrolled in the study were either very satisfied or satisfied with the method, and stated that they would choose this method if termination of an unwanted pregnancy is needed in the future. The majority of participants would opt for home

administration of mifepristone as well as misoprostol, and nearly all would recommend medical abortion method to a friend.

Women who take mifepristone at home may be better able to schedule their bleeding around their work and family responsibilities, and previous research has shown that this option is safe and acceptable to women and providers[11]. This study confirmed the desirability of this option, evidenced by the high proportion of participants (74%) who opted for home administration of mifepristone. However, the opportunity to time the bleeding so that it did not conflict with daily activities did not seem to be the prime motivation of women's wish to use the mifepristone at home, contrary to what we believed, as most in the home group did not delay mifepristone administration after seeing the doctor, even if their appointments were earlier in the week.

Misoprostol home administration is a widespread practice in many countries[12] and appeared to be similarly preferable for women in Azerbaijan. The study demonstrated that women were able to take mifepristone and misoprostol on their own without increasing the burden on clinic staff through extra calls and visits, and providers were confident in their patients' abilities to take the mifepristone and misoprostol independently as well.

Reports of side effects were higher in Baku than in the regions, which may be due to differences in the method of data collection between the rounds. Women from Baku were told to record side effects on the home study card each day, while women in the regions were asked to recall them during the exit interview at the follow-up visit. However, previous research that collected side effects information from the same women through both means of data collection found differences of less than 10%[13]. Regardless of the data source, nausea was by far the most commonly reported side effect.

Despite widely varying ultrasound rates at the follow-up visit, success rates across all sites were 97 to 98%. Because medical abortion was a new method, some doctors were reluctant not to use this diagnostic tool. Yet, reducing the unnecessary use of ultrasound could decrease the cost of the procedure and make the method more accessible to women.

For the purposes of the study, all participants were encouraged to return to the clinic for follow-up in order to provide information on the outcome of their abortion. However, WHO's most recent recommendations state that there is no medical need for a routine follow-up visit following an uncomplicated medical abortion[6]. In the future, providers as well as women in Azerbaijan should be advised that follow-up can occur by phone in most cases, saving women time and costs associated with travel, and reducing the burden on clinics.

Strengths and weaknesses of the study

Our study was conducted in both the capital of Azerbaijan and in regional areas of the country. Having information on women residing in other parts of the country allows us to generalise the results to the majority of women in Azerbaijan.

One weakness of our study is that women were interviewed by study doctors to ascertain their satisfaction and acceptability of the medical abortion method, which may have led to over-reporting due to social desirability bias. Additionally, more women in the capital are likely to work outside of the home but because we did not offer them the option of taking mifepristone outside of the clinic, we were unable to assess the acceptability of this option among those who may find it more beneficial to schedule their bleeding for convenience than women living in the regions.

Differences in results and conclusions in relation to other studies

The success rate of 97% of complete abortions and an ongoing pregnancy rate of 0.8% are comparable to the rates our team reported earlier for the use of the same regimen (800 μg buccal misoprostol 24 to 48 h after 200 mg mifepristone)[13,14]. In addition, the high levels of satisfaction among women were similar to those from trials conducted in other countries of the former Soviet Union[15–17].

Compared to earlier research, the home mifepristone option was even more popular in this setting (with 74% choosing this option, compared to 46% in a US population)[11]. In some settings like Moldova where the drugs can be purchased at the pharmacy with a prescription, home use of mifepristone may be the norm (Bracken H., Personal communication, 12 May 2014). Whereas American women primarily chose home mifepristone because it afforded them flexibility in their schedule, participants in this study

strongly valued having their partner present. This may reflect the higher proportions who were working and/or in school in the US study.

Relevance of the findings: Implications for clinicians and policymakers

Our results provide evidence to support the use of medical abortion in Azerbaijan. At the time of study implementation, only surgical abortion services were available in the country. The success of this study convinced health officials that medical abortion services should be established and triggered negotiations with pharmaceutical companies to register mifepristone in the country, with the drug receiving approval in July 2013. In addition, local experts developed national guidelines for medical abortion in the early first trimester, which will be used to foster the process of institutionalising medical abortion services country-wide now that mifepristone is registered and becoming available.

More broadly, the results of this study contribute to the evidence and can help build confidence among clinicians everywhere that this step in increasing convenience and autonomy for women is a feasible and important one to take.

Unanswered questions and future research

This study identified a need to train providers on when ultrasound use is warranted. Additional research on alternatives to in-person follow-up would be helpful to demonstrate the safety of relaxing this requirement, which would be especially pertinent to those who travel long distances to seek care.

CONCLUSION

This study, conducted in the capital as well as in regional cities in Azerbaijan, provides strong evidence that mifepristone-misoprostol medical abortion is a highly effective, safe and acceptable option to women which can be expanded nationwide. Offering a simplified, non-surgical method for pregnancy termination will be a beneficial and important step in improving the quality of reproductive health care for women in the country.

ABSTRACT

Objective: To simplify follow-up after medical abortion by examining whether women could use a semi-quantitative pregnancy test at home to screen for ongoing pregnancy. *Methods:* Three hundred women seeking medical abortion at a tertiary hospital in Vietnam participated in the study. Participants used a semi-quantitative pregnancy test at the hospital to estimate baseline human chorionic gonadotropin (hCG) levels and administered another test at home 2 weeks later for comparison. Women interpreted the test result at home and then returned to hospital for follow-up care. At this visit, self-assessment was verified. To assess further the feasibility of the test as a follow-up tool in service delivery, 200 additional women completed a user comprehension survey. *Results:* The tests identified all 11 ongoing pregnancies among study participants (100% sensitivity; 89.7% specificity). Women reported that the test was easy to use (255/292 [87.3%]) and that provider instructions helped them to use the test (291/292 [99.7%]). *Conclusion:* Semi-quantitative pregnancy tests offer high sensitivity and negative predictive value. If user instructions can be further simplified, the tests could be used in lieu of transvaginal ultrasound and/or serum hCG at clinic-based follow-up or by women themselves for home-based follow-up.

1. Introduction

Common practice for medical abortion includes clinic-based follow-up and clinical assessment, including transvaginal ultrasound, to determine abortion status. This follow-up visit can be costly and time consuming for both the healthcare system and the woman [1,2]. As medical abortion becomes more widely used, many women simply do not return to the clinic to receive clinician confirmation of complete abortion. Providing women with a safe, effective, and affordable at-home diagnostic tool to confirm whether a pregnancy is ongoing after administration of mifepristone and misoprostol could reduce costs and simplify the procedure by limiting the number of clinic visits and costly exams, and reducing waiting time. Ideally, during her initial clinic visit, a woman would receive misoprostol, a pregnancy test, and counseling on how to manage her abortion at home. With these tools, the majority of women could manage their abortion at home on their own. With this objective in mind, providers and researchers have explored ways to simplify medical abortion follow-up with serial human chorionic gonadotropin (hCG) testing, high- and low-sensitivity pregnancy tests, and telephone or other virtual follow-up [3–7].

Quantitative serum hCG testing to confirm abortion completion is commonly used in the USA and Europe. Previous research has documented change in hCG level after medical abortion [6,8–10]. Since 2005, Planned Parenthood Federation of America has waived the follow-up visit if it poses undue hardships owing to distances from abortion facilities or other reasons, and women manage their follow-up with serial hCG testing [11]. This method of follow-up has proven effective because ongoing pregnancies exhibit increasing hCG levels (hCG levels that do not increase in the 2 weeks after mifepristone administration indicate that no viable pregnancy is present). In general, in the event of a successful medical abortion, the hCG level decreases by at least half of its pretreatment level within a week of mifepristone administration [12]. Service delivery programs seeking to integrate serum hCG testing into medical abortion follow-up services must confirm that it is acceptable and affordable to women and compatible with the infrastructure and human resources available. In some instances, laboratory confirmation of hCG results can be delayed for hours or days, depending on the location of the laboratory and the volume of specimens processed. This delay might be incompatible with efficient service delivery.

Serum hCG testing can also be very expensive. Furthermore, in some low-resource settings, serum hCG testing is not yet widely available.

Urine pregnancy tests offer another way to measure hCG level. Several studies have documented that urine hCG level is highly correlated with serum hCG level in confirming pregnancy status [3,4,13]. Other research has modeled various algorithms to confirm abortion success using patient symptoms and a low-sensitivity urine pregnancy test [14]. Grossman et al. [7] reviewed published studies examining alternatives to follow-up, including serial hCG testing, urine pregnancy tests, and telephone interview. The authors concluded that alternative follow-up modalities could successfully identify ongoing pregnancy and proposed that further research examine service delivery options that include both at-home urine pregnancy tests and self- or clinician assessment.

In an effort to offer something potentially less costly and less invasive than serum hCG testing or sonography but more informative than a simple low-sensitivity pregnancy test, the aim of the present study was to investigate the feasibility of Vietnamese women performing a semi-quantitative pregnancy test at home, on their own, to determine their abortion status.

2. Materials and methods

From September 14, 2009, to April 2, 2010, 300 women presenting for medical abortion with pregnancies dated up to 63 days since last menstrual period were recruited at a large tertiary facility in Ho Chi Minh City, Vietnam. Additional inclusion criteria were intrauterine pregnancy; no known contraindications to abortion with mifepristone and/or misoprostol; general good health; ability to provide informed consent; and willingness to return for follow-up.

Study clinical staff identified potential participants and offered them enrollment. After the consent and screening process was completed, study staff taught participants how to perform the urine-based semi-quantitative pregnancy test. The result of this initial test, carried out prior to mifepristone administration, located the range of each participant's hCG level before abortion. A 5-bracketed semi-quantitative immunochromatographic assay panel (dBest hCG Panel Test; Ameritek, Seattle, WA, USA) was used (Fig. 1). The test operates as both a high-sensitivity (at least 25-mIU/mL reading) and a low-sensitivity (at least 2000-mIU/mL and at least 10 000-mIU/mL reading) test, in addition to providing readings at 2 other ranges (>100 mIU/mL and >500 mIU/mL). The test offers a technical improvement compared with other pregnancy tests because it provides greater precision to help minimize the likelihood of false-negative results and, uniquely, provides information about the trend in hCG level, which can be compared with the pre-abortion level for each woman. Tests were conducted by dipping the test strip into a urine cup and stirring the strips for at least 10 seconds to saturate the test thoroughly. Training emphasized the need to stir and soak the panel to achieve saturation. The tests were then placed face-up on a flat surface and read 15 minutes later.

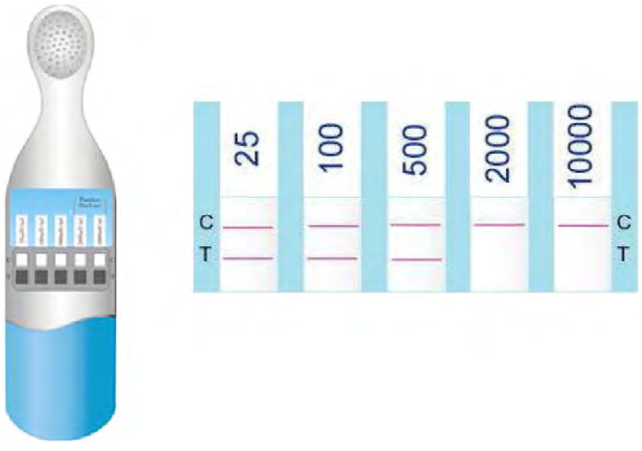

Fig. 1. The dBest (Ameritek, Seattle, WA, USA) semi-quantitative pregnancy test showing a reading of 500 mIU/mL of human chorionic gonadotropin (hCG). C denotes control line. A control line indicates that the test strip has been properly saturated with urine. A control line must appear in all 5 columns for the test to be considered valid. T denotes test line. A test line indicates a positive test result. A column with 1 line (a C line but not a T line) is indicative of a negative test reading. A column consisting of 2 lines (a C line and a T line) indicates a positive test reading for the specific level of hCG.

Each woman was provided with misoprostol for home administration, a second semi-quantitative pregnancy test, a urine sample cup, an instruction sheet, and a questionnaire to take home. Participants administered misoprostol at home 1–2 days later. Women were instructed to take the test and complete the form on the morning of their follow-up visit, which was approximately 2 weeks after mifepristone administration. Either first morning urine or random urine could be used. Emphasis was placed on the importance of saturating all 5 paper strips and waiting at least 15 minutes before reading the tests. The instruction sheet included information on how to read the test and pictorial images of each possible result, as well as a list of commonly asked questions with responses.

Regardless of the results of the pregnancy test conducted at home, each participant was scheduled for clinic-based follow-up. Participants were asked to bring their completed pregnancy tests and study questionnaires with them to this visit. Clinicians then documented the result of the at-home pregnancy tests and assessed each participant's abortion status using standard clinical means, including physical examination and/or transvaginal ultrasound. The results of this standard clinic-based examination were used to determine whether additional care was needed. Women who forgot to complete the at-home pregnancy test or for whom the at-home test showed an inconclusive result were given an additional test to perform at the clinic.

A user comprehension survey was also conducted among 200 additional women of any age from the patient waiting area to ascertain whether potential users understood how to use and interpret the test. Participants were randomly provided with a sample semi-quantitative pregnancy test that indicated 1 of the 5 possible results, the instruction sheet, and a questionnaire. Women were asked to use the instruction sheet to interpret the test results and to complete the questionnaire.

The primary outcome of the clinical study was the feasibility of using the test as part of follow-up for medical abortion. To that end, we documented whether the tests identified all ongoing pregnancies (the main outcome of interest) and whether participants were able to interpret the test correctly. Clinician assessment, via pregnancy test or ultrasound/clinical examination, determined abortion status; semi-quantitative pregnancy test results were evaluated in comparison with this assessment. The primary outcomes of the user comprehension study were the ability to both understand and interpret the test. Data entry and analysis were performed using SPSS version 15 (IBM, Armonk, NY, USA) and STATA version 11 (StataCorp, College Station, TX, USA). Sensitivity/specificity and positive/negative predictive values were calculated to assess the accuracy of the pregnancy test in identifying ongoing pregnancies. Because the main outcome of interest—identification of ongoing pregnancy—would be rare following early medical abortion with mifepristone and misoprostol, it was determined that 300 participants for the clinical study and 200 participants for the user comprehension study would be sufficient for assessing the feasibility of the test in medical abortion care. Ethics approval was provided by Hung Vuong Hospital, Ho Chi Minh City.

3. Results

On average, participants were 29 years of age and most had a secondary education or higher (Table 1). Medical abortion was successful

Table 1
Clinical participant characteristics (n = 300).[a]

Characteristic	Value
Age, y	29 ± 6 (18–44)
Education completed	
Primary school (1–5 years)	10 (3.3)
Secondary school (6–12 years)	232 (77.3)
University level or higher	58 (19.3)
Gestational age, d	42.4 ± 5.9 (30–64)
Medical abortion outcome[b]	
Complete abortion	275 (93.9)
Surgical intervention	18 (6.1)
Ongoing pregnancy	11 (3.8)
Medically indicated (persistent/heavy bleeding)	2 (0.7)
Persistent non-viable pregnancy or sac	4 (1.4)
Provider or woman's preference	1 (0.3)
Participant thought she was still pregnant (or was unsure) prior to taking at-home test[c]	54 (18.5)
Participant had complete medical abortion	41 (75.9)
Participant had surgical intervention	13 (24.1)

[a] Values are given as mean ± SD (range) or number (percentage).
[b] Data do not include 4 women who were lost to follow-up and 3 women who left the study early.
[c] Data do not include 4 women who were lost to follow-up, 3 women who left the study early, and 1 woman with successful medical abortion who did not return her home questionnaire.

for 275 of 293 (93.9%) participants. Eighteen women underwent surgical intervention owing to: ongoing pregnancy (11 [3.8%]); bleeding (2 [0.7%]); persistent non-viable pregnancy or sac (4 [1.4%]); or provider or woman's preference (1 [0.3%]). Fig. 2 shows the trial profile.

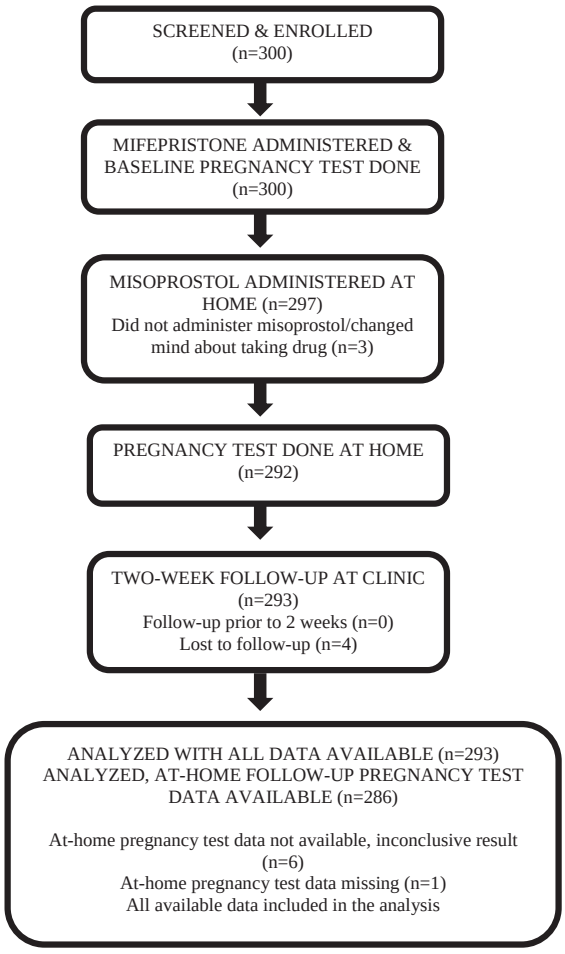

Fig. 2. Clinical trial profile.

Table 2
Sensitivity/specificity and positive/negative predictive values of SQPT to detect ongoing pregnancy versus all other outcomes based on user reading in the clinical study.[a]

	Ongoing pregnancy	All other outcomes
Test indicated steady or increasing hCG level, or test inconclusive[b]	100.0% (11/11)	10.3% (29/281)
Test indicated decreasing hCG level	0.0% (0/11)	89.7% (252/281)
Sensitivity: 100.0%		Specificity: 89.7%
Positive predictive value: 27.5%		Negative predictive value: 100.0%

Abbreviations: hCG, human chorionic gonadotropin; SQPT, semi-quantitative pregnancy test.
[a] User reading unavailable for 1 woman for whom home pregnancy test data were not available.
[b] All 6 women with inconclusive test results had successful medical abortions with no additional intervention.

On the morning of the follow-up visit, participants used the semi-quantitative pregnancy test at home and recorded their interpretation of the result. Fifty-four of 292 (18.5%) participants reported that they thought they were still pregnant prior to using the at-home test (Table 1). The test identified all 11 ongoing pregnancies, with 100% sensitivity (11/11) and 89.7% specificity (252/281) (Table 2). In addition to identifying all of the ongoing pregnancies, the test did not show a decrease in hCG level for an additional 29 women (Table 3). Of these, 24 received no intervention at follow-up and 5 underwent treatment for persistent non-viable pregnancy or sac. None of the participants whose tests showed a decrease in hCG level from baseline to follow-up was later identified as having an ongoing pregnancy. Four of 252 (1.6%) women who showed a reduction in hCG level received interventions at the follow-up visit (Table 3).

Among the 11 women for whom the test identified an ongoing pregnancy, 10 (90.9%) understood that an additional clinic visit was needed. Of the 252 women whose test indicated that clinic-based follow-up was not needed, 147 (58.3%) understood that no additional visit was necessary. Most participants (255/292 [87.3%]) reported that the test was “very easy” or “easy” to use. Nearly all participants (291/292 [99.7%]) felt that the information given by providers helped them use the test.

Results from the user comprehension survey are shown in Table 4. Participants had similar profiles to women participating in the clinical study. When given a test with a pre-configured result and shown an illustration of the 5 possible test outcomes, 195 (97.5%) women correctly matched the test they had been given with the correlating illustrated result. Education level did not impact the capacity of survey participants to interpret the test correctly. In total, 190 of 195 (97.4%) women understood the numeric value of the test. Only 7 (3.5 %) women felt that the test was difficult to use. Overall, 196 (98.0%) participants felt that they could use the test on their own in the future; this perception was not impacted by education level.

4. Discussion

The present results complement previous findings that urine hCG testing can be used as part of early medical abortion follow-up [3–5]. The use of a semi-quantitative test instead of universal clinic-based follow-up could significantly impact medical abortion service delivery because the test could be used as at-home follow-up for women living away from abortion facilities who may wish to avoid a follow-up visit if not required. For women undergoing clinic-based follow-up, the test could provide an alternative to transvaginal ultrasound (often repeated several times for each woman) as the primary means for confirming a complete medical abortion. A tool such as the semi-quantitative pregnancy test could reduce the proportion of women paying for and receiving ultrasound. It would also free-up

Table 3
Effectiveness and acceptability of SQPT in assessing medical abortion outcomes.

	No. (%)
Intervention at follow-up among women whose at-home pregnancy test showed steady or increasing hCG level, or test was inconclusive (n = 40)[a]	
No intervention	24 (60.0)
Intervention performed	16 (40.0)
Ongoing pregnancy managed surgically	11 (27.5)
Persistent non-viable pregnancy or sac managed surgically or with additional dose of misoprostol	5 (12.5)
Intervention at follow-up among women whose at-home pregnancy test showed decreasing hCG level (n = 252) [a]	
No intervention	248 (98.4)
Intervention performed	4 (1.6)
Ongoing pregnancy managed surgically	0 (0.0)
Persistent non-viable pregnancy or sac managed surgically or with additional dose of misoprostol	1 (0.4)
Medically indicated (persistent/heavy bleeding)	2 (0.8)
Provider or woman's preference	1 (0.4)
SQPT reading identified ongoing pregnancy	11/11 (100.0)
Participant understood that this result meant that an additional clinic visit was needed	10 (90.9)
Participant did not understand that an additional clinic visit was needed	1 (9.1)
SQPT reading indicated that clinic-based follow-up was not needed	252/281 (89.7)
Participant understood that this result meant that no additional clinic visit was needed	147 (58.3)
Participant did not understand that no additional clinic visit was needed	105 (41.7)
Participant report on ease of use of test (n = 292)	
Test was neither easy nor difficult	37 (12.7)
Test was "easy" to use	143 (49.0)
Test was "very easy" to use	112 (38.4)
Participant felt that the information given by providers helped them use the test (n = 292)	291 (99.7)

Abbreviations: hCG, human chorionic gonadotropin; SQPT, semi-quantitative pregnancy test.
[a] Includes 14 of the 18 women who underwent surgical intervention (all 11 with ongoing pregnancies and 3 with persistent non-viable pregnancy or sac); the other 4 had pregnancy tests indicating a decrease in hCG level.

provider time for other services and may reduce the number of unnecessary surgical completions for retained products of conception. Such effects may be especially beneficial in resource-poor countries, where clinics may be overcrowded and understaffed, with limited access to serum hCG testing and ultrasound.

The semi-quantitative pregnancy test, with its 5-bracketed ranges, enabled ongoing pregnancy to be ruled out earlier than in previous studies using high- or low-sensitivity pregnancy tests. For instance, Perriera et al. [5] investigated the at-home use of a high-sensitivity pregnancy test 4 weeks after mifepristone administration as part of a telephone follow-up study. Nearly three-quarters of participants were able to avoid clinic-based follow-up; however, they had to wait 4 weeks to confirm that their abortion was complete [5]. In the present study, women were able to confirm their abortion outcome 2 weeks after mifepristone administration. In another study using the same semi-quantitative pregnancy test, women in the USA obtained results using the test just 1 week after mifepristone administration [15]. The semi-quantitative pregnancy test enables women to find out their abortion status sooner, thereby shortening the duration of the procedure. Furthermore, in the rare event of a continued ongoing pregnancy after early medical abortion, diagnosis of a growing embryo 1 to 2 weeks after mifepristone administration facilitates earlier clinical action.

Table 4
Results of user comprehension survey (n = 200).[a,b]

Characteristic	Value
Age, y	31 ± 8 (18–55)
Education completed	
Primary school (1–5 years)	26 (13.0)
Secondary school (6–12 years)	130 (65.0)
University level or higher	44 (22.0)
Pregnancy test was matched with correct corresponding image	195 (97.5)
Among women with less than college degree	151/156 (96.8)
Among women with college degree or higher	44/44 (100.0)
Understood numeric value of test	190/195 (97.4)
Among women with less than college degree	147/151 (97.4)
Among women with college degree or higher	43/44 (97.7)
Instruction sheet helped with interpreting pregnancy test results	198/199 (99.5)
Test was easy to use	
Very easy/easy	100 (50.0)
Neither easy nor difficult	93 (46.5)
Difficult/very difficult	7 (3.5)
Woman believed she could use test on her own in the future to determine pregnancy status	196 (98.0)
Among women with less than college degree	153/156 (98.1)
Among women with college degree or higher	43/44 (97.7)

[a] Values are given as mean ± SD (range) or number (percentage).
[b] Participants in the user comprehension survey were not the same women as in the clinical study.

The potential feasibility of using this test in resource-poor settings is underscored by the fact that nearly all of the participants in both the clinical study and the user comprehension survey reported that the test was easy to use. It should be noted, however, that most of the participants in the present study had completed at least secondary-school education. Despite the nearly unanimous responses that the test was easy to use, when asked to interpret their own test results, nearly half of the women with a decrease in hCG level were not sure whether they needed clinic-based follow-up. Interestingly, an increase or no change in hCG level seemed to be more easily understandable for participants: nearly all (90.9%) of those with ongoing pregnancy correctly interpreted their results. Future simplifications of the instructions sheet should help to improve user comprehension in this regard. Upon discussion with the study investigators, we hypothesize that the design of the study protocol—stipulating that all women must return for follow-up—may have confused women when asked to respond to the question of whether they felt they "needed" to return for follow-up.

The present study was limited by its small sample size and geographic specificity to a single hospital in 1 country, with results that may not be generalizable to other settings. The small sample size meant that potential differences in the cohort could not be examined; instead, the feasibility of this potential service delivery innovation was examined and information was collected from which larger prospective studies could be conducted.

Future research should document how post-abortion contraception can be integrated into medical abortion services with at-home follow-up protocols. More operational research to document "virtual" reporting of at-home follow-up using cellular phones and/or the Internet could also reveal the benefits of this type of service delivery in a range of settings.

Allowing women the option to use semi-quantitative pregnancy tests as at-home tools in lieu of clinic-based follow-up with ultrasound has potential for significant cost-savings for both the healthcare system and women. Yet, for this to be realized, the test must be widely available and at a low cost. Currently, only 1 manufacturer produces the semi-quantitative pregnancy test, meaning that wide availability is inhibited. Future efforts should seek to increase access to this promising technology.

FDA U.S. FOOD & DRUG ADMINISTRATION

June 2, 2025

The Honorable Josh Hawley
United States Senate
Washington, D.C. 20510

Dear Senator Hawley:

Thank you for your letter to the Food and Drug Administration (FDA or the Agency) regarding the safety of mifepristone for the medical termination of early pregnancy. I appreciate your continued interest in this topic.

FDA is committed to safeguarding public health by ensuring the safety, efficacy, and quality of the products it regulates. The Agency carefully evaluates the scientific data, leveraging rigorous science to make informed decisions. As with all drugs, FDA continues to closely monitor the postmarketing safety data on mifepristone for the medical termination of early pregnancy. As the Commissioner of Food and Drugs, I am committed to conducting a review of mifepristone and working with the professional career scientists at the Agency who review this data.

Mifepristone for medical termination of early pregnancy is the subject of pending litigation. FDA generally does not comment on matters that are the subject of pending litigation and therefore is unable to provide further information on this topic at this time.

Thank you again for contacting the Agency regarding this matter. Please do not hesitate to reach out if there are any additional questions.

Sincerely,

Martin A. Makary, M.D., M.P.H.
Commissioner of Food and Drugs

U.S. Food & Drug Administration
10903 New Hampshire Avenue
Silver Spring, MD 20993

GenBioPro, Inc.
P.O. Box 32011
Las Vegas, NV 89103

The Honorable Robert M. Califf, MD
Commissioner
Food and Drug Administration
10903 New Hampshire Avenue
Building 32, Room 2346
Silver Spring, MD 20993-0002

March 1, 2023

Dear Commissioner Califf:

GenBioPro, Inc. ("GBP") is dedicated to ensuring that people have access to evidence-based, essential medications and, to that end, markets a generic version of Mifeprex (mifepristone) 200 mg consistent with FDA's regulatory regime. Given the external environment, I write to request prompt confirmation that any withdrawal of the approval of GBP's abbreviated new drug application ("ANDA") for mifepristone—whether by court order or otherwise—will follow all applicable procedures afforded by law and regulation to GBP as the ANDA holder and that FDA will permit GBP to continue marketing and selling mifepristone until those procedures have been completed.

GBP's ANDA (No. 091178) was approved by FDA on April 11, 2019, following almost a decade of efforts by GBP to bring the first and only generic version of Mifeprex (mifepristone) 200mg tablet to market. As you know, mifepristone 200 mg tablet is the first drug in a two-drug regimen approved by FDA for medication abortion. FDA's approval of GBP's ANDA reflects its judgment that this drug is safe and effective and was based on a robust review of vast amounts of data and hundreds of medical studies over more than two decades, including data submitted by GBP to support approval of its ANDA. FDA's decisions regarding mifepristone have twice been found to be legally and factually valid by the U.S. Government Accountability Office. *See* U.S. Gov't Accountability Off., *Approval and Oversight of the Drug Mifeprex* (Aug. 2008); U.S. Gov't Accountability Off., *Information on Mifeprex Labeling Changes and Ongoing Monitoring Efforts* (Mar. 2018).

Moreover, in the 2007 enactment of the Food and Drug Amendments Act of 2007, Pub. L. No. 110-85, 121 Stat. 823, Congress specified that, for 16 drugs that FDA had approved previously with "elements to assure safe use," Congress deemed them to have an effective Risk Evaluation and Mitigation Strategy (REMS) in effect. As to the set of drugs, including mifepristone, that have a REMS with elements to assure safe use, Congress mandated that any elements provide "safe access" for patients for the drug, and not be "unduly burdensome on patient access to the drug." 21 U.S.C. § 355-1(f). FDA thus regulates mifepristone under this congressional mandate, which requires safe access for patients. FDA most recently revised the REMS for mifepristone on January 3, 2023, after an extensive review of updated research and data.

Despite mifepristone's longstanding congressional and regulatory approval and despite widespread acknowledgment of the public health benefits of access to mifepristone, in the aftermath of the Supreme Court's decision last year in *Dobbs*, FDA's approvals have come under challenge and efforts are

underway to seek withdrawal of the approval for mifepristone. These ill-advised and unfounded attacks on FDA's decisions pursuant to its congressional mandate are of grave concern to GBP, which has invested considerable effort and expense in reliance on FDA's past regulatory actions with respect to mifepristone, as well as on FDA's well-established regulatory process for the withdrawal of existing drug approvals. Withdrawal of the mifepristone ANDA approval would threaten irreparable harm to both GBP as a company and the public interest, as expressed in the 2007 Amendments, in continued access to the medication.

As you are aware, in addition to mandating that FDA ensure safe access to mifepristone, Congress also granted FDA, and FDA alone, the authority to oversee the withdrawal of an approved drug application. See 21 U.S.C. § 355(e). Withdrawal requires a finding by FDA that one of the relevant statutory criteria has been met, as well as "due notice and opportunity for hearing to the applicant." Under the Food Drug and Cosmetic Act ("FDCA"), and as relevant here, the Secretary of HHS shall withdraw approval of an application if the Secretary finds that:

> clinical or other experience, tests or other scientific data show that such drug is unsafe for use under the conditions of use upon the basis of which the application was approved . . . [or] on the basis of new information before him with respect to such drug, evaluated together with the evidence available to him when the application was approved, that there is a lack of substantial evidence that the drug will have the effect it purports or is represented to have under the conditions of use prescribed, recommended or suggested in the labeling thereof.

21 U.S.C. § 355(e)(1), (3).

The Secretary, in turn, has delegated the responsibility for making such a finding to the FDA Commissioner. *See* FDA Staff Medical Guides, Staff Manual Guides 1410.10, *Delegations of Authority to the Commissioner of Food and Drugs* 1.A(1) (Nov. 29, 2022) (all functions vested in the Secretary under the FDCA are delegated to the Commissioner). Any withdrawal of a drug approval on safety or efficacy grounds therefore mandates that the Commissioner find that the evidence demonstrates that the drug's benefit-risk balance requires withdrawal. As the Supreme Court has emphasized, the statute does "not provide any mechanism other than the Commissioner's suspension authority under [section 355(e)], whereby an NDA once effective could cease to be effective." *See Weinberger v. Hynson, Wescott & Dunning, Inc.*, 412 U.S. 609, 633 (1973).

The regulations that implement section 355(e)'s requirements of notice and opportunity to be heard set out specific and detailed procedures the Agency must follow when analyzing withdrawal of a drug approval. In addition to notice and the opportunity for a hearing on a proposal to withdraw a drug, those regulations also expressly permit the applicant to submit studies, data and other information. *See* 21 C.F.R. §§ 314.150, 314.200, 314.530. Specifically with regard to the holder of an ANDA, like GBP, the regulations require an opportunity to submit written comments and, if a hearing is granted, the opportunity to participate and to submit written objections to an initial decision. *See* 21 C.F.R. §

314.151. The due process protections embodied within these statutory and regulatory procedures are constitutionally necessary for the protection of GBP's property interest in its mifepristone ANDA.[1]

Accordingly, GBP respectfully requests FDA's confirmation that for any FDA withdrawal of GBP's ANDA approval, including in response to a court order, FDA will initiate the statutory and regulatory procedures and apply the substantive criteria set forth above and that GBP would be permitted to continue to market and sell mifepristone in the United States while the established process for withdrawal of any approval for a drug process runs its lawful course.

Thank you for your consideration of this matter of pressing public importance. In light of the exigency of this matter, we respectfully request FDA's response as soon as practicable, but, in any event, no later than March 15, 2023. If you or your staff have questions, please do not hesitate to reach out.

Sincerely,

Evan Masingill
Chief Executive Officer

Re: ANDA #A091178 (GenBioPro / Mifepristone)

Dear Commissioner Califf:

I am writing regarding GenBioPro's ("GBP") abbreviated new drug application ("ANDA") for mifepristone (No. 091178), GBP's March 1, 2023 Letter to FDA ("March 1 Letter"), and FDA's March 24, 2023 Letter from Center for Drug Evaluation and Research Director Patrizia Cavazzoni, MD ("March 24 Letter") responding to our March 1 Letter. On April 7, 2023, two separate federal district courts issued rulings relating to mifepristone and FDA's approval of GBP's ANDA. In view of these two rulings, the issues raised in our prior correspondence have taken on even greater and more pressing importance. GBP respectfully submits that those issues require FDA's immediate attention and action.

As explained in the March 1 Letter, GBP is dedicated to ensuring that people have access to evidence-based, essential medications and, to that end, GBP markets a generic version of Mifeprex® (mifepristone) 200 mg consistent with FDA's regulatory framework. In the March 1 Letter, we wrote to request confirmation that any withdrawal or suspension of the approval of GBP's ANDA for mifepristone—whether by court order or otherwise—would follow all applicable procedures afforded by law and regulation to GBP as the ANDA holder, and that FDA would permit GBP to continue marketing and selling mifepristone unless and until those procedures have been completed.

In the March 24 Letter, FDA declined to confirm that it would follow all applicable rules and procedures for any withdrawal or suspension of GBP's ANDA. Indicating the reason for its response, FDA referenced the litigation in *Alliance for Hippocratic Medicine v. FDA* ("*AHM*"), No. 2:22-CV-00223-Z (N.D. Tex.), in which the plaintiffs had argued that "'the Court, on its own accord, can order the FDA to withdraw or suspend the approval of the drug,' rather than 'order the FDA to begin a suspension or withdrawal' process under 21 U.S.C. § 355(e)." March 24 Letter (quoting Arg. Tr. at 145-46). The March 24 Letter then stated that FDA would "need to review the Court's opinion and order before determining what steps may be necessary to comply with it."

On April 7, the *AHM* court issued an order that dramatically increased the legal importance of the March 24 Letter. Mem. Op. and Order, *All. for Hippocratic Med.*, No. 2:22-CV-00223-Z (N.D. Tex. Apr. 7, 2023), ECF No. 137 ("*AHM* Order"). The *AHM* Order purported to "stay" the effective

GenBioPro

GenBioPro, Inc.
P.O. Box 32011
Las Vegas, NV 89103

date of a number of FDA actions, including FDA's approval of GBP's ANDA for mifepristone, under 5 U.S.C. § 705. *Id.* at 65-67.

On the same day as the *AHM* Order, a federal court in Washington state issued a separate ruling enjoining FDA from "altering the status quo and rights as it relates to the availability of Mifepristone under the current operative January 2023 Risk Evaluation and Mitigation Strategy under 21 U.S.C. § 355-1 in" 17 states and the District of Columbia. *Washington v. FDA*, No. 1:23-CV-3026-TOR (E.D. Wash. Apr. 7, 2023), ECF No. 80 ("*Washington* Order") at 30.

In light of these two conflicting orders—and particularly the *AHM* Order, which purports to alter the validity of FDA's approval of GBP's ANDA—GBP respectfully requests the following:

First, FDA should immediately commit that it will not withdraw, suspend, or otherwise take action that would impair GBP's ANDA approval and associated rights. In particular, but without limitation, FDA should not make any changes to GBP's registration or product listing with the agency, and it should not remove GBP's ANDA from the Orange Book. The *AHM* Order does not order FDA to take any of these actions, and FDA should not interpret the *AHM* Order to require them. Disrupting the status quo—and upending more than 22 years of mifepristone access—is premature at this stage and would have devastating public health consequences.

As detailed in the March 1 Letter, GBP's ANDA was approved by FDA on April 11, 2019, following almost a decade of efforts by GBP to bring the first and only generic version of Mifeprex (mifepristone) 200mg tablet to market. As you know, mifepristone 200 mg tablet is the first drug in a two-drug regimen approved by FDA for medication abortion. FDA's approval of mifepristone reflected its judgment that this medication is safe and effective and was based on a robust review of vast amounts of data and hundreds of medical studies over more than two decades, including data submitted by GBP to support approval of its ANDA. FDA's decisions regarding mifepristone have twice been found to be legally and factually valid by the U.S. Government Accountability Office. *See* U.S. Gov't Accountability Off., *Approval and Oversight of the Drug Mifeprex* (Aug. 2008); U.S. Gov't Accountability Off., *Information on Mifeprex Labeling Changes and Ongoing Monitoring Efforts* (Mar. 2018).

Congress has recognized the public health benefits of mifepristone as well. As the March 1 Letter explained, in enacting the Food and Drug Administration Amendments Act of 2007, Pub. L. No. 110-85, 121 Stat. 823, Congress specified that 16 drugs that FDA had approved previously with "elements to assure safe use" would be deemed by statute to have an effective Risk Evaluation and Mitigation Strategy (REMS) in place. As to the set of drugs, including mifepristone, that have a REMS with elements to assure safe use, Congress mandated that any elements provide "safe access" for patients to the drug, and not be "unduly burdensome on patient access to the drug." 21 U.S.C. § 355-1(f). FDA thus regulates mifepristone under this congressional mandate, which requires safe access for patients. FDA most recently revised the REMS for mifepristone on January 3, 2023, after an extensive review of updated research and data. The *Washington* Order commands FDA to maintain the REMS as currently in effect with respect to the 17 plaintiff states and the District of Columbia in that lawsuit. *Washington* Order at 30.

GenBioPro

GenBioPro, Inc.
P.O. Box 32011
Las Vegas, NV 89103

The *AHM* Order, in contrast, purports to order a "stay" of, among other things, the 2000 Mifeprex approval and the 2019 approval of GBP's ANDA. *AHM* Order at 67. But in recognition of the public and private reliance on FDA's approval of drugs as safe and effective, Congress vested the authority to stay or suspend an approved drug application *exclusively* in the Secretary of Health and Human Services; Congress also restricted that authority to be used only in extraordinary circumstances. *See* 21 U.S.C. § 355(e). Specifically, under the Federal Food, Drug, and Cosmetic Act ("FDCA"), if the Secretary "finds that there is an imminent hazard to the public health, he may suspend the approval of [an NDA] immediately." 21 U.S.C. § 355(e).[1]

Contrary to the *AHM* Order's suggestion that a federal court is permitted to "second-guess FDA's decision-making," *AHM* Order at 57, Congress expressly directed that the Secretary's suspension authority "shall not be delegated" to anyone, 21 U.S.C. § 355(e). Rather, as the Supreme Court has explained, "an NDA remains effective unless it is suspended" pursuant to the authority vested exclusively in the Secretary by 21 U.S.C. § 355(e). *See Weinberger v. Hynson, Wescott & Dunning, Inc.*, 412 U.S. 609, 633 (1973). Moreover, in the extreme circumstances in which the Secretary finds an "imminent hazard" and orders the immediate suspension of an application approval, the approval holder is entitled to immediate procedural protections, including "prompt notice," and "an expedited hearing." 21 U.S.C. § 355(e); *see* 21 C.F.R. § 314.150(a)(1).

Secretary Becerra has made no "imminent hazard" finding with respect to mifepristone. Under Supreme Court precedent, therefore, all mifepristone approvals "remain[] effective." *See Weinberger*, 412 U.S. at 633.[2]

Second, FDA should immediately commit that, in the event the *AHM* Order is deemed to alter the validity of FDA's Mifeprex approval, FDA nonetheless will not withdraw, suspend, or otherwise take action that would impair GBP's ANDA approval and associated rights. As the *AHM* Order itself recognizes, "[i]f FDA withdraws the listed drug on which the ANDA-approved generic drug is based, the agency is *generally* required to withdraw the generic drug as well." *AHM* Order at 60 (emphasis added). Though it recognizes that rule as "general[]," the *AHM* Order ignores the actual criteria for any such withdrawal. *See id.* (declaring the court is "inclined to agree with Plaintiffs" based solely on analysis of the Mifeprex NDA without analyzing the generic drug withdrawal provisions at 21 U.S.C. § 355(j)). Those legal criteria do not apply here.

Specifically, FDA regulations provide that, if the reference drug in GBP's ANDA is required to be withdrawn for reasons other than *FDA's determination* that the reference drug is unsafe or ineffective for use under the conditions set forth in its application, then its withdrawal has no impact on GBP's ANDA for mifepristone. *See* 21 U.S.C § 355(j)(6); 21 C.F.R. § 314.151. Here, FDA has made no determination that the reference drug is not safe or effective. Instead, a court has purported to "stay" the effective date of approval of the approved reference drug. While the

[1] The *AHM* Order appears to equate a judicially ordered "stay" with the Secretary's suspension authority, noting that the court considered ordering FDA to "suspend the chemical abortion approval" as an alternative to its "stay." *See AHM* Order at 67.

[2] The FDCA also allows for the withdrawal of an approved drug application under specified circumstances. 21 U.S.C. § 355(e). Withdrawal requires a finding by FDA that one of the relevant statutory criteria has been met. *Id.* It also requires extensive procedures before a withdrawal may occur. *Id.*; *see* 21 C.F.R. §§ 314.150, 314.200, 314.530.

GenBioPro

GenBioPro, Inc.
P.O. Box 32011
Las Vegas, NV 89103

effect of that "stay" on Mifeprex is also without legal basis, at a minimum, the Mifeprex "stay" can have no legal effect on approval of GBP's ANDA under section 355(j) and its implementing regulations. Moreover, GBP is not a party to the *AHM* litigation and, as the Supreme Court has held, "[i]t is a violation of due process for a judgment to be binding on a litigant who was not a party or a privy and therefore has never had an opportunity to be heard." *Parklane Hosiery Co. v. Shore*, 439 U.S. 322, 327 n.7 (1979).

Third, regardless of any other action FDA takes in response to the *AHM* Order, FDA should immediately issue a non-enforcement order declaring that it will not, under any circumstances, take any enforcement action against GBP or its distributors, customers, and partners based on the *AHM* Order's purported "stay" of GBP's ANDA. This includes, but is not limited to, any enforcement action pursuant to 21 U.S.C. §§ 355(a), 331(d), 333(a), and 334(a). FDA is authorized to issue such a non-enforcement order based on its wide discretion to develop enforcement priorities and to articulate the exercise of that discretion to regulated entities. *See Heckler v. Chaney*, 470 U.S. 821, 832 (1985).

A non-enforcement order is particularly appropriate here because there is a direct conflict between two federal courts. *See Nat'l Env't Dev. Assoc.'s Clean Air Project v. EPA*, 891 F.3d 1041, 1045 (D.C. Cir. 2018) (upholding agency's adoption of "permissible and sensible solutions to issues emanating from intercircuit conflicts and agency nonacquiescence"). The *AHM* Order "stays the effective date" of FDA's approval of Mifeprex and GBP's ANDA. *AHM* Order at 67. At the same time, the *Washington* Order prohibits FDA from "altering the status quo and rights as it relates to the availability of Mifepristone under the current operative" REMS in 17 states. *Washington* Order at 30. These two rulings cannot be reconciled, and distributors, doctors, patients, and manufacturers all require guidance.

Fourth, FDA should issue an interim final rule with immediate effect, declaring that FDA's approval of GBP's ANDA shall remain effective pending public comments and any further judicial review of the *AHM* Order. Such a rule is authorized by the FDCA, 21 U.S.C. § 371(a) ("The authority to promulgate regulations for the efficient enforcement of this chapter, except as otherwise provided in this section, is vested in the Secretary"), and the Administrative Procedure Act, 5 U.S.C. § 553(b)(B) (notice-and-comment procedures not required when they are "impracticable, unnecessary, or contrary to the public interest").[3] With an interim rule in effect, FDA can then accept public comments to address, among other things, how it should reconcile the conflicts between the *Washington* Order and the *AHM* Order, including but not limited to the relevant geographic scope of the *AHM* Order.

Even aside from the conflicting judicial orders, good cause exists to issue an interim rule here. *See* 5 U.S.C. § 553(b). The potential nationwide unavailability of mifepristone due to court action presents a grave threat to public health. FDA should accordingly issue an interim final rule to affirm all mifepristone approvals and open a comment period to gather public input.

[3] FDA commonly issues interim final rules with subsequent comment periods, including for issues surrounding drugs. *See, e.g., Applications for Food and Drug Administration Approval To Market a New Drug; Revision of Postmarketing Reporting Requirements—Discontinuance*, 76 Fed. Reg. 78,530 (Dec. 19, 2011).

Re: ANDA #A091178 (GenBioPro / Mifepristone)

Dear Commissioner Califf:

I am writing regarding GenBioPro's ("GBP") abbreviated new drug application ("ANDA") for mifepristone (No. 091178) and following up on GBP's March 1, 2023 Letter to FDA ("March 1 Letter"), FDA's March 24, 2023 Letter from Center for Drug Evaluation and Research Director Patrizia Cavazzoni, MD ("March 24 Letter") and GBP's April 9, 2023 Letter to FDA ("April 9 Letter").

As you are aware, just before midnight last night, the U.S. Court of Appeals for the Fifth Circuit issued an unpublished order granting in part and denying in part Defendants' Emergency Motion for a Stay Pending Appeal in *Alliance for Hippocratic Medicine v. FDA* ("*AHM*"), No. 2:23-10362 ("*AHM* Fifth Circuit Order"). The *AHM* Fifth Circuit Order granted Defendant's requested stay only as to the district court's "stay" of the 2000 Approval of Mifeprex and denied the stay as to the district court's "stay" of "all subsequent actions," including FDA's approval of GBP's ANDA for mifepristone.

As you are aware, a federal court in Washington state has also enjoined FDA from "altering the status quo and rights as it relates to the availability of Mifepristone under the current operative January 2023 Risk Evaluation and Mitigation Strategy under 21 U.S.C. § 355-1 in" 17 states and the District of Columbia. *Washington v. FDA*, No. 1:23-CV-3026-TOR (E.D. Wash. Apr. 7, 2023), ECF No. 80 ("*Washington* Order") at 30.

Given the conflicts between these orders, GBP urgently requests that FDA confirm it will follow all applicable rules and procedures afforded by law and regulation to GBP as the ANDA holder, and that GBP is permitted to continue marketing and selling mifepristone under its 2019 approval and subsequent approved supplements and the operative 2023 REMs. As you know, GBP is not a party to the *AHM* litigation and is thus not bound by the orders in that case. Instead, FDA is the

GenBioPro

GenBioPro, Inc.
P.O. Box 32011
Las Vegas, NV 89103

regulatory agency that exercises authority over GBP and GBP is seeking much needed clarity from FDA regarding the status of its ANDA and related regulatory approvals.

GBP once again seeks immediate confirmation from FDA of the following requests:

First, please confirm that GBP's ANDA approval remains in effect as currently approved, particularly given that the reference drug upon which GBP's ANDA is based remains approved pursuant to the *AHM* Fifth Circuit Order reversing the district court's stay. Given that the reference drug has not been withdrawn for safety or efficacy reasons—and indeed, remains fully approved—GBP's ANDA must also remain approved. 21 U.S.C. § 355(j)(6); 21 C.F.R. § 314.151.

Second, please commit that FDA will not withdraw, suspend, or otherwise take action that would impair GBP's ANDA approval and associated rights. Congress vested the authority to stay or suspend an approved drug application *exclusively* in the Secretary of Health and Human Services; Congress also restricted that authority to be used only in extraordinary circumstances. *See* 21 U.S.C. § 355(e). Specifically, under the Federal Food, Drug, and Cosmetic Act ("FDCA"), if the Secretary "finds that there is an imminent hazard to the public health, he may suspend the approval of [an NDA] immediately." 21 U.S.C. § 355(e). Secretary Becerra has made no "imminent hazard" finding with respect to mifepristone.

Third, please confirm that FDA will issue a non-enforcement order declaring that it will not, under any circumstances, take any enforcement action against GBP or its distributors, customers, and partners based on the *AHM* Order's purported "stay" of GBP's ANDA. This includes, but is not limited to, any enforcement action pursuant to 21 U.S.C. §§ 355(a), 331(d), 333(a), and 334(a). A non-enforcement order is particularly appropriate here because there is a direct conflict between two federal courts. *See AHM* District Court Order at 67 ("stay[ing] the effective date" of FDA's approval of GBP's ANDA); *Washington* Order at 30 (enjoining FDA from "altering the status quo and rights as it relates to the availability of Mifepristone under the current operative" REMS in 17 states). These rulings cannot be reconciled, and distributors, doctors, patients, and manufacturers all require guidance.

Fourth, the *AHM* Fifth Circuit Order refused to stay the district court's order relating to several subsequent regulatory decisions related to the REMs that apply to mifepristone. GBP requests immediate guidance from FDA confirming that mifepristone may continue to be sold under the existing 2023 REMs, which reapproved the safety and efficacy of the drug, until further guidance. Any other outcome creates an untenable situation where mifepristone will become unavailable to the public and thus presents a grave threat to public health.

Fifth, as GBP previously proposed, an immediate remedy for the existing conflict between the two federal court orders is for FDA to issue an interim final rule with immediate effect, declaring that FDA's approval of GBP's ANDA shall remain effective pending public comments and any further judicial review of the *AHM* Order. Such a rule is authorized by the FDCA and the APA. *See* 21 U.S.C. § 371(a); 5 U.S.C. § 553(b)(B).

Abstract

Aims and objectives: To define the role and scope of the nurse and midwife within the global context of abortion.

Background: An estimated 56 million women seek abortions each year; nurses and midwives are commonly involved in their care (Singh et al., 2018, https://www.guttmacher.org/sites/default/files/report_pdf/abortion-worldwide-2017.pdf). As new models of abortion care emerge, there is a pressing need to develop a baseline understanding of the role and scope of nurses and midwives who care for women seeking abortions.

Design: The review design was Arksey and O'Malley's five-stage methodological framework. The review follows the PRISMA-ScR checklist.

Methods: MEDLINE, CINAHL, Scopus and ScienceDirect were used to identify original research, commentaries and reports, published between 2008–2019, from which we selected 74 publications reporting on the nursing or midwifery role in abortion care.

Results: Nurses and midwives provide abortion care in a variety of practice. Three themes emerged from the literature: the regulated role; providing psychosocial care; and the expanding scope of practice.

Conclusions: The literature on nursing and midwifery practice in abortion care is broad. Abortion-related practices are potentially over-regulated. Appropriately trained nurses and midwives can provide abortions as safely as physicians. The preparation of nurses and midwives to provide abortion care requires further research. Also, healthcare organisations should explore person-centred models of abortion care.

Relevance to clinical practice: Abortion care is a common procedure performed across many healthcare settings. Nurses and midwives provide technical and psychosocial care to women who seek abortions. Governments and regulatory bodies could safely extend their scope of practice to increase women's access to safe abortions. Introduction of education programmes, as well as embedding practice in person-centred models of care, may improve outcomes for women seeking abortions.

1 | INTRODUCTION

Access to safe abortion is considered a human right and has directly contributed to a steep decrease in maternal mortality and morbidity worldwide (Erdman, Depiñeres, & Kismödi, 2013). Still, women seek unsafe abortions in places where safe and legal abortion is inaccessible. For every 100,000 unsafe abortions performed in developed areas, 30 women will die from complications. In developing regions, this number rises to between 220–520 deaths per 100,000 (Ganatra et al., 2017). Estimates from a decade ago put the global economic impact of treating the complications of unsafe abortion at $US553 million per year (Vlassoff, Shearer, Walker, & Lucas, 2008).

This paper reports on a systematic scoping review of research on nursing or midwifery abortion care to define the role and scope of the nurse and midwife within the global context of abortion.

Nurses and midwives together form the largest group of professionals employed in healthcare services and potentially play an important role in abortion care worldwide (Levi, Simmonds, & Taylor, 2009; Singh, 2018; Sutherland, Fontenot, & Fantasia, 2014). The activities undertaken by individual nurses and midwives are regulated and standardised according to their scope of practice, which is determined by education and law (Nursing & Midwifery Board of Australia, 2016). Scope of practice is influenced by the context of practice, the nurse or midwife's confidence and competence, the health needs of the people and the policy requirements of the health service (Nursing & Midwifery Board of Australia, 2016). Internationally, there has been a call to enhance the reproductive rights of women by integrating self-managed medical abortions (m-tops) into the current abortion service model (Jelinska & Yanow, 2018) as well expand the scope of nurses and midwives to provide medical and surgical abortions (s-top) (Renner, Brahmi, & Kapp, 2013). Improved research is needed to inform the nurse/midwives' scope in emerging abortion care frameworks to improve practice, streamline service provision and improve the health and reproductive autonomy of women. Ultimately, this may increase the availability, access and affordability of abortion services. The first step in this process is to identify the main types and sources of evidence available to develop future research priorities.

2 | AIMS

This scoping review is part of a larger doctoral study exploring the experiences of nurses managing the care of women seeking abortions in the context of violence. This review aims to define the role and scope of the nurse/midwife within the global context of abortion care.

The review addressed the following overarching question:

1. What is the nurse or midwife's role and scope of practice within abortion care?

What does this paper contribute to the wider global clinical community?

- This review consolidates the literature regarding the nurse and midwife's role in abortion care. In doing so it highlights research and practice gaps.
- This review demonstrates that nurses and midwives are essential to the delivery of abortion care. However, there are political and educational barriers that prevent nurses and midwives from working to an extended scope of practice. Further research is required to determine the extent of evidence-based abortion practice taught across nursing and midwifery curricula.
- This review demonstrates that nurses and midwives can improve access to women in rural and remote areas. Further inquiry is needed to ensure that care is provided within a person-centred model of care.

3 | METHODS

3.1 | Protocol registration

This scoping literature review is not registered and is not associated with a pre-existing protocol. The authors did not find any published systematic review protocols on this topic in Prospero, OSF Registries, Joanna Briggs Institute or Research Registry. Nor did the database search unearth published reviews of a similar nature.

3.2 | Study design

We have employed Arksey and O'Malley's (2005) systematic five-stage methodological framework for scoping reviews to identify, analyse and synthesise the literature. The five stages are (a) identify the search question (outlined above), (b) identify relevant studies, (c) study selection, (d) charting the data and (e) collating, summarising and report the results. The review follows the Preferred Reporting Items for Systematic Review and Meta-Analysis Extension for Scoping Reviews (Tricco et al., 2018; Appendix S1).

3.3 | Eligibility criteria

To identify relevant studies (stage one), we selected the initial search terms using the SPIDER tool (Sample, Phenomenon of Interest, Design, Evaluation and Research type). While other search tools may have been appropriate, SPIDER is purported to be more efficient than other search strategy tools with qualitative and mixed-method research questions (Cooke, Smith, & Booth, 2012).

Sample—nurses or midwives
Phenomenon of Interest—abortion care
Design—any
Evaluation—nursing or midwifery practice
Research Type—qualitative, quantitative and mixed methods

Search terms were tested and modified iteratively to find relevant articles. We restricted abortion to elective abortions and not those conducted for foetal abnormalities. We deemed studies eligible if they were published from 2008 onwards, citing both qualitative and quantitative original research data and published in English. We also included discussion papers and reports where they directly related to the role of the nurse or midwife (refer to Table 1 for inclusions/exclusions).

3.4 | Information sources and data collection process

LM searched MEDLINE, CINAHL, Scopus and ScienceDirect databases from 2008–December 2019 to identify relevant articles. LM drafted the search strategy and further refined through team discussion. The MEDLINE search strategy is demonstrated below.

3.5 | Search

The final search strategy for MEDLINE can be found in Table 2.

3.6 | Selection of sources of evidence

The articles collected in the previous step were imported into EndNote and screened for duplicates. To select the studies (stage three), LM performed title and abstract screening on the articles collected in the previous step and tracked this process in an Excel spreadsheet. These results were discussed with CO. LM then read the full-text articles and assessed them against inclusion and exclusion criteria to confirm their eligibility in the scoping review. Study relevance and validity were evaluated by considering how helpful each article was in answering the overarching scoping review question. The reviewers did not conduct a critical appraisal of individual articles; this is not a requirement for scoping reviews (Arksey & O'Malley, 2005; Pham et al., 2014).

3.7 | Data charting process (stage four)

LM charted data from eligible studies using a standardised data abstraction tool designed for this study. We abstracted data on nursing or midwifery care and charted the article characteristics including author, study population, methodology and outcomes. This information is presented in Appendix S2.

4 | RESULTS

4.1 | Selection of sources of evidence

A total of 140 records were identified using the outlined search strategy. Citations were imported to EndNote and screened for duplicates. Thirty articles were removed. Next, titles and abstracts were scrutinised against the inclusion and exclusion criteria. Twenty-two articles were removed as they were found not to meet the study criteria: 12 articles did not focus on the nurse or midwife's scope of practice and 10 articles were unrelated to nurses or midwives (e.g. DNA-testing, healthcare economics, patient attitudes to a support person in theatre). Full-text articles were then read and assessed with respect to how they answered the overarching research question. Ten articles were excluded as they did not report on nursing or midwifery care. Four articles were unavailable. Seventy-four articles, considered relevant to the study, were included in the synthesis (Figure 1): 27 qualitative, 29 quantitative, 4 mixed-methods studies and 3 systematic reviews. Eleven articles were reports or commentaries.

4.2 | Characteristics of sources of evidence

Each study's aim, setting, method and findings are presented in Appendix S2.

4.3 | Results of individual sources of evidence

Individual sources of evidence are presented in Appendix S2.

4.4 | Synthesis of results (stage five)

While the studies differed in purpose, design, study population and geographical location, all had a focus of nursing or midwifery practise in abortion care. The (74) articles demonstrated variation in work settings, qualifications, training and regulated practice. Three themes emerged from the articles: (a) regulated role, (b) psychosocial care and (c) expanding scope. The first theme related to the legal and clinical context in which abortion care can be delivered by nurses and midwives, as well as the education required to undertake the role. The second theme referred to aspects of abortion care, beyond task-based nursing and midwifery care. The final theme represented articles about nurses and midwives assuming the responsibilities in abortion care, more traditionally controlled by physicians.

4.4.1 | Theme 1: The regulated role

The 74 studies demonstrate that abortion care is delivered across diverse health settings by nurses and midwives who have varying

TABLE 1 Inclusions/exclusions table

Criteria	Inclusion criteria	Exclusion criteria
Time period	January 2008 onwards (December 2019)	Before January 2008
Type of article	Original research article, reviews, published in a peer-reviewed article. In English; quantitative and qualitative or mixed methods. Discussion papers and reports directly related to the role of nurse/midwife in abortion care	Articles which reported views about the provision of abortion by nurses (i.e. conscientious objectors)
Study focus	Nursing and midwifery care of women who present for abortion	No reference made to the nursing care of women who present for abortion

degrees of education and training. Two subthemes were identified: (a) context and law, and (b) qualifications and training.

Subtheme 1—Context and law

Except where nurses and midwives worked in specialist abortion services, abortion care was just one aspect of the nurse or midwives' overall responsibilities. Nurses and midwives worked in obstetric and gynaecological wards, operating theatres, primary practice, community sexual and reproductive health centres, telemedicine clinics, pharmacies and stand-alone abortion clinic contexts across metropolitan rural and remote areas. The broad skill sets of nurses and midwives were seen as helpful in the provision of comprehensive abortion care (CAC; Freedman & Levi, 2014; Hulme-Chambers, Clune, & Tomnay, 2018; Taylor, Safriet, & Weitz, 2009; Yarnall, Swica, & Winikoff, 2009).

Nursing and midwifery work was largely influenced by the work context as well as national law and local policy. Table 3 provides an overview of the laws governing abortion globally and the associated effect on the provision of care by nurses and midwives. However, nurses and midwives did not always have a good understanding of the law (Oppong-Darko, Amponsa-Achiano, & Darj, 2017). Indeed, some countries interpreted laws ambiguously (Cleeve, Nalwadda, Zadik, Sterner, & Klingberg-Allvin, 2019), conservatively or enacted special laws restricting nurse/midwifery involvement (Biggs et al., 2019; Sheldon & Fletcher, 2017; Taylor et al., 2009).

The routine nursing and midwifery tasks described in the articles were pregnancy diagnosis and options counselling (Levi et al., 2009), pharmacological and nonpharmacological pain relief (Lindström, Wulff, Dahlgren, & Lalos, 2011), administration of anti-D, and antibiotic prophylaxis (Cappiello, Beal, & Simmonds, 2011), handling the products of conception (Andersson, Gemzell-Danielsson, & Christensson, 2014; Mauri, Ceriotti, Soldi, & Guerrini Contini, 2015; Michalik et al., 2019; Mizuno, 2011; Nicholson, Slade, & Fletcher, 2010), gestational dating, bimanual examination (Averbach, Puri, Blum, & Rocca, 2018) screening for domestic violence, postabortion contraception care (Purcell, Cameron, Lawton, Glasier, & Harden, 2016), referrals (Grace, 2016), health education (Cappiello et al., 2011; Halldén, Lundgren, & Christensson, 2011), counselling (Hulme-Chambers et al., 2018), prescription of abortion drugs (Simmonds, Beal, & Eagen-Torkko, 2017), administration of abortion drugs, manual vacuum aspiration abortions (MVA) (Berer, 2009; Bridgman-Packer & Kidanemariam, 2018; Paul, Gemzell-Danielsson, Kiggundu, Namugenyi, & Klingberg-Allvin, 2014), postabortion phone counselling (Dawson, Bateson, Estoesta, & Sullivan, 2016), peer education (Puri, Regmi, Tamang, & Shrestha, 2014; Puri, Tamang, Shrestha, & Joshi, 2015), care of or referral for postabortion complications (Hulme-Chambers et al., 2018; Yegon et al., 2019), screening and treatment of sexually transmitted infections and human immunovirus (Yegon et al., 2019) and management of postabortion complications (Cleeve et al., 2019; Paul et al., 2014; Yarnall et al., 2009; Yegon et al., 2019). These tasks were not ubiquitous. A qualitative longitudinal study suggested where policy allowed for specially trained nurses and midwives to provide abortions, access and quality of care improved; however, the changes to clinical operations and staffing created barriers (Battistelli, Magnusson, Biggs, & Freedman, 2018).

Subtheme 2—Qualifications and training

Qualifications and training required to provide abortion nursing and midwifery care were reported in 15 articles. They varied significantly

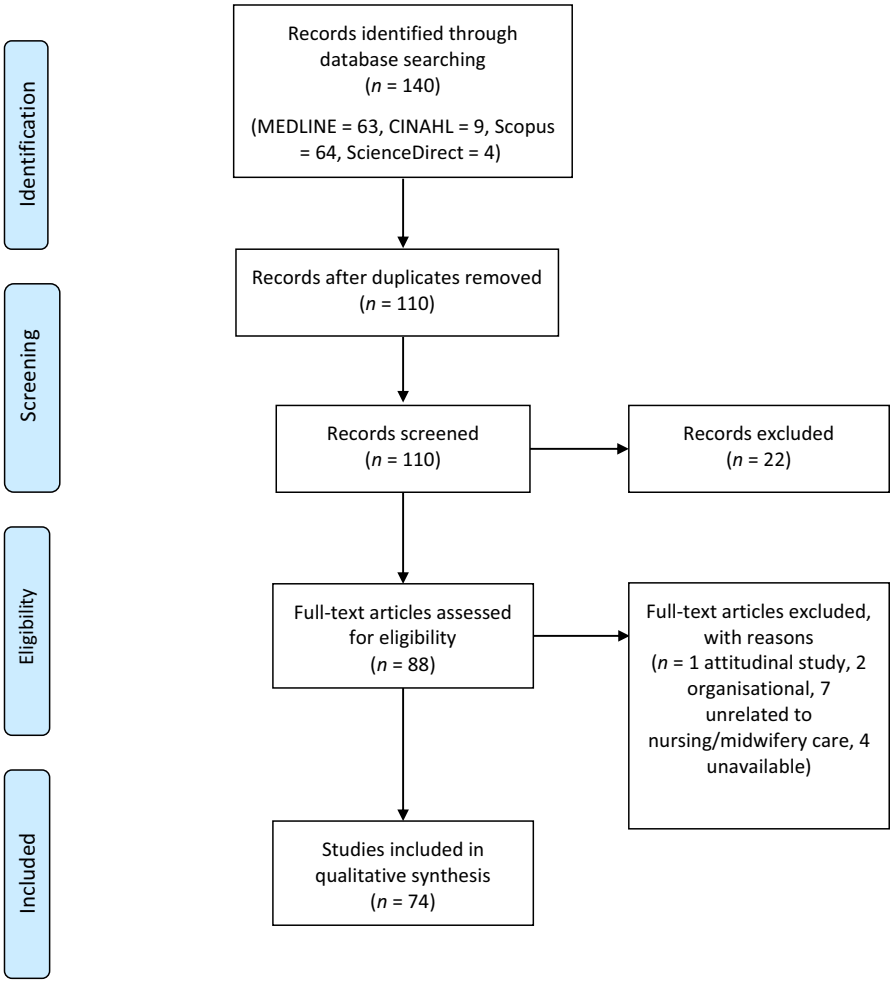

FIGURE 1 PRISMA 2009 flow diagram

across the studies and depended on the regulation of abortion generally and specialist clinical practices specifically, and the country setting. For example, the degree to which qualifications and training were necessary for MVA was not uniform. In Nigeria, MVAs were performed by generalist nurses who did not routinely receive formal education around the practice (Adinma, Adinma, Ikeako, & Ezeama, 2011). Ugandan midwives had similar experiences and performed MVAs for postabortion care with or without specific training and in emergencies would perform dilatation and curettage, and manual removal of placentas (Paul et al., 2014). Tanzanian nurses and midwives reported that they performed postabortion care with inadequate training and supervision (Yegon et al., 2019). Twenty per cent of Ethiopian mid-level healthcare workers reported training in safe abortion care despite the country having the fifth highest rate of maternal deaths in the world (Assefa, 2019). In contrast, Californian certified midwives, nurse practitioners and physician assistants underwent training, based on education programmes used for family practice residence, to perform MVAs. The health practitioners' confidence grew after they became competent and their ability to manage clinical issues increased with experience (Levi, Angel James, & Taylor, 2012; Levi et al., 2018).

In Nepal, nurses and auxiliary nurse midwives in the Rupandehi district received a 3-day training to provide unbiased counselling, MVA, m-top, management of minor complications and early identification and escalation of adverse conditions. Postintervention interviews revealed that nurses and auxiliary nurse midwives were confident about performing m-tops independently (Puri et al., 2014).

Recently, the International Confederation of Midwifery amended its competency standards for basic midwifery education, adding a new competency specific to individualised, culturally sensitive abortion-related care provision (Fullerton, Thompson, Severino, & International Confederation of, 2011). In accordance, the Nigerian Midwifery curriculum has been upgraded to improve postabortion care material. The intervention has increased the quality of instruction as well as the skills of graduates using MVA (Akiode, Fetters, Daroda, Okeke, & Oji, 2010). Ghanaian midwifery schools added CAC to the curriculum in 2007 (Rominski, Lori, Nakua, Dzomeku, & Moyer, 2016). In Poland, the midwifery degree is regulated nationally and requires theoretical and practical preparation of students to provide abortion care, though students feel abortion is inadequately covered in the curriculum (Michalik et al., 2019). A descriptive study carried out across 77 nursing and midwifery schools in Japan found little content devoted to the abortion procedure itself, favouring instead the legal aspects of abortion as well as family planning, emergency contraception, postabortion complications and psychological effects

TABLE 3 Abortion laws by country

Country	Law	Effect on nurses/midwives and women
Kenya	Abortion illegal except to save the woman's life. Postabortion care is legal	High mortality rate PAC currently only performed by physicians (Makenzius et al., 2017)
Nigeria	Criminal except in certain circumstances	High mortality rate Nurses and midwives can perform postabortion care (Adinma et al., 2011; Akiode et al., 2010; Fawole et al., 2012)
Ethiopia	Abortion is illegal except in the case of rape or incest, a risk to the woman's life or health, foetal malformation, maternal disability or age under 18 years up until foetal viability (28 weeks) (Assefa, 2019). Medical abortion beyond 9 weeks. CAC country model	Services have expanded but still unavailable for many women. Nurses able to provide first-trimester abortions (Bridgman-Packer & Kidanemariam, 2018)
Zambia	Abortion is legal on socio-economic grounds since 1994 (Kishen, Stedman, Kishen, & Stedman, 2010)	Midwives can perform medical and surgical abortions up to 12 weeks of gestation and postabortion care. CAC training was added to the midwifery curricula in 2007
Uganda	Abortion is only legal to save the life of the woman (Paul et al., 2014)	40% of admissions to emergency obstetric units are due to unsafe abortion. Specially trained midwives may perform postabortion care
Ghana	The liberalisation of abortion laws in 1985 to allow abortion in context of rape, defilement, incest, risk to the life or physical/mental health, risk of child suffering (Oppong-Darko et al., 2017). 2003 National Reproductive Health strategy includes access to safe abortion care	Unsafe abortion continues to be a public health challenge. Midwives authorised to provide early abortion (Oppong-Darko et al., 2017)
South Africa	Abortion on demand available up to 12 weeks under the Choice on Termination of Pregnancy Act, 1996	A registered nurse may lawfully perform first-trimester abortions (Kishen, Stedman, Kishen, & Stedman, 2010; Mamabolo & Tjallinks, 2010)
Mozambique	Abortion is legal	Maternal-child nurses provide comprehensive care including ultrasound, administration of misoprostol, MVA, follow-up and postabortion care (Yarnall et al., 2009)
Tanzania	Government committed to postabortion care (Yegon et al., 2019)	Nurses and nurse–midwives treat abortion complications using misoprostol, MVA and curettage. Also expected to provide contraception counselling
Poland	Legal if there is a risk to life, if the pregnancy results from an illegal act, or in the case where a foetal abnormality will impact independent life (Michalik et al., 2019)	Estimated 80–150 thousand illegal abortions annually. Midwives may conscientiously object to providing abortion care
England, Wales and Scotland	Abortion Act 1967 made abortion legal on request up to 24 weeks. The interpretation of the law is disputed, and some believe that surgical abortions could be performed by nurses and midwives as part of the healthcare team (Sheldon & Fletcher, 2017)	Abortion Act 1967—nurses may accept delegated instructions from a registered medical practitioner allowing for nurse-delivered termination services (Cherry & Sokolovs, 2008; Gallagher, Porock, & Edgley, 2010; Kishen et al., 2010; Lipp, 2011). Abortion almost exclusively provided through the National Health Service in hospital gynaecology departments however moving into community-based sexual and reproductive health centres. Misoprostol must be delivered in the healthcare setting
Northern Ireland	Abortion remains illegal (Kishen et al., 2010)	
France	Abortion legal if performed by a qualified medical doctor (Kishen et al., 2010)	Must be performed by a physician; however, nurses are regularly involved in abortion care
Italy	Law no 194 of 22 May 1978 abortion is legal 12 weeks. After 12 weeks, only legal under circumstances that preserve the woman's life or when malformations are detected that could risk the physical or mental maternal health	Registered nurses may conscientiously object to being part of the abortion but not the before/aftercare (Mauri et al., 2015)

(Continues)

TABLE 3 (Continued)

Country	Law	Effect on nurses/midwives and women
Sweden	Abortion is legal under the Swedish Abortion Act of 1974 up to 18 weeks and must be performed by a doctor	Performed by physicians but nurses or midwives are usually involved in caring for the woman (Andersson et al., 2014; Kishen et al., 2010; Kopp Kallner et al., 2015; Lindström et al., 2011)
Norway	Abortion Act of 1978 made abortion legal in the first trimester. Medical abortion was introduced in 1998	In some instances, the nurse can be delegated the whole medical abortion procedure by the physician. Usually, nurses have a more limited role (Kjelsvik et al., 2018)
Nepal	First-trimester abortions became legal in 2002. CAC initiated in 2004	Access to abortion care has increased for many women; however, those in remote areas still have limited access. One in seven maternal deaths is attributable to unsafe abortion (Kishen et al., 2010) Nurses and midwives (as well as auxiliary nurse midwives) can legally provide abortions (Andersen et al., 2016). Medical abortions can be provided up to 63 days of gestation in government-certified health facilities (Averbach et al., 2018)
India	Medical Termination of Pregnancy Act of 1972 up to 20 weeks of gestation	Access to abortion remains limited. Estimates that 3 unsafe abortions are performed to every 2 legal abortions. Carried out in registered facilities by gynaecologists or specially trained allopathic physicians (Jejeebhoy et al., 2011, 2012; Kishen et al., 2010)
Bangladesh	The law permits induced abortion to save the life of the woman. "Menstrual regulation" though vacuum aspiration is available up to 10 weeks of pregnancy	Vacuum aspiration is performed by family-welfare visitors (Kishen et al., 2010)
Kyrgyzstan	Abortion is legal on request without restriction up to 12 weeks' gestation and up to 22 weeks for economic and social reasons	Must be provided by an obstetrician–gynaecologist in public or private institution. Nurses and midwives are involved in the care of women undergoing abortions (Johnson et al., 2018)
Canada	1988 abortion was decriminalised entirely (Kishen et al., 2010)	Must be provided by a medical practitioner (Kishen et al., 2010)
USA	Abortion legal in many US states. Roe v. Wade 1973 enacted due to concern over untrained providers harming women. March 2016, Food and Drug Administration updated the labelling of mifepristone to allow midwives, nurse practitioners and physician's assistant to obtain and prescribe mifepristone without physician supervision (Simmonds et al., 2017). Physician-only laws in some states restrict the provision of abortion (Taylor et al., 2009)	2003 Assembly Bill (154) allows trained nurse practitioners, certified nurse–midwives and physicians assistants to perform aspiration abortions in California (Battistelli et al., 2018; Freedman et al., 2015; Freedman & Levi, 2014). Physician-only abortion law in Arizona (Jackson, 2011). Advance practice clinicians (APCs) provide abortions in Vermont and Montana since 1973; APCs perform medical abortions in 14 states and surgical abortions in six states (Kishen et al., 2010). Certified nurse–midwives can legally provide medical and aspiration abortions in the USA as determined by State law (Levi et al., 2012)
Mexico	Abortion legalised in 2007 (Olavarrieta et al., 2015)	Patient demand still outpaces service delivery. Most abortions are still illegal. Nurses could be trained and authorised to perform medical terminations (Olavarrieta et al., 2015)
Chile	Abortion legalised in 2017 in situations when the woman's life is at risk, for foetal abnormality and for pregnancies resulting from rape (Biggs et al., 2019)	Midwives have a limited role in abortion care as legally, only physicians can perform the procedure
Vietnam	Abortion legal since 1945 and can be performed by a doctor, doctor-assistant or trained midwife (Kishen et al., 2010)	Trained midwives can perform abortions (Kishen et al., 2010)
Japan	Abortion legal up until 21 weeks of gestation for justifiable reasons such as rape, physical health, socio-economic hardship (Mizuno, 2011)	People seeking abortions are cared for within maternity units. Midwives provide care for people undergoing abortions. Medical abortions are still rare (Mizuno, 2014). Nurses and midwives do not have the option to contentiously object (Mizuno, 2014)

TABLE 3 (Continued)

Country	Law	Effect on nurses/midwives and women
Cambodia	Abortion legal on any grounds in the first trimester and performed by a doctor, medical assistant or midwife at public or private health facilities (Kishen et al., 2010)	Authorised midwives can perform surgical abortions (Yarnall et al., 2009)
Myanmar	Penal code of 1,860 criminalises abortion unless it is performed to save the life of the woman	Unsafe abortion is common and contributes to 10% of maternal deaths countrywide and 50% of maternal deaths in conflict-affected areas (Sheehy, Aung, & Foster, 2015). Commonly performed by untrained traditional birth attendants. Few trained midwives (m-top)
Australia	Legislation differs between states. Restrictions on abortion in most states	Abortions must be performed by a medical doctor. Nurses and midwives assist in the care of the woman during the procedure (Dawson et al., 2016; Hulme-Chambers et al., 2018). Doctors who wish to become medical abortion providers must undergo online training through MS Health. Only pharmacists who are registered providers with the MS-2Step programme can dispense medication abortion drugs

Abbreviations: CAC, comprehensive abortion care; MVA, manual vacuum aspiration.

of abortion (Mizuno, 2014). Comparable results were found in a Canadian study which aimed to understand the curriculum coverage of abortion in nurse practitioner programmes. The national survey of nurse practitioner programme directors revealed 63% of programmes covered ethics of abortion, counselling and post-abortion care, and approximately half of the programmes covered first-trimester abortion procedures (Sheinfeld, Arnott, El-Haddad, & Foster, 2016).

The context of care presented unique educational needs for nurses and midwives. For example, labour and delivery nurses in Quebec, Canada, identified that they needed more knowledge of pre-abortion counselling to assess the woman's understanding of the procedure as well as more training on how to support women who had received abortions through the postpartum period (Parker, Swanson, & Frunchak, 2014). Lack of m-top training opportunities was seen as a barrier to nurse-led medical abortion in the primary health care setting in regional and rural Victoria, Australia (de Moel-Mandel, Graham, & Taket, 2019). A support network for abortion care nurses, established in Wales, provides ongoing professional development to its members to extend their knowledge, expertise and skills (Cherry & Sokolovs, 2008).

4.4.2 | Theme 2: Providing psychosocial care

Nine articles explored broader aspects of nursing and midwifery care referred to here as psychosocial care. English gynaecology nurses from a ward-based abortion service felt that psychological care was one of their major roles. They employed nonjudgemental counselling and interpersonal skills, though this proved challenging for the nurses if women presented for multiple abortions or had an abortion after fertility treatment (Nicholson et al., 2010). Nurses in UK abortion clinics described how they used therapeutic communication to reduce the controversy and shame around the stigmatised procedure (Fullerton et al., 2011) and joint decision-making around contraception uptake (Purcell et al., 2016). Developing the therapeutic relationship and establishing professional boundaries were two important elements of abortion care for labour and delivery nurses in Quebec, Canada (Parker et al., 2014). Nurses and midwives who provided care for women undergoing home abortions in Sweden explained that they adapted their care depending on the woman's need to cope or deal with loss, grief and sorrow associated with the procedure (Lindström et al., 2011).

An exploration of the experiences and perceptions of Swedish nurses and midwives caring for women undergoing late-term abortions found themselves being selective with the information they gave the woman about the procedure to increase comfort and responded to the woman's emotional and existential needs (Andersson et al., 2014). In a similar study conducted in Italy, midwives explained that caring for women undergoing late-term abortions required practical and psychological competence, excellent communication skills and empathy (Mauri et al., 2015).

A qualitative study of Norwegian nurses and doctors who cared for women ambivalent about their abortions explained that they employed a therapeutic use of self as well as intuition to assess the woman's ambivalence. They changed their language so as not to seem confrontational, remained neutral about the woman's choice and pragmatically prepared them for the procedure (Kjelsvik, Tveit Sekse, Moi, Aasen, & Gjengedal, 2018). A phenomenological hermeneutic analysis of midwives who provide abortion care to teenagers in Sweden uncovered that midwives used a variety of psychosocial techniques to engage young women and assist them to make decisions about abortion and contraception. Midwives felt that understanding the teen's social situation was an essential element that allowed them to refer her to a social worker and tailor their preventative care. They also created a space where the young woman could work through her feelings, consider the consequences of terminating or continuing the pregnancy and negotiate low-dosage contraceptives. They employed unconventional contact methods, such as calling the teen's friends when they missed appointments (Halldén

et al., 2011). Providing abortion care to Swedish women from immigrant backgrounds required midwives to adapt their care since some women did not see their bodies as their own, had a lack of understanding about sex and pregnancy, made decisions with their families and came from backgrounds that accepted honour-based violence (Larsson, Fried, Essén, & Klingberg-Allvin, 2016).

4.4.3 | Theme 3: Expanding scope of practice

Expanding the scope of practice to allow nurses and midwives to have a greater role in abortion care was the focus of 27 articles. Three subthemes emerged: (a) as safe as doctors, (b) pragmatism and (c) moving away from the hospital.

Subtheme 1—As safe as doctors

A 2009 summary of evidence article by Yarnall et al. (2009) found that mid-level providers (such as nurses and midwives), especially those who manage normal pregnancies, possess the requisite clinical skills to provide m-tops. Such skills include the administration of medications, assessment of gestational age, diagnosis of ectopic pregnancy, family planning counselling and the management of obstetric complications. A systematic review, by Barnard, Kim, Park and Ngo (Barnard, Kim, Park, & Ngo, 2015), compared the effectiveness or safety of abortion provided by mid-level providers against medical and s-tops performed by doctors. They identified eight studies (three of which were identified by our search protocol), including randomised control trials, prospective cohort studies and observational studies. The quality of evidence varied from high quality to very low quality. The combined data from the s-top rate found no difference between doctors and mid-level providers failure and complication rates. A systematic review by Renner et al. (2013) had similar findings, which is not surprising as the articles selected for the meta-analysis were similar. A 4-year prospective observational cohort study to assess the safety of first-trimester MVA performed by advanced nurses, midwives and physicians assistants across four services in California found that these health providers were no less safe than physicians (Freedman, Battistelli, Gerdts, & McLemore, 2015; Weitz et al., 2013; Weitz, Taylor, Upadhyay, Desai, & Battistelli, 2014). A cohort study conducted in Oregon, USA, compared the outcomes of 669 first-trimester MVA with immediate intra-uterine device insertion between nurse practitioners, certified nurse–midwives and physicians and found no differences in outcomes between provider type (Patil et al., 2016). A 3-month noninferiority trial to examine the effectiveness, safety and acceptability of nurse provision of early m-tops compared to physicians was conducted across three facilities in Mexico City (Olavarrieta et al., 2015). A total of 844 women were randomly assigned to a nurse or physician. Like the previous study, nurses were found to be no less safe than physicians. The study also found that there was no difference between physicians and nurses in determining gestation or the uptake of contraception postabortion. The women rated care provided by the nurse and physician groups as highly acceptable.

A randomised controlled equivalence trial in Sweden assessed nurse/midwife provision of first-trimester m-top where ultrasound was used as part of the protocol. The study found the effectiveness of m-top provided by nurses to be superior to doctors (though there were no differences in patient safety outcomes) (Kopp Kallner et al., 2015). A 12-month randomised controlled equivalence trial conducted across five districts in Nepal. It set out to (a) assess whether first-trimester m-tops provided by mid-level providers were as safe and effective as that provided by doctors and (b) assess the level of satisfaction women who received m-tops felt when the services were provided by trained nurses and auxiliary nurse midwives (independently from doctors) or doctors. The study found that safety and effectiveness were similar between groups (Warriner et al., 2011), and women's satisfaction was also similar between the groups (Tamang et al., 2017). A retrospective review of CAC service register at Tribhuvan University Teaching Hospital in Nepal also found that nurses were as competent as doctors in providing abortions but were underutilised (Sayami, 2019). Studies carried out in India (Jejeebhoy et al., 2011, 2012) concluded that nurses could assess gestation and complete abortions, and perform MVA as well as physicians. Abortion failure rates were equivalent to physicians.

A prospective cohort study carried out by Gebreselassie, Ustá, and Mitchel (Gebreselassie, Ustá, Andersen, & Mitchell, 2012) found that when nurses were consistently able to diagnose complete abortions using clinical history taking and physical examination as proficiently as gynaecologists using ultrasound. The same nurses had a moderate agreement with physicians diagnosing incomplete abortions and ongoing pregnancy. A nonrandomised implementation study of 32 nurses and midwives who provided medical termination to 554 women across four remote services in Kyrgyzstan found that there was a high level of complete abortions with no adverse events or safety issues and a high level of patient satisfaction (Johnson et al., 2018). A multicentre randomised controlled equivalence trial of 1,094 women with incomplete first-trimester abortions in Kenya found that women who were administered misoprostol by midwives to complete their abortions had slightly better outcomes than when administer by physicians (94.8% compared with 94.3%) (Makenzius et al., 2017). An open-label prospective study in Nigeria had similar findings where nurses performed first-line treatment for incomplete abortions using misoprostol (Fawole, Diop, Adeyanju, Aremu, & Winikoff, 2012).

Conversely, an Australian study, which investigated the expansion of general practice to provide m-top, found doctors were resistant to the exclusive provision of m-top by primary care nurses. Study participants felt that nurses lacked skill and experience, and their nursing care was of a lower standard than other countries with nurse-led m-top models of care (Newton et al., 2016). On the other hand, a study investigating the enablers and barriers to decentralising m-top service provision in Victoria found that some general practice providers utilised nurse-led integration models of abortion care. Unsurprisingly, general practitioners and primary care nurses felt that training by providers that had partnered with trusted rural organisations and being able to adapt resources used by rural services

Case 6:25-cv-01491-DCJ-DJA Document 54-10 Filed 02/03/26 Page 122 of 239 PageID #: 3358

facilitated the provision of abortion care (Hulme-Chambers et al., 2018). de Moel-Mandel Graham and Taket's (2019) Delphi study exploring a nurse-led model of m-top provision in rural and regional Victoria achieved a consensus that primary health care nurses could provide m-top in collaboration with general practitioners, refer for blood tests and ultrasound scans, interpret pathology, administer mifepristone and prophylactically manage pain. The panel also believed legislation changes were necessary to allow nurses to prescribe m-top medications. They could not reach consensus on nurses managing the m-top process autonomously or the responsibility of the general practitioner managing non-life-threatening complications. The barriers to a nurse-led model of care were training, support from general practitioners and other stakeholders (such as local health professionals), funding models, abortion stigma, and distribution of labour between doctors and nurses.

Subtheme 2—Pragmatism

Under-resourced countries, such as Nepal, Bangladesh, Myanmar and Uganda, pragmatically extend the scope of nurses and midwives, as well as incorporate other auxiliary health professionals (such as auxiliary nurses and female paramedics) to provide abortion or postabortion care (Andersen et al., 2016; Cleeve et al., 2019; K C et al., 2011; Puri et al., 2015). Nonetheless, in some under-resourced settings, such as areas of Uganda, midwives were forced to practice outside of their extended scope, with improvised equipment (Paul et al., 2014), in inadequate facilities and for low pay (Cleeve et al., 2019). The use of auxiliary nurses and midwives in abortion care, without specific training, should be approached cautiously. A mixed-method study describing the knowledge, attitudes and roles of auxiliary nurse midwives and other community health intermediaries in Karnataka, India, demonstrates that the health workers had limited understanding of abortion law, held negative views towards abortion and would not support women in their abortion decision-making (Nandagiri, 2019).

Subtheme 3—Moving away from the hospital

Expanding scope was described in other ways such as in Sweden, where a focus group of nurses and midwives foreshadowed the provision of home abortions. This shift, from the hospital to the home, would give control of the process to the woman. The nurses believed their role would change to be that of advocate, providing phone support and offering advice for pain relief (Lindström et al., 2011). A 12-month observational noninferiority study carried out in semi-urban and remote areas in two Nepali districts compared the safety and effectiveness of m-tops provided by trained auxiliary nurse midwives at six pharmacies and six health facilities (Rocca et al., 2018). M-top provided through pharmacies was as effective as provided through health facilities.

5 | DISCUSSION

This scoping review adds to the literature by consolidating a large body of international research in the field of nursing and midwifery abortion care. The evidence demonstrated that nurses and midwives provide a wide range of abortion-related services and are essential to abortion care delivery. From this review, we have learnt that the nurse and midwife's role in abortion may be over-regulated in many countries. The risk profile of abortion care, especially m-top, appears to be lower than many other roles advanced-practice nurses and midwives already perform. However, we learnt little about the education and training that midwives and especially nurses receive to provide abortion-related care. While some momentum has been made to determine the essential abortion care competencies by Hewitt and Cappiello (2015), further work is needed to establish the extent of abortion content taught across the international undergraduate nursing and midwifery curricula.

Furthermore, although this review illustrates that nurses and midwives are essential providers of abortion care, few articles provided a framework of person-centred abortion care. CAC, identified in four articles, is a framework which incorporates high-quality integrated services, safe induced abortion, treatment of complications, counselling, contraceptive and family planning services and decentralisation of services. It is affordable to both women and health systems and attends to other issues relevant to the woman's health (IPAS, 2011). However, we do not know whether nurses or midwives situate their practice activities within such a framework. Further research is therefore required in this area.

There was evidence that psychosocial care was a central element of abortion care, and this is not surprising given the stigmatised nature of the procedure. Treatment by healthcare staff is a consistent finding in overall satisfaction rates among women seeking abortions (Regmi & Madison, 2010; Taylor et al., 2013). Nevertheless, these findings were overshadowed by the volume of studies that focused on the nurse/midwife's task-based scope of practice.

There was consistent evidence that adequately trained nurses and midwives could work more autonomously, and within nurse-led care models to provide m-top and MVA in the first trimester as well as postabortion care. Legislation, however, acts as a barrier for nurses and midwives and presents a significant access threat to women living in regional or remote areas globally. In an era where safe, self-managed abortions are gaining traction, the current risk profile of the abortion medication, mifepristone, needs review to make it available in the midwifery and nurse practitioner formulary.

5.1 | Limitations

We undertook this review throughout 2019, and information contained in Table 3 may be outdated. Any recent changes to abortion law reform, not captured by the search strategy, are not displayed in this article. We completed our literature search after the first round of database searching. While this could indicate that some articles may have been missed, Nussbaumer-Streit et al. (2018) suggest that when 10 or more studies are combined, there is a reduced risk that conclusions may be false; we found 74 articles. They also found that combining two separate databases (we combined four) increases the

reliability of conclusions. The effectiveness of citation searching for reviews of qualitative data, especially on public health topics, has also been called into question by Cooper, Booth, Varley-Campbell, Britten, and Garside (2018). These topics usually generate large numbers of studies, the data are not needed for meta-analysis and there is difficulty in demonstrating the value of missed studies. Finally, Horsley, Dingwall, and Sampson (2011) recommend citation searching when the identification of all relevant studies through database searching is difficult. We believe that the inclusion of 74 articles indicates that most relevant studies have been identified. Further, the scoping review consolidated findings from varied research topics, study populations, methods and findings and generalisable conclusions should not be drawn from the study. As our search strategy was limited to English, some articles may have been missed.

6 | CONCLUSIONS

In this scoping review, we set out to map research on the nurse/midwife's role and scope of practice in abortion care. The literature was extensive, with many studies focussing on task-based duties and the feasibility of nurses and midwives providing abortions. Several studies explored nursing practices beyond task-based care. Future research should be directed towards abortion care education, nursing practice within the comprehensive care model and nurse-led models of care.

7 | RELEVANCE TO CLINICAL PRACTICE

The findings of this scoping review are relevant for clinical practice. Abortion care is a common procedure performed across many healthcare settings. Currently, nurses and midwives provide technical and emotional care to women who seek abortion care. Governments and regulatory bodies could safely extend the scope of practice to increase women's access to safe abortion care. Introduction of education programmes, as well as embedding practice in person-centred models of care, may improve outcomes for women seeking abortions.

CONFLICT OF INTEREST

The authors have no conflict of interest to declare.

MIFEPREX™ (mifepristone) Tablets, 200 mg
For Oral Administration Only

If Mifeprex* results in incomplete abortion, surgical intervention may be necessary. Prescribers should determine in advance whether they will provide such care themselves or through other providers. Prescribers should also give patients clear instructions on whom to call and what to do in the event of an emergency following administration of Mifeprex.

Prescribers should make sure that patients receive and have an opportunity to discuss the Medication Guide and the PATIENT AGREEMENT.

DESCRIPTION

Mifeprex tablets each contain 200 mg of mifepristone, a synthetic steroid with antiprogestational effects. The tablets are light yellow in color, cylindrical and biconvex, and are intended for oral administration only. The tablets include the inactive ingredients colloidal silica anhydrous, corn starch, povidone, microcrystalline cellulose, and magnesium stearate.

Mifepristone is a substituted 19-nor steroid compound chemically designated as 11ß-[*p*-(Dimethylamino)phenyl]-17ß-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one. Its empirical formula is $C_{29}H_{35}NO_2$. Its structural formula is:

The compound is a yellow powder with a molecular weight of 429.6 and a melting point of 191-196°C. It is very soluble in methanol, chloroform and acetone and poorly soluble in water, hexane and isopropyl ether.

* Mifeprex is a trademark of Danco Laboratories, LLC.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

CLINICAL PHARMACOLOGY

Pharmacodynamic Activity

The anti-progestational activity of mifepristone results from competitive interaction with progesterone at progesterone-receptor sites. Based on studies with various oral doses in several animal species (mouse, rat, rabbit and monkey), the compound inhibits the activity of endogenous or exogenous progesterone. The termination of pregnancy results.

Doses of 1 mg/kg or greater of mifepristone have been shown to antagonize the endometrial and myometrial effects of progesterone in women. During pregnancy, the compound sensitizes the myometrium to the contraction-inducing activity of prostaglandins.

Mifepristone also exhibits antiglucocorticoid and weak antiandrogenic activity. The activity of the glucocorticoid dexamethasone in rats was inhibited following doses of 10 to 25 mg/kg of mifepristone. Doses of 4.5 mg/kg or greater in human beings resulted in a compensatory elevation of adrenocorticotropic hormone (ACTH) and cortisol. Antiandrogenic activity was observed in rats following repeated administration of doses from 10 to 100 mg/kg.

Pharmacokinetics and Metabolism

Absorption

Following oral administration of a single dose of 600 mg, mifepristone is rapidly absorbed, with a peak plasma concentration of 1.98 mg/l occurring approximately 90 minutes after ingestion. The absolute bioavailability of a 20 mg oral dose is 69%.

Distribution

Mifepristone is 98% bound to plasma proteins, albumin and α_1-acid glycoprotein. Binding to the latter protein is saturable, and the drug displays nonlinear kinetics with respect to plasma concentration and clearance. Following a distribution phase, elimination of mifepristone is slow at first (50% eliminated between 12 and 72 hours) and then becomes more rapid with a terminal elimination half-life of 18 hours.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Metabolism

Metabolism of mifepristone is primarily via pathways involving N-demethylation and terminal hydroxylation of the 17-propynyl chain. *In vitro* studies have shown that CYP450 3A4 is primarily responsible for the metabolism. The three major metabolites identified in humans are: (1) RU 42 633, the most widely found in plasma, is the N-monodemethylated metabolite; (2) RU 42 848, which results from the loss of two methyl groups from the 4-dimethylaminophenyl in position 11ß; and (3) RU 42 698, which results from terminal hydroxylation of the 17-propynyl chain.

Excretion

By 11 days after a 600 mg dose of tritiated compound, 83% of the drug has been accounted for by the feces and 9% by the urine. Serum levels are undetectable by 11 days.

Special Populations

The effects of age, hepatic disease and renal disease on the safety, efficacy and pharmacokinetics of mifepristone have not been investigated.

Clinical Studies

Safety and efficacy data from the U.S. clinical trials and from two French trials of mifepristone are reported below. The U.S. trials provide safety data on 859 women and efficacy data on 827 women with gestation durations of 49 days or less (dated from the first day of the last menstrual period). In the two French clinical trials, safety evaluable data are available for 1800 women, while efficacy information is available for 1681 of these women. Success was defined as the complete expulsion of the products of conception without the need for surgical intervention. The overall rates of success and failure, shown by reason for failure, for the U.S. and French studies appear in Table 1.

In the U.S. trials, 92.1% of the 827 subjects had a complete medical abortion, as shown in Table 1. In 52 women (6.3%) expulsion occurred within two days, and resulted from the action of mifepristone (600 mg) alone, unaided by misoprostol, an analog of prostaglandin E_2. All other women without an apparent expulsion took a 400 µg dose of misoprostol two days after taking mifepristone. Many women (44.1%) in the U.S. trials expelled the products of conception within four hours after taking misoprostol and 62.8% experienced expulsion within 24 hours after the misoprostol administration. There were 65 women (7.9%) who received surgical interventions: 13 (1.6%) were medically indicated interventions during the study period, mostly for excessive bleeding; five (0.6%) interventions occurred at the patient's request; 39 women (4.7%) had incomplete abortions at the end of the study protocol; and eight (1.0%) had ongoing pregnancies at the end of the study protocol.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Women who participated in the U.S. trials reflect the racial and ethnic composition of American women. The majority of women (71.4%) were Caucasian, while 11.3% were African American, 10.9% were East Asian, and 4.7% were Hispanic. A small percentage (1.7%) belonged to other racial or ethnic groups. Women aged 18 to 45 were enrolled in the trials. Nearly two-thirds (66.0%) of the women were under 30 years old with a mean age of 27 years.

In the French trials, complete medical abortion occurred in 95.5% of the 1681 subjects, as shown in Table 1. In 89 women (5.3%), complete abortion occurred within two days of taking mifepristone (600 mg). About half of the women (50.3%) in the French trials expelled the products of conception during the first four hours immediately following administration of misoprostol and 72.3% experienced expulsion within 24 hours after taking misoprostol. In total, 4.5% of women in the French trials ultimately received surgical intervention for excessive bleeding, incomplete abortions, or ongoing pregnancies at the end of the protocol.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Total	**827**	**100**	**1681**	**100**

Note: Mifepristone 600 mg oral was administered on Day 1, misoprostol 400 µg oral was given on Day 3 (second visit).

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

INDICATION AND USAGE

Mifeprex is indicated for the medical termination of intrauterine pregnancy through 49 days' pregnancy. For purposes of this treatment, pregnancy is dated from the first day of the last menstrual period in a presumed 28 day cycle with ovulation occurring at mid-cycle. The duration of pregnancy may be determined from menstrual history and by clinical examination. Ultrasonographic scan should be used if the duration of pregnancy is uncertain, or if ectopic pregnancy is suspected.

Any intrauterine device ("IUD") should be removed before treatment with Mifeprex begins.

Patients taking Mifeprex must take 400 µg of misoprostol two days after taking mifepristone unless a complete abortion has already been confirmed before that time (see DOSAGE AND ADMINISTRATION).

Pregnancy termination by surgery is recommended in cases when Mifeprex and misoprostol fail to cause termination of intrauterine pregnancy (see PRECAUTIONS).

CONTRAINDICATIONS

Administration of Mifeprex and misoprostol for the termination of pregnancy (the "treatment procedure") is contraindicated in patients with any one of the following conditions:

- Confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass (the treatment procedure will not be effective to terminate an ectopic pregnancy);
- IUD in place (see INDICATION AND USAGE);
- Chronic adrenal failure;
- Concurrent long-term corticosteroid therapy;
- History of allergy to mifepristone, misoprostol or other prostaglandin;
- Hemorrhagic disorders or concurrent anticoagulant therapy;
- Inherited porphyrias.

Because it is important to have access to appropriate medical care if an emergency develops, the treatment procedure is contraindicated if a patient does not have adequate access to medical facilities equipped to provide emergency treatment of incomplete abortion, blood transfusions, and emergency resuscitation during the period from the first visit until discharged by the administering physician.

Mifeprex also should not be used by any patient who may be unable to understand the effects of the treatment procedure or to comply with its regimen. Patients should be instructed to review the Medication Guide and the PATIENT AGREEMENT provided with Mifeprex carefully and should be given a copy of the product label for their review.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Patients should discuss their understanding of these materials with their health care providers, and retain the Medication Guide for later reference (see PRECAUTIONS).

WARNINGS
(see CONTRAINDICATIONS)

1. Bleeding

Vaginal bleeding occurs in almost all patients during the treatment procedure. According to data from the U.S. and French trials, women should expect to experience bleeding or spotting for an average of nine to 16 days, while up to 8% of all subjects may experience some type of bleeding for 30 days or more. Bleeding was reported to last for 69 days in one patient in the French trials. In general the duration of bleeding and spotting increased as the duration of the pregnancy increased.

In some cases, excessive bleeding may require treatment by vasoconstrictor drugs, curettage, administration of saline infusions, and/or blood transfusions. In the U.S. trials, 4.8% of subjects received administration of uterotonic medications and nine women (1.0%) received intravenous fluids. Vasoconstrictor drugs were used in 4.3% of all subjects in the French trials, and in 5.5% of women there was a decrease in hemoglobin of more than 2 g/dL. Blood transfusions were administered in one of 859 subjects in the U.S. trials and in two of 1800 subjects in the French trials. Since heavy bleeding requiring curettage occurs in about 1% of patients, special care should be given to patients with hemostatic disorders, hypocoagulability, or severe anemia.

2. Confirmation of Pregnancy Termination

Patients should be scheduled for and return for a follow-up visit at approximately 14 days after administration of mifepristone to confirm that the pregnancy is completely terminated and to assess the degree of bleeding. Vaginal bleeding is not evidence of the termination of pregnancy. Termination can be confirmed by clinical examination or ultrasonographic scan. Lack of bleeding following treatment, however, usually indicates failure. Medical abortion failures should be managed with surgical termination.

PRECAUTIONS

General

Mifeprex is available only in single dose packaging. Administration must be under the supervision of a qualified physician (see DOSAGE AND ADMINISTRATION).

The use of Mifeprex is assumed to require the same preventive measures as those taken prior to and during surgical abortion to prevent rhesus immunization.

There are no data on the safety and efficacy of mifepristone in women with chronic medical conditions such as cardiovascular, hypertensive, hepatic, respiratory or renal

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

disease; insulin-dependent diabetes mellitus; severe anemia or heavy smoking. Women who are more than 35 years of age and who also smoke 10 or more cigarettes per day should be treated with caution because such patients were generally excluded from clinical trials of mifepristone.

Although there is no clinical evidence, the effectiveness of Mifeprex may be lower if misoprostol is administered more than two days after mifepristone administration.

Information for Patients

Patients should be fully advised of the treatment procedure and its effects. Patients should be given a copy of the Medication Guide and the PATIENT AGREEMENT. (Additional copies of the Medication Guide and the PATIENT AGREEMENT are available by contacting Danco Laboratories at 1-877-4 Early Option) (1-877-432-7596). Patients should be advised to review both the Medication Guide and the PATIENT AGREEMENT, and should be given the opportunity to discuss them and obtain answers to any questions they may have. Each patient must understand:

- the necessity of completing the treatment schedule, including a follow-up visit approximately 14 days after taking Mifeprex;
- that vaginal bleeding and uterine cramping probably will occur;
- that prolonged or heavy vaginal bleeding is not proof of a complete expulsion;
- that if the treatment fails, there is a risk of fetal malformation;
- that medical abortion treatment failures are managed by surgical termination; and
- the steps to take in an emergency situation, including precise instructions and a telephone number that she can call if she has any problems or concerns.

Another pregnancy can occur following termination of pregnancy and before resumption of normal menses. Contraception can be initiated as soon as the termination of the pregnancy has been confirmed, or before the woman resumes sexual intercourse.

Patient information is included with each package of Mifeprex (see Medication Guide).

Laboratory Tests

Clinical examination is necessary to confirm the complete termination of pregnancy after the treatment procedure. Changes in quantitative human Chorionic Gonadotropin (hCG) levels will not be decisive until at least 10 days after the administration of Mifeprex. A continuing pregnancy can be confirmed by ultrasonographic scan.

The existence of debris in the uterus following the treatment procedure will not necessarily require surgery for its removal.

Decreases in hemoglobin concentration, hematocrit and red blood cell count occur in some women who bleed heavily. Hemoglobin decreases of more than 2 g/dL occurred in 5.5% of subjects during the French clinical trials of mifepristone and misoprostol.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Clinically significant changes in serum enzyme (serum glutamic oxaloacetic transaminase (SGOT), serum glutamic pyruvic transaminase (SGPT), alkaline phosphatase, gamma-glutamyltransferase (GT)) activities were rarely reported.

Drug Interactions

Although specific drug or food interactions with mifepristone have not been studied, on the basis of this drug's metabolism by CYP 3A4, it is possible that ketoconazole, itraconazole, erythromycin, and grapefruit juice may inhibit its metabolism (increasing serum levels of mifepristone). Furthermore, rifampin, dexamethasone, St. John's Wort, and certain anticonvulsants (phenytoin, phenobarbital, carbamazepine) may induce mifepristone metabolism (lowering serum levels of mifepristone).

Based on in vitro inhibition information, coadministration of mifepristone may lead to an increase in serum levels of drugs that are CYP 3A4 substrates. Due to the slow elimination of mifepristone from the body, such interaction may be observed for a prolonged period after its administration. Therefore, caution should be exercised when mifepristone is administered with drugs that are CYP 3A4 substrates and have narrow therapeutic range, including some agents used during general anesthesia.

Carcinogenesis, Mutagenesis, Impairment of Fertility

No long-term studies to evaluate the carcinogenic potential of mifepristone have been performed. Results from studies conducted *in vitro* and in animals have revealed no genotoxic potential for mifepristone. Among the tests carried out were: Ames test with and without metabolic activation; gene conversion test in *Saccharomyces cerevisiae* D4 cells; forward mutation in *Schizosaccharomyces pompe* P1 cells; induction of unscheduled DNA synthesis in cultured HeLa cells; induction of chromosome aberrations in CHO cells; i*n vitro* test for gene mutation in V79 Chinese hamster lung cells; and micronucleus test in mice.

The pharmacological activity of mifepristone disrupts the estrus cycle of animals, precluding studies designed to assess effects on fertility during drug administration. Three studies have been performed in rats to determine whether there were residual effects on reproductive function after termination of the drug exposure.

In rats, administration of the lowest oral dose of 0.3 mg/kg/day caused severe disruption of the estrus cycles for the three weeks of the treatment period. Following resumption of the estrus cycle, animals were mated and no effect on reproductive performance was observed. In a neonatal exposure study in rats, the administration of a subcutaneous dose of mifepristone up to 100 mg/kg on the first day after birth had no adverse effect on future reproductive function in males or females. The onset of puberty was observed to be slightly premature in female rats neonatally exposed to mifepristone. In a separate study in rats, oviduct and ovary malformations in female rats, delayed male puberty,

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

deficient male sexual behavior, reduced testicular size, and lowered ejaculation frequency were noted after exposure to mifepristone (1 mg every other day) as neonates.

Pregnancy

Mifepristone is indicated for use in the termination of pregnancy (through 49 days' pregnancy) and has no other approved indication for use during pregnancy.

Teratogenic Effects

Human Data

Over 620,000 women in Europe have taken mifepristone in combination with a prostaglandin to terminate pregnancy. Among these 620,000 women, about 415,000 have received mifepristone together with misoprostol. As of May 2000 a total of 82 cases have been reported in which women with on-going pregnancies after using mifepristone alone or mifepristone followed by misoprostol declined to have a surgical procedure at that time. These cases are summarized in Table 2.

Table 2

Reported Cases (as of May 2000) of On-going Pregnancies Not Terminated by Surgical Abortion at the End of Treatment with Mifepristone Alone or with Mifepristone-Misoprostol

	Mifepristone Alone	**Mifepristone-Misoprostol**	**Total**
Subsequently had surgical abortion	**3**	**7**	**10**
No abnormalities detected	*2*	*7*	*9*

Subsequently resulted in live birth	**13**	**13**	**26**
No abnormalities detected at birth	*13*	*13*	*26*
Abnormalities detected at birth	*0*	*0*	*0*
Other/Unknown	**26**	**20**	**46**
Total	**42**	**40**	**82**

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Several reports in the literature indicate that prostaglandins, including misoprostol, may have teratogenic effects in human beings. Skull defects, cranial nerve palsies, delayed growth and psychomotor development, facial malformation and limb defects have all been reported after exposure during the first trimester.

Animal Data

Teratology studies in mice, rats and rabbits at doses of 0.25 to 4.0 mg/kg (less than 1/100 to approximately 1/3 the human exposure level based on body surface area) were carried out. Because of the antiprogestational activity of mifepristone, fetal losses were much higher than in control animals. Skull deformities were detected in rabbit studies at approximately 1/6 the human exposure, although no teratogenic effects of mifepristone have been observed to date in rats or mice. These deformities were most likely due to the mechanical effects of uterine contractions resulting from decreased progesterone levels.

Nonteratogenic Effects

The indication for use of Mifeprex in conjunction with misoprostol is for the termination of pregnancy through 49 days' duration of pregnancy (as dated from the first day of the last menstrual period). These drugs together disrupt pregnancy by causing decidual necrosis, myometrial contractions and cervical softening, leading to the expulsion of the products of conception.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Nursing Mothers

It is not known whether mifepristone is excreted in human milk. Many hormones with a similar chemical structure, however, are excreted in breast milk. Since the effects of mifepristone on infants are unknown, breast-feeding women should consult with their health care provider to decide if they should discard their breast milk for a few days following administration of the medications.

Pediatric Use

Safety and effectiveness in pediatric patients have not been established.

ADVERSE REACTIONS

The treatment procedure is designed to induce the vaginal bleeding and uterine cramping necessary to produce an abortion. Nearly all of the women who receive Mifeprex and misoprostol will report adverse reactions, and many can be expected to report more than one such reaction. About 90% of patients report adverse reactions following administration of misoprostol on day three of the treatment procedure. Those adverse events that occurred with a frequency greater than 1% in the U.S. and French trials are shown in Table 3.

Bleeding and cramping are expected consequences of the action of Mifeprex as used in the treatment procedure. Following administration of mifepristone and misoprostol in the French clinical studies, 80 to 90% of women reported bleeding more heavily than they do during a heavy menstrual period (see WARNINGS, Bleeding for additional information). Women also typically experience abdominal pain, including uterine cramping. Other commonly reported side effects were nausea, vomiting and diarrhea. Pelvic pain, fainting, headache, dizziness, and asthenia occurred rarely. Some adverse reactions reported during the four hours following administration of misoprostol were judged by women as being more severe than others: the percentage of women who considered any particular adverse event as severe ranged from 2 to 35% in the U.S. and French trials. After the third day of the treatment procedure, the number of reports of adverse reactions declined progressively in the French trials, so that by day 14, reports were rare except for reports of bleeding and spotting.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

OVERDOSAGE

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

No serious adverse reactions were reported in tolerance studies in healthy non-pregnant female and healthy male subjects where mifepristone was administered in single doses greater than threefold that recommended for termination of pregnancy. If a patient ingests a massive overdose, she should be observed closely for signs of adrenal failure.

The oral acute lethal dose of mifepristone in the mouse, rat and dog is greater than 1000 mg/kg (about 100 times the human dose recommended for termination of pregnancy).

DOSAGE AND ADMINISTRATION

Treatment with Mifeprex and misoprostol for the termination of pregnancy requires three office visits by the patient. Mifeprex should be prescribed only by physicians who have read and understood the prescribing information. Mifeprex may be administered only in a clinic, medical office, or hospital, by or under the supervision of a physician, able to assess the gestational age of an embryo and to diagnose ectopic pregnancies. Physicians must also be able to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.

Day One: Mifeprex Administration

Patients must read the Medication Guide and read and sign the PATIENT AGREEMENT before Mifeprex is administered.

Three 200 mg tablets (600 mg) of Mifeprex are taken in a single oral dose.

Day Three: Misoprostol Administration

The patient returns to the healthcare provider two days after ingesting Mifeprex. Unless abortion has occurred and has been confirmed by clinical examination or ultrasonographic scan, the patient takes two 200 µg tablets (400 µg) of misoprostol orally.

During the period immediately following the administration of misoprostol, the patient may need medication for cramps or gastrointestinal symptoms (see ADVERSE REACTIONS). The patient should be given instructions on what to do if significant discomfort, excessive bleeding or other adverse reactions occur and should be given a phone number to call if she has questions following the administration of the misoprostol. In addition, the name and phone number of the physician who will be handling emergencies should be provided to the patient.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Day 14: Post-Treatment Examination

Patients will return for a follow-up visit approximately 14 days after the administration of Mifeprex. This visit is very important to confirm by clinical examination or ultrasonographic scan that a complete termination of pregnancy has occurred.

According to data from the U.S. and French studies, women should expect to experience bleeding or spotting for an average of nine to 16 days. Up to 8% of women may experience some type of bleeding for more than 30 days. Persistence of heavy or moderate vaginal bleeding at this visit, however, could indicate an incomplete abortion.

Patients who have an ongoing pregnancy at this visit have a risk of fetal malformation resulting from the treatment. Surgical termination is recommended to manage medical abortion treatment failures (see PRECAUTIONS, Pregnancy).

Adverse events, such as hospitalization, blood transfusion, ongoing pregnancy, or other major complications following the use of Mifeprex and misoprostol must be reported to Danco Laboratories. Please provide a brief clinical and administrative synopsis of any such adverse events in writing to:

Medical Director
Danco Laboratories, LLC
P.O. Box 4816
New York, NY 10185
1-877-4-Early Option (1-877-432-7596)

For immediate consultation 24 hours a day, 7 days a week with an expert in mifepristone, call Danco Laboratories at 1-877-4 Early Option (1-877-432-7596).

HOW SUPPLIED

Mifeprex will be supplied only to licensed physicians who sign and return a Prescriber's Agreement. Distribution of Mifeprex will be subject to specific requirements imposed by the distributor, including procedures for storage, dosage tracking, damaged product returns and other matters. Mifeprex is a prescription drug, although it will not be available to the public through licensed pharmacies.

Mifeprex is supplied as light yellow, cylindrical, bi-convex tablets imprinted on one side with "MF." Each tablet contains 200 mg of mifepristone. Tablets are packaged in single dose blister packets containing three tablets and are supplied in individual cartons (National Drug Code 6487500103).

Store at 25^0C (77^0F); excursions permitted to 15-30^0C (59-86^0F) [see USP Controlled Room Temperature].

HIGHLIGHTS OF PRESCRIBING INFORMATION

These highlights do not include all the information needed to use MIFEPREX safely and effectively. See full prescribing information for MIFEPREX.

MIFEPREX® (mifepristone) tablets, for oral use
Initial U.S. Approval: 2000

WARNING: SERIOUS AND SOMETIMES FATAL INFECTIONS OR BLEEDING

See full prescribing information for complete boxed warning.

Serious and sometimes fatal infections and bleeding occur very rarely following spontaneous, surgical, and medical abortions, including following MIFEPREX use.

- **Atypical Presentation of Infection. Patients with serious bacterial infections and sepsis can present without fever, bacteremia or significant findings on pelvic examination. A high index of suspicion is needed to rule out serious infection and sepsis. (5.1)**
- **Bleeding. Prolonged heavy bleeding may be a sign of incomplete abortion or other complications and prompt medical or surgical intervention may be needed. (5.2)**

MIFEPREX is only available through a restricted program called the Mifepristone REMS Program (5 3).
Before prescribing MIFEPREX, inform the patient about these risks. Ensure the patient knows whom to call and what to do if they experience sustained fever, severe abdominal pain, prolonged heavy bleeding, or syncope, or if they experience abdominal pain or discomfort or general malaise for more than 24 hours after taking misoprostol.

----------INDICATIONS AND USAGE----------

MIFEPREX is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. (1)

----------DOSAGE AND ADMINISTRATION----------

- 200 mg MIFEPREX on Day 1, followed 24-48 hours after MIFEPREX dosing by 800 mcg buccal misoprostol. (2.1)
- Instruct the patient what to do if significant adverse reactions occur. (2.2)
- Follow-up is needed to confirm complete termination of pregnancy. (2.3)

----------DOSAGE FORMS AND STRENGTHS----------

Tablets containing 200 mg of mifepristone each, supplied as 1 tablet on one blister card (3)

----------CONTRAINDICATIONS----------

- Confirmed/suspected ectopic pregnancy or undiagnosed adnexal mass (4)
- Chronic adrenal failure (4)
- Concurrent long-term corticosteroid therapy (4)
- History of allergy to mifepristone, misoprostol, or other prostaglandins (4)
- Hemorrhagic disorders or concurrent anticoagulant therapy (4)
- Inherited porphyria (4)
- Intrauterine device (IUD) in place (4)

----------WARNINGS AND PRECAUTIONS----------

- Ectopic pregnancy: Exclude before treatment. (5.4)
- Rhesus immunization: Prevention needed as for surgical abortion. (5.5)

----------ADVERSE REACTIONS----------

Most common adverse reactions (>15%) are nausea, weakness, fever/chills, vomiting, headache, diarrhea, and dizziness. (6)

To report SUSPECTED ADVERSE REACTIONS, contact Danco Laboratories, LLC at 1-877-432-7596 or medicaldirector@earlyoptionpill.com or FDA at 1-800-FDA-1088 or *www.fda.gov/medwatch*.

----------DRUG INTERACTIONS----------

- CYP3A4 inducers can lower mifepristone concentrations. (7.1)
- CYP3A4 inhibitors can increase mifepristone concentrations. Use with caution. (7.2)
- CYP3A4 substrate concentrations can be increased. Caution with coadministration of substrates with narrow therapeutic margin. (7.3)

----------USE IN SPECIFIC POPULATIONS----------

- Pregnancy: Risk of fetal malformations in ongoing pregnancy if not terminated is unknown. (8.1)

See 17 for PATIENT COUNSELING INFORMATION, Medication Guide.

FULL PRESCRIBING INFORMATION

WARNING: SERIOUS AND SOMETIMES FATAL INFECTIONS OR BLEEDING

Serious and sometimes fatal infections and bleeding occur very rarely following spontaneous, surgical, and medical abortions, including following MIFEPREX use. No causal relationship between the use of MIFEPREX and misoprostol and these events has been established.

- **Atypical Presentation of Infection. Patients with serious bacterial infections (e.g., *Clostridium sordellii*) and sepsis can present without fever, bacteremia, or significant findings on pelvic examination following an abortion. Very rarely, deaths have been reported in patients who presented without fever, with or without abdominal pain, but with leukocytosis with a marked left shift, tachycardia, hemoconcentration, and general malaise. A high index of suspicion is needed to rule out serious infection and sepsis *[see Warnings and Precautions (5.1)]*.**
- **Bleeding. Prolonged heavy bleeding may be a sign of incomplete abortion or other complications and prompt medical or surgical intervention may be needed. Advise patients to seek immediate medical attention if they experience prolonged heavy vaginal bleeding *[see Warnings and Precautions (5.2)]*.**

Because of the risks of serious complications described above, MIFEPREX is available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS) called the Mifepristone REMS Program *[see Warnings and Precautions (5.3)]*.

Before prescribing MIFEPREX, inform the patient about the risk of these serious events. Ensure that the patient knows whom to call and what to do, including going to an Emergency Room if none of the provided contacts are reachable, if they experience sustained fever, severe abdominal pain, prolonged heavy bleeding, or syncope, or if they experience abdominal pain or discomfort, or general malaise (including weakness, nausea, vomiting, or diarrhea) for more than 24 hours after taking misoprostol.

1 INDICATIONS AND USAGE

MIFEPREX is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation.

2 DOSAGE AND ADMINISTRATION

2.1 Dosing Regimen

For purposes of this treatment, pregnancy is dated from the first day of the last menstrual period. The duration of pregnancy may be determined from menstrual history and clinical examination. Assess the pregnancy by ultrasonographic scan if the duration of pregnancy is uncertain or if ectopic pregnancy is suspected.

Remove any intrauterine device (“IUD”) before treatment with MIFEPREX begins [*see Contraindications (4)*].

The dosing regimen for MIFEPREX and misoprostol is:

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

- MIFEPREX 200 mg orally + misoprostol 800 mcg buccally
  - *Day One:* MIFEPREX Administration
    One 200 mg tablet of MIFEPREX is taken in a single oral dose.
  - *Day Two or Three:* Misoprostol Administration (minimum 24-hour interval between MIFEPREX and misoprostol)
    Four 200 mcg tablets (total dose 800 mcg) of misoprostol are taken by the buccal route.

    Tell the patient to place two 200 mcg misoprostol tablets in each cheek pouch (the area between the cheek and gums) for 30 minutes and then swallow any remnants with water or another liquid (see Figure 1).

    Figure 1

    2 pills between cheek and gum on left side + 2 pills between cheek and gum on right side

Patients taking MIFEPREX must take misoprostol within 24 to 48 hours after taking MIFEPREX. The effectiveness of the regimen may be lower if misoprostol is administered less than 24 hours or more than 48 hours after mifepristone administration.

Because most women will expel the pregnancy within 2 to 24 hours of taking misoprostol *[see Clinical Studies (14)]*, discuss with the patient an appropriate location for them to be when taking the misoprostol, taking into account that expulsion could begin within 2 hours of administration.

2.2 Patient Management Following Misoprostol Administration

During the period immediately following the administration of misoprostol, the patient may need medication for cramps or gastrointestinal symptoms *[see Adverse Reactions (6)].*

Give the patient:

- Instructions on what to do if significant discomfort, excessive vaginal bleeding or other adverse reactions occur
- A phone number to call if the patient has questions following the administration of the misoprostol
- The name and phone number of the healthcare provider who will be handling emergencies.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

2.3 Post-treatment Assessment: Day 7 to 14

Patients should follow-up with their healthcare provider approximately 7 to 14 days after the administration of MIFEPREX. This assessment is very important to confirm that complete termination of pregnancy has occurred and to evaluate the degree of bleeding. Termination can be confirmed by medical history, clinical examination, human Chorionic Gonadotropin (hCG) testing, or ultrasonographic scan. Lack of bleeding following treatment usually indicates failure; however, prolonged or heavy bleeding is not proof of a complete abortion.

The existence of debris in the uterus (e.g., if seen on ultrasonography) following the treatment procedure will not necessarily require surgery for its removal.

Patients should expect to experience vaginal bleeding or spotting for an average of 9 to 16 days. Women report experiencing heavy bleeding for a median duration of 2 days. Up to 8% of women may experience some type of bleeding for more than 30 days. Persistence of heavy or moderate vaginal bleeding at the time of follow-up, however, could indicate an incomplete abortion.

If complete expulsion has not occurred, but the pregnancy is not ongoing, patients may be treated with another dose of misoprostol 800 mcg buccally. There have been rare reports of uterine rupture in women who took MIFEPREX and misoprostol, including women with prior uterine rupture or uterine scar and women who received multiple doses of misoprostol within 24 hours. Patients who choose to use a repeat dose of misoprostol should have a follow-up visit with their healthcare provider in approximately 7 days to assess for complete termination.

Surgical evacuation is recommended to manage ongoing pregnancies after medical abortion *[see Use in Specific Populations (8.1)]*. Advise the patient whether you will provide such care or will refer them to another provider as part of counseling prior to prescribing MIFEPREX.

2.4 Contact for Consultation

For consultation 24 hours a day, 7 days a week with an expert in mifepristone, call Danco Laboratories at 1-877-4 Early Option (1-877-432-7596).

3 DOSAGE FORMS AND STRENGTHS

Tablets containing 200 mg of mifepristone each, supplied as 1 tablet on one blister card. MIFEPREX tablets are light yellow, cylindrical, and bi-convex tablets, approximately 11 mm in diameter and imprinted on one side with “MF.”

4 CONTRAINDICATIONS

- Administration of MIFEPREX and misoprostol for the termination of pregnancy (the “treatment procedure”) is contraindicated in patients with any of the following conditions:
  - Confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass (the treatment procedure will not be effective to terminate an ectopic pregnancy) *[see Warnings and Precautions (5.4)]*
  - Chronic adrenal failure (risk of acute adrenal insufficiency)
  - Concurrent long-term corticosteroid therapy (risk of acute adrenal insufficiency)
  - History of allergy to mifepristone, misoprostol, or other prostaglandins (allergic reactions including anaphylaxis, angioedema, rash, hives, and itching have been reported *[see Adverse Reactions (6.2)]*)
  - Hemorrhagic disorders or concurrent anticoagulant therapy (risk of heavy bleeding)

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

- Inherited porphyrias (risk of worsening or of precipitation of attacks)

- Use of MIFEPREX and misoprostol for termination of intrauterine pregnancy is contraindicated in patients with an intrauterine device ("IUD") in place (the IUD might interfere with pregnancy termination). If the IUD is removed, MIFEPREX may be used.

5 WARNINGS AND PRECAUTIONS

5.1 Infection and Sepsis

As with other types of abortion, cases of serious bacterial infection, including very rare cases of fatal septic shock, have been reported following the use of MIFEPREX *[see Boxed Warning]*. Healthcare providers evaluating a patient who is undergoing a medical abortion should be alert to the possibility of this rare event. A sustained (> 4 hours) fever of 100.4°F or higher, severe abdominal pain, or pelvic tenderness in the days after a medical abortion may be an indication of infection.

A high index of suspicion is needed to rule out sepsis (e.g., from *Clostridium sordellii*) if a patient reports abdominal pain or discomfort or general malaise (including weakness, nausea, vomiting, or diarrhea) more than 24 hours after taking misoprostol. Very rarely, deaths have been reported in patients who presented without fever, with or without abdominal pain, but with leukocytosis with a marked left shift, tachycardia, hemoconcentration, and general malaise. No causal relationship between MIFEPREX and misoprostol use and an increased risk of infection or death has been established. *Clostridium sordellii* infections have also been reported very rarely following childbirth (vaginal delivery and caesarian section), and in other gynecologic and non-gynecologic conditions.

5.2 Uterine Bleeding

Uterine bleeding occurs in almost all patients during a medical abortion. Prolonged heavy bleeding (soaking through two thick full-size sanitary pads per hour for two consecutive hours) may be a sign of incomplete abortion or other complications, and prompt medical or surgical intervention may be needed to prevent the development of hypovolemic shock. Counsel patients to seek immediate medical attention if they experience prolonged heavy vaginal bleeding following a medical abortion *[see Boxed Warning]*.

Women should expect to experience vaginal bleeding or spotting for an average of 9 to 16 days. Women report experiencing heavy bleeding for a median duration of 2 days. Up to 8% of all subjects may experience some type of bleeding for 30 days or more. In general, the duration of bleeding and spotting increased as the duration of the pregnancy increased.

Decreases in hemoglobin concentration, hematocrit, and red blood cell count may occur in patients who bleed heavily.

Excessive uterine bleeding usually requires treatment by uterotonics, vasoconstrictor drugs, surgical uterine evacuation, administration of saline infusions, and/or blood transfusions. Based on data from several large clinical trials, vasoconstrictor drugs were used in 4.3% of all subjects, there was a decrease in hemoglobin of more than 2 g/dL in 5.5% of subjects, and blood transfusions were administered to ≤ 0.1% of subjects. Because heavy bleeding requiring surgical uterine evacuation occurs in about 1% of patients, special care should be given to patients with hemostatic disorders, hypocoagulability, or severe anemia.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

5.3 Mifepristone REMS Program

MIFEPREX is available only through a restricted program under a REMS called the Mifepristone REMS Program, because of the risks of serious complications *[see Warnings and Precautions (5.1, 5.2)]*.

Notable requirements of the Mifepristone REMS Program include the following:

- Prescribers must be certified with the program by completing the Prescriber Agreement Form.
- Patients must sign a Patient Agreement Form.
- MIFEPREX must only be dispensed to patients by or under the supervision of a certified prescriber, or by certified pharmacies on prescriptions issued by certified prescribers.

Further information is available at 1-877-4 Early Option (1-877-432-7596).

5.4 Ectopic Pregnancy

MIFEPREX is contraindicated in patients with a confirmed or suspected ectopic pregnancy because MIFEPREX is not effective for terminating ectopic pregnancies *[see Contraindications (4)].* Healthcare providers should remain alert to the possibility that a patient who is undergoing a medical abortion could have an undiagnosed ectopic pregnancy because some of the expected symptoms experienced with a medical abortion (abdominal pain, uterine bleeding) may be similar to those of a ruptured ectopic pregnancy. The presence of an ectopic pregnancy may have been missed even if the patient underwent ultrasonography prior to being prescribed MIFEPREX.

Patients who became pregnant with an IUD in place should be assessed for ectopic pregnancy.

5.5 Rhesus Immunization

The use of MIFEPREX is assumed to require the same preventive measures as those taken prior to and during surgical abortion to prevent rhesus immunization.

6 ADVERSE REACTIONS

The following adverse reactions are described in greater detail in other sections:

- Infection and sepsis *[see Warnings and Precautions (5.1)]*
- Uterine bleeding *[see Warnings and Precautions (5.2)]*

6.1 Clinical Trials Experience

Because clinical studies are conducted under widely varying conditions, adverse reaction rates observed in the clinical studies of a drug cannot be directly compared to rates in the clinical studies of another drug and may not reflect the rates observed in practice.

Information presented on common adverse reactions relies solely on data from U.S. studies, because rates reported in non-U.S. studies were markedly lower and are not likely generalizable to the U.S. population. In three U.S. clinical studies totaling 1,248 women through 70 days gestation who used mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally, women reported adverse reactions in diaries and in interviews at the follow-up visit. These studies enrolled generally healthy women of reproductive age without contraindications to mifepristone or misoprostol use according to the MIFEPREX product label. Gestational age was assessed prior to study enrollment using the date of the woman's last menstrual period, clinical evaluation, and/or ultrasound examination.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

About 85% of patients report at least one adverse reaction following administration of MIFEPREX and misoprostol, and many can be expected to report more than one such reaction. The most commonly reported adverse reactions (>15%) were nausea, weakness, fever/chills, vomiting, headache, diarrhea, and dizziness (see Table 1). The frequency of adverse reactions varies between studies and may be dependent on many factors, including the patient population and gestational age.

Abdominal pain/cramping is expected in all medical abortion patients and its incidence is not reported in clinical studies. Treatment with MIFEPREX and misoprostol is designed to induce uterine bleeding and cramping to cause termination of an intrauterine pregnancy. Uterine bleeding and cramping are expected consequences of the action of MIFEPREX and misoprostol as used in the treatment procedure. Most patients can expect bleeding more heavily than they do during a heavy menstrual period *[see Warnings and Precautions (5.2)]*.

Table 1 lists the adverse reactions reported in U.S. clinical studies with incidence >15% of women.

Table 1
Adverse Reactions Reported in Women Following Administration of Mifepristone (oral) and Misoprostol (buccal) in U.S. Clinical Studies

Adverse Reaction	# U.S. studies	Number of Evaluable Women	Range of frequency (%)	Upper Gestational Age of Studies Reporting Outcome
Nausea	3	1,248	51-75%	70 days
Weakness	2	630	55-58%	63 days
Fever/chills	1	414	48%	63 days
Vomiting	3	1,248	37-48%	70 days
Headache	2	630	41-44%	63 days
Diarrhea	3	1,248	18-43%	70 days
Dizziness	2	630	39-41%	63 days

One study provided gestational-age stratified adverse reaction rates for women who were 57-63 and 64-70 days; there was little difference in frequency of the reported common adverse reactions by gestational age.

Information on serious adverse reactions was reported in six U.S. and four non-U.S. clinical studies, totaling 30,966 women through 70 days gestation who used mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally. Serious adverse reaction rates were similar between U.S. and non-U.S. studies, so rates from both U.S. and non-U.S. studies are presented. In the U.S. studies, one studied women through 56 days gestation, four through 63 days gestation, and one through 70 days gestation, while in the non-U.S. studies, two studied women through 63 days gestation, and two through 70 days gestation. Serious adverse reactions were reported in <0.5% of women. Information from the U.S. and non-U.S. studies is presented in Table 2.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Table 2
Serious Adverse Reactions Reported in Women Following Administration of Mifepristone (oral) and Misoprostol (buccal) in U.S. and Non-U.S. Clinical Studies

Adverse Reaction	U.S.			Non-U.S.		
	# of studies	Number of Evaluable Women	Range of frequency (%)	# of studies	Number of Evaluable Women	Range of frequency (%)
Transfusion	4	17,774	0.03-0.5%	3	12,134	0-0.1%
Sepsis	1	629	0.2%	1	11,155	<0.01%*
ER visit	2	1,043	2.9-4.6%	1	95	0
Hospitalization Related to Medical Abortion	3	14,339	0.04-0.6%	3	1,286	0-0.7%
Infection without sepsis	1	216	0	1	11,155	0.2%
Hemorrhage	NR	NR	NR	1	11,155	0.1%

NR= Not reported
* This outcome represents a single patient who experienced death related to sepsis.

6.2 Postmarketing Experience

The following adverse reactions have been identified during postapproval use of MIFEPREX and misoprostol. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Infections and infestations: post-abortal infection (including endometritis, endomyometritis, parametritis, pelvic infection, pelvic inflammatory disease, salpingitis)
Blood and the lymphatic system disorders: anemia
Immune system disorders: allergic reaction (including anaphylaxis, angioedema, hives, rash, itching)
Psychiatric disorders: anxiety
Cardiac disorders: tachycardia (including racing pulse, heart palpitations, heart pounding)
Vascular disorders: syncope, fainting, loss of consciousness, hypotension (including orthostatic), light-headedness
Respiratory, thoracic and mediastinal disorders: shortness of breath
Gastrointestinal disorders: dyspepsia
Musculoskeletal, connective tissue and bone disorders: back pain, leg pain
Reproductive system and breast disorders: uterine rupture, ruptured ectopic pregnancy, hematometra, leukorrhea
General disorders and administration site conditions: pain

7 DRUG INTERACTIONS

7.1 Drugs that May Reduce MIFEPREX Exposure (Effect of CYP 3A4 Inducers on MIFEPREX)

CYP450 3A4 is primarily responsible for the metabolism of mifepristone. CYP3A4 inducers such as rifampin, dexamethasone, St. John's Wort, and certain anticonvulsants (such as phenytoin, phenobarbital, carbamazepine) may induce mifepristone metabolism (lowering serum concentrations of mifepristone). Whether this action has an impact on the efficacy of the dose

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

regimen is unknown. Refer to the follow-up assessment *[see Dosage and Administration (2.3)]* to verify that treatment has been successful.

7.2 Drugs that May Increase MIFEPREX Exposure (Effect of CYP 3A4 Inhibitors on MIFEPREX)

Although specific drug or food interactions with mifepristone have not been studied, on the basis of this drug's metabolism by CYP 3A4, it is possible that ketoconazole, itraconazole, erythromycin, and grapefruit juice may inhibit its metabolism (increasing serum concentrations of mifepristone). MIFEPREX should be used with caution in patients currently or recently treated with CYP 3A4 inhibitors.

7.3 Effects of MIFEPREX on Other Drugs (Effect of MIFEPREX on CYP 3A4 Substrates)

Based on *in vitro* inhibition information, coadministration of mifepristone may lead to an increase in serum concentrations of drugs that are CYP 3A4 substrates. Due to the slow elimination of mifepristone from the body, such interaction may be observed for a prolonged period after its administration. Therefore, caution should be exercised when mifepristone is administered with drugs that are CYP 3A4 substrates and have narrow therapeutic range.

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

MIFEPREX is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. Risks to pregnant patients are discussed throughout the labeling.

Refer to misoprostol labeling for risks to pregnant patients with the use of misoprostol.

The risk of adverse developmental outcomes with a continued pregnancy after a failed pregnancy termination with MIFEPREX in a regimen with misoprostol is unknown; however, the process of a failed pregnancy termination could disrupt normal embryo-fetal development and result in adverse developmental effects. Birth defects have been reported with a continued pregnancy after a failed pregnancy termination with MIFEPREX in a regimen with misoprostol. In animal reproduction studies, increased fetal losses were observed in mice, rats, and rabbits and skull deformities were observed in rabbits with administration of mifepristone at doses lower than the human exposure level based on body surface area.

Data

Animal Data

In teratology studies in mice, rats and rabbits at doses of 0.25 to 4.0 mg/kg (less than 1/100 to approximately 1/3 the human exposure based on body surface area), because of the antiprogestational activity of mifepristone,fetal losses were much higher than in control animals. Skull deformities were detected in rabbit studies at approximately 1/6 the human exposure, although no teratogenic effects of mifepristone have been observed to date in rats or mice. These deformities were most likely due to the mechanical effects of uterine contractions resulting from inhibition of progesterone action.

8.2 Lactation

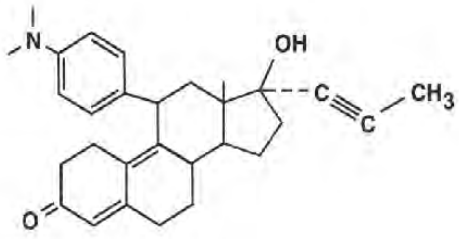
MIFEPREX is present in human milk. Limited data demonstrate undetectable to low levels of the drug in human milk with the relative (weight-adjusted) infant dose 0.5% or less as compared to maternal dosing. There is no information on the effects of MIFEPREX in a regimen with

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

misoprostol in a breastfed infant or on milk production. Refer to misoprostol labeling for lactation information with the use of misoprostol. The developmental and health benefits of breast-feeding should be considered along with any potential adverse effects on the breast-fed child from MIFEPREX in a regimen with misoprostol.

8.4 Pediatric Use

Safety and efficacy of MIFEPREX have been established in pregnant females. Data from a clinical study of MIFEPREX that included a subset of 322 females under age 17 demonstrated a safety and efficacy profile similar to that observed in adults.



10 OVERDOSAGE

No serious adverse reactions were reported in tolerance studies in healthy non-pregnant female and healthy male subjects where mifepristone was administered in single doses greater than 1800 mg (ninefold the recommended dose for medical abortion). If a patient ingests a massive overdose, the patient should be observed closely for signs of adrenal failure.

11 DESCRIPTION

MIFEPREX tablets each contain 200 mg of mifepristone, a synthetic steroid with antiprogestational effects. The tablets are light yellow in color, cylindrical, and bi-convex, and are intended for oral administration only. The tablets include the inactive ingredients colloidal silica anhydrous, corn starch, povidone, microcrystalline cellulose, and magnesium stearate.

Mifepristone is a substituted 19-nor steroid compound chemically designated as 11ß-[*p*-(Dimethylamino)phenyl]-17ß-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one. Its empirical formula is $C_{29}H_{35}NO_2$. Its structural formula is:

The compound is a yellow powder with a molecular weight of 429.6 and a melting point of 192-196°C. It is very soluble in methanol, chloroform and acetone and poorly soluble in water, hexane and isopropyl ether.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

The anti-progestational activity of mifepristone results from competitive interaction with progesterone at progesterone-receptor sites. Based on studies with various oral doses in several animal species (mouse, rat, rabbit, and monkey), the compound inhibits the activity of endogenous or exogenous progesterone, resulting in effects on the uterus and cervix that, when combined with misoprostol, result in termination of an intrauterine pregnancy.

During pregnancy, the compound sensitizes the myometrium to the contraction-inducing activity

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

of prostaglandins.

12.2 Pharmacodynamics

Use of MIFEPREX in a regimen with misoprostol disrupts pregnancy by causing decidual necrosis, myometrial contractions, and cervical softening, leading to the expulsion of the products of conception.

Doses of 1 mg/kg or greater of mifepristone have been shown to antagonize the endometrial and myometrial effects of progesterone in women.

Antiglucocorticoid and antiandrogenic activity: Mifepristone also exhibits antiglucocorticoid and weak antiandrogenic activity. The activity of the glucocorticoid dexamethasone in rats was inhibited following doses of 10 to 25 mg/kg of mifepristone. Doses of 4.5 mg/kg or greater in human beings resulted in a compensatory elevation of adrenocorticotropic hormone (ACTH) and cortisol. Antiandrogenic activity was observed in rats following repeated administration of doses from 10 to 100 mg/kg.

12.3 Pharmacokinetics

Mifepristone is rapidly absorbed after oral ingestion with non-linear pharmacokinetics for Cmax after single oral doses of 200 mg and 600 mg in healthy subjects.

Absorption

The absolute bioavailability of a 20 mg mifepristone oral dose in females of childbearing age is 69%. Following oral administration of a single dose of 600 mg, mifepristone is rapidly absorbed, with a peak plasma concentration of 1.98 ± 1.0 mg/L occurring approximately 90 minutes after ingestion.

Following oral administration of a single dose of 200 mg in healthy men (n=8), mean Cmax was 1.77 ± 0.7 mg/L occurring approximately 45 minutes after ingestion. Mean $AUC_{0-\infty}$ was 25.8 ± 6.2 mg*hr/L.

Distribution

Mifepristone is 98% bound to plasma proteins, albumin, and α_1-acid glycoprotein. Binding to the latter protein is saturable, and the drug displays nonlinear kinetics with respect to plasma concentration and clearance.

Elimination

Following a distribution phase, elimination of mifepristone is slow at first (50% eliminated between 12 and 72 hours) and then becomes more rapid with a terminal elimination half-life of 18 hours.

Metabolism

Metabolism of mifepristone is primarily via pathways involving N-demethylation and terminal hydroxylation of the 17-propynyl chain. *In vitro* studies have shown that CYP450 3A4 is primarily responsible for the metabolism. The three major metabolites identified in humans are: (1) RU 42 633, the most widely found in plasma, is the N-monodemethylated metabolite; (2) RU 42 848, which results from the loss of two methyl groups from the 4-dimethylaminophenyl in position 11ß; and (3) RU 42 698, which results from terminal hydroxylation of the 17-propynyl chain.

Excretion

By 11 days after a 600 mg dose of tritiated compound, 83% of the drug has been accounted for by the feces and 9% by the urine. Serum concentrations are undetectable by 11 days.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Specific Populations

The effects of age, hepatic disease and renal disease on the safety, efficacy and pharmacokinetics of mifepristone have not been investigated.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

No long-term studies to evaluate the carcinogenic potential of mifepristone have been performed.

Mutagenesis

Results from studies conducted *in vitro* and in animals have revealed no genotoxic potential for mifepristone. Among the tests carried out were: Ames test with and without metabolic activation; gene conversion test in *Saccharomyces cerevisiae* D4 cells; forward mutation in *Schizosaccharomyces pompe* P1 cells; induction of unscheduled DNA synthesis in cultured HeLa cells; induction of chromosome aberrations in CHO cells; *in vitro* test for gene mutation in V79 Chinese hamster lung cells; and micronucleus test in mice.

Impairment of Fertility

In rats, administration of 0.3 mg/kg mifepristone per day caused severe disruption of the estrus cycles for the three weeks of the treatment period. Following resumption of the estrus cycle, animals were mated and no effects on reproductive performance were observed.

14 CLINICAL STUDIES

Safety and efficacy data from clinical studies of mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally through 70 days gestation are reported below. Success was defined as the complete expulsion of the products of conception without the need for surgical intervention. The overall rates of success and failure, shown by reason for failure based on 22 worldwide clinical studies (including 7 U.S. studies) appear in Table 3.

The demographics of women who participated in the U.S. clinical studies varied depending on study location and represent the racial and ethnic variety of American females. Females of all reproductive ages were represented, including females less than 18 and more than 40 years of age; most were 27 years or younger.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

Table 3
Outcome Following Treatment with Mifepristone (oral) and Misoprostol (buccal) Through 70 Days Gestation

	U.S. Trials	Non-U.S. Trials
N	16,794	18,425
Complete Medical Abortion	97.4%	96.2%
Surgical Intervention*	2.6%	3.8%
Ongoing Pregnancy**	0.7%	0.9%

* Reasons for surgical intervention include ongoing pregnancy, medical necessity, persistent or heavy bleeding after treatment, patient request, or incomplete expulsion.
** Ongoing pregnancy is a subcategory of surgical intervention, indicating the percent of women who have surgical intervention due to an ongoing pregnancy.

The results for clinical studies that reported outcomes, including failure rates for ongoing pregnancy, by gestational age are presented in Table 4.

Table 4
Outcome by Gestational Age Following Treatment with Mifepristone and Misoprostol (buccal) for U.S. and Non-U.S. Clinical Studies

	≤49 days			50-56 days			57-63 days			64-70 days		
	N	**%**	**Number of Evaluable Studies**	**N**	**%**	**Number of Evaluable Studies**	**N**	**%**	**Number of Evaluable Studies**	**N**	**%**	**Number of Evaluable Studies**
Complete medical abortion	12,046	98.1	10	3,941	96.8	7	2,294	94.7	9	479	92.7	4
Surgical intervention for ongoing pregnancy	10,272	0.3	6	3,788	0.8	6	2,211	2	8	453	3.1	3

One clinical study asked subjects through 70 days gestation to estimate when they expelled the pregnancy, with 70% providing data. Of these, 23-38% reported expulsion within 3 hours and over 90% within 24 hours of using misoprostol.

16 HOW SUPPLIED/STORAGE AND HANDLING

is only available through a restricted program called the Mifepristone REMS Program *[see Warnings and Precautions (5.3)].*

MIFEPREX is supplied as light yellow, cylindrical, and bi-convex tablets imprinted on one side with “MF.” Each tablet contains 200 mg of mifepristone. One tablet is individually blistered on one blister card that is packaged in an individual package (National Drug Code 64875-001-01).

Store at 25°C (77°F); excursions permitted to 15 to 30°C (59 to 86°F) [see USP Controlled Room Temperature].

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide), included with each package of MIFEPREX. Additional copies of the Medication Guide are available by contacting Danco Laboratories at 1-877-4 Early Option (1-877-432-7596) or from www.earlyoptionpill.com.

Serious Infections and Bleeding

- Inform the patient that uterine bleeding and uterine cramping will occur [*see Warnings and Precautions (5.2)*].
- Advise the patient that serious and sometimes fatal infections and bleeding can occur very rarely [*see Warnings and Precautions (5.1, 5.2)*].
- MIFEPREX is only available through a restricted program called the Mifepristone REMS Program [*see Warnings and Precautions (5.3)*]. Under the Mifepristone REMS Program:
    - Patients must sign a Patient Agreement Form.
    - MIFEPREX is only dispensed by or under the supervision of certified prescribers or by certified pharmacies on prescriptions issued by certified prescribers.

Provider Contacts and Actions in Case of Complications

- Ensure that the patient knows whom to call and what to do, including going to an Emergency Room if none of the provided contacts are reachable, or if the patient experiences complications including prolonged heavy bleeding, severe abdominal pain, or sustained fever *[see Boxed Warning]*.
-

Compliance with Treatment Schedule and Follow-up Assessment

- Advise the patient that it is necessary to complete the treatment schedule, including a follow-up assessment approximately 7 to14 days after taking MIFEPREX *[see Dosage and Administration (2.3)]*.
- Explain that
    - prolonged heavy vaginal bleeding is not proof of a complete abortion,
    - if the treatment fails and the pregnancy continues, the risk of fetal malformation is unknown,
    - it is recommended that ongoing pregnancy be managed by surgical termination *[see Dosage and Administration (2.3)]*. Advise the patient whether you will provide such care or will refer them to another provider.

Subsequent Fertility

- Inform the patient that another pregnancy can occur following medical abortion and before resumption of normal menses.
- Inform the patient that contraception can be initiated as soon as pregnancy expulsion has been confirmed, or before resuming sexual intercourse.

MEDICATION GUIDE

Mifeprex (MIF-eh-prex) (mifepristone tablets, for oral use

Read this information carefully before taking Mifeprex and misoprostol. It will help you understand how the treatment works. This Medication Guide does not take the place of talking with your healthcare provider.

What is the most important information I should know about Mifeprex?

What symptoms should I be concerned with? Although cramping and bleeding are an expected part of ending a pregnancy, rarely, serious and potentially life-threatening bleeding, infections, or other problems can occur following a miscarriage, surgical abortion, medical abortion, or childbirth. Seeking medical attention as soon as possible is needed in these circumstances. Serious infection has resulted in death in a very small number of cases. There is no information that use of Mifeprex and misoprostol caused these deaths. If you have any questions, concerns, or problems, or if you are worried about any side effects or symptoms, you should contact your healthcare provider. You can write down your healthcare provider's telephone number here _____.

Be sure to contact your healthcare provider promptly if you have any of the following:

- **Heavy Bleeding.** Contact your healthcare provider right away if you bleed enough to soak through two thick full-size sanitary pads per hour for two consecutive hours or if you are concerned about heavy bleeding. In about 1 out of 100 women, bleeding can be so heavy that it requires a surgical procedure (surgical aspiration or D&C).
- **Abdominal Pain or "Feeling Sick."** If you have abdominal pain or discomfort, or you are "feeling sick," including weakness, nausea, vomiting, or diarrhea, with or without fever, more than 24 hours after taking misoprostol, you should contact your healthcare provider without delay. These symptoms may be a sign of a serious infection or another problem (including an ectopic pregnancy, a pregnancy outside the womb).
- **Fever.** In the days after treatment, if you have a fever of 100.4°F or higher that lasts for more than 4 hours, you should contact your healthcare provider right away. Fever may be a symptom of a serious infection or another problem.

If you cannot reach your healthcare provider, go to the nearest hospital emergency room.

What to do if you are still pregnant after Mifeprex with misoprostol treatment. If you are still pregnant, your healthcare provider will talk with you about a surgical procedure to end your pregnancy. In many cases, this surgical procedure can be done in the office/clinic. The chance of birth defects if the pregnancy is not ended is unknown.

Talk with your healthcare provider. Before you take Mifeprex, you should read this Medication Guide and you and your healthcare provider should discuss the benefits and risks of your using Mifeprex.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

What is Mifeprex?

Mifeprex is used in a regimen with another prescription medicine called misoprostol, to end an early pregnancy. Early pregnancy means it is 70 days (10 weeks) or less since your last menstrual period began. Mifeprex is not approved for ending pregnancies that are further along. Mifeprex blocks a hormone needed for your pregnancy to continue. When you use Mifeprex on Day 1, you also need to take another medicine called misoprostol 24 to 48 hours after you take Mifeprex, to cause the pregnancy to be passed from your uterus.

The pregnancy is likely to be passed from your uterus within 2 to 24 hours after taking Mifeprex and misoprostol. When the pregnancy is passed from the uterus, you will have bleeding and cramping that will likely be heavier than your usual period. About 2 to 7 out of 100 women taking Mifeprex will need a surgical procedure because the pregnancy did not completely pass from the uterus or to stop bleeding.

Who should not take Mifeprex?

Some patients should not take Mifeprex. Do not take Mifeprex if you:

- Have a pregnancy that is more than 70 days (10 weeks). Your healthcare provider may do a clinical examination, an ultrasound examination, or other testing to determine how far along you are in pregnancy.
- Are using an IUD (intrauterine device or system). It must be taken out before you take Mifeprex.
- Have been told by your healthcare provider that you have a pregnancy outside the uterus (ectopic pregnancy).
- Have problems with your adrenal glands (chronic adrenal failure).
- Take a medicine to thin your blood.
- Have a bleeding problem.
- Have porphyria.
- Take certain steroid medicines.
- Are allergic to mifepristone, misoprostol, or medicines that contain misoprostol, such as Cytotec or Arthrotec.

Ask your healthcare provider if you are not sure about all your medical conditions before taking this medicine to find out if you can take Mifeprex.

What should I tell my healthcare provider before taking Mifeprex?

Before you take Mifeprex, tell your healthcare provider if you:

- cannot follow-up within approximately 7 to 14 days of your first visit
- are breastfeeding. Mifeprex can pass into your breast milk. The effect of the Mifeprex and misoprostol regimen on the breastfed infant or on milk production is unknown.
- are taking medicines, including prescription and over-the-counter medicines, vitamins, and herbal supplements.
  Mifeprex and certain other medicines may affect each other if they are used together. This can cause side effects.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

How should I take Mifeprex?

- Mifeprex will be given to you by a healthcare provider or pharmacy.
- You and your healthcare provider will plan the most appropriate location for you to take the misoprostol, because it may cause bleeding, cramps, nausea, diarrhea, and other symptoms that usually begin within 2 to 24 hours after taking it.
- Most women will pass the pregnancy within 2 to 24 hours after taking the misoprostol tablets.

Follow the instruction below on how to take Mifeprex and misoprostol:

Mifeprex (1 tablet) orally + misoprostol (4 tablets) buccally

Day 1:

- Take 1 Mifeprex tablet by mouth.

24 to 48 hours after taking Mifeprex:

- Take 4 misoprostol tablets by placing 2 tablets in each cheek pouch (the area between your teeth and cheek - see Figure A) for 30 minutes and then swallow anything left over with a drink of water or another liquid.
- The medicines may not work as well if you take misoprostol sooner than 24 hours after Mifeprex or later than 48 hours after Mifeprex.
- Misoprostol often causes cramps, nausea, diarrhea, and other symptoms. Your healthcare provider may send you home with medicines for these symptoms.

Figure A (2 tablets between your left cheek and gum and 2 tablets between your right cheek and gum).

Follow-up Assessment at Day 7 to 14:

- This follow-up assessment is very important. You must follow-up with your healthcare provider about 7 to 14 days after you have taken Mifeprex to be sure you are well and that you have had bleeding and the pregnancy has passed from your uterus.
- Your healthcare provider will assess whether your pregnancy has passed from your uterus. If your pregnancy continues, the chance that there may be birth defects is unknown. If you are still pregnant, your healthcare provider will talk with you about a surgical procedure to end your pregnancy.
- If your pregnancy has ended, but has not yet completely passed from your uterus, your provider will talk with you about other choices you have, including waiting, taking another dose of misoprostol, or having a surgical procedure to empty your uterus.

This label may not be the latest approved by FDA.
For current labeling information, please visit https://www.fda.gov/drugsatfda

When should I begin birth control?

You can become pregnant again right after your pregnancy ends. If you do not want to become pregnant again, start using birth control as soon as your pregnancy ends or before you start having sexual intercourse again.

What should I avoid while taking Mifeprex and misoprostol?

Do not take any other prescription or over-the-counter medicines (including herbal medicines or supplements) at any time during the treatment period without first asking your healthcare provider about them because they may interfere with the treatment. Ask your healthcare provider about what medicines you can take for pain and other side effects.

What are the possible side effects of Mifeprex and misoprostol?

Mifeprex may cause serious side effects. See "What is the most important information I should know about Mifeprex?"

Cramping and bleeding. Cramping and vaginal bleeding are expected with this treatment. Usually, these symptoms mean that the treatment is working. But sometimes you can get cramping and bleeding and still be pregnant. This is why you must follow-up with your healthcare provider approximately 7 to 14 days after taking Mifeprex. See "How should I take Mifeprex?" for more information on your follow-up assessment. If you are not already bleeding after taking Mifeprex, you probably will begin to bleed once you take misoprostol, the medicine you take 24 to 48 hours after Mifeprex. Bleeding or spotting can be expected for an average of 9 to16 days and may last for up to 30 days. Your bleeding may be similar to, or greater than, a normal heavy period. You may see blood clots and tissue. This is an expected part of passing the pregnancy.

The most common side effects of Mifeprex treatment include: nausea, weakness, fever/chills, vomiting, headache, diarrhea and dizziness. Your provider will tell you how to manage any pain or other side effects. These are not all the possible side effects of Mifeprex.

Call your healthcare provider for medical advice about any side effects that bother you or do not go away. You may report side effects to FDA at 1-800-FDA-1088.

General information about the safe and effective use of Mifeprex.

Medicines are sometimes prescribed for purposes other than those listed in a Medication Guide. This Medication Guide summarizes the most important information about Mifeprex. If you would like more information, talk with your healthcare provider. You may ask your healthcare provider for information about Mifeprex that is written for healthcare professionals.

For more information about Mifeprex, go to www.earlyoptionpill.com or call 1-877-4 Early Option (1-877-432-7596).

Introduction

The National Abortion Federation's (NAF) mission is to unite, represent, serve, and support abortion providers in delivering patient-centered, evidence-based care. An important part of this work is to develop and maintain evidence-based guidelines and standards as well as to educate providers in the latest technologies and techniques.(1) NAF's programs make it possible for people to obtain the highest quality abortion care.

Like its precursors, the 2024 edition of NAF's *Clinical Policy Guidelines for Abortion Care* (CPGs) serve to provide guidance for facilities to use in establishing their clinical policies. The CPGs are developed by consensus, based on rigorous review of the relevant medical literature and patient outcomes.(2-6) These guidelines are intended to provide parameters to ensure access to the highest quality abortion care.

NAF's *Clinical Policy Guidelines* were first published in 1996 and have been revised annually since then. Since inception, they have been based on the methodology described by David Eddy, MD, in *A Manual for Assessing Health Practices and Designing Practice Policies: The Explicit Approach*.(7) Clinical policy guidelines are defined as a systematically developed series of statements, which assist practitioners and patients in making decisions about appropriate health care. They represent an attempt to distill a large body of medical knowledge into a convenient and readily usable format. Since 2018, we have incorporated the Institute of Medicine's recommendations.(8)

When the outcomes of an intervention are known, practitioner choices are limited. But when the outcomes of an intervention are uncertain or variable, and/or when patients' preferences for those outcomes are uncertain or variable, practitioners must be given flexibility to tailor a policy to individual cases. This is addressed by having three types of policies according to their intended flexibility: standards, recommendations, and options:

1) **STANDARDS** are intended to be applied in virtually all cases. Deviations will be rare and difficult to justify.

2) **RECOMMENDATIONS** are steering in nature. They do not have the force of standards, but when not adhered to, there should be documented, rational clinical justification. They allow some latitude in clinical management.

3) **OPTIONS** are neutral with respect to a treatment choice. They merely note that different interventions are available, and that different people make different choices. They may contribute to the educational process, and they require no justification.

NAF's CPGs include a list of references for each section and include discussion material for clarification when appropriate. These guidelines are meant to be living documents, subject to revision as new medical evidence becomes available.

Medline was searched monthly on Pubmed. An automated search using the following terms was created and checked monthly:

((((abortion induced [MeSH Major Topic]) OR mifepristone) OR medical abortion) OR (dilation and evacuation)) OR uterine aspiration.

The search was limited to clinical trials, case reports, comparative studies, reviews, meta-analysis, and systematic reviews in humans from January 1, 2022. The search run on December 31, 2023, yielded 667 results. In addition, abstracts from major conferences, references in articles, and related non-abortion searches (for example, in analgesia and sedation) were run.

Studies were included that addressed CPG topics and either changed, updated, or substantially added support to a current recommendation. Studies were excluded that were not relevant, had poor methodology or inconclusive results, or did not substantially add to a current recommendation.

Thirty-three new papers were included in the 2024 CPGs because they changed one or more statements, supported a new recommendation, or substantially improved the level of evidence supporting a current statement. Changes to each policy statement were drafted by NAF's Interim Medical Advisor, Alice Mark, MD, MSc, and Senior Director of Clinical Services, Reesa Roberts, PA-C, MSPA, based on the included papers. These papers were reviewed by the NAF Clinical Policy Committee and changes to each policy statement were edited and approved by the entire committee. A synthesis of how the new study altered the existing policy statement will be available in an online module.

NAF 2022-2023 Clinical Policy Committee members:

Sarah Prager, MD, MAS; Chair
Justin T. Diedrich, MD, MSCI
Angel M. Foster, DPhil, MD, AM
Tiffany Hailstorks, MD, MPH
John C. Markley, MD, PhD
Tram Nguyen, MHA/MBA
Alisha Nord-Stewart, RN, BScN
Lisa Perriera, MD, MPH
Rolanda Ryan, RN, MHSA
TaRhonda Slydell, BSN, MBA-HCA
Maria Mercedes Vivas, MD, MPH
Lin Fan Wang, MD
Beverly Winikoff, MD, MPH
Ying Zhang, MD, MPH

Note: The *Clinical Policy Guidelines for Abortion Care* are not intended to educate members regarding legal and regulatory issues, which may affect abortion practice. It is expected that administrators, staff, and clinicians will be aware of pertinent local, state/provincial/territorial, and national laws as well as the requirements and limitations of their individual duties and scope of professional practice. NAF provider members should ensure that all employees have access to appropriate resources for information and support.

Commitment to diversity, inclusion, equity, and anti-racism: Abortion is affected by structural, institutional, interpersonal, and individual-level racism that affects safety and quality of care, and degrades the abortion experience for many of those who seek it.(9,10) NAF holds itself accountable to anti-racist principles and endorses evidence-based clinical guidelines that are not a source of harm but promote health for people with historically marginalized identities, including but not limited to Black, Indigenous, and People of Color, lesbian, gay, bisexual, transgender, gender expansive, intersex, asexual and two spirit people, immigrants, refugees, people with limited financial resources, people with limited exposure to formal education, people who don't speak the dominant language, young people, people of all body sizes, and people with disabilities, chronic illness, or other conditions.

A note about language: NAF and our members understand and respect that not every person with the capacity for pregnancy identifies as a woman. We embrace and respect each individual's gender identity, expression, and experience, and desire to be inclusive and helpful to all who need information about abortion or support as providers. While we do make an effort to use gender-inclusive language (person/people/they/them/patient) in this document and our other materials, we do also use woman/women in some cases. We do so in order to acknowledge the long history of gender discrimination targeting women, the specialized health care that many of our members provide, and the need to be clear to various audiences.

Notes on Formatting

As presented here, standards, recommendations, and options are hierarchical in nature. It is therefore expected that clinical practices will favor the highest level of guidance available on a given point. To clarify the relationships of Recommendations and/or Options that are subordinate to higher level Standards and/or Recommendations, NAF's guidelines are numbered and formatted according to the following scheme:

Within each section, **Standards** are numbered consecutively starting with the section number with the standard to the right of a decimal. For example, the first standard in Section 1 will be Standard 1.1.

Recommendations are also numbered consecutively within each main subject heading, with numbers that are placed to the right of a second decimal point. Where a recommendation follows a standard, it is included below the standard and the number of that standard will be found to the left of the decimal point (e.g., Recommendation 1.1.1). Where the recommendation stands alone and is not related to a specific standard, there will be a zero in the position to the left of the decimal point (e.g., Recommendation 1.0.1).

The consecutive numbers denoting *Options* within each main subject heading are placed to the right of the third decimal point. Where an option follows a preceding standard or recommendation, it is indented below that standard or recommendation and the numbers identifying that option will be found to the right of a third decimal point added to the end of the standard or recommendation (e.g., Option 1.1.0.1 or Option 1.1.1.1). Where the option stands alone and is not related to a specific standard or recommendation, zeros will be placed in the position for the standard and recommendation (e.g., Option 1.0.0.1).

1. Who Can Provide Abortions

Policy Statement: Abortion should be decriminalized. Abortion is a safe procedure when provided by qualified individuals.(1) The vast majority of abortions, including uterine aspiration, dilation and evacuation, and medication abortion after the first trimester, can be safely provided in medical offices or freestanding clinics.(2) Telemedicine can be safely used to provide abortion care, including medication abortion provision, informed consent, and follow-up.(3, 4) People may manage all or part of an abortion on their own.(5, 6)

Standard 1.1
Abortion will be provided by trained providers. This category is intended to include physicians from various specialties as well as nurse midwives, nurse practitioners, physician assistants, registered nurses, other health professionals and community-based providers.(7)

Recommendation 1.1.1
Documentation specifying privileges in accordance with each practitioner's scope of practice should be maintained.

Recommendation 1.1.2
Complex Family Planning accreditation or sub-specialty status are not necessary or required for the provision of safe abortion care.

Recommendation 1.1.3
Neither hospital admitting privileges nor transfer agreements are needed to provide safe abortion care.(2)

Recommendation 1.1.4
Community-based providers with appropriate training may safely provide care.(6, 8, 9)

Standard 1.2
People may manage all or part of an abortion on their own. People using self-managed abortion need access to evidence-based information, effective medications, and supportive services before, during, and after the abortion.

Recommendation 1.2.1
Don't engage in any behavior that criminalizes abortion or those who use it.

Standard 1.3
All individuals providing abortions must have received training to competency in abortion care, including the prevention, recognition, and management of complications.

Recommendation 1.3.1
When making changes to clinical practice, consider values clarification for providers and staff to optimize patient-centered care.

Standard 1.4
All individuals providing ancillary services must have appropriate training, for example, in ultrasound, counseling, sedation, laboratory, infection control, and other services.

Standard 1.5
Appropriate referrals must be available for patients who cannot be cared for by an individual or facility.

Discussion: Values clarification is an essential part of hiring, training, and retaining abortion staff. Values clarification should be done routinely but particularly needs to be revisited if a clinic expands its services, increases gestational limits, if staff changes roles at clinic, or when new staff are hired. Resources for values clarification can be found on NAF's members-only website at https://members.prochoice.org in the Learning Lab.

(https://doi.org/10.1080/26410397.2021.2009103)

2. Patient Education, Informed Consent, and Counseling

Policy Statement: A person must give voluntary, informed consent prior to an abortion and express understanding. The goal of abortion education is to give people the knowledge they need to make an informed decision about whether to have an abortion and which type of procedure to choose.

Informed Consent

Standard 2.1
The practitioner must ensure that accurate information is provided about the abortion process and its alternatives, and the potential risks and benefits. The patient must have the opportunity to have any questions answered to their satisfaction prior to intervention.

> *Option 2.1.0.1*
> Information may be provided either on an individual basis, in group sessions, or with appropriate patient information materials, and can be done in person or remotely.(1)

Standard 2.2
Documentation must show that the patient affirms their decision to have an abortion, that their decision is voluntary, and that they are aware of the potential risks and benefits of the abortion procedure. Although other risks may be addressed, at a minimum, the following risks must be included (2-6):

1) Hemorrhage
2) Infection
3) Continuing pregnancy
4) Death.

Recommendation 2.2.1
For abortion procedures (uterine aspiration or dilation and evacuation), the additional risks must be included:

5) Perforation
6) Damage to organs including hysterectomy.

Patient Education and Counseling

Standard 2.3
Each person must have a private opportunity to ask questions about the abortion.(7-9)

Standard 2.4
A person must undergo the abortion as expeditiously as possible in accordance with good medical practice.

Recommendation 2.4.1
Information about aftercare and contraception must be available. The importance of contacting the provider for any concerns should be emphasized.

Recommendation 2.4.2
Evidence-based guidelines for contraceptive counseling should be followed.(10)

Standard 2.5
All reasonable precautions must be taken to ensure confidentiality.

Recommendation 2.5.1
The person should be informed of the communication of information to any third party.

Recommendation 2.5.2
People need to know which individuals or agencies may receive communications regarding services. This information should include confidentiality implications of using insurance or governmental health care coverage.

Discussion: Informed consent and abortion counseling are two different processes. The goal of informed consent is to assure that the person's decision is voluntary and informed, and that they understand the risks and benefits of the abortion procedure. Education and counseling includes a discussion of the feelings and concerns expressed by the patient, which may include help with decision-making and contraceptive choices, values clarification, or referral to other professionals. Although the large majority of people who present for abortion are sure of their decision,(8) a referral to community services should be available if that becomes necessary or the needs of the patient are outside the scope of training of clinic staff.

Where abortion is safe and legal, the risk of death overall is less than 1 per 100,000 abortions.(5, 6, 11) Pregnancy-related deaths are significantly higher.(12)

Risks of pregnancy-related death by country, 2020 WHO data (12)

Country	Maternal mortality ratio*
Canada	11
United States	21
Mexico	59
Colombia	75

*deaths per 100,000 live births

3. Infection Prevention and Control

Policy Statement: Patients and health care personnel are at risk for exposure to blood borne pathogens, aerosol transmissible disease, and other potentially infectious material. Infectious material may be transmitted to patients when proper engineering* and work-practice controls,† which reduce exposure, are not followed. Proper handling of chemicals and other materials needed for proper disinfection is important to prevent harm to staff. Prevention and treatment of infection will reduce post-abortion morbidity.

Standard 3.1
Proper engineering and work-practice controls must be in place to reduce exposure of patient and staff to infectious agents. Clinics must protect employees and patients from being exposed to biohazardous material.(1)

Standard 3.2
Hands must be washed or disinfected before and after patient contact.(2-4)

Standard 3.3
Personal protective equipment must be provided to all staff.(1, 5-8)

Recommendation 3.3.1
New staff with potential exposure should have an initial training as part of orientation.

Recommendation 3.3.2
Periodic facility-level training should occur at least every three years.

Recommendation 3.3.3
Hepatitis B vaccine should be provided at no cost to the staff.

Standard 3.4
Exposure control plans must be established and followed.(5, 7, 9)

Recommendation 3.4.1
Post-exposure evaluation, prophylaxis, and follow-up should be available to exposed patients or staff for any potentially infectious agent, regardless of source.

Standard 3.5
All instruments coming into contact with patients must be properly cleaned and disinfected between patients.(10)

*Engineering control—available technology and devices that isolate or remove hazards from the workplace, such as puncture-resistant sharps disposal containers, needleless systems for withdrawing medications, and safer sharps devices.

†Work-practice control—an alteration in the way a task is performed that reduces the likelihood that an employee will be exposed to blood or other potentially infectious materials, for example, prohibiting needle recapping.

Standard 3.6
All instruments entering the uterus must be sterile.

Option 3.6.0.1
The cervix and vagina may be cleansed with a bactericidal agent though randomized trials have failed to show a benefit to this practice.(11)

Standard 3.7
Tubing and manual uterine aspirators must be high-level disinfected or sterilized.(10)

Standard 3.8
All tissue removed in the facility must be considered biohazardous and be handled, stored, and disposed of in a manner that minimizes the risk of exposure. A protocol for tissue handling, storage, and disposal must be in place.

Standard 3.9
Sharps containers must be readily available. Sharps containers must be made of rigid, puncture-resistant material, have a tight-fitting lid, and be labeled as hazardous material.

Standard 3.10
Routine antibiotic prophylaxis must be used for uterine aspiration and dilation and evacuation.(12, 13)

Recommendation 3.10.1
All patients having uterine aspiration or dilation and evacuation should receive antibiotics pre-procedure.(11, 14, 15)

Recommendation 3.10.2
Prophylactic antibiotics should not be continued after the day of the procedure.(11, 14, 15)

Option 3.10.2.1
Antibiotics may be initiated at the time of insertion of osmotic dilators.

Option 3.10.2.2
Antibiotics are not required for patients choosing medication abortion.(16) Insufficient evidence exists to support routine antibiotic prophylaxis for medication abortion.

Recommendation 3.10.3
Additional antibiotics are not recommended for endocarditis prophylaxis in patients with heart murmurs or other cardiac conditions.(13, 17, 18)

Recommendation 3.10.4
Patients should be offered or referred for testing for chlamydia and gonorrhea according to local guidelines.(19) Testing should not delay the procedure.

Option 3.10.4.1
Empiric treatment of chlamydia may be considered for patients with history, signs, or symptoms of current infection.

Standard 3.11
Diagnosed infection must be appropriately treated.

Recommendation 3.11.1
For documented infections of the reproductive tract, evidence-based regimens should be followed.(19, 20)

Discussion: Regulatory agency policies (see references) may be helpful in developing exposure plans that protect personnel and patients from potentially infectious material, including aerosol transmissible diseases. A sample exposure control plan can be found in the online learning resources on NAF's members-only site at https://members.prochoice.org. Techniques for collection, labeling, and disposal of biohazardous material and for the processing of instruments are integral to any complete plan.

Expedited partner treatment may be considered for patients with a known diagnosis of a sexually transmitted infection.(21, 22)

4. Laboratory Practice

Policy Statement: Rh alloimmunization may jeopardize the health of a subsequent pregnancy.(1) There is no evidence that providing anti-D immunoglobulin in early pregnancy prevents alloimmunization and poor outcome in a subsequent pregnancy, however, it is recommended later in pregnancy.(2-7)

Standard 4.1
Rh status testing must be offered to all people with unknown Rh status over 12 weeks from the last menstrual period (LMP) and anti-D immune globulin must be offered to patients over 12 weeks who are Rh negative.

Recommendation 4.1.1
Below 12 weeks from the last menstrual period, patients and providers may forego Rh testing and anti-D immune globulin for patients who are Rh negative.(2-7) This recommendation applies to both medication abortion and aspiration procedures.

Recommendation 4.1.2
If anti-D immune globulin is not administered in the facility, other arrangements for administration must be documented.

Recommendation 4.1.3
A person who is over 12 weeks LMP and declines Rh testing or anti-D immune globulin should sign an informed waiver.

Recommendation 4.1.4
Documentation of Rh status may be obtained by on-site testing, outside source, or self-report.

Recommendation 4.1.5
Additional testing for either sensitization or other antibodies is not required in patients undergoing pregnancy termination, including testing for Du (“weak D”).

Standard 4.2
Anemia and the risk of bleeding must be evaluated.(8)

Recommendation 4.2.1
Hemoglobin or hematocrit testing should be readily available.

Recommendation 4.2.2
Prior to uterine aspiration and medication abortion in the first trimester, hemoglobin/ hematocrit and other laboratory evaluation should be done as indicated by medical history and patient symptoms. Routine hemoglobin or hematocrit has not been shown to improve outcomes.

Recommendation 4.2.3
Hemoglobin or hematocrit should be checked before all abortions after the first trimester.

Discussion: Epidemiologic and clinical evidence indicates that the risk of maternal-fetal hemorrhage caused by early abortion is negligible and Rh testing and provision of Rh immune globulin is not necessary.(2-7) There is no evidence to show that Rh testing and anti-D immune globulin is beneficial in the setting of early abortion, and added testing and treatment is a burden for many patients and providers. Therefore, it is reasonable to forego Rh testing and anti-D immunoglobulin for people having any type of abortion before 12 weeks LMP.

The use of approved slide/tube/spot methods is acceptable for on-site Rh testing.

Moderate or asymptomatic anemia is rarely a reason to delay abortion care.

5. Limited Sonography in Abortion Care

Policy Statement: The use of ultrasound is not a requirement for the provision of first-trimester abortion care. Proper use of ultrasound may inform clinical decision-making in abortion care.

Standard 5.1
Staff members who perform ultrasound exams and clinicians who interpret those exams must either show documentation of proficiency or complete a program of training. Training must include a period of supervision. Documentation of this training must be maintained.

Standard 5.2
A system of proficiency review must be in place for staff members who perform ultrasound exams and clinicians who interpret those exams.

Standard 5.3
Patients must be informed of the purpose and limitations of the ultrasound exam in the abortion care setting.

Standard 5.4
Patients must be informed of the sonographic diagnosis, including early pregnancy loss.(1, 2)

Standard 5.5
The findings of all ultrasound exams and the interpretation of those findings must be documented in the medical record. This documentation must also include the name(s) of staff who performed and interpreted the exam.(3)

Recommendation 5.5.1
Ultrasound images should be included as part of the documentation, particularly for the purposes of proficiency review.

Recommendation 5.5.2
A standard form for documenting findings and interpretation should be used.

Standard 5.6
A limited ultrasound exam must include the following:

1) a full scan of the uterus in both the transverse and longitudinal planes to confirm an intrauterine pregnancy;
2) evaluation of embryo/fetal number;
3) measurements to document gestational age;(4, 5)
4) evaluation of pregnancy landmarks, such as yolk sac or the presence or absence of fetal/embryonic cardiac activity; and
5) placental location in second trimester.

Recommendation 5.6.1
When clinically indicated, evaluation of other pelvic structures (i.e., adnexal structures and the cul de sac) should be performed and documented or an appropriate referral should be made for further evaluation.

Standard 5.7
When a patient with a prior uterine scar is found to have placenta previa or a low anterior placenta after 14 weeks, or when other placental abnormality is suspected, additional sonographic imaging should be performed on-site or an appropriate referral made.(6-8)

Standard 5.8
Ultrasound equipment must be properly maintained.

Standard 5.9
All ultrasound transducers must be disinfected between patients.

Discussion: Resources for ultrasound training can be found in the Learning Lab on NAF's members-only website at https://members.prochoice.org.

According to the American Institute of Ultrasound in Medicine (AIUM), in collaboration with the American College of Obstetrics and Gynecology and the American College of Radiology, a "limited ultrasound examination" is performed when a specific question requires investigation.(3, 9, 10)

6. Early Medication Abortion

Policy Statement: Medication abortion is a safe and effective method for early abortion.(1, 2) Adequate counseling and follow-up care will enhance its safety and acceptability. Providing medication abortion by telemedicine is a safe option.(3, 4) For most patients, testing before a medication abortion, including ultrasound, is not required.(5, 6) People can safely manage early medication abortion on their own.

Standard 6.1
Initial evaluation must include pertinent medical history.

Standard 6.2
The patient must be informed about the efficacy, side effects, and risks, including excessive bleeding, infection, and teratogenicity of the medications used.(7)

Recommendation 6.2.1
Breastfeeding is not a contraindication to medication abortion with mifepristone and misoprostol. Patients should be informed that breastfeeding can continue uninterrupted without concern for side effects in infants.(8, 9)

> *Option 6.2.1.1*
> As appropriate, patients may be informed that no evidence-based way to reverse mifepristone exists.(10)
>
> *Option 6.2.1.2*
> Not taking an evidence-based regimen of misoprostol after mifepristone may be associated with unusual bleeding, particularly after 49 days.(11)

Standard 6.3
The patient must be informed that a uterine aspiration may be necessary.

Standard 6.4
Patient instructions must include information about use of medications at home, expected symptoms and side effects, and symptoms of abortion complications.

Recommendation 6.4.1
Providers should discuss what patients may see depending on gestational duration.

Recommendation 6.4.2
For patients who travel for abortion or are using medications prescribed through telehealth, providers should discuss how to safely seek emergency care.

Standard 6.5
The provider must provide an emergency contact service on a 24-hour basis to assist with further care as needed.

Standard 6.6
Confirmation of pregnancy must be documented with a positive pregnancy test and/or ultrasound. Pregnancy dating must be verified to be within the limits of the facility medication abortion protocol.

Recommendation 6.6.1
If an ultrasound has been performed and an intrauterine gestation has not been confirmed, the medication abortion regimen should be offered concurrently with evaluation for pregnancy of unknown location, as outlined in CPG Section 9 Management of Pregnancy of Uncertain Location.

Standard 6.7
IUDs must be removed prior to proceeding with medication abortion.

Recommendation 6.7.1
If an IUD cannot be removed without delaying the medication abortion, the patient should be offered a uterine aspiration.

Standard 6.8
An evidence-based medication abortion regimen must be used.

Recommendation 6.8.1
Where legally available and accessible, mifepristone and misoprostol should be used.(12-14)

Recommendation 6.8.2
A dose of 200mg of mifepristone is recommended for combined mifepristone-misoprostol regimens.(2)

Option 6.8.2.1
Mifepristone may be taken outside the clinic setting.(15)

Recommendation 6.8.3
For medication abortion, oral mifepristone followed by vaginal, buccal, or sublingual misoprostol 800mcg is recommended.(16-21)

Recommendation 6.8.4
An additional dose of misoprostol 800mcg is recommended for patients over 63 days gestational duration.(22,23)

Recommendation 6.8.5
More than two doses of misoprostol may be provided for patients as gestational duration increases or if a patient is remote from care (see Table 1 in the discussion).(24,25)

Recommendation 6.8.6
Where mifepristone is either not legally available or inaccessible, misoprostol-alone regimens or other evidence-based regimens may be offered.(24-27) See discussion for more information.

Standard 6.9
People can safely manage early medication abortion on their own.

Recommendation 6.9.1
People who self-manage abortion may need support from providers at different stages in the abortion process, including determining eligibility, understanding the regimen, accessing effective medications, and managing follow-up or complications.

Recommendation 6.9.2
People who self-manage abortion, along with those who support them through the process, should not be criminalized for their actions.

Standard 6.10
Misoprostol with or without mifepristone can be used for management of pregnancy loss.

Recommendation 6.10.1
Mifepristone and misoprostol are more effective than misoprostol alone for patients with an anembryonic gestation or who have embryonic or fetal demise.(28, 29)

Standard 6.11
Analgesia or other comfort measures must be discussed and offered as needed.

Recommendation 6.11.1
Non-steroidal anti-inflammatories such as ibuprofen are more effective than acetaminophen for pain control.(30)

Recommendation 6.11.2
The risk of routine narcotic analgesics for pain management may outweigh the benefits.(31-33)

Standard 6.12
Patients must be offered a follow-up assessment to confirm absence of ongoing pregnancy. Confirmation can be established by ultrasonography, hCG testing, physical exam, or self-assessment.(34, 35)

Recommendation 6.12.1
For people who do not want further contact with the health care provider, self-assessment of abortion outcomes may be used.

Recommendation 6.12.2
High-sensitivity urine hCG testing should not be checked within four weeks of medication abortion.(36)

Option 6.12.2.1
Multi-level or low-sensitivity urine pregnancy tests may be used.(37-39)

Recommendation 6.12.3
Endometrial thickness should not be used to guide management after medication abortion.(41, 42)

Recommendation 6.12.4
Prolonged courses of misoprostol should not be given routinely to improve success.(43)

Option 6.12.4.1
Additional doses of misoprostol with or without mifepristone may be given for persistent gestational sac or continuing pregnancy.(29, 44)

Standard 6.13
Medications dispensed and prescribed must be documented.

Discussion: Medication abortion regimens and follow-up have evolved rapidly over the past decade and are likely to continue to improve.

The NAF recommended protocol for medication abortion up to 70 days gestation is 200mg mifepristone followed in 24 to 48 hours by 800mcg misoprostol buccally, vaginally, or sublingually. For those who wish to use misoprostol less than 24 hours after mifepristone, the vaginal route is recommended. Repeat dosing of misoprostol should be considered over 63 days and is recommended over 70 days. (See Table 1) In the later first trimester, repeat doses of misoprostol are recommended. For patients with a previous uterine scar, the dose of misoprostol does not need to be adjusted. More information on medication abortion regimens and follow-up may be found in NAF's Learning Lab on the members-only site at https://members.prochoice.org.

Table 1: Efficacy of mifepristone 200mg orally and misoprostol regimens by weeks in selected publications

	Overall efficacy	**Ongoing pregnancy**
57-63 days gestation (18)		
o Misoprostol 800mcg buccal x 1 dose	93.5%	3.1%
64-70 days gestation		
o Misoprostol 800mcg buccal x 1 dose (18)	92.8%	3.0%

o Misoprostol 800mcg buccal q 4 hours x 2 doses (23)	99.6%	0.4%
71-77 days gestation		
o Misoprostol 800mcg buccal x 1 dose (22)	86.7%	8.7%
o Misoprostol 800mcg buccal q 4 hours x 2 doses (23)	97.7%	1.4%
78-84 days gestation (24)		
o Misoprostol 600 sublingually or 800mcg vaginally q 3 hours up to five doses (mean 2.32 doses)	95%	2%
85-90 days gestation (24)		
o Misoprostol 600mcg sublingually or 800mcg vaginally q 3 hours up to five doses (mean 2.73 doses)	92%	5.1%

Mifepristone alone is not as effective as a combined regimen and has a higher risk of ongoing pregnancy. There is no high-quality evidence that progesterone given directly after mifepristone ingestion increases the rate of ongoing pregnancy compared to no intervention.(10) A recent small randomized controlled trial of progesterone vs. placebo after mifepristone was stopped early due to bleeding requiring intervention, especially in patients over 49 days gestation.(11) Laws that require abortion providers to discuss unproven methods to interrupt the abortion process with their patients are a violation of medical ethics in that they require providers to discuss an experimental treatment with no proven benefit.

There is no evidence that mifepristone exposure has a teratogenic effect on an ongoing pregnancy.(46) Misoprostol exposure early in pregnancy doubles the risk of causing major fetal malformations in a continuing pregnancy, from approximately 2% in cases with no exposure to 4% in cases of misoprostol exposure.(47) High-dose methotrexate exposure increases the risk of malformations or pregnancy loss.(48)

If mifepristone is not available, misoprostol-only or other evidence-based regimens may be used. These regimens are all more effective when multiple doses of misoprostol are used. Prolonged follow-up may be required to reach the maximum efficacy without intervention. The efficacy of these regimens for very early pregnancy (that is, pregnancy of unknown location) and pregnancies in the later first trimester are not well studied. People who use these regimens need to understand their efficacy, side effects, and the potential exposure to known teratogens if the pregnancy continues.

Where mifepristone is not available, NAF recommends misoprostol, 800mcg sublingually every three hours for 3-4 doses for people ≤77 days LMP. An extra dose may be provided in case the patient has no bleeding or ongoing symptoms. Patient information, instructions, and a detailed sample protocol may be found on NAF's members-only site at https://members.prochoice.org.

When methotrexate and misoprostol are used, an evidence-based regimen of methotrexate 50mg oral or intramuscular followed in three to five days with misoprostol 800mcg vaginally may be used.(26, 49) Adding repeat doses of misoprostol is likely to improve the efficacy of this regimen.

When letrozole and misoprostol are used, the World Health Organization (WHO) regimen of letrozole 10mg daily by mouth x three days followed by misoprostol 800mcg sublingually on day four is recommended. Adding repeat doses of misoprostol is likely to improve the efficacy of this regimen.(50)

High-sensitivity pregnancy tests, such as those found in the pharmacy, typically detect hCG levels under 25-50mIU/mL. People should not take a high-sensitivity pregnancy test less than four weeks after medication abortion. At four weeks, approximately 20% of people with a successful medication abortion will still have a positive pregnancy test.(36) Providers should be aware that delayed assessment of completion could result in the discovery of an ongoing pregnancy in the second trimester.

If pregnancy loss is diagnosed for a patient presenting for abortion, this must be disclosed to the patient. Patients with pregnancy loss who choose medication management should be offered mifepristone pretreatment prior to misoprostol unless there is evidence the expulsion is actively underway, in which case mifepristone is unlikely to provide additional benefit. Providers can use the same medication regimen for early pregnancy loss as they would with abortion at a similar gestational age. There is limited data that misoprostol may be optimally effective 7-20 hours post mifepristone pre-treatment for early pregnancy loss, and waiting 24 hours may not have added benefit.(51)

7. Providing Abortion Medications Without a Positive Pregnancy Test

Policy Statement: Providers can prescribe and dispense abortion medications for patients who are at risk for pregnancy for future use (advance provision) or for use in the setting of suspected, but not confirmed, pregnancy (menstrual regulation or "missed period pills"). Once the patient either confirms or suspects they are pregnant and uses medication abortion, the guidelines in CPG 6 for Early Medication Abortion apply.

Standard 7.1
Prior to prescribing and dispensing medication, the patient must be evaluated, either in-person or remotely, and eligibility for medication abortion must be confirmed.

Standard 7.2
The patient needs to be informed about the appropriate time to take medications in relationship to their pregnancy dating, the efficacy, side effects, and risks of medication abortion. They must be instructed on how to use the medications and symptoms of abortion complications.

Recommendation 7.2.1
The patient can contact the provider once they decide to use medications to review dating, eligibility, the medication abortion process, and follow-up.

Recommendation 7.2.2
The provider must offer a follow-up assessment for those who decide to take the medications and want further assessment.

Discussion: Advance provision or "missed period pills" may be acceptable to people who want medication abortion on hand, but there is, as yet, little evidence to show how frequently pills dispensed in this manner are used, and the efficacy and safety of this mode of abortion provision.(1-4)

8. Procedural Abortion by Aspiration Alone

Policy Statement: Procedural abortion by aspiration is one of the safest procedures in medicine. The following guidelines are intended to outline steps that maximize this safety.

Standard 8.1
Pertinent medical history must be obtained.

Standard 8.2
Pregnancy must be confirmed, and gestational age must be assessed.

Recommendation 8.2.1
When gestational age cannot be reasonably determined by other means, ultrasonography should be used.

Standard 8.3
Appropriate initial evaluation must be performed. Baseline blood pressure and pulse must be obtained for all patients.

Recommendation 8.3.1
Physical exam should be done as indicated by medical history and patient symptoms.

Recommendation 8.3.2
Weight and/or BMI alone are not contraindications to procedural abortion.

Standard 8.4
The cervix should be appropriately dilated for the gestational age.

Recommendation 8.4.1
Cervical dilation may be achieved through the use of rigid cervical dilators. Tapered dilators such as Pratt or Denniston dilators are recommended over non-tapered dilators such as Hegar dilators.(1)

Recommendation 8.4.2
When cervical preparation with misoprostol is used, an evidence-based regimen should be followed.(2-5)

> *Option 8.4.2.1*
> The routine use of misoprostol before procedures may reduce rare complications but must be balanced against increased pain and other side effects for all patients.(5)
>
> *Option 8.4.2.2*
> Osmotic dilators may be considered when cervical dilation is expected to be difficult.(6)

Standard 8.5
First-trimester abortion procedures must be performed by aspiration of the uterus, not by sharp curettage.(7-9)

Recommendation 8.5.1
Uterine aspiration is effective throughout the first trimester including prior to confirmation of a definitive intrauterine pregnancy on ultrasound.(10)

Recommendation 8.5.2
Sharp curettage should not be routinely used after uterine aspiration.

Recommendation 8.5.3
Uterotonics should not be used routinely after first-trimester uterine aspiration.(11)

Discussion: No evidence supports the routine use of sharp curettage or any uterotonic after first-trimester uterine aspiration.

Cervical preparation has limited effectiveness and is not needed before a routine first-trimester abortion. Its use must be balanced against the prolonged time in the facility, side effects, and patient satisfaction. If misoprostol is used for cervical preparation, an evidence-based regimen is misoprostol 400mcg buccally, vaginally, or sublingually, one to three hours prior to the abortion procedure.(4, 5)

9. Management of Pregnancy of Uncertain Location

Policy Statement: Many patients seek care very early in pregnancy before an intrauterine pregnancy can be visualized on ultrasound.(1, 2) When a patient has a positive pregnancy test and pregnancy of uncertain location, the most common diagnosis is an intrauterine pregnancy, but the possibility of ectopic pregnancy must be considered. For these patients, abortion care should be offered, and the patient must be followed to ensure that the pregnancy has ended. If abortion care is delayed allowing for visualization of pregnancy on ultrasound, the patient must be evaluated by a clinician, ectopic precautions must be given, and a plan for follow-up must be made.

Standard 9.1
The patient must be evaluated by a clinician to assess for the risk of ectopic pregnancy in pregnancy of uncertain location.(3-5)

Recommendation 9.1.1
Evaluation should involve assessment of the history in combination with one or more of the following: physical exam, sonography, serial quantitative hCG, and/or uterine aspiration.(6)

Recommendation 9.1.2
Abortion care should be offered even if pregnancy location is uncertain.(7-9)

Standard 9.2
Each facility must have a written protocol to evaluate pregnancy of uncertain location. All relevant staff at the site must be familiar with the protocol.

Recommendation 9.2.1
This protocol may include referrals as appropriate.

Standard 9.3
All patients with a pregnancy of uncertain location must be informed of the options for evaluation and management. The symptoms and dangers associated with ectopic pregnancy, and a plan for when and how to seek emergency medical attention must be reviewed and documented.

Recommendation 9.3.1
Each facility should have a patient education handout describing ectopic warning signs and the medical record should reflect that the patient has received this handout.

Standard 9.4
When a medication or aspiration abortion is initiated for a patient with a pregnancy of uncertain location, resolution of the pregnancy must be verified and documented. This may be demonstrated by either the examination of aspirated tissue or by following serial serum beta-hCG levels according to evidence-based regimens.

Recommendation 9.4.1
Where it is not possible to follow serial serum beta-hCG levels, urine pregnancy testing may be used.(10)

Standard 9.5
When an intrauterine pregnancy cannot be definitively seen on ultrasound, a clinician must review the patient's history, ultrasound images, and signs and symptoms of ectopic pregnancy. A clinician must discuss the risks and warning factors for ectopic pregnancy with the patient.

> *Option 9.5.0.1*
> Serum beta-hCG levels may be used to determine whether a patient is at elevated risk of ectopic pregnancy and needs immediate evaluation if abortion care is deferred.

Standard 9.6
Patient follow-up must continue until one of the following:
1. the diagnosis of ectopic pregnancy has been excluded;
2. clinical resolution of a pregnancy of uncertain location has been ensured; or
3. transfer of care to an appropriate provider has been made and documented.

Standard 9.7
Patients experiencing symptoms suspicious for ectopic pregnancy must be evaluated emergently.

Discussion: Treatment of pregnancy of uncertain location is not the same as "no-test" abortion. Pregnancy of uncertain location describes a situation in which an ultrasound is performed, and an intrauterine pregnancy is not visualized. "No-test abortion" describes a situation in which a patient has a certain or estimated last menstrual period, is otherwise eligible for abortion care, and ultrasound is not used prior to abortion.(11, 12)

Although the majority of patients who present with a low-risk pregnancy of uncertain location (that is, known early LMP, no history of ectopic pregnancy or significant risk factors, no signs and symptoms of ectopic pregnancy) will have an intrauterine pregnancy, ectopic pregnancy is more common in patients with a pregnancy of uncertain location compared to the general population of abortion seekers and needs to be assessed as the abortion proceeds. Providing abortion care to patients with pregnancy of uncertain location will decrease the time to definitive diagnosis of ectopic while at the same time providing most patients with a successful abortion.(1, 2) Abortion care, along with a combination of clinical assessment, pelvic ultrasound, serum quantitative hCG, urine hCG, and/or examination of uterine aspirate can be used to distinguish between an intrauterine and an ectopic pregnancy.(3)

Following medication abortion, hCG can be used to rule out ectopic pregnancy while simultaneously evaluating success of the medication abortion.(1, 2) When medication

abortion is initiated and no pregnancy is visible on ultrasound, patients should understand that the risk of ectopic pregnancy may be higher than the general population of abortion seekers, and the risk of medication abortion failure is higher. As such, follow-up is essential.

For more information and protocols for management of pregnancy of uncertain location, as well as information on diagnosis of early pregnancy on ultrasound, please visit NAF's members-only website at https://members.prochoice.org and access the Learning Lab.

10. Procedural Abortion by Dilation and Evacuation

Policy Statement: Abortion by dilation and evacuation (D&E) is a safe outpatient procedure when performed by appropriately trained clinicians in medical offices, freestanding clinics, ambulatory surgery centers, and hospitals.(1-6)

Standard 10.1
Pertinent medical history must be obtained, and relevant physical examination must be performed.

Recommendation 10.1.1
Weight and/or BMI alone are not contraindications to D&E.(7-9)

Standard 10.2
Gestational age must be verified by ultrasonography, using a consistent and published table of fetal measurements, prior to the termination of a pregnancy clinically estimated to be more than 14 weeks from LMP.

Standard 10.3
The patient must be appropriately evaluated and prepared for the procedure.

Recommendation 10.3.1
Intravenous access should be established prior to evacuation.

Recommendation 10.3.2
When induced fetal demise is used, it should be provided through an evidence-based protocol.(10-16)

Recommendation 10.3.3
In a patient with a prior uterine scar, after appropriate evaluation to exclude placenta accreta spectrum, the patient may have a procedure in the outpatient setting.(17)

Recommendation 10.3.4
Patients should be given anticipatory guidance on breast symptoms after later abortion or pregnancy loss.

> *Option 10.3.4.1*
> Cabergoline, 1mg orally x one dose may be used immediately after the procedure to reduce breast symptoms and lactation for those who want it.(18)

Standard 10.4
When cervical preparation agents are used overnight or outside the facility, a plan for emergency care must be in place and communicated to the patient.

Standard 10.5
Appropriate dilation of the cervix must be obtained gently and gradually.(19, 20)

Recommendation 10.5.1
Osmotic dilators, misoprostol, mifepristone, transcervical catheter, and/or other cervical preparation agents should be used to facilitate adequate dilation.(21-25)

Recommendation 10.5.2
Local anesthesia should be used for pain management with osmotic dilator placement.(26, 27)

Recommendation 10.5.3
An evidence-based regimen should be used for dosage, timing, and route of misoprostol.(22-24, 28-32)

Option 10.5.0.1
Synthetic osmotic dilators or a foley/Cook catheter and/or misoprostol may be used for same-day cervical dilation.(25, 28, 30, 33)

Standard 10.6
All instruments entering the uterine cavity must be sterile.

Standard 10.7
Evidence-based practices must be used to lower the risk of complications.

Recommendation 10.7.1
Intra-procedure ultrasonography should be used to aid in visualizing instruments, locating fetal parts, verifying an empty uterus, reducing the risk of uterine perforation, and shortening the procedure.(34-36)

Recommendation 10.7.2
Inhaled anesthesia should be avoided if possible due to the increased risk of hemorrhage.(37, 38)

Standard 10.8
Uterotonics must be available to aid in control of uterine bleeding.(17)

Option 10.8.0.1
An intra- or paracervical prophylactic vasoconstrictor can be used to reduce blood loss.(39)

Discussion: Cervical preparation before dilation and evacuation can be achieved with multiple agents either alone or in combination. Misoprostol is commonly used, with a dose of 400mcg supported by most studies.(40)

Induced fetal demise should be provided using an evidence-based regimen. A sample protocol for digoxin injection is available on the NAF members-only site at https://members.prochoice.org. Intraamniotic or intrafetal digoxin may be used.(41, 42) Intracardiac potassium chloride or lidocaine may also be used.(11, 16, 43) Injections may be done either transabdominally or transvaginally.(44, 45) Cord transection may also be used.(46)

Prophylactic use of methergine for prevention of postabortion hemorrhage is not recommended.(47) Prophylactic pitocin for procedures between 18-24 weeks gestation may be considered.(49)

11. Medication Abortion After the First Trimester

Policy Statement: Medication abortion is a safe and effective method for termination of pregnancies beyond the first trimester when performed by trained clinicians in medical offices, freestanding clinics, ambulatory surgery centers, and hospitals. Induced fetal demise may be particularly important at later gestational ages.

Standard 11.1
Pertinent medical history must be obtained, and relevant physical examination must be performed.

Standard 11.2
Gestational age must be verified by ultrasonography, using a consistent and published table of fetal measurements, prior to the termination of a pregnancy clinically estimated to be more than 14 weeks from LMP.

Standard 11.3
The patient must be appropriately evaluated and prepared.

Recommendation 11.3.1
Intravenous access should be established.

Recommendation 11.3.2
Patients should be given anticipatory guidance on breast symptoms after later abortion or pregnancy loss.

> *Option 11.3.2.1*
> Cabergoline, 1mg orally x one dose may be used immediately after the abortion to reduce breast symptoms and lactation for those who want it.(1)

Standard 11.4
Facilities must have a policy that addresses whether and when to induce fetal demise.

Recommendation 11.4.1
When induced fetal demise is used, it should be provided through a standard protocol.(2-9)

Standard 11.5
Evidence-based regimens of medication abortion must be used.

Recommendation 11.5.1
Mifepristone 200mg followed in 24 to 48 hours by repeat doses of misoprostol should be used, when available and feasible.(10-13)

Option 11.5.1.1
Simultaneous or short interval administration of mifepristone and repeat doses of misoprostol may also be used.(14)

Option 11.5.1.2
Repeat dosing of misoprostol may also be used alone.(15)

Option 11.5.1.3
Oxytocin may be used according to a protocol.

Option 11.5.1.4
Osmotic dilators may be useful at later gestations.(16-18)

Recommendation 11.5.2
Intraamniotic injection or instillation methods should be avoided as they are less effective and result in more complications than mifepristone-misoprostol or misoprostol-alone regimens.(19)

Standard 11.6
Once regular contractions have been confirmed, patients must be observed by health care staff trained to monitor contractions and expulsion, and who can recognize emergent situations.

Standard 11.7
A trained clinician must be available from initiation of induction until post-abortion discharge.

Standard 11.8
Access to surgical management or appropriate referral must be available if surgical intervention is required.

Standard 11.9
The facility and/or clinician should continue care of the patient until completion of the abortion or transfer of care to an appropriate provider is made.

Discussion: Evidence-based regimens for later medication abortion are difficult to compare. Mifepristone increases the efficacy and decreases the total time and doses needed for misoprostol to cause pregnancy expulsion. Misoprostol dosing can be repeated until expulsion with no limit on the number of doses**. For abortion over 12 weeks LMP, the WHO recommends a regimen of mifepristone 200mg orally followed in one to two days by misoprostol, 400mcg buccally, vaginally, or sublingually every four hours until pregnancy expulsion**.(20) The dosage of misoprostol may be adjusted as the pregnancy progresses or with previous cesarean section; however, when those adjustments need to be made is not well established. The risk of uterine rupture during later medication abortion with misoprostol may be

significantly increased for patients with two or more previous cesarean sections, however, the absolute risk remains low.(21) The risks should be balanced with alternative procedures for later abortion.

Caution should be used with osmotic dilators in the second trimester as they may prolong the induction time.(16-18)

Induced fetal demise should be provided using an evidence-based regimen. A sample protocol for digoxin injection is available on NAF's members-only site at https://members.prochoice.org. Intraamniotic or intrafetal digoxin may be used.(22) Intracardiac potassium chloride or lidocaine may also be used.(7-9) Injections may be done either transabdominally or transvaginally.(23)

Uterine curettage or aspiration should not routinely be performed.

12. Analgesia and Sedation

Policy Statement: Anxiolysis, analgesia, or anesthesia should be provided during abortion procedures for any patient for whom the benefits outweigh the risks, with the aim of providing the appropriate level of analgesia and sedation required for each patient's needs. Patients should be involved in a shared decision-making process about pain control and sedation during the procedure.

Implicit and explicit bias causes providers to undertreat pain for specific populations, including Black, Indigenous, and people of color, and people with substance use disorders.(1-3) All people seeking abortion care are entitled to adequate pain management.

ON THE USE OF SEDATION IN GENERAL - All medications used in procedural sedation have the potential for serious risk. This risk may be reduced to a minimum by adherence to established practice guidelines. Guidelines developed by other organizations concern themselves with anesthesia and sedation delivered primarily in hospital settings and to patients varying widely in age and general health. Regardless of the drug or route of administration, the degree of central nervous system (CNS) depression is the basis for the NAF guidelines.

These guidelines do not address the use of deep sedation or general anesthesia except to identify basic monitoring practices and appropriate providers of such care, who are expected to follow their professional standards in the delivery of anesthesia services. It is expected that those individuals providing deep sedation or general anesthesia will have appropriate emergency medication and equipment in place to ensure the safe care of a patient in the event of an anesthesia complication.

The promulgation of guidelines for the delivery and monitoring of anesthesia care issued by organizations such as the American Society of Anesthesiologists (ASA), the Canadian Anesthesiologists' Society (CSA), the American Dental Society of Anesthesiologists (ADSA), American Society for Gastrointestinal Endoscopy (ASGE), and others have clarified many of the issues related to anesthesia care.

Patient comfort and reduced anxiety are significantly affected by patient counseling and by the presence of family, friends, and supportive staff, and are not solely dependent on pharmacologic measures. Alternative modalities (such as relaxation techniques, acupuncture, hypnosis) may be helpful for some patients. The focus of NAF guidelines for analgesia and sedation, however, is on the safe provision of pharmacologic methods generally used in outpatient abortion facilities.

Definitions(4)

1. Local Anesthesia - Elimination or reduction of sensation, especially pain, in one part of the body by topical application or local injection of a drug. In the context of abortion practice, local anesthesia almost always involves a paracervical block.

2. Minimal Sedation (Anxiolysis) - A drug-induced state during which patients respond normally to verbal commands. Although cognitive function and physical coordination may be impaired, airway reflexes, ventilatory, and cardiovascular functions are unaffected.

3. Moderate Sedation/Analgesia - A drug-induced depression of consciousness during which patients respond purposefully* to verbal commands, either alone or accompanied by light tactile stimulation. No interventions are required to maintain a patent airway, and spontaneous ventilation is adequate. Cardiovascular function is usually maintained but may be impaired. This level of sedation was previously referred to as "Conscious Sedation." However, this term is no longer recommended.

4. Deep Sedation/Analgesia - A drug-induced depression of consciousness during which patients cannot be easily aroused but respond purposefully following repeated or painful stimulation. The ability to independently maintain ventilatory function may be impaired. Patients may require assistance in maintaining a patent airway, and spontaneous ventilation may be inadequate. Cardiovascular function is usually maintained but may be impaired.

5. General Anesthesia - A drug-induced loss of consciousness during which patients are not arousable, even by painful stimulation. The ability to independently maintain ventilatory function is often impaired. Patients often require assistance in maintaining a patent airway, and positive pressure ventilation may be required because of depressed spontaneous ventilation or drug-induced depression of neuromuscular function. Cardiovascular function may be impaired.

Because sedation is a continuum, it is not always possible to predict how an individual patient will respond. Hence, practitioners intending to produce any level of sedation should be able to rescue patients whose level of sedation becomes deeper than initially intended. *Rescue* corrects adverse physiologic consequences of the deeper-than-intended level of sedation (such as hypoventilation, hypoxia, and hypotension) and returns the patient to the originally intended level of sedation.

Standard 12.1
Pain control options must be discussed with the patient.

*Reflex withdrawal from a painful stimulus is NOT considered a purposeful response.

Standard 12.2
When minimal, moderate, deep sedation, or general anesthesia is to be given, patients must be given information about the risks, benefits, and side effects of the medications to be used.

Recommendation 12.2.1
Documentation should include precautions relevant to transient mental impairment.

Option 12.2.0.1
An informed consent form specific for analgesia and sedation may be used.

Standard 12.3
Levels of sedation depend on the patient response, not the route of drug administration. Oral anxiolytics and analgesics given in combination can cause moderate sedation for some patients.

Standard 12.4
The amount of anesthesia given depends on the desired level of sedation and the individual patient response. Patient characteristics such as age, race, parity, body size, weight, or current or past substance use disorder, and use of medication for opioid use disorder should not be used to limit appropriate anesthesia and analgesia.

Standard 12.5
Prior to moderate sedation, a pre-sedation evaluation of the patient must take place.

Recommendation 12.5.1
Evaluation should include a relevant history and review of systems; medication review; targeted exam of the heart, lung, and airway as indicated by the patient's history and review of systems; and baseline vital signs.

Recommendation 12.5.2
For patients receiving moderate sedation who are not at increased risk of aspiration, time from last meal should not limit access to abortion care.(5-7)

Recommendation 12.5.3
A reduced level of sedation, an alternate abortion procedure, or provision of care by an anesthesia professional should be considered for patients with an atypical airway assessment or ASA Physical Status Classification 3 or greater.(8, 9)

Standard 12.6
No additional evaluation is needed prior to paracervical block and/or NSAID administration.

Standard 12.7
The supervising practitioner must be immediately available when sedation is administered.

Standard 12.8
When local anesthesia or sedation is provided, the practitioner responsible for the treatment of the patient and/or the administration of drugs must be appropriately trained, with approval by the medical director or their designee.(9, 10)

Standard 12.9
To administer moderate sedation, a provider must have the following: licensure as appropriate, basic airway skills, the ability to monitor and effectively rescue patients in an emergency, and the ability to screen patients appropriately for sedation.

Standard 12.10
The potential need for intravenous access must be considered prior to administering any level of sedation.

Recommendation 12.10.1
When more than minimal sedation is intended, intravenous access should be maintained at least until discharge criteria are met.

Standard 12.11
Pulse oximetry, with appropriate alarms, must be employed when moderate or deeper levels of sedation are used.

Standard 12.12
When sedation is provided, monitoring must be adequate to detect the respiratory, cardiovascular, and neurological effects of the drugs being administered, and this monitoring must be documented.

Recommendation 12.12.1
The patient should be checked frequently for verbal responsiveness.

Standard 12.13
When moderate sedation or deeper is provided, a person other than the clinician performing the procedure, and who is trained to monitor appropriate physiological parameters, must be present. This person must not be performing duties other than monitoring the patient.(9)

Moderate Sedation

Standard 12.14
When moderate sedation is intended, sedation medication must be started at a reasonable low dose and titrated as needed, based on individual circumstances, such as weight and drug tolerance.(11-13)

Recommendation 12.14.1
The following table should be used for guidance for these commonly used drugs when used for moderate sedation. Similar ranges of other opioids and benzodiazepines may be used.

Option 12.14.1.1
A regimen that includes ketamine may be used as an alternative or in conjunction with opioids for moderate sedation. Please see discussion for more information.(14)

Drug	Usual initial dose	Max initial dose	Usual incremental Dose	Max incremental Dose
Fentanyl	50-100mcg	200mcg	50-100mcg	100mcg
Midazolam	1-3mg	4mg	1-2mg	2mg
Ketamine (when used with fentanyl)	10mg	20mg	10mg	20mg
Ketamine (when used without fentanyl)	20mg	20mg	10mg	20mg

Standard 12.15
When moderate sedation is administered, at least one individual with documented airway skills must be present in the procedure room.

Deep Sedation or General Anesthesia

Standard 12.16
Supplemental oxygen must be used with deep sedation and general anesthesia.

Standard 12.17
The practitioner administering deep sedation or general anesthesia must not be the practitioner performing the abortion.

Recommendation 12.17.1
For deep sedation and general anesthesia, the following should be monitored: continuous pulse oximetry, intermittent blood pressure, and respiration, either by measuring end-tidal CO_2 or clinical observation.

Recommendation 12.17.2
The capability to monitor temperature should be available.

Standard 12.18
Any individual responsible for administering, supervising, or monitoring a patient receiving any level of sedation must have current, health care provider level basic life support (BLS) certification.

Standard 12.19
The practitioner administering deep sedation or general anesthesia must adhere to established professional standards of care.(15)

Nitrous Oxide

Standard 12.20
N_2O must be self-administered by the patient or by a qualified anesthesia provider.

Recommendation 12.20.1
N_2O may be an alternative to local or oral sedation but is less effective for pain management than moderate intravenous sedation.(16, 17)

Standard 12.21
If not self-administered, the provision of N_2O must follow guidelines for patient monitoring for moderate sedation.

Standard 12.22
Equipment for the delivery of N_2O/O_2 must:
1) provide a concentration of N_2O of no more than 70% inspired;
2) provide a minimum of 30% O_2; and
3) be checked and calibrated regularly.

Recommendation 12.22.1
The concentration of nitrous oxide should not routinely exceed 50% in the absence of qualified anesthesia personnel.

Recommendation 12.22.2
Equipment for the delivery of N_2O/O_2 should include an oxygen analyzer.

Recommendation 12.22.3
Due to the potential for occupational exposure, room or personnel monitoring for levels of N_2O should be conducted.

Emergency Equipment

Standard 12.23
Functioning equipment and current medications must be available on-site to handle medical emergencies and must include: an oxygen delivery system, oral airways, epinephrine, and antihistamines.

Standard 12.24
In settings where benzodiazepines and opioids are used, appropriate antagonists, bronchodilators, and bag-valve masks capable of delivering supplemental oxygen must be available.

Recommendation 12.24.1
Facilities should have a specified area for emergency equipment, which includes oxygen, medications, and supplies. A protocol and time schedule for checking equipment and removing expired medications must be in place.

Standard 12.25
In settings where deep sedation and general anesthesia are used, it is expected that providers maintain the appropriate medication and equipment required for an anesthesia emergency.

Recommendation 12.25.1
A defibrillator should be available.

Discussion: The time of last food intake does not increase the risk of moderate sedation.(4-7)

ON THE USE OF N_2O/O_2 - Nitrous oxide has a long history of use for analgesia and sedation, as well as an excellent safety record in the hands of both anesthesiologists and non-anesthesiologists. Occupational exposure to N_2O has been associated with increased risks of neurologic impairment, spontaneous abortion, subfertility, and hepatic and renal disease. Recommendations for safe use of nitrous oxide can be found in the reference section. In addition to employing adequate ventilation and scavenger systems, it is also recommended to deliver 100% oxygen to the patient for five minutes before removing the mask. This will purge the system, and the patient, of any residual nitrous oxide. Occupational exposure can be monitored by asking staff members to wear personal dosimetry badges or by placing an infrared spectrophotometer in the room. Although there is no OSHA standard for N_2O, NIOSH recommends that airborne levels of N_2O be kept below 25 ppm through well-designed scavenger systems and other engineering controls, equipment maintenance, exposure monitoring, and safe work practices.

Ketamine offers an alternative or addition to opioid containing regimens for intravenous moderate sedation. Ketamine is effective in patients with opioid use disorder, allows

clinicians to use a lower dose of opioids in combined regimens, and has a reduced risk of respiratory depression.(14, 18) Ketamine, whether used alone or with an opioid, needs to be combined with a benzodiazepine to prevent adverse side effects, particularly dysphoria and hallucinations. When ketamine is used without an opioid, a higher or repeated dose of benzodiazepine may be required to prevent hallucinations.

13. Post-Procedure Care

Policy Statement: Appropriate and accessible post-procedure and follow-up care is essential to patients' wellbeing.

Standard 13.1
Patients who want contraception must receive their chosen method immediately following an abortion or appropriate referral should be made.

Recommendation 13.1.1
When desired by the patient, intrauterine contraception or contraceptive implants should be initiated immediately after first-trimester uterine evacuation or second-trimester D&E.(1-3)

Recommendation 13.1.2
When desired by the patient after medication abortion, intrauterine contraception should be initiated as soon as expulsion of the pregnancy is confirmed.(4-6)

Recommendation 13.1.3
When desired by the patient, contraceptive implants should be initiated on the day of mifepristone administration for medication abortion.(7-10)

> *Option 13.1.3.1*
> Depot Medroxyprogesterone acetate (Depo-Provera®) may be given at the time of mifepristone with appropriate counseling.(10-12)

Recommendation 13.1.4
Emergency contraception should be discussed and either dispensed or prescribed to patients who want it.

Standard 13.2
All patients receiving more than minimal sedation or in the second trimester must be continuously observed during the recovery period by a health care worker trained in post-procedure care.

Standard 13.3
Patients who received moderate or deeper sedation must be monitored until determined to be no longer at risk for hemodynamic instability or respiratory depression.

Recommendation 13.3.1
A pulse oximeter with alarms should be used until the patient is alert and ambulatory.

Standard 13.4
A clinician must remain in the facility until all patients are medically stable.

Standard 13.5
The following criteria must be documented prior to discharge: the patient must be ambulatory with a stable blood pressure and pulse, and bleeding and pain must be controlled.

Standard 13.6
The patient must be given oral and written instructions outlining what to expect post-procedure, self-care, and signs and symptoms of complications.

Recommendation 13.6.1
Patients who receive sedation should have access to this information prior to the administration of medication.

Standard 13.7
The facility must provide an emergency contact service on a 24-hour basis, where calls are triaged in accordance with written policies. A recorded message alone is unacceptable.

Standard 13.8
Any non-clinician involved with first-call triage must be trained to take a post-abortion health history and follow clear written guidelines indicating when immediate consultation with a clinician is indicated.

Standard 13.9
Any patient who gives a history suggestive of a post-procedure complication must have access to a clinician. The facility must establish a pathway for physician referral if indicated.

Recommendation 13.9.1
Uterotonic agents should be given as indicated and not on a routine basis. When used, an evidence-based regimen should be followed.

> *Option 13.9.1.1*
> Routine post-procedure follow-up is not required. Clinicians may offer a visit for patients who would like one.(13, 14)

Discussion: A recent study shows that Depot Medroxyprogesterone acetate (DMPA) (Depo-Provera®) given on the day of mifepristone may increase the risk of continuing pregnancy but does not increase the risk of needing aspiration to complete the abortion compared to when it is given at a follow-up visit.(12) Patient satisfaction is higher with immediate DMPA, but six-month use rates and pregnancy rates are the same due to high rates of discontinuation. If a patient understands the potential risk of ongoing pregnancy, DMPA may be offered and given at the time of mifepristone. DMPA given in the 24-48 hours after mifepristone, on the day of misoprostol, does not affect the rate of continuing pregnancy.(15)

14. Evaluation of Evacuated Uterine Contents

Policy Statement: Identification of appropriate products of conception (POC) following evacuation abortion procedures confirms termination of an intrauterine pregnancy.

Standard 14.1
Termination of pregnancy must be confirmed prior to the patient leaving the facility or further evaluation must be initiated.

Recommendation 14.1.1
Evacuated uterine contents should be examined before the patient leaves the facility.

Recommendation 14.1.2
In first-trimester terminations, flotation of tissue should be used to identify products of conception, including gestational sac.

> *Option 14.1.2.1*
> Backlighting of tissue may be useful.
>
> *Option 14.1.2.2*
> Sending the evacuated uterine contents for additional pathological examination is not required.(1, 2)

Standard 14.2
In the first trimester, when insufficient tissue or incomplete products of conception are obtained, the patient must be reevaluated.

Recommendation 14.2.1
Re-aspiration, serial quantitative hCG, and/or ultrasonographic examination should be considered.(3-5)

Recommendation 14.2.2
Ectopic pregnancy should be considered.

Standard 14.3
After the first trimester, examination of the uterine contents must be performed to identify the placenta and all major fetal parts.

Recommendation 14.3.1
If the above are not identified, ultrasonographic evaluation and uterine exploration under ultrasound guidance should be considered.

Recommendation 14.3.2
The facility and/or clinician should continue care of the patient until completion of the abortion or transfer of care to an appropriate provider is made.

Discussion: One option for additional evaluation if sufficient POC are not identified is the use of serum quantitative hCG tests. A baseline hCG can be drawn and a second hCG can be done in 24-48 hours. If there is a decrease of 50% or more, no further ectopic follow-up is necessary. Otherwise, further evaluation should be initiated including consideration of ectopic pregnancy. In this situation, Section 9 (Management of Pregnancy of Uncertain Location) may be useful.

15. Emergency Procedures

Policy Statement: Appropriate management of abortion emergencies reduces morbidity and mortality. Hemorrhage can be one of the most serious immediate complications of an abortion procedure. Early recognition of the source of bleeding can reduce morbidity and mortality. Uterine perforation is a complication of abortion that can lead to significant morbidity. Morbidity is related to site of perforation, instrumentation, and gestational age.

Standard 15.1
Protocols for the management of medical emergencies must be in place. These protocols must include indications for emergency transport and written, readily available directions for contacting external emergency assistance (e.g., an ambulance).

Recommendation 15.1.1
Protocols for the following topics should be in place: bleeding, perforation, respiratory arrest/depression, anaphylaxis, and emergency transfer.

Recommendation 15.1.2
Staff should review protocols annually.

> *Option 15.1.2.1*
> Annual drills of the emergency protocols are encouraged.

Recommendation 15.1.3
Clinics should consider developing a transfer agreement with a hospital outlining the means of communication and transport and the protocol for emergent transfer of care.

Standard 15.2
All staff must know their appropriate roles in the management of medical emergencies.

Standard 15.3
Emergency supplies must be in known, appropriate locations and regularly updated.

Standard 15.4
When abortion procedures are being performed, at least one medical staff member with health care provider level basic life support (BLS) training must be present.

Recommendation 15.4.1
All medical staff providing direct patient care should have current health care provider level BLS certification.

Standard 15.5
All facilities must have a protocol for the management of acute hemorrhage.(1) This protocol must address the following items:

1) establishment of intravenous access;
2) administration of uterotonics;
3) evaluation of the cause and/or source of bleeding; and
4) criteria for hospital transfer.

Standard 15.6
The facility must have at least two uterotonics and/or mechanical methods of controlling bleeding.

Standard 15.7
If a perforation occurs or is suspected, even if the patient is asymptomatic, a protocol must address the following items:

1) establishment of intravenous access;
2) additional observation;
3) plan for follow-up including plans for completing the abortion if needed; and
4) criteria for transfer to a hospital such as the following:
    a. intra-abdominal viscera are detected in the uterine cavity, cervix, vagina, suction tubing, or on tissue examination;
    b. fetal parts are detected in the abdominal cavity;
    c. expanding intra-abdominal or retroperitoneal hematoma is detected; or
    d. hemodynamic instability is present.

Recommendation 15.7.1
If the procedure is completed after a suspected perforation, uterine evacuation should be performed under direct ultrasound guidance or laparoscopic visualization.(2, 3)

Discussion: Excessive bleeding during the procedure and in the post-procedure period is almost always due to uterine atony, often caused by incomplete emptying of the uterus. Therefore, the most important initial efforts should be directed at assuring complete evacuation of the uterus and at increasing uterine tone through uterotonics or uterine massage. Problems arise when bleeding is ignored, or its severity underestimated. Clinicians must always remember to do the simple things when confronted with a developing bleeding problem: continue assessment of the blood loss, measure and record vital signs frequently, and assure intravenous access.

The following measures may be used for treatment of post-abortion hemorrhage:

1) uterine massage;
2) methylergonovine (Methergine);
3) oxytocin (Pitocin);
4) vasopressin (Vasostrict);
5) misoprostol (Cytotec);
6) carboprost tromethamine (Hemabate);

7) Tranexamic acid;(4)
8) intrauterine pressure using a Foley or Bakri balloon or vaginal pack; or
9) uterine re-aspiration.

When bleeding continues after assurance of complete uterine emptying and when there are no visible cervical or vaginal lacerations, the clinician must consider other complications such as perforation, coagulopathy, or placenta accreta. The patient may need immediate transfer to manage these conditions.

Perforations are often occult and may be difficult to identify.(5-7) If a perforation is suspected, it is safest to proceed as if there has been a perforation.

In the first trimester, perforations are often asymptomatic and self-healing.(8, 9) Most perforations are midline and/or fundal in location.(10) If they occur before suction, these usually can be managed with observation and close follow-up.(9) A lateral perforation may involve uterine blood vessels and, if so, will be more significant.

In the second trimester, even an asymptomatic perforation may warrant transfer to a hospital for evaluation depending on the instrumentation involved.(11, 12) There may be more significant morbidity due to increased uterine blood flow and the use of larger grasping instruments.

The Safety and Quality of Current Abortion Methods

In the more than 40 years since national legalization of abortion, investigators have conducted randomized controlled trials (RCTs), large retrospective cohort studies, patient and provider surveys, systematic reviews, and other types of research on abortion care and its health effects on women, resulting in an extensive literature. The objective of this chapter is to examine this literature, focusing on the safety and effectiveness of current abortion methods and the extent to which these methods could expose women to the risk of such serious complications as the need for blood transfusion, surgery, or hospitalization. The chapter also examines whether the type of facility or method of sedation or anesthesia affects the risk of adverse outcomes. The chapter is organized as follows:

- The first section describes the clinical assessment, informed consent, patient education, and counseling that precede the abortion procedure.
- The second section addresses the initial clinical assessment.
- The next section describes current abortion methods and, for each method, reviews what is known about the procedure's effectiveness, expected side effects, and risk of complications. Note that, for the purposes of this review, efficacy or effectiveness refers to the successful completion of the abortion without the need for a follow-up aspiration.
- The fourth section turns to postabortion care.
- The fifth section examines the evidence on the use of analgesia, sedation, and anesthesia in abortion care, including its safety and implications for the site of care.
- The following section compares the mortality rates for abortion and other common outpatient procedures.
- The next section presents a brief discussion of state regulation of abortion care.

- The final, summary section reviews state regulation of abortion safety in light of the clinical evidence presented earlier in the chapter.

The committee's review emphasizes contemporary approaches to abortion care because abortion methods have been refined in response to new evidence. Some research conducted before 2000 is unlikely to reflect the outcomes of how abortions are typically performed in the United States today. As discussed below, for example, the U.S. Food and Drug Administration (FDA)-approved protocol for medication abortion was updated in 2016 based on extensive research showing improved outcomes with a revised regimen (CDER, 2016). Techniques used in aspiration procedures are also safer and more effective than in the past. Sharp metal curettes, once commonly used, are considered obsolete by many professional groups, and their use is no longer recommended for abortion because of the increased (albeit rare) risk of injury (NAF, 2017a; RCOG, 2011, 2015; Roblin, 2014; SFP, 2013; WHO, 2012). New approaches to cervical preparation and the use of ultrasound guidance have also improved abortion safety (Darney and Sweet, 1989; SFP, 2013).

This chapter draws primarily on the scientific literature but also includes the recommendations (i.e., clinical practice guidelines and best practices) of professional groups that provide obstetrical and gynecological care or are concerned with the quality of abortion services. Appendix D summarizes the literature search strategies the committee used to identify the relevant evidence, while Table 2-1 describes the sources of the clinical guidelines cited throughout this report.

PREABORTION CARE

When women seek an abortion, they present with a variety of experiences and needs (Moore et al., 2011; Zurek et al., 2015). Patient-centeredness—a fundamental attribute of quality health care—means "providing care that is respectful of and responsive to individual patient preferences, needs, and values and ensuring that patient values guide all clinical decisions" (IOM, 2001, p. 6). Thus, when women seek an abortion, they should have the opportunity to discuss their questions and concerns and receive support in their decision making. They should also be provided evidence-based information on their procedure options so they can make an informed and independent decision.

TABLE 2-1 Selected Organizations That Issue Clinical Guidelines on Abortion Care

American College of Obstetricians and Gynecologists (ACOG)	A professional membership organization of obstetricians and gynecologists. ACOG produces clinical guidelines and other educational materials for its members and patients.

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 16 of 140 PageID #: 3491

National Abortion Federation (NAF)	A standards-based membership organization of abortion facilities (clinics, physicians' offices, and hospitals). To qualify for and maintain NAF membership, providers must meet NAF clinical and safety standards. The standards are revised annually to reflect current evidence and are the basis for members' certification.
Royal College of Obstetricians and Gynaecologists (RCOG)	A global reproductive health professional society based in the United Kingdom. Its more than 14,000 members include individuals involved in obstetrics or gynecology worldwide. RCOG's mission is to improve the standard of care and to advance the science and practice of obstetrics and gynecology.
Society of Family Planning (SFP)	A professional membership organization for qualified individuals who have an interest in family planning demonstrated through training, clinical or laboratory practice, or academic publication. SFP develops clinical guidelines and supports research on contraception and abortion.
World Health Organization (WHO)	The international public health organization of the United Nations, based in Geneva, Switzerland. WHO develops clinical guidelines on reproductive health care with the stated objective of improving health outcomes.

SOURCES: ACOG, 2017a; NAF, 2017b; RCOG, 2017; SFP, 2017; WHO, 2017.

There is little evidence on how preabortion care is typically provided, but there is consensus among professional guidelines that the preabortion encounter includes the following elements (Baker and Beresford, 2009; NAF, 2017a; RCOG, 2015; WHO, 2014):

- individualized, sensitive, and respectful communication;
- cultural sensitivity;
- review of the risks and benefits of the available abortion procedures that is based on evidence and is easy to understand;
- options for pain management, including nonpharmaceutical approaches, analgesia, sedation, and anesthesia;
- support for emotional and other needs as they arise;
- confirmation that the abortion decision is voluntary (not coerced);
- explanation of what will be done before, during, and after the procedure, including the preabortion evaluation;

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 17 of 140 PageID #: 3492

- description of what the patient is likely to experience, clear instruction on aftercare, and how to recognize potential complications requiring emergency care;
- whom to call and where to go for services for both routine and follow-up care; and
- information and counseling on future prevention of unintended pregnancy and contraceptive options, including the option to obtain contraception immediately following the procedure.

Patient education, counseling, and informed consent are overlapping components of preabortion care. Patient education refers to the information women should receive regarding the available treatment options and the risks and benefits of these options (Baker and Beresford, 2009). It is also integral to the informed consent process—a legal and ethical obligation to all patients defined by state and federal law, malpractice standards, and professional standards (ACOG, 2015; AMA, 2016; Joint Commission Resources, 2016; Kinnersley et al., 2013). Counseling involves addressing the patient's emotions, expectations, and beliefs about abortion care (Baker and Beresford, 2009).

Health care providers are legally required to obtain patients' informed consent before performing a medical procedure. Specific definitions of informed consent may vary from state to state, but the goal of the informed consent process is well established: to ensure that patients understand the nature and risks of the procedure they are considering and that their decision to undergo it is voluntary (AAAHC, 2016; AMA, 2016; HHS, 2017a; Joint Commission, 2016). The discussion should also include options for analgesia, sedation, or anesthesia, including their associated risks and benefits (AANA, 2016; ASA Committee on Ethics, 2016).

Not every woman wants or needs psychological counseling in addition to patient education before an abortion (Baker and Beresford, 2009; Baron et al., 2015; Brown, 2013; Moore et al., 2011). Some women may wish to discuss the emotional aspects of the abortion with a counselor (Moore et al., 2011), and individualized counseling may be helpful for women having difficulty with their decision (Baker and Beresford, 2009). Women should also be referred to and have access to additional counseling and social services if needed (e.g., for counseling on intimate partner violence, sexual abuse care, rape crisis counseling, mental health services, substance abuse services, and postabortion counseling) (Goodman et al., 2016). As noted in Chapter 1, most women who undergo abortions are poor or low-income. Three-quarters of abortion patients have family incomes below 200 percent of the federal poverty level (Jerman et al., 2016) and thus may benefit from social support services. In addition, although the evidence is drawn largely from non-U.S. data (Australia, Canada, China, New Zealand, and the United Kingdom), epidemiological studies have shown that women who have abortions are disproportionately at risk of interpersonal and other types of violence (Bourassa and Berube, 2007; Evins and Chescheir, 1996; Fanslow et al., 2008; Fisher et al., 2005; Glander et al., 1998; Janssen et al., 2003; Keeling et al., 2004;

Leung et al., 2002; Russo and Denious, 2001; Saftlas et al., 2010; Steinberg and Russo, 2008; Taft and Watson, 2007; Taft et al., 2004). Little is known about the extent to which abortion patients receive the follow-up social and psychological supports they need. A study of Finnish registry data provides some evidence that monitoring for mental health status in a follow-up visit after abortion may help reduce the consequences of serious mental health disorders (Gissler et al., 2015).

Providing evidence-based information on how to prevent a future unintended pregnancy—including the option to obtain contraception contemporaneously with the procedure—is a standard component of abortion care (Goodman et al., 2016; NAF, 2017a; RCOG, 2015; WHO, 2014). Contraception discussions should be patient-centered, based on principles of informed consent using evidence-based information on the contraceptive alternatives, and guided by the patient's preferences (Goodman et al., 2016; RCOG, 2015). Most contraceptive methods can be administered safely immediately after an abortion (Fox et al., 2011; Goodman et al., 2016; Grimes et al., 2010; Okusanya et al., 2014; Patil et al., 2016; Sääv et al., 2012; WHO, 2014). Recent studies suggest improved contraceptive use with the placement of implants or the initiation of other contraceptive methods at the time of the abortion or when mifepristone is administered for an early medication abortion (Hognert et al., 2016; Raymond et al., 2016a; Whaley and Burke, 2015).

While numerous options for contraception are available, long-acting reversible contraception (LARC) methods are the most effective for pregnancy prevention (ACOG, 2017b; Winner et al., 2012). Further, they are associated with higher rates of continuation, even for adolescents and young women, and fewer repeat abortions compared with other forms of contraception (ACOG, 2017b; Ames and Norman, 2012; Diedrich et al., 2015; Goodman et al., 2008; Goyal et al., 2017; Kilander et al., 2016; Rose and Lawton, 2012; Rosenstock et al., 2012; Winner et al., 2012). A prospective cohort study of women of reproductive age in the St. Louis area—the Contraceptive CHOICE project—assessed the impact of an educational intervention designed to increase awareness of LARC among women who wanted to avoid pregnancy for at least 1 year. The 10,000 women who enrolled in the project had the opportunity to obtain the contraceptive method of their choice at no cost in a variety of clinical settings where they received family planning, obstetrical, gynecological, and primary care (including two facilities providing abortion care) (McNicholas et al., 2014; Secura et al., 2010). The study found that offering LARC at the time of enrollment was well received; 75 percent of the 9,256 participants opted for intrauterine devices (IUDs) or implants. LARC users were more likely than non-LARC users to continue using contraception at 12 and 24 months (86 percent versus 55 percent at 12 months, 77 percent versus 41 percent at 24 months). The generalizability of these findings, however, is uncertain given that the contraceptives were free, and the study population included only women who wanted to avoid pregnancy. The CHOICE

study also evaluated a structured approach to contraceptive counseling and found that counseling could be provided effectively by trained personnel without a medical background (Madden et al., 2013).

INITIAL CLINICAL ASSESSMENT

Abortion care should always begin with a clinical evaluation, including a pertinent medical history and clinical assessment to assess the presence of comorbidities or contraindications relevant to the procedure. The primary aim of the evaluation is to confirm an intrauterine pregnancy and determine gestation. The physical exam may involve laboratory tests and ultrasonography to confirm an intrauterine pregnancy; assess gestation; screen for sexually transmitted infections (STIs) and cervical infections; document Rh status; or evaluate uterine size, position, and possible anomalies (ACOG and SFP, 2014; Goldstein and Reeves, 2009; Goodman et al., 2016; NAF, 2017a; RCOG, 2015; WHO, 2014). Women whose Rh status is unknown should be offered Rh testing and, if Rh negative, offered Rh immune globulin (ACOG and SFP, 2014, NAF, 2017a; RCOG, 2015). No evidence, however, indicates that Rh immune globulin is needed in pregnancies under 8 weeks' gestation (NAF, 2017a). While it should not delay the abortion procedure, screening for STIs may be appropriate if available (NAF, 2017a ; RCOG, 2015). The contraindications and other circumstances affecting the appropriateness of each abortion method are discussed later in the chapter.

Pregnancy is dated from the first day of the last menstrual period (LMP) and is commonly measured by days' or weeks' gestation (Goldstein and Reeves, 2009). Either clinical evaluation or ultrasound examination can be used to establish gestation (ACOG and SFP, 2014; WHO, 2014). Ultrasound is not required, however, and there is no direct evidence that it improves the safety or effectiveness of the abortion (Kaneshiro et al., 2011; NAF, 2017a; Raymond et al., 2015; RCOG, 2015). In a study of nearly 4,500 medication abortion patients aimed at assessing the feasibility and efficacy of foregoing routine use of ultrasound, Bracken and colleagues (2011) found that LMP date combined with physical examination was highly effective at determining eligibility for medication abortion—patients accurately assessed their eligibility (Bracken et al., 2011).

SAFETY AND EFFECTIVENESS OF CURRENT ABORTION METHODS

Several methods—medication, aspiration, dilation and evacuation (D&E), and induction—are used to perform an abortion depending on weeks' gestation, patient preference, provider skill, need and desire for sedation, costs, clinical setting, and state policies and regulations.

Medication Abortion

Medication abortion in early pregnancy is accomplished using mifepristone, a progesterone receptor antagonist that competitively interacts with progesterone at the progesterone receptor site, thereby inhibiting the activity of endogenous or exogenous progesterone. This process initiates the breakdown of the endometrium and implanted embryo (Borkowski et al., 2015). Mifepristone, sold under the brand name Mifeprex,[1] is the only medication specifically approved by the FDA for use in medication abortion (Woodcock, 2016). Taken orally, it has been shown to increase sensitivity to prostaglandins and is most commonly used in conjunction with misoprostol, a prostaglandin E1 analogue. Misoprostol causes uterine contractions as well as cervical ripening and can be administered orally, sublingually, buccally, or vaginally.[2] Since mifepristone's initial FDA approval in 2000, an extensive body of research has led to improvements in the drug's protocol, including a lower recommended dosage, an increased period of eligibility from 49 days' to 70 days' (10 weeks') gestation, and a recommendation that the misoprostol be taken buccally rather than sublingually or orally to minimize side effects (Borkowski et al., 2015; Chai et al., 2013). The World Health Organization (WHO) has included mifepristone and misoprostol on its Model List of Essential Medicines since 2005 (WHO, 2015).[3]

Few women have contraindications to medication abortion (ACOG and SFP, 2014). The FDA-approved Mifeprex label states that the drug should not be used for women with confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass; an IUD in place; chronic adrenal failure; concurrent long-term systemic corticosteroid therapy; hemorrhagic disorders or concurrent anticoagulant therapy; allergy to mifepristone, misoprostol, or other prostaglandins; or inherited porphyrias (FDA, 2016a).

BOX 2-1

FDA Risk Evaluation and Mitigation Strategy (REMS) Program for Mifeprex

The FDA REMS program restricts the chain of supply of certain drug products to ensure that the drugs are distributed only by authorized prescribers or pharmacies under specified conditions. The FDA considers the following when determining the necessity of a REMS:

- estimated size of the population likely to use the drug involved;
- seriousness of the disease or condition that is to be treated with the drug;
- expected benefit of the drug with respect to such disease or condition;
- expected or actual duration of treatment with the drug;

- seriousness of any known or potential adverse events that may be related to the drug and the background incidence of such events in the population likely to use the drug; and
- whether the drug is a new molecular entity.

As of March 2017, there were 77 approved REMS programs, including that of Mifeprex. A drug requiring a REMS must have at least one of the following:

- a Medication Guide for consumers;
- a communication plan for health care providers; and
- one of six "elements to assure safe use" of the medication (e.g., specifications for prescribers, places and conditions where the drug can be dispensed, and patient monitoring).

The FDA first established a REMS program for Mifeprex in 2011 and revised it in March 2016 along with an update to the drug's label. The revised REMS requirements do not differ substantially from the original. They include the following:

- Mifeprex may be dispensed only to patients in clinics, hospitals, or medical offices under the supervision of a certified prescriber. It cannot be dispensed through retail pharmacies.
- To be certified, health care providers must submit a Prescriber Agreement to the drug's distributor, Danco Laboratories, attesting to their ability to assess duration of pregnancy and to diagnose ectopic pregnancy. They must be able to provide or arrange for surgical intervention as well as access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary. Nonphysicians, such as certified nurse-midwives and other advanced practice clinicians, may prescribe Mifeprex if they have prescription authority under state law.
- Before patients receive the drug, the prescriber must provide the patient the FDA-approved Medication Guide, fully explain the potential risks related to the treatment regimen, and review and complete the Patient Agreement form with the patient.

The revised label

- lowered the recommended Mifeprex dosage to 200 mg;
- extended the gestation period appropriate for its use from 49 days' to 70 days' (10 weeks') gestation;
- eliminated the requirement for an in-person follow-up visit; and
- eliminated mandatory reporting of nonfatal adverse events.

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 22 of 140 PageID #: 3497

SOURCES: Borkowski et al., 2015; Dabrowska, 2017; FDA, 2016a,b,c; Gassman et al., 2017; Woodcock, 2016.

Since 2011, the distribution and use of Mifeprex has been restricted under the requirements of the FDA Risk Evaluation and Mitigation Strategy (REMS) program (see Box 2-1). (See Chapter 3 for additional details on REMS requirements for clinicians who prescribe Mifeprex.) Despite the restriction, use of the medication method is increasing, especially in early pregnancy. As noted in Chapter 1, the percentage of all abortions by medication rose by 110 percent between 2004 and 2013 and is expected to increase further (Jatlaoui et al., 2016). In 2014, medication abortions accounted for approximately 45 percent of all U.S. abortions performed <9 weeks' gestation (Jones and Jerman, 2017).

Effectiveness of the Current Medication Regimen

The current FDA-approved regimen for medication abortion is 200 mg of mifepristone taken orally, followed by 800 mcg of misoprostol taken buccally 24 to 48 hours later (FDA, 2016a). A recent systematic review of this regimen—including 33,846 medication abortions—found an overall effectiveness rate of 96.7 percent for gestations up to 63 days (9 weeks) (Chen and Creinin, 2015).[4]

Reversal of Medication Abortion

There has recently been media attention to claims that medication abortions can be "reversed" by taking progesterone after the mifepristone but before taking the misoprostol (Graham, 2017). The claims are based on a case series report of seven patients who did not receive standardized doses or formulations of the medications (i.e., mifepristone or progesterone) (Delgado and Davenport, 2012). Case series are descriptive reports that are considered very low-quality evidence for drawing conclusions about a treatment's effects (Guyatt et al., 2011). In a related subsequent systematic review, Grossman and colleagues (2015) assessed the likelihood of a pregnancy continuing if the abortion medication regimen is not completed (i.e., the mifepristone dosage is not followed by misoprostol). However, the review found that there were insufficient data to conclude that the progesterone treatment is more likely to lead to continued pregnancy compared with expectant management after mifepristone alone.

Expected Side Effects

It is common for medical procedures to result in side effects in addition to the intended outcome. Medication abortions involve cramping, pain, and bleeding, similar to the symptoms of a miscarriage (

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 23 of 140 PageID #: 3498

ACOG and SFP, 2014; Borkowski et al., 2015; FDA, 2016a). Vaginal bleeding is expected during and after an abortion and occurs in almost all patients during a medication abortion (FDA, 2016a). Bleeding generally starts as the tissue begins to separate from the endometrium and continues for several days after the abortion is complete. The heaviest bleeding occurs during and immediately following the passage of the gestational sac and lasts 1 to 2 days. Some bleeding and spotting may occur up to 9–16 days.

Like bleeding, uterine pain and cramping are an expected and normal consequence of medication abortion (FDA, 2016a). Cramping can last from a half-day to 3 days (Ngo et al., 2011). Nonsteroidal anti-inflammatory drugs (NSAIDs) are typically recommended to manage the pain. Ibuprofen—after the onset of cramping—has been shown to reduce both pain and later analgesia use (Jackson and Kapp, 2011 ; Livshits et al., 2009). However, some women still report high levels of pain, and pain is commonly reported as the worst feature of the method. Prophylactic regimens for pain management are an area of active research (Dragoman et al., 2016).

Other side effects reported by women who undergo medication abortion include nausea, vomiting, weakness, diarrhea, headache, dizziness, fever, and chills (Chen and Creinin, 2015; FDA, 2016a). About 85 percent of patients report at least one of these side effects, and many patients are expected to report more than one (FDA, 2016a).

Complications

Complications after medication abortion, such as hemorrhage, hospitalization, persistent pain, infection, or prolonged heavy bleeding, are rare—occurring in no more than a fraction of a percent of patients (Chen and Creinin, 2015; FDA, 2016a; Ireland et al., 2015; Kulier et al., 2011; Woodcock, 2016). Obesity (i.e., a body mass index [BMI] of 30 or greater) has not been found to increase the risk for adverse outcomes after medication abortion (Strafford et al., 2009). The Society of Family Planning suggests that medication abortion may be preferable to aspiration abortion when patients, including those with extreme obesity, are at risk of procedural and anesthetic complications (SFP, 2012).

Hemorrhage Prolonged heavy bleeding is rare but may indicate an incomplete abortion[5] or other complications. Hemorrhage requiring assessment or treatment following medication abortion is also rare. The FDA advises that women contact a health care provider immediately if bleeding after a medication abortion soaks through two thick full-size sanitary pads per hour for two consecutive hours (FDA, 2016a). In a study of 11,319 medication abortions performed in California between 2009 and 2010, hemorrhage occurred in 16 cases (0.14 percent) (Upadhyay et al., 2015).

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 24 of 140 PageID #: 3499

The need for a blood transfusion—an uncommon occurrence—is an indication of clinically significant hemorrhage. In a study of more than 1,000 women receiving medication abortion in Norway, 1 patient required a transfusion (0.1 percent) and 32 required an aspiration procedure because of continued bleeding (3.0 percent) (Løkeland et al., 2014). In Chen and Creinin's (2015) systematic review of 20 studies and 33,846 women (described above), 0.03 to 0.6 percent of women required a blood transfusion after a medication abortion.

Infection Serious infection occurs rarely after medication abortion; reports of fatal sepsis are exceedingly rare (<1 in 100,000) (FDA, 2011; Woodcock, 2016). Signs and symptoms of serious infection are fever of 100.4°F or higher lasting more than 4 hours, tachycardia, severe abdominal pain, pelvic tenderness, or general malaise with or without fever occurring more than 24 hours after administration of misoprostol (ACOG and SFP, 2014; FDA, 2016a). There is no evidence of a causal relationship between use of mifepristone and misoprostol and an increased risk of infection or death (FDA, 2016a; Woodcock, 2016). The incidence of infection in recent studies ranges from 0.01 to 0.5 percent (Chen and Creinin, 2015; Cleland et al., 2013; Upadhyay et al., 2015). According to the FDA's Adverse Event Reporting System, there were nine reports of severe bacterial infections following medication abortion from November 1, 2012, through April 30, 2015 (Woodcock, 2016). The FDA has concluded that the available evidence does not support the use of prophylactic antibiotics for medication abortion (CDER, 2016).

Need for uterine aspiration Some women require a uterine aspiration after medication abortion because of retained products of conception, persistent pain or bleeding, or ongoing pregnancy (Chen and Creinin, 2015; Cleland et al., 2013; Ireland et al., 2015; Raymond et al., 2013; Upadhyay et al., 2015). Ireland and colleagues (2015) analyzed more than 13,000 electronic medical records documenting the outcomes of medication abortions (up to 9 weeks' gestation) performed in private Los Angeles clinics from November 2010 to August 2013. Of these, 2.1 percent required an unanticipated uterine aspiration either because of an ongoing pregnancy (0.4 percent) or for persistent pain, bleeding, or both (1.8 percent). Other recent estimates of the need for an unanticipated uterine aspiration range from 1.8 to 4.2 percent (Chen and Creinin, 2015). Rates vary in part because of differences in study populations (including weeks' gestation) and in treatment regimens (Cleland et al., 2013; Raymond et al., 2013; Upadhyay et al., 2015).

Impact of Clinical Setting on the Safety and Effectiveness of Medication Abortion

There is no direct evidence suggesting that specific types of facilities (e.g., ambulatory surgery centers or hospitals) or facility factors (e.g., size of procedure room or corridor width) are needed to ensure the safety of medication abortion. Indeed, most women in the United States return home after taking mifepristone and take the misoprostol 28 to 48 hours later. As a result, medication abortions occur largely in nonclinical settings. Moreover, as described above, a body of research including systematic reviews (Chen and Creinin, 2015; Kulier et al., 2011; Raymond et al., 2013) and large cohort studies (Cleland et al., 2013; Ireland et al., 2015; Upadhyay et al., 2015) demonstrates that complications such as infection, hemorrhage requiring transfusion, or hospitalization occur in fewer than 1.0 percent of patients.

Some research has focused specifically on medication abortion outside the hospital or clinic setting. A variety of studies, for example, have assessed the self-administration of misoprostol after receiving mifepristone in a clinic. This largely observational research shows that home use of misoprostol produces outcomes similar to those of the clinic-supervised method (Clark et al., 2005; Fiala et al., 2004; Guengant et al., 1999; Løkeland et al., 2014; Ngoc et al., 2004; Shannon et al., 2005; Shrestha and Sedhai, 2014).

Other research has assessed the safety and effectiveness of home use of both mifepristone and misoprostol (Chong et al., 2015; Conkling et al., 2015; Platais et al., 2016). In one U.S. prospective nonrandomized study, 400 women with pregnancies up to 63 days' gestation were offered the choice of either clinic-supervised or home use of mifepristone. Of these women, 128 chose home administration, and 272 chose clinic administration; the women did not differ significantly in terms of gravidity, gestation, or other measured characteristics. The women choosing home use were slightly older (27.8 versus 26.0 years) and more likely to be doing paid work (78.9 versus 68.0 percent). Success rates did not differ between the groups (96.3 versus 96.9 percent), and the 2 patients who required hospitalization were in the clinic-supervised group. One patient was diagnosed with an incomplete abortion and underwent a follow-up dilation and curettage procedure, and the other was treated for severe nausea and vomiting (Chong et al., 2015). A related study found that among 301 women offered the choice of home use, the factor most cited by women who chose this option was flexibility in scheduling (Swica et al., 2013).

Telemedicine

Telemedicine is the use of telecommunications and information technology to provide access to health assessment, diagnosis, intervention, consultation, supervision, and information across distance (HHS, 2017b). For medication abortion, the process involves a health care provider's reviewing the relevant medical information and having a discussion with the patient via teleconference. If clinical criteria are

met, the health care provider remotely dispenses or issues a prescription for the medication abortion regimen (Aiken et al., 2018; Grossman et al., 2011a). Grossman and colleagues (2011a) investigated the effectiveness and acceptability of telemedicine for medication abortion (mean days' gestation was 47 days) compared with face-to-face physician visits in Iowa. Roughly half of the 578 patients were enrolled in the telemedicine option. The success rates for the two options were similar: 98.7 percent for the telemedicine patients and 96.9 percent for the clinic patients. No patient in either group required hospitalization, and there was no significant difference in the occurrence of adverse events. One of the 223 patients in the telemedicine group received a blood transfusion. In a recent 7-year retrospective cohort study in Iowa, researchers compared the rate of clinically significant adverse events (hospital admission, surgery, blood transfusion, emergency department treatment, or death) after medication abortion for 8,765 telemedicine patients and 10,405 in-person patients (Grossman and Grindlay, 2017). The overall rate of adverse events was less than 0.3 percent. The difference between the telemedicine patients (0.18 percent) and in-person patients (0.32 percent) was not statistically significant and was within the authors' margin of noninferiority. This finding indicates that telemedicine provision of medication abortion was not associated with a significantly higher prevalence of adverse events compared with in-person provision.

These reported risks are both low and similar in magnitude to the reported risks of serious adverse effects of commonly used prescription and over-the-counter medications. For example, it has been estimated that the use of NSAIDs is responsible for 3,500 hospitalizations and 400 deaths per year in UK residents aged 60 or older, a risk rate of 0.23 and 0.03 percent, respectively (Hawkey and Langman, 2003). The NSAID-related risk of hospitalization in elderly Medicaid patients in the United States has been estimated to be even higher—1.25 percent in one study (Smalley et al., 1995). The risk of diarrhea with many common antibiotics is as high as 39 percent (McFarland, 1998), and the risk of hospitalization due to the more serious *Clostridium difficile* infection may be as high as 0.02 percent with some antibiotic combinations (Hirschhorn et al., 1994). Taken together, these findings provide additional indirect evidence that no facility-specific factors are needed to ensure the safety of medication abortion, as there is no perceived need for facility-specific factors to ensure the safety of these other common pharmaceuticals. These safety data accord with professional guidelines or best practices according to which routine early medication abortion does not require sophisticated settings and can be safely performed in settings typical for the delivery of women's health care and family planning services (ACOG and SFP, 2014; NAF, 2017a; RCOG, 2015; WHO, 2014).

In their analysis of the Iowa study described above, Grossman and colleagues (2013) conducted a geographic analysis to assess the effect of the telemedicine model on access to medication abortion for

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 27 of 140 PageID #: 3502

women in different areas of the state. They found that the proportion of all Iowa abortions that were medication abortions had increased, from 33.4 to 45.3 percent (p <.001), in the 2-year periods before and after telemedicine was introduced. The increase was especially notable among women living in more remote areas. Women who lived more than 50 miles from an abortion clinic that provided only surgical abortions were 16 percent more likely to have a medication abortion (adjusted odds ratio [aOR] = 1.16; 95% confidence interval [CI] = 1.05, 1.28). The proportion of medication abortions at the study sites had also increased from 46 to 54 percent after telemedicine was introduced (p <.001). Overall, women in Iowa had a 46 percent greater likelihood of having an earlier abortion (<14 weeks' gestation) (aOR = 1.46; 95% CI = 1.22, 1.75).

Aspiration Abortion

Aspiration is a minimally invasive and commonly used gynecological procedure (Meckstroth and Paul, 2009; Roblin, 2014).[6] The procedure time is typically less than 10 minutes (Edelman et al., 2001; Goldberg et al., 2004). As noted in the previous chapter, aspiration is currently the most common abortion method used in the United States regardless of gestation, accounting for almost 68 percent of abortions in 2013.[7] The method may be used up to 14 to 16 weeks' gestation. Aspiration is also used in cases of early pregnancy loss (miscarriage) and management of incomplete abortion for medication abortion.

The first steps in the procedure are cervical dilation and priming (when appropriate) so that the contents of the uterus can be evacuated. Cervical dilation is usually done using tapered mechanical dilators and is recommended over routine priming except for adolescents and others for whom cervical dilation may be challenging (Allen and Goldberg, 2016). Cervical priming is accomplished with either osmotic dilators[8] or pharmacological agents (e.g., misoprostol), or both. When placed in the cervix, the osmotic dilator absorbs moisture from the tissues surrounding the cervix and gradually swells to slowly open the cervical orifice (os). The pharmaceutical agents are prostaglandin analogues or progesterone antagonists, such as the drug misoprostol, which is also used in medication abortion.

After cervical dilation and, when indicated, priming, a suction cannula (plastic or metal tube) is inserted through the cervix into the uterus. The cannula is attached to a vacuum source—an electric vacuum pump for electric vacuum aspiration or a handheld, hand-activated aspirator (syringe) for manual vacuum aspiration—to empty the uterine contents. Ultrasound guidance is sometimes used (RCOG, 2011).

See later in this chapter for a discussion of the use of sedation and anesthesia during abortion procedures, including the implications for personnel needs and facility requirements.

Effectiveness of Aspiration Abortion

Recent comparisons of aspiration and medication abortion methods indicate that aspiration may be only slightly more effective than medication abortion in early pregnancy. In Ireland and colleagues' (2015) study of private Los Angeles clinics described in the prior section, the efficacy rate for almost 17,000 aspiration abortions performed up to 9 weeks' gestation was 99.8 percent, compared with 99.6 percent for medication abortions[9] for the same gestational period (Ireland et al., 2015).

Expected Side Effects

As in medication abortion, bleeding, uterine pain, and cramping are expected and normal consequences of aspiration abortion.

Complications

Aspiration abortions rarely result in complications. In a recent retrospective analysis of California fee-for-service Medicaid claims data, 57 of almost 35,000 women (0.16 percent) were found to have experienced a serious complication (hospital admission, surgery, or blood transfusion) after an aspiration abortion (Upadhyay et al., 2015). A systematic review on aspiration-related complications documents a somewhat higher complication rate (ranging from 0 to 5 percent), but a large proportion of the studies in that review included now outdated procedures, including dilation and sharp curettage (White et al., 2015).

In a historical cohort study, Guiahi and colleagues (2015) analyzed the outpatient medical records of women who had undergone an aspiration abortion between January 2009 and March 2014 in a Colorado clinic. The researchers compared the outcomes of women with (n = 587) and without (n = 1,373) medical comorbidities, including diabetes, hypertension, obesity (weight ≥200 lb or BMI ≥30), HIV, epilepsy, asthma, thyroid disease, and/or bleeding and clotting disorders having aspiration abortions. The researchers found no difference in the rate of complications between the women with at least one comorbidity and those with no comorbidity (odds ratio [OR] = 0.9; 95% CI = 0.5, 1.6).

Need for repeat aspiration Repeat aspiration is most often required for retained products of conception after an abortion. Rates of <0.1 to 8.0 percent have been reported for this complication, related to gestation, experience of the provider, and use of ultrasound guidance (White et al., 2015). Studies

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 29 of 140 PageID #: 3504

showing the highest rates of repeat aspiration included women at ≤6 weeks' gestation and were conducted more than 20 years ago (Bassi et al., 1994). Tissue inspection is recommended after aspiration abortion, regardless of gestation, but products of conception may be difficult to identify prior to 7 weeks' gestation (NAF, 2017a; SFP, 2013). Additional protocols, including magnification of aspirate, follow-up by serum beta-hCG estimation, and flotation of tissue with backlighting may be used to confirm abortion completion (NAF, 2017a; RCOG, 2011; SFP, 2013).

Hemorrhage Hemorrhage requiring transfusion or other treatment (medication administration or repeat aspiration) complicates 0.0 to 4.7 percent of aspiration abortions, with more recent studies reporting a rate of 1.3 percent (Upadhyay et al., 2015; White et al., 2015). In the California Medicaid study, 0.13 percent of aspiration procedures were complicated by hemorrhage (Upadhyay et al., 2015).

Infection Current clinical guidelines recommend routine antibiotic prophylaxis before all aspiration abortions (NAF, 2017a; RCOG, 2015; SFP, 2011b; WHO, 2014). Like any invasive procedure, aspiration abortion carries some risk of infection. If untreated, an upper genital tract infection subsequent to abortion can lead to chronic pelvic pain, dyspareunia, ectopic pregnancy, and infertility (Low et al., 2012). Serious infection after aspiration, however, is rare. In a 2012 systematic review, the Cochrane Collaboration evaluated the effectiveness of perioperative antibiotics in preventing upper genital tract infection (including infection of the uterus and fallopian tubes) (Low et al., 2012). The researchers concluded that universal antibiotic prophylaxis is effective in preventing infection after an aspiration procedure: the incidence of upper genital tract infection among women who received prophylactic antibiotics was 59 percent of that among women who received a placebo. The rate of infection was 5.8 percent among women who received antibiotics (n = 3,525) and 9.4 percent among women in the placebo group (n = 3,500).

In a more recent systematic review of complications following aspiration abortion (up to 14 weeks' gestation), White and colleagues (2015) report that 0.0 to 0.4 percent of 188,395 women undergoing aspiration abortions required intravenous (IV) antibiotics after the procedure in 11 of 12 office-based settings. In Upadhyay and colleagues' (2015) analysis of almost 35,000 aspiration abortions in California, 94 women (0.27 percent) developed an infection after the procedure. Most infections after outpatient aspiration procedures are treated with oral antibiotics, with up to 0.4 percent of patients with infection requiring IV antibiotic administration (White et al., 2015).

Uterine perforation Uterine perforation involves injury to the uterine wall, as well as potential injury to other abdominal organs. While the risk of uterine perforation in older studies has been reported as ≤0.1

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 30 of 140 PageID #: 3505

to 2.3 percent, the majority of more recent studies of aspiration abortion report no cases of uterine perforation or note that perforations that occurred were successfully managed conservatively without the need for additional surgery or hospitalization (White et al., 2015). In the study of almost 35,000 California Medicaid-covered aspiration abortions referenced above, 0.01 percent resulted in a perforation (Upadhyay et al., 2015).

Cervical laceration Cervical laceration (injury to the cervix from instrumentation) is also very rare, with most studies reporting none or 1 case (<0.1 to 0.6 percent) (Ohannessian et al., 2016; White et al., 2015). In a study evaluating the risks of aspiration abortion in teens versus adults, an increased risk of cervical laceration was noted for adolescent patients (0.5 versus 0.2 percent), but this study was conducted prior to current approaches to cervical preparation (Cates et al., 1983; White et al., 2015). Use of osmotic dilators was common in older studies, but the more common approach today is medical, using misoprostol 2 to 3 hours prior to the procedure (Allen and Goldberg, 2016; O'Connell et al., 2009). While current recommendations do not include routine use of medical or mechanical cervical preparation because of the delay that would result, misoprostol is commonly used in nulliparous women and young adolescents between 12 and 14 weeks' gestation (Allen and Goldberg, 2016).

Dilation and Evacuation

Fewer than 9 percent of abortions in the United States occur after 13 weeks' gestation (Jatlaoui et al., 2016). The D&E method, sometimes referred to as a second-trimester surgical abortion, appears to account for the majority of procedures performed between 14 and 20 weeks' gestation. Precise estimates of the rate of abortions by type during these weeks are not available. Reports often cite CDC surveillance statistics as suggesting that D&Es account for up to 96 percent of abortions between 14 and 20 weeks' gestation (ACOG, 2013; Hammond and Chasen, 2009). However, the oft-cited CDC data are actually aggregate estimates that include not only D&E but also other methods (Jatlaoui et al., 2016; Pazol et al., 2009).

D&E techniques have evolved in the decades since the method was first developed (ACOG, 2013; Hammond and Chasen, 2009; Lohr et al., 2008). The procedure is typically performed in two stages, although the specific approaches to cervical preparation, instrumentation, and other aspects may vary (Grossman et al., 2008; Ibis Reproductive Health, 2015; Lohr et al., 2008). The procedure itself generally takes less than 30 minutes (Ben-Ami et al., 2009; Grossman et al., 2008, 2011b). The first step is cervical preparation, dilating the cervix with laminaria (or other type of osmotic dilator) and/or a prostaglandin (e.g., misoprostol). Slow dilation is recommended (e.g., over a few hours, overnight, or

sometime repeated over 24 to 48 hours) to minimize the need for supplemental manual or mechanical dilation (Grossman et al., 2008; Lohr et al., 2008). With a greater degree of dilation, the uterus is more easily emptied, instruments are easier to use, and procedure time is shortened (Hern, 2016). Once dilation is adequate and analgesia, sedation, and/or anesthesia have been administered, the amniotic fluid is aspirated (Lohr et al., 2008; WHO, 2014). Before 16 weeks' gestation, suction aspiration may suffice to empty the uterus. At 16 weeks, forceps extraction may also be required. Beyond 16 weeks, suction is not effective, and forceps should be used to remove fetal parts and the placenta. A curette and/or additional suction are also used to remove any remaining tissue or blood clots. Following the procedure, the provider examines the tissue to confirm that the evacuation was complete. Patients should be observed following the procedure to monitor for any postoperative complications (Hammond and Chasen, 2009; Lohr et al., 2008).

Ultrasonography is recommended so the physician can visualize the surgical instruments, locate fetal parts, and confirm an empty uterus (NAF, 2017a). Routine intraoperative ultrasonography has been demonstrated to significantly reduce the risk of uterine perforation and shorten the time required to complete the procedure (Darney and Sweet, 1989).

Performing D&E procedures requires advanced training and/or experience (Cates et al., 1982; Hern, 2016; Lohr et al., 2008; RCOG, 2015; WHO, 2012). Chapter 3 reviews the required clinical skills for performing abortions.

Complications

Although the risk of complications increases with weeks' gestation (Bartlett et al., 2004; Grossman et al., 2008; Zane et al., 2015), a range of retrospective cohort studies, case series, chart reviews, and a prospective case series have shown D&E to be effective with minimal rates of complications, ranging from 0.05 to 4 percent (ACOG, 2013; Autry et al., 2002; Bryant et al., 2011; Cates et al., 1982; Frick et al., 2010; Grimes et al., 1977; Grossman et al., 2008; Jacot et al., 1993; Mauelshagen et al., 2009; Peterson et al., 1983).

One study, however, suggests that a history of multiple prior cesarean deliveries may significantly increase the risk of a major complication. In a multivariable logistic analysis of 2,973 D&Es performed between 2004 and 2007 at an urban public hospital, Frick and colleagues (2010) found an overall rate of major complications (i.e., transfusion required; disseminated intravascular coagulation; or a reoperation involving uterine artery embolization, laparoscopy, or laparotomy) of about 1.0 percent. However, women with two or more prior cesarean sections had a sevenfold increased risk of a major complication (OR = 7.37; 95% CI = 3.35, 15.80) (Frick et al., 2010). A history of one prior cesarean section was not

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 32 of 140 PageID #: 3507

associated with an increased risk of complications, although the authors note that a larger sample might lead to different results.

Obesity has also been studied as a possible risk factor for women undergoing D&E abortions (Benson et al., 2016; Lederle et al., 2015; Murphy et al., 2012). In a retrospective cohort study of 4,968 women undergoing aspiration and D&E abortions at a large outpatient clinic in 2012–2014, obesity was not associated with increased risk of complications[10] (Benson et al., 2016). The same conclusion resulted from a retrospective cohort study of 4,520 D&Es performed in a hospital-based abortion practice in 2009–2013 and a retrospective review of 1,044 women undergoing D&E or dilation and suction (D&S)[11] between 13 and 24 weeks' gestation in 2007–2010 (Lederle et al., 2015; Murphy et al., 2012). Lederle and colleagues (2015) found no association between BMI and D&E complications[12] after adjustment for age, ethnicity, prior vaginal delivery, prior cesarean delivery, and gestational duration. Murphy and colleagues (2012) compared complication rates, operative times, and anesthesia times between obese and nonobese (BMI <30) women and found no significant difference in complication rates. Finally, a retrospective analysis of D&E procedures performed between 2009 and 2014 found an association between obesity and increased risk for complications[13] in abortions performed after 14 weeks' gestation (Mark et al., 2017). Complications increased by BMI category,[14] and the increase in complications in women with Class III obesity was significant (OR = 5.04; 95% CI = 1.65–15.39).

Hemorrhage In studies of abortions performed in the year 2000 or later, D&E-related hemorrhage requiring transfusion or other treatment occurred in 0.0 to 1.0 percent of cases (Frick et al., 2010; Grossman et al., 2011a; Mauelshagen et al., 2009).

Infection Routine antibiotic prophylaxis is recommended for all surgical abortions (ACOG, 2013; NAF, 2017a; RCOG, 2015; WHO, 2014). Infection after a D&E is uncommon, with rates ranging from 0.0 to 2.0 percent (Autry et al., 2002; Grossman et al., 2011a; Mauelshagen et al., 2009). In the California Medicaid study described above, Upadhyay and colleagues (2015) found that 0.3 percent or 18 of 8,837 abortions performed after 13 weeks' gestation resulted in an infection, although these procedures included both D&Es and inductions.

Cervical lacerations Injuries to the cervix and uterus have decreased significantly with routine cervical preparation prior to D&E (ACOG, 2013). Recent studies have reported rates of 0.02 to 3.3 percent (Autry et al., 2002; Frick et al., 2010). The risk of cervical laceration is associated with mechanical dilation, nulliparity, advanced gestation, and provider inexperience (ACOG, 2013). Thus, as noted above, performing D&E procedures requires advanced training and/or experience.

Uterine perforation While uterine perforation is more common in D&E than in aspiration procedures, the incidence remains quite low and is likely related to the availability of cervical preparation and ultrasound guidance (Grossman et al., 2008). Limited clinician experience and underestimation of the duration of pregnancy are also factors that have been associated with uterine perforation (Grossman et al., 2008). A 1989 study compared the incidence of perforation during 810 D&E procedures with and without sonography (Darney and Sweet, 1989). Using ultrasound to guide the use of intrauterine forceps clearly improved the safety of the procedure: the rate of perforation declined significantly from 1.4 to 0.2 percent. Studies dating from 2010 to 2015 report perforation rates ranging from 0.2 to 0.8 percent (Frick et al., 2010; Upadhyay et al., 2015).

The facility requirements that are appropriate for D&Es depend on the level of sedation and anesthesia that is used. (See later in this chapter for a review of the use of analgesia, sedation, and anesthesia during abortions.)

Induction Abortions

As noted in Chapter 1, abortion terminology can be confusing. All abortion methods are sometimes referred to as “induced,” and the term “medical” is often used to describe any nonsurgical method regardless of how early or late in pregnancy it occurs. In this section, the term “induction abortion” refers specifically to nonsurgical abortions that use medications to induce labor and delivery of the fetus. Relevant research and clinical guidelines use varying lower and upper gestation limits. In practice, the gestational parameters for induction vary depending on the facility, patient and provider preference, and state laws and regulations (SFP, 2011a).

Induction abortions are rarely performed in the United States; in 2013, they accounted for approximately 2 percent of all abortions at 14 weeks’ gestation or later (Jatlaoui et al., 2016). For many women in the United States, D&E is often the preferred alternative because induction is more painful, its timing is less predictable and slower (sometimes taking more than 24 hours), and it is more expensive (see below) (ACOG, 2013; Ashok et al., 2004; Grimes et al., 2004; Grossman et al., 2008; Kelly et al., 2010; Lohr et al., 2008). In some clinical settings, however, D&E is not an option because the available clinicians lack the necessary experience and/or training in D&E procedures (SFP, 2011a).[15] In addition, D&E abortions are illegal in Mississippi and West Virginia.[16]

Optimal Medication Regimen for Induction Abortions

The Safety and Quality of Abortion Care in the United States, National Academies Press, 2018. ProQuest Ebook Central, http://ebookcentral.proquest.com/lib/nyli/detail.action?docID=5407012.

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 34 of 140 PageID #: 3509

The medication regimens for performing an induction abortion have evolved and improved in response to a growing body of research—most notably with respect to the combined use of mifepristone and misoprostol (Gemzell-Danielsson and Lalitkumar, 2008; Wildschut et al., 2011). The safety and efficacy of different medications and medication regimens for inducing abortion has been assessed in RCTs, retrospective analyses, prospective observational studies, and systematic reviews (Ashok et al., 2002, 2004; Constant et al., 2016; Goh and Thong, 2006; Gouk et al., 1999; Hamoda et al., 2003; Kapp et al., 2007; Mauelshagen et al., 2009; Ngoc et al., 2011; Sonalkar et al., 2017; Wildschut et al., 2011).

In a systematic review of the effectiveness and side effects of different induction abortion medication regimens, the Cochrane Collaboration identified 36 RCTs that used various agents and methods of administration. The researchers concluded that a combination of mifepristone and misoprostol is the most effective approach and requires the shortest amount of time (Wildschut et al., 2011).

Guidelines developed by the American College of Obstetricians and Gynecologists (ACOG) and endorsed by the Society of Family Planning (SFP) and the Society of Maternal-Fetal Medicine recommend an alternative misoprostol regimen when mifepristone is not available (ACOG, 2013). Although effective, misoprostol-only regimens take longer (Wildschut et al., 2011) and as a result, are likely to be more costly to the patient with respect to time, discomfort, and out-of-pocket expense.

The National Abortion Federation (NAF) guidelines note that, when performed by trained clinicians, induction abortions can be provided in medical offices, clinics, or higher-level health care facilities (NAF, 2017a).

Complications

The expected side effects of induction abortions are similar to those described above for medication abortions at or before 10 weeks' gestation: cramping, pain, and bleeding, as well as nausea, vomiting, diarrhea, chills, and headache (Borgatta, 2011; Ngoc et al., 2011; Wildschut et al., 2011). The side effects are a result of the medications that are used for induction, the abortion process itself, or the medications used to manage pain (Borgatta, 2011).

The literature on complications resulting from induction abortions is limited by a variety of factors. The available research is a mix of study designs analyzing a variety of treatment protocols and patient populations that differ in important ways, including weeks' gestation, parity, fetal anomaly, and the pharmaceutical regimens and agents used to induce labor (Goyal, 2009; SFP, 2011a). All of these factors may affect patient outcomes. Moreover, while the research on the outcomes of medication and aspiration abortions draws on the outcomes of thousands of patients, the study samples for research on inductions are relatively small and thus have limited statistical power. Nevertheless, the available evidence

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 35 of 140 PageID #: 3510

consistently finds that induction abortion rarely leads to serious complications, although they occur more often than in D&E procedures (Bryant et al., 2011; Grossman, et al., 2008; Mauelshagen et al., 2009; SFP, 2011b).

In addition, among women with a prior cesarean delivery, the use of prostaglandins (particularly misoprostol) to induce labor during a normal vaginal delivery has been associated with an increased risk of uterine rupture—a potentially life-threatening condition (Lydon-Rochelle et al., 2001). Because methods to induce abortion are similar to those used to induce vaginal deliveries, research has assessed whether women with a prior cesarean are at similar risk of uterine rupture when undergoing an induction abortion. The evidence suggests that misoprostol-induced abortions are safe after a cesarean. Uterine rupture has been documented in fewer than 0.4 percent of induction abortions among women with a prior cesarean (Berghella et al., 2009; Goyal, 2009).

POSTABORTION CARE

Clinical guidelines suggest that, regardless of abortion method, routine in-person follow-up care is not necessary. However, clinicians may choose to offer an in-person follow-up visit to women 7–14 days after the procedure to confirm the absence of ongoing pregnancy and to assess recovery (NAF, 2017a; WHO, 2014). In the case of medication abortion, which usually occurs in a nonclinical setting, confirmation of termination of the pregnancy is the primary concern after the abortion. The FDA advises that follow-up is needed to confirm complete termination of pregnancy, but that termination can be confirmed by medical history, clinical examination, hCG testing, or ultrasound (FDA, 2016a). Similarly, NAF advises that confirmation can be established by any of these methods in an office, by telephone, or through electronic communication (NAF, 2017a).

Before a woman leaves a facility after an abortion procedure (or after she has taken the appropriate medication in the case of medication abortion), she should receive instructions on what to expect after the procedure, self-care, resuming intercourse, recognizing signs and symptoms of complications, and how and where to seek assistance if needed (NAF, 2017a; RCOG, 2015; WHO, 2014). Fertility goals and future pregnancy should be discussed, and if a woman opts for contraceptive counseling or a method of contraception, it should be provided before she leaves the facility (NAF, 2017a; RCOG, 2016; WHO, 2014). Other treatment (pain medication, medication for RhD-negative patients, emotional support) and referrals for other services (STI/HIV counseling and testing, abuse support services, psychological or social services, and services of other physician specialists) should also be provided before discharge, as needed (RCOG, 2016; WHO, 2014).

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 36 of 140 PageID #: 3511

As with any other procedure, women who receive minimal, moderate, or deeper sedation should be monitored continuously during a recovery period until they have been evaluated and determined to be no longer at risk for hemodynamic instability or respiratory depression (NAF, 2017a). Prior to discharge, women must be ambulatory with stable blood pressure and pulse, bleeding and pain must be controlled, and these criteria must be documented (NAF, 2017a).

USE OF ANALGESIA, SEDATION, AND ANESTHESIA IN ABORTION CARE

Patient comfort not only is of critical interest to the patient but also affects the ability of the clinician to perform a procedure safely and effectively (Allen et al., 2013). People differ in their experience of and tolerance for pain. In their review of pain relief for obstetrical and gynecological procedures in outpatient settings, Allen and colleagues (2013) observed that anxiety, depression, and a woman's expectation of pain are strong predictors of her actual experience of pain during a procedure.

NAF recommends that providers involve women in the analgesia/sedation/anesthesia decision and that the choice be based on the individual patient's needs and an assessment of the risks and benefits (NAF, 2017a). The pain management approach that is best for women undergoing medication, aspiration, D&E, or induction abortions depends not only on which method is used but also on weeks' gestation, the patient's preferences for pain control, her comorbidities (if any), the availability of equipment and specialized personnel, provider preferences, cost, and facility licensure (Allen et al., 2012, 2013; NAF, 2017a; Nichols et al., 2009; RCOG, 2015). Results of a 2002 survey of NAF administrators and providers offer some insight into providers' preferred methods for pain control during aspiration abortions. Almost half (46 percent) of the 110 survey respondents preferred using local and/or oral medication, 33 percent preferred local plus IV sedation, and 21 percent preferred deep sedation or general anesthesia (O'Connell et al., 2009). The survey also elicited information regarding pain control for D&E and induction abortions. Most clinics that offered combined local and IV conscious sedation or general anesthesia used these methods for more than 80 percent of their patients (O'Connell et al., 2008).

The literature on the effectiveness of nonpharmacological approaches to reducing pain during abortion is inconclusive (Tschann et al., 2016). While a variety of methods have been assessed, including relaxation techniques (e.g., focused breathing, visualization, vocal coaching, and positive suggestion), hypnosis, aromatherapy, and abortion doulas, more definitive research is needed.

Pain Management During Aspiration, D&E, and Induction Abortions

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 37 of 140 PageID #: 3512

The pharmaceutical options for pain management during an abortion range from oral analgesics (e.g., NSAIDs), to local anesthesia (typically a paracervical block), to minimal sedation/anxiolysis, to moderate sedation/analgesia, to deep sedation/analgesia, to general anesthesia (NAF, 2017a). Along this continuum, the physiological effects of sedation have increasing clinical implications and, depending on the depth of sedation, may require special equipment and personnel to ensure the patient's safety (see Tables 2-2 and 2-3). The greatest risk of using sedative agents is respiratory depression.

The American Society of Anesthesiologists (ASA) issues clinical standards for the safe use of pain medications and anesthesia in the types of outpatient clinical settings where abortions are provided (ASA, 2013, 2014b, 2015). The standards use a physical health classification system—ASA I through ASA VI—to guide clinicians' decisions about anesthesia options. ASA I patients are healthy, and ASA II patients have mild systemic disease;[17] both are medically eligible for all options up to deep sedation in office-based settings. The vast majority of abortion patients—young women—are in these categories. Women with severe systemic disease (ASA III and IV) require further medical assessment and may be eligible for deep sedation (monitored anesthesia care [MAC]) or general anesthesia in an accredited ambulatory surgery center (ASC) or hospital. Table 2-2 shows the ASA levels of sedation and their effects on cognitive, respiratory, and cardiovascular function.

TABLE 2-2 Levels and Effects of Analgesia, Sedation, and Anesthesia

Effect on	Minimal Sedation/ Anxiolysis[a]	Moderate Sedation/ Analgesia[b]	Deep Sedation/ Analgesia	General Anesthesia
Responsiveness	Normal response to verbal stimulation	Purposeful response to verbal or tactile stimulation	Purposeful response with repeated or painful stimulation	Unarousable by painful stimulus
Airway	Unaffected	No intervention required	Intervention may be required	Intervention often required
Spontaneous ventilation	Unaffected	Adequate	May be inadequate	Frequently inadequate
Cardiovascular function	Unaffected	Usually maintained	Usually maintained	May be impaired

[a] Minimal sedation includes local anesthesia, e.g., in the form of a paracervical block.

[b] Moderate sedation is sometimes described as "conscious sedation."

Safeguards for Managing Complications and Emergencies During an Abortion

The key safeguards—for abortions and all outpatient procedures—are whether the facility has the appropriate equipment, personnel, and emergency transfer plan to address any complications that might occur. While data on the use of specific pain management methods during an abortion are very limited, studies that report outcomes for patients after an abortion find that current pain management methods are safe when appropriate precautions are followed (Dean et al., 2011; Gokhale et al., 2016; Renner et al., 2012).

TABLE 2-3 Minimum Facility Requirements Related to Level of Sedation for Medication, Aspiration, and Dilation and Evacuation (D&E) Abortions

	Minimum Facility Requirements[a]			
Abortion Method	Equipment to Monitor Oxygen Saturation, Heart Rate, and Blood Pressure	Equipment to Monitor Ventilation (e.g., end-tidal carbon dioxide)[b]	Emergency Resuscitation Equipment	Emergency Transfer Plan
Medication	—	—	—	—
Aspiration with moderate sedation[a]	√	—	√	√
D&E				
Deep sedation, or monitored anesthesia care (MAC)	√	√	√	√
General anesthesia	√	√	√	√

NOTES: Checkmarks denote American Society of Anesthesiologists (ASA) minimal facility requirements as they relate to the level of sedation used in medication, aspiration, and D&E abortions.

[a] These requirements are for healthy patients or patients with mild systemic disease, i.e., ASA physical health status classifications ASA I and ASA II. Women with severe systemic disease (i.e., ASA III and IV) should be evaluated, and consideration should be given to using deep sedation (MAC) or general anesthesia in an accredited facility such as an ambulatory surgery center or hospital.

[b] End-tidal carbon dioxide monitoring refers to the noninvasive measurement of exhaled carbon dioxide.

SOURCES: Allen et al., 2013; ASA, 2013, 2014a,b, 2015; ASA Task Force, 2002.

Facility Requirements

Table 2-3 shows the ASA minimal facility requirements as they relate to the level of sedation used in medication, aspiration, and D&E abortions. No special equipment or emergency arrangements are

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 39 of 140 PageID #: 3514

required for medication abortions. If moderate sedation is used during an aspiration abortion, the facility should have emergency resuscitation equipment and an emergency transfer plan, as well as equipment to monitor oxygen saturation, heart rate, and blood pressure. D&Es that involve deep sedation or general anesthesia should be provided in similarly equipped facilities that also have equipment to monitor ventilation (e.g., end-tidal carbon dioxide) (ASA Task Force, 2002).

New insights into the safe provision of sedation and anesthesia for abortions in outpatient settings are forthcoming. A unique research project, currently ongoing, is comparing the relative safety, cost, and complications of providing abortions in office-based settings and ASCs (ANSIRH, 2017; Roberts, 2017). The investigators are using a national private insurance claims database containing approximately 50 million patient records to compare adverse events, including anesthesia-related outcomes, in the two settings. The study's results were not available when the committee prepared this report. However, analyses of large-scale databases suggest that the risk of hospital admission after outpatient surgery (involving deep sedation) is rare for healthy patients undergoing procedures that last less than 120 minutes (Fleisher et al., 2007). As noted earlier, aspiration abortions typically take 10 minutes, and D&E procedures less than 30 minutes.

Personnel Requirements

The use of sedation and anesthesia also has important implications for personnel. If moderate sedation is used, it is essential to have a nurse or other qualified clinical staff—in addition to the person performing the abortion—available to monitor the patient (ASA Task Force, 2002; NAF, 2017a). Both deep sedation and general anesthesia require the expertise of an anesthesiologist or certified registered nurse anesthetist (CRNA) to ensure patient safety.

Evidence on Complications of Analgesia, Sedation, and Anesthesia During Abortions

This section reviews the available evidence on complications related to pain management during aspiration, D&E, and induction abortions. As noted above, NSAIDs reduce the discomfort of pain and cramping safely and effectively during a medication abortion.

Aspiration Pain Management

Paracervical blocks are used routinely to reduce the pain of cervical dilation during aspiration procedures (Allen et al., 2013; Nichols et al., 2009). Moderate and deep sedation are also options for aspiration abortion. The blocks are effective in decreasing pain related to cervical dilation and uterine

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 40 of 140 PageID #: 3515

aspiration, although administration of the block itself is painful (Allen et al., 2013; Renner et al., 2012), and some providers use other medications to reduce the pain of the injection (Allen et al., 2013). Because some women report experiencing moderate to significant procedural pain even with the block, researchers are trying to identify an optimal approach to pain management without sedation during aspiration (Allen et al., 2013; O'Connell et al., 2009; Renner et al., 2012, 2016).

Adverse events related to the use of local anesthesia, regardless of the clinical circumstances, are rare (Nichols et al., 2009). In a recent retrospective cohort study, Horwitz and colleagues (2018) used electronic medical record data to assess whether obesity increased the risk of anesthesia-related complications[18] after an aspiration abortion with moderate IV sedation. The study, based in several Massachusetts outpatient clinics, included 20,381 women. Complications were rare and not associated with BMI[19] (Horwitz et al., 2018).

The White and colleagues (2015) systematic review described above identified 11 studies that report patient outcomes related to the use of local anesthesia, moderate sedation, or general anesthesia for aspiration abortions. Anesthesia-related complications were rare regardless of the clinical setting or level of sedation: ≤0.2 percent of office-based procedures and ≤0.5 percent of procedures in surgical centers and hospital-based clinics.

D&E Pain Management

A typical D&E regimen includes a paracervical block supplemented with either moderate sedation (using benzodiazepines and/or opiates) or deep sedation with propofol (without intubation) (NAF, 2017a ; RCOG, 2015; WHO, 2012, 2014). In office settings, deep sedation should be used only for healthy patients (ASA I) or patients with mild systemic disease (ASA II), and strict fasting guidelines should be followed before the procedure (ASA Task Force, 2002).

Two large-scale, retrospective analyses have demonstrated the safety of using deep sedation for aspiration and D&E abortions in clinic settings (Dean et al., 2011; Gokhale et al., 2016). Dean and colleagues (2011) assessed the experience of 62,125 women who had an aspiration or D&E abortion (up to 24 weeks' gestation) using deep sedation with propofol (without intubation) in a high-volume licensed clinic in New York State between 2001 and 2008.[20] Deep sedation was provided only to medically eligible patients who followed strict fasting guidelines. The procedures were monitored by an anesthesiologist or CRNA. The researchers reviewed the medical records of all women who were transferred to a hospital (n = 26) because of complications and found that no hospital transfers occurred because of an anesthesia complication.

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 41 of 140 PageID #: 3516

In a more recent study, Gokhale and colleagues (2016) assessed the outcomes for 5,579 aspiration and D&E abortions using IV sedation (without intubation) at a freestanding abortion clinic in Cleveland from 2012 to 2013. Patients were screened for medical eligibility and followed fasting guidelines. Sedation was administered by registered nurses or by CRNAs if propofol was administered. There were no hospital transfers for anesthesia-related indications. Naloxone was required for opioid reversal in 0.2 percent of patients. The study also compared outcomes for obese and nonobese women; no differences were found.

Induction Pain Management

There is little research on how best to manage pain during an induction (Jackson and Kapp, 2011). Comparisons of different analgesic regimens are not available, and the optimal approach to effective treatment of pain is not well established (Wiebe and Renner, 2014). The options will depend on the provider's resources and the particular clinical circumstances. Nulliparous women may require more analgesia compared with multiparous women (Ashok et al., 2004). The levels of pain in later-gestation induction abortions are said to be similar to those in normal delivery, but the committee found no studies documenting this (Smith et al., 2016; Viviand et al., 2003).

MORTALITY

Death associated with a legal abortion in the United States is an exceedingly rare event. As Table 2-4 shows, the risk of death subsequent to a legal abortion[21] (0.7 per 100,000) is a small fraction of that for childbirth (8.8 per 100,000) (Bartlett et al., 2004; Zane et al., 2015).[22] Abortion-related mortality is also lower than that for colonoscopies (2.9 per 100,000), plastic surgery (0.8 to 1.7 per 100,000), dental procedures (0.0 to 1.7 per 100,000), and adult tonsillectomies (2.9 to 6.3 per 100,000). Comparable data for other common medical procedures are difficult to find.

TABLE 2-4 Comparison of Mortality Rates for Abortion, Childbirth, Colonoscopy, Dental Procedures, Plastic Surgery, and Tonsillectomy, United States

Procedure (Study Period)	Mortality Rate (number of deaths per 100,000 procedures)
Abortion (legal) (1988–2010)	0.7
Childbirth (1988–2005)	8.8

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 42 of 140 PageID #: 3517

Colonoscopy (2001–2015)	2.9
Dental procedures (1999–2005)	0.0 to 1.7
Plastic surgery (2000–2012)	0.8 to 1.7
Tonsillectomy (1968–1972)	2.9 to 6.3

NOTE: Reported tonsillectomy rates were recalculated to reflect the rate per 100,000 procedures.

SOURCES: Baugh et al., 2011; Raymond and Grimes, 2012; Raymond et al., 2014; Reumkens et al., 2016; Zane et al., 2015.

The CDC monitors abortion-related deaths through its Pregnancy Mortality Surveillance System (Jatlaoui et al., 2017). The surveillance data underscore the increased risk of having an abortion later in pregnancy. Zane and colleagues (2015) assessed differences in abortion-related mortality by race, maternal age, and weeks' gestation using data from the CDC surveillance system. Among the 16.1 million legal abortions performed from 1998 to 2010, there were 108 deaths (0.7 per 100,000). Twenty deaths occurred among high-risk women whose pregnancy was life threatening. Infection and anesthesia complications were the most frequent cause of death for procedures performed up to 13 weeks' gestation. After 13 weeks, the deaths reported were due primarily to infection or hemorrhage.

The researchers found that weeks' gestation was the strongest predictor of abortion-related mortality. At 8 weeks' gestation or less, the death rate was 0.3 per 100,000; after 17 weeks, the rate was 6.7 per 100,000. Death rates were approximately three times as high for black women as for white women—similar to the disparities found in pregnancy outcomes overall (Creanga et al., 2012, 2015, 2017; MacDorman et al., 2017). From 2011 to 2013, for example, the overall maternal mortality ratio for non-Hispanic black women was 3.4 times higher than that for non-Hispanic white women (Creanga et al., 2017). A study of maternal mortality in 2013 to 2014 found a 22 percent lower ($p = .02$) mortality rate for Hispanic women compared with non-Hispanic white women; in 2008–2009, the mortality rate for Hispanic women was similar to that for non-Hispanic white women, but the difference was attributed to the 28 percent increase ($p < .001$) in mortality for non-Hispanic white women (MacDorman et al., 2017). MacDorman and colleagues (2017) note that almost all of the increase in maternal mortality was among woman aged 40 and older and for nonspecific causes of death.

STATE REGULATION OF ABORTION CARE

States play an essential role in ensuring the safety of health care services, especially through their licensure of clinicians and health care facilities. In every state, clinicians and inpatient facilities (e.g.,

hospitals, rehabilitation centers) must be licensed by a state board or agency to provide health care services legally (Chaudhry et al., 2013). State licensure may require the facility to be accredited by an independent accrediting organization. Regardless, Medicare and Medicaid, as well as private insurers, require accreditation for inpatient facilities and ASCs to be eligible for reimbursement (CMS, 2012). ASCs provide surgical services to patients not requiring hospitalization when the expected duration of services does not exceed 24 hours (CMS, 2016). In most states, ASCs must also be licensed to provide outpatient surgery, and in many states, ASCs must be accredited (ACFAS, 2017).[23]

Unlike other health care procedures provided in office-based settings, abortions are subject to a wide array of regulations that vary by state. Except for abortion, states typically regulate individual, office-based health services only when the service involves using sedation or general anesthesia (and depending on the level of sedation) (Jones, 2017). Twenty-five states regulate office-based procedures (other than abortion). In 23 of these states,[24] the regulation is triggered by the level of sedation, and in most cases, it requires that the facility be either accredited or licensed by the state in order to offer patients moderate or deep sedation (Jones, 2017; Jones et al., 2018).[25]

State abortion regulations often have a direct impact on the delivery of abortion care. They may stipulate the type of clinician that is allowed to perform an abortion independently of the relevant scope of practice laws (e.g., qualified advanced practice clinicians [APCs] or physicians without hospital privileges may be barred from performing abortions); how the informed consent process is conducted (e.g., providers may be required to misrepresent the risks of the procedure); the abortion method that is used (e.g., D&Es may be banned); the timing and scheduling of procedures (e.g., women may have to wait 18 to 72 hours after a counseling appointment); the physical attributes of the clinical setting (e.g., procedure room size, corridor width); and other basic elements of care. In most states, the regulations apply to all abortion methods regardless of weeks' gestation, use of sedation, or the invasiveness of the procedure.

See Table 1-1 in Chapter 1 for a listing of abortion-specific regulations by states as of September 1, 2017.

SUMMARY

The clinical evidence presented in this chapter on the provision of safe and high-quality abortion care stands in contrast to the extensive regulatory requirements that state laws impose on the provision of abortion services. These requirements may influence the efficiency of abortion care by requiring medically unnecessary services and multiple visits to the abortion facility, in addition to requiring that

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 44 of 140 PageID #: 3519

care take place in costlier and more sophisticated settings than are clinically necessary. These requirements go beyond the accepted standards of care in the absence of evidence that they improve safety. Some requirements, such as multiple visits and waiting periods, delay abortion services, and by doing so may increase the clinical risks and cost of care. They may also limit women's options for care and impact providers' ability to provide patient-centered care. Furthermore, many of these laws have been documented to reduce the availability of care by imposing unneeded regulations on abortion providers and the settings in which abortion services are delivered. The implications of abortion-specific regulations for the safety and quality of abortion care are described below.

Delaying the Procedure

The clinical evidence makes clear that legal abortions in the United States—whether by medication, aspiration, D&E, or induction—are safe and effective. Serious complications are rare; in the vast majority of studies, they occur in fewer than 1 percent of abortions, and they do not exceed 5 percent in any of the studies the committee identified. However, the risk of a serious complication increases with weeks' gestation. As the number of weeks increases, the invasiveness of the required procedure and the need for deeper levels of sedation also increase. Thus, delaying the abortion increases the risk of harm to the woman.

State regulations that require women to make multiple in-person visits and wait multiple days delay the abortion. If the waiting period is required *after* an in-person counseling appointment, the delay is exacerbated (Roberts et al., 2016; Sanders et al., 2016; White et al., 2017). Restrictions on the types of providers and on the settings in which abortion services can be provided also delay care by reducing the availability of care (Baum et al., 2016; Fuentes et al., 2016; Gerdts et al., 2016; Grossman et al., 2014, 2017).

Financial burdens and difficulty obtaining insurance are frequently cited by women as reasons for delay in obtaining an abortion (Bessett et al., 2011; Drey et al., 2006; Finer et al. 2006; Foster and Kimport, 2013; Foster et al., 2008; French et al., 2016; Janiak et al., 2014; Kiley et al., 2010; Roberts et al., 2014; Upadhyay et al., 2014). As noted in Chapter 1, 33 states prohibit public payers from paying for abortions, and other states have laws that either prohibit health insurance exchange plans (25 states) or private insurance plans (11 states) sold in the state from covering or paying for abortions, with few exceptions.[26]

Counseling and Informed Consent

The Safety and Quality of Abortion Care in the United States, National Academies Press, 2018. ProQuest Ebook Central, http://ebookcentral.proquest.com/lib/nyli/detail.action?docID=5407012.

Long-established ethical and legal standards for informed consent in health care appear to have been compromised in the delivery of abortion care in many areas of the country. Thirty-five states have abortion-specific regulations requiring women to receive counseling before an abortion is performed, and abortion patients in many of these states are offered or given inaccurate or misleading information (verbally or in writing) on reversing medication abortions, risks to future fertility, possible breast cancer risk, and/or long-term mental health consequences of abortion (Guttmacher Institute, 2017a) (see Table 1-1 in Chapter 1). As noted earlier in this chapter, the principal objective of the informed consent process is that patients understand the nature and risks of the procedure they are considering (AAAHC, 2016; AMA, 2016; HHS, 2017a; Joint Commission, 2016). However, legally requiring providers to inform women about risks that are not supported and are even invalidated by scientific research violates the accepted standards of informed consent. For example, some states require that providers inform women that abortion puts them at greater risk for breast cancer; mental health disorders; and difficulties in having a healthy, successful pregnancy (Guttmacher Institute, 2017a) (see Table 1-1 in Chapter 1 for a detailed list of states' informed consent requirements). Three states require providers to inform women that a medication abortion can be reversed after the woman takes mifepristone (Guttmacher Institute, 2017a). This information is not supported by research that meets scientific standards. See Chapter 4 for an in-depth review of the long-term health effects of abortion.

Medication Abortion

There is no evidence that the dispensing or taking of mifepristone tablets requires the physical presence of a clinician[27] or a facility with the attributes of an ASC or hospital to ensure safety or quality. The effects of mifepristone occur after women leave the clinic, and extensive research shows that serious complications are rare. The risks of medication abortion are similar in magnitude to the risks of taking commonly prescribed and over-the-counter medications such as antibiotics and NSAIDs. In 35 states, however, only physicians are permitted to give women the mifepristone tablet(s) required to begin the process of medication abortion (RHN, 2017). In 19 states, the clinician (a physician or other provider if allowed) must be physically present to provide the medication, thus prohibiting the use of telemedicine to prescribe the medication remotely for abortion (Guttmacher Institute, 2017b). In 17 states, medication abortions must be performed in a facility that meets the structural standards of ASCs even though the abortion will occur outside the clinical setting, and there is no evidence to suggest that these regulations improve safety or quality.

Aspiration Abortions

The Safety and Quality of Abortion Care in the United States, National Academies Press, 2018. ProQuest Ebook Central, http://ebookcentral.proquest.com/lib/nyli/detail.action?docID=5407012.

Aspirations are minimally invasive and commonly used for a variety of purposes in gynecology practices, including for early pregnancy loss (miscarriage). Aspiration abortions are performed safely in office-based settings and can be provided by appropriately trained APCs, as well as family practice physicians and OB/GYNs. If moderate sedation is used, the procedure should be performed in a facility that meets the relevant ASA facility standards. There is no evidence that performing aspiration abortions in ASCs increases the safety or efficacy of the procedure. The state regulations described above also affect aspiration abortion procedures: 44 states do not allow APCs to perform aspirations, and 16 states mandate that the procedure be performed in an ASC-like facility.

D&E and Induction Abortions

D&E is usually the medically preferred method for abortions at 14 weeks' gestation or later. The alternative—induction—is more painful, slower, and more expensive. D&Es are banned in Mississippi[28] and West Virginia[29] except if the woman's physical health or life is severely threatened.

---

[1] Mifeprex is manufactured and distributed by Danco Laboratories. Danco is the only distributer of Mifeprex in the United States.

[2] A sublingual medication is dissolved under the tongue. Buccal medications are placed between the gums and the cheek.

[3] Where permitted under national law and where culturally acceptable (WHO, 2015).

[4] The review also included 332 abortions that were performed between 64 and 70 days' gestation; the efficacy rate for these procedures was 93.1 percent.

[5] An "incomplete abortion" occurs when parts of the products of conception are retained in the uterus.

[6] There is no standard terminology for this type of abortion. As noted in Chapter 1, this report uses the term "aspiration abortion," although others commonly refer to the same procedure as "surgical abortion," "vacuum aspiration," "suction curettage," or "suction evacuation."

[7] Centers for Disease Control and Prevention (CDC) surveillance reports use the catchall category of "curettage" to refer to nonmedical abortion methods. The committee assumed that CDC curettage estimates before 13 weeks' gestation refer to aspiration procedures and that curettage estimates after 13 weeks' gestation are D&E procedures.

[8] Laminaria, small tubes made of dried seaweed, and manmade sterile sponges are common types of osmotic dilators.

[9] $p < .001$.

[10] Complications assessed included need for uterine reaspiration (including same-day reaspiration), uterine perforation, cervical laceration, infection, emergency department visit or hospitalization, and excessive blood loss (defined as estimated blood loss greater than or equal to 100 mL).

[11] Dilation and curettage/suction denoted procedures performed when no other instruments besides suction were used; 5.3 percent of procedures in the study were D&S.

[12] Complications assessed included cervical laceration, hemorrhage, uterine atony, anesthesia complications, uterine perforation, disseminated intravascular coagulation, retained products of conception, and major complications (defined as those requiring hospitalization, transfusion, or further surgical intervention).

[13] Complications assessed included hemorrhage, need for repeat evacuation, uterine perforation, cervical laceration, medication reaction, unexpected surgery, or unplanned admission to the hospital.

[14] The cohort was classified into categories based on the WHO classification of underweight (BMI <18.5), normal weight (BMI 18.5–24.9), overweight (BMI 25.0–29.9), obese Class I (BMI 30–34.9), obese Class II (BMI 35–39.9), and obese Class III (BMI 40 or greater).

[15] See Chapter 3 for a review of factors contributing to the dearth of trained providers.

[16] Both states allow exceptions in cases of life endangerment or severe physical health risk to the woman.

[17] ASA II patients (mild systemic disease) have no functional limitations and well-controlled disease, such as controlled hypertension or diabetes (without systemic effects), mild lung disease, or mild obesity (BMI between 30 and 40) (ASA, 2014a).

[18] The primary outcome assessed was supplemental oxygen administration. Secondary outcomes included reversal agent administration, anesthesia-related adverse events, and intraoperative lowest level of consciousness.

[19] Obesity groups (BMI = 30–34.9; BMI = 35–39.9; BMI ≥40) were compared with women with BMI <25.

[20] One patient received an endotracheal intubation.

[21] The CDC defines an abortion-related death as "a death resulting from a direct complication of an induced abortion, an indirect complication caused by a chain of events initiated by an abortion procedure, or the aggravation of a pre-existing condition by the physiologic or psychological effects of the abortion" (Jatlaoui et al., 2016, p. 4).

[22] The CDC calculates the rate of abortion mortality using deaths reported to the CDC Abortion Surveillance System and dividing them by the estimated number of abortion procedures in the United States (CDC, 2017; Jones and Jerman, 2014).

[23] According to the American College of Foot and Ankle Surgeons, 46 states require ASCs to be licensed, and 28 states (including the District of Columbia) require accreditation (ACFAS, 2017).

[24] The 23 states are Alabama, Arizona, Arkansas, California, Connecticut, Delaware, Florida, Indiana, Kansas, Louisiana, Mississippi, Nevada, New Jersey, New York, Ohio, Oregon, Pennsylvania, Rhode Island, South Carolina, Tennessee, Texas, Virginia, and Washington.

[25] Personal communication, B. S. Jones, Advancing New Standards in Reproductive Health (ANSIRH), July 3, 2017.

[26] Exceptions are limited and vary by state. They are often made for pregnancies resulting from rape or incest, pregnancies that endanger the woman's life or severely threaten the health of the woman, and cases of fetal impairment.

[27] Chapter 3 reviews the clinical competencies needed to provide safe and high-quality abortions, as well as state regulations regarding the role of APCs.

[28] Mississippi Unborn Child Protection from Dismemberment Abortion Act, Mississippi HB 519, Reg. Sess. 2015–2016 (2016).

[29] Unborn Child Protection from Dismemberment Abortion Act, West Virginia SB 10, Reg. Sess. 2015–2016 (2016).

What the new FDA commissioner says about possible restrictions on abortion medication

Apr 24, 2025 6:30 PM EDT

Many conservatives want the FDA to impose tighter restrictions on mifepristone and misoprostol, which can be delivered by mail. The medication accounted for 63 percent of U.S. abortions in 2023. Amna Nawaz spoke with the new FDA commissioner, Dr. Marty Makary, about what the agency may do.

Read the Full Transcript

Notice: Transcripts are machine and human generated and lightly edited for accuracy. They may contain errors.

Amna Nawaz:

Now to the new Food and Drug Administration commissioner, Dr. Marty Makary, and a wide-ranging conversation I had with them earlier today as part of Semafor's World Economy Summit.

Among the many topics we discussed, mifepristone and what plans the FDA may have in store for medication abortion, which accounted for 63 percent of U.S. abortions in 2023. Many conservatives want the FDA to impose tighter restrictions on mifepristone and misoprostol, which can be delivered by mail.

Here is some of what Dr. Makary said.

On mifepristone, do you expect to take action further restricting the pill?

Dr. Marty Makary, FDA Commissioner:

I have no plans to take action on mifepristone.

Amna Nawaz:

Could that be changed over the course of your tenure, given the pressure that I know has come from a lot of the political forces at play on this?

Dr. Marty Makary:

GBP-PET00031

So, look, I believe as a scientist, you got to evolve as the data comes in.

And, as you may know, there is an ongoing set of data that is coming into FDA on mifepristone. So if the data suggests something or tells us that there's a real signal, then I — we can't promise we're not going to act on that data that we have not yet seen.

Amna Nawaz:

But if that new data contradicts the decades of data that said that it's overwhelmingly safe and effective, you would go with the new data, rather than the precedent of decades of data?

Dr. Marty Makary:

Well, it's very hypothetical, right, because you're talking about the strength of the data, the safety of the data, the reliability of the data. So it's very hypothetical what you're asking, but in general I'm a data guy.

Amna Nawaz:

Commissioner Makary also seemed to agree today that the federal government should reverse itself and no longer recommend the COVID booster for children. HHS Secretary Robert F. Kennedy Jr. is reportedly considering that.

Previous scientific panels have found it safe and beneficial to prevent kids from getting seriously ill, but Makary told me today he believes that evidence is insufficient.

Acceptability and Feasibility of Phone Follow-up After Early Medical Abortion in Vietnam

A Randomized Controlled Trial

Nguyen Thi Nhu Ngoc, MD, MSc, Hillary Bracken, PhD ,MHS, Jennifer Blum, MPH, Nguyen Thi Bach Nga, MD, Nguyen Hong Minh, MD, Ngo van Nhang, MD, Kelsey Lynd, MPH, RN, Beverly Winikoff, MD, MPH, and Paul D. Blumenthal, MD, MPH

OBJECTIVE: To investigate phone follow-up with a semiquantitative urine pregnancy test and symptom checklist as a replacement for universal clinic follow-up after medical abortion.

METHODS: One thousand four hundred thirty-three women seeking early medical abortion at four hospitals in Vietnam were randomized to clinic or phone follow-up. Women allocated to clinic follow-up returned to the hospital for confirmation of abortion outcome 2 weeks after mifepristone administration. Women assigned to phone follow-up completed a semiquantitative pregnancy test at initial visit to determine baseline human chorionic gonadotropin range and again at home 2 weeks later. Clinic staff called women to review the pregnancy test results and symptom checklist. Women who screened positive were referred to the clinic. Effectiveness, feasibility, and acceptability of the follow-up methods were assessed.

RESULTS: The rate of ongoing pregnancy was not significantly different between the two groups (clinic: 2.7% phone, 2.5%, relative risk 0.9, 95% confidence interval 0.99–1.02). Eighty-five percent of women in the phone group did not need an additional clinic visit. Phone follow-up was highly effective in screening for ongoing pregnancy with a sensitivity and specificity of 92.8% and 90.6%, respectively. Specificity of the pregnancy test alone (eg, without the symptom checklist) was higher (95.7%).

CONCLUSION: Phone follow-up offers a feasible and effective approach to identify women with ongoing pregnancy after early medical abortion. When used with the semiquantitative pregnancy test, the symptom checklist offered no additional benefit and decreased the specificity of the screening. Given its effectiveness and ease of use, the semiquantitative pregnancy test alone could replace routine clinic follow-up after early medical abortion.

LEVEL OF EVIDENCE: I

Despite the high efficacy and safety of early medical abortion using a combined regimen of mifepristone plus misoprostol, clinic follow-up remains an integral part of standard medical abortion service delivery globally.[1,2] In-person clinic visits can be costly and time-consuming for both the woman and the health care system. In many clinics, a transvaginal ultrasound examination is performed routinely. Some women find that the additional follow-up visit decreases the acceptability of medical abortion[1] and it is not uncommon for women to fail to return for the 2-week follow-up appointment.

Preprocedure and postprocedure system of serum human chorionic gonadotropin (hCG) measures are accurate in identifying ongoing pregnancies after medical abortion.[3–5] Quantitative serum hCG testing to confirm successful medical abortion is commonly used in the United States and Europe and recommended as a means of follow-up by the Royal College of Obstetricians and Gynecologists and the World Health Organization.[6,7]

Urine pregnancy tests offer another way to measure hCG levels after medical abortion.[8–10] Semiquantitative pregnancy tests have been used successfully in two subsequently published medical abortion studies in the United States and Vietnam. In both studies, the test correctly identified all of the ongoing pregnancies among study participants.[11,12]

The goal of this study was to test the efficacy and feasibility of a service delivery protocol that replaces the routine clinic visit with ultrasonographic examination with sequential semiquantitative pregnancy tests and a standardized self-administered follow-up questionnaire administered over the phone.

MATERIALS AND METHODS

This multicenter study enrolled women seeking early medical abortion at four hospitals (Hung Vuong Hospital, National Ob-Gyn Hospital, Hanoi Ob-Gyn Hospital, and HocMon General District Hospital) in Vietnam. The most common treatment regimen used for early medical abortion services at the hospitals consists of oral 200 mg mifepristone followed in 24–48 hours by 800 micrograms buccal misoprostol administered at home. Women presenting for early medical abortion at one of these four facilities were screened for participation and those meeting the eligibility criteria were enrolled. Eligibility criteria included intrauterine pregnancy less than or equal to 63 days of gestation; no known contraindications to abortion with mifepristone, misoprostol, or both; general good health; ability to provide informed consent and willingness to return for follow-up; literate and able to complete an at-home symptom checklist; and possessing a working, personal phone number. Women not eligible or choosing not to participate in the study received standard clinic follow-up.

Participants were randomly assigned to one of two study groups: 1) clinic follow-up (eg, standard care); or 2) phone follow-up. Standard care entailed a clinic visit 2 weeks after mifepristone administration. At the visit, each participant was interviewed about her clinical condition and underwent bimanual examination and transvaginal ultrasonography to confirm her abortion status. In the event of an ongoing pregnancy, immediate surgical evacuation was offered. Women with incomplete abortion at follow-up were given the option of immediate surgical completion or an additional dose of misoprostol followed by a clinic visit 1 week later. All additional clinic visits, additional treatment received, or both were recorded on study forms. Once complete abortion was ascertained, participants were asked about their future preferences and satisfaction and acceptability with the follow-up procedure and released from the study.

Women randomized to phone follow-up were scheduled for a telephone call 2 weeks after mifepristone administration. Women assigned to phone follow-up were asked to use a urine-based semiquantitative pregnancy test before swallowing mifepristone to locate the range of their hCG before the abortion (baseline). In contrast to typical urine-based pregnancy tests, the semiquantitative pregnancy test provides estimates of hCG levels by individual strips reading sequential ranges of hCG: at least 25 milli-international units/mL, at least 100 milli-international units/mL, at least 500 milli-international units/mL, at least 2,000 milli-international units/mL, and at least 10,000 milli-international units/mL. A study nurse explained how to perform the semiquantitative pregnancy test and provided each participant with an additional test, a urine sample cup, an information sheet explaining how to perform and interpret the test, and a questionnaire to use at home. Tests were conducted by dipping the test panel into the urine sample cup and stirring it for a minimum of 10 seconds to achieve strip saturation. Either first morning or random urine could be used. The tests were then placed face up on a flat surface and read approximately 15 minutes later. Each woman's baseline hCG as determined by the semiquantitative test was noted on her at-home symptom checklist. Participants were instructed to complete the pregnancy test and the symptom checklist before their scheduled telephone follow-up weeks later. On the assigned date, participants were contacted by phone by the clinic staff. During the call, a study nurse reviewed the pregnancy test result and checklist responses with the woman. The pregnancy test result at follow-up was compared with the baseline result and a drop of at least one bracket was considered a success. In the event that she had not performed the pregnancy test at the time of the call, she was asked to perform the test immediately and the nurse would call back in approximately 30 minutes.

The symptom checklist used was derived from an earlier study[12] and included the following questions: 1) Did you experience less than 2 days of heavy bleeding during treatment? 2) Are you experiencing any of

the following symptoms now: breast tenderness, nausea or morning sickness, frequent urination, or exhaustion or tiredness or both? 3) Do you still feel pregnant? If the woman answered "yes" to any of the questions on the checklist or her pregnancy test was invalid or indicated an increase or no change in the hCG level, she was asked to return to the clinic for follow-up. If a woman screened negative for referral, she was released from the study after the call. Participants who screened positive for clinic referral were asked by the health care provider to return for any reason or requested a clinic visit were scheduled for additional clinic follow-up. During the follow-up phone call, participants were also asked about the satisfaction and acceptability of the phone follow-up procedure.

Participants were randomized to a study group by opening the next sequentially numbered sealed opaque envelope. The envelopes were prepared by staff at Gynuity Health Projects in New York. Randomization was stratified by study site using random blocks of eight to ensure equal distribution in the two study groups. Regardless of study group, any participant failing to return for the follow-up visit or make the scheduled telephone follow-up call was contacted by telephone up to three times by a study provider.

The sample size was based on the least common outcome of interest: ongoing pregnancy after medical abortion. Based on previous studies conducted in Vietnam, we estimated that ongoing pregnancy would occur in approximately 2.0% of medical abortion cases.[12,13] Assuming that routine clinic-based follow-up will diagnose 100% of ongoing pregnancies, we designed the study to have 80% power to demonstrate that phone follow-up (using a semiquantitative pregnancy test in combination with a self-administered checklist) would be as effective as standard clinic-based follow-up in detecting ongoing pregnancies with an α of 0.05. To achieve this, we estimated that 28 ongoing pregnancies (14 in each study arm) would be needed, with a total sample size of 1,400 participants (700 in each study arm).

Data entry and analysis were performed using SPSS 15.0. Study data were entered and cleaned in Vietnam for analysis jointly by the investigators in Vietnam and New York. The two study groups were compared using *t* tests or the Mann-Whitney *U* test for continuous variables and χ^2 or Fisher's exact tests for categorical variables. The main study outcomes were compared using relative risks (RRs), 95% confidence intervals (CIs), and *P* values. A *P* value $<.05$ was considered statistically significant. Sensitivity and specificity of the pregnancy test and checklist in detecting ongoing pregnancy was also calculated. Ethical approvals were obtained at Hung Vuong Hospital, Hoc Mon General District Hospital in Ho Chi Minh City, and National Hospital in OBGYN and Hanoi OBGYN Hospital in Hanoi, Vietnam, and the trial is registered at clinical trials.gov as NCT01150422.

RESULTS

One thousand four hundred thirty-three women were enrolled at the study sites between May 26, 2010, and April 14, 2011. Seven hundred thirteen women were randomized to the phone follow-up group and 720 women assigned to clinic follow-up (Fig. 1). There was no statistically significant difference between the two groups (Table 1). The medical abortion outcomes for the two groups are presented in Table 2. There were no statistically significant differences in rates of complete abortion without surgical evacuation (clinic: 94.6% [626/662], phone: 94.8% [672/709], RR 1.002, 95% CI 0.977–1.028) or ongoing pregnancy between the two groups (clinic: 2.7% [18/720], phone: 2.5% [18/713], RR 0.934, 95% CI 0.985–1.019).

In the phone follow-up group, 2.2% of women (16/713) did not complete the scheduled follow-up call because they came to the clinic early (Table 2; Fig. 1). Seven women had a complete abortion without surgical evacuation. Four women underwent a uterine evacuation for a continuing pregnancy. Five participants had aspirations for other reasons including profuse bleeding (n=1) and woman's request (n=4). One woman made an interim visit to the clinic 10 days after mifepristone administration and was hospitalized for treatment of a suspected infection. She received intravenous antibiotics and her fever resolved after 4 days.

In the clinic follow-up group, 1.4% of women (10/720) made an interim visit to the study clinic before their scheduled appointment (Table 2; Fig. 1). Half of women who returned early (5/10) underwent a uterine evacuation for an ongoing pregnancy confirmed by ultrasonography. Two women underwent an evacuation for retained products of conception. The remaining women (n=3) had a successful abortion confirmed by ultrasonography.

Most women in both study arms completed follow-up. In the phone follow-up group, almost all women who did not make an interim visit to the clinic had their telephone follow-up as scheduled (99.4% [693/697]). Four women (0.6% [4/697]) could not be contacted and were classified as lost to follow-up. In the clinic follow-up group, 8.1% (58/710) did not return for their scheduled 2-week clinic visit. The difference between the two study groups in the proportion of women lost to follow-up (0.6%

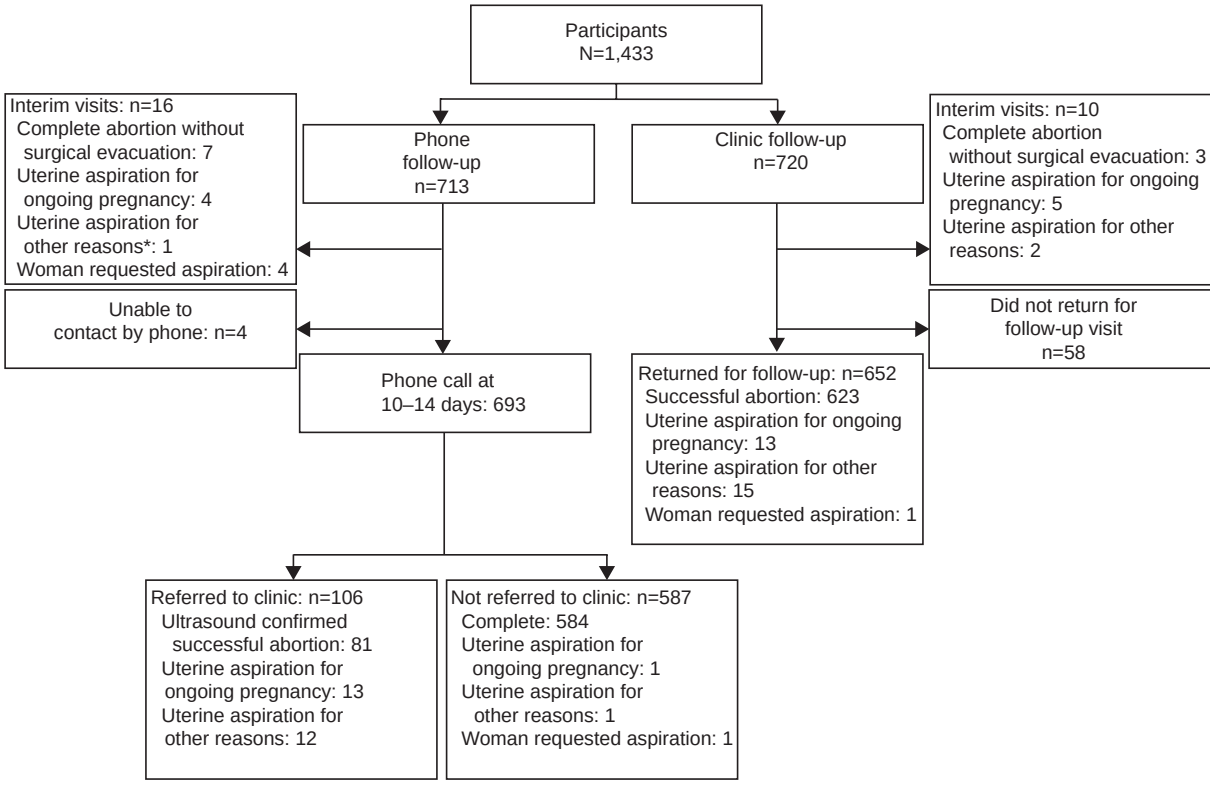

Fig. 1. Consolidated Standards of Reporting Trials (CONSORT) flow chart. *Uterine aspiration for other reasons includes evacuation for retained products of conception, incomplete or missed abortion, or heavy bleeding.

Ngoc. Phone Follow-up After Early Medical Abortion. Obstet Gyncol 2014.

compared with 8.2%) was statistically significant (RR 0.070, 95% CI 0.025–0.191).

In the clinic follow-up group, most women who returned for a scheduled appointment had a successful medical abortion confirmed by ultrasonography (95.5% [623/652]) (Fig. 1). At this visit, 13 women received a uterine aspiration for an ongoing pregnancy (1.9% [13/652]). Fifteen women underwent an aspiration for other medical reasons and one woman requested a surgical evacuation.

Most women in the phone follow-up group who were contacted were not referred to the clinic for additional medical abortion related care (84.7% [587/693]) (Fig. 1). In the phone follow-up group, only 15% of women (106/693) were referred to the clinic for additional follow-up care after their phone assessment (Fig. 1). More than one third of these women referred reported either no change or an increase in hCG from the time of mifepristone administration (39.6% [42/106]). More than half of these women reported a positive response to one of the checklist questions (56.6% [60/106]). Almost one fourth of women referred to the clinic for follow-up (25.4% [27/106]) screened negative on both tests, ie, reported a decrease in hCG from the time of mifepristone administration and answered "no" to all of the symptom checklist questions. Among the women referred without

CI, confidence interval.
Data are % (n) or % (n/N) unless otherwise specified.
* Other reasons include evacuation for retained products of conception, missed abortion, or heavy bleeding.

a positive screen test (n=27), the reported reasons for referral included ongoing bleeding (25.9% [7/27]), suspected ongoing pregnancy based on other symptoms (25.9% [7/27]), inconclusive pregnancy test (18.5% [5/27]), woman felt anxious (11.1% [3/27]), or other reasons (18.5% [5/27]) (data not shown).

The outcomes of the 106 women in the phone follow-up group who were referred to the clinic for further follow-up are presented in Figure 1. All women who were referred returned to the clinic. Most women who were referred (76.4% [81/106]) had successful medical abortions confirmed by ultrasonography. Thirteen women underwent a uterine evacuation for an ongoing pregnancy confirmed by ultrasonography. Twelve women underwent a surgical evacuation for other medical reasons. All nine cases of missed abortion were identified by no decrease or change in hCG from initial baseline at the time of the scheduled phone follow-up call.

Three women who screened negative and were not asked to return to the clinic for follow-up subsequently received additional medical abortion-related care. In one case, the woman reported in her phone interview that she had experienced more than 2 days of bleeding, had no pregnancy symptoms, and that her pregnancy test result showed a decrease in hCG level. Still, she returned to the clinic 5 days later and was diagnosed with an ongoing pregnancy. Another woman underwent an aspiration for retained products of conception when she returned to the clinic 9 days after her phone interview (study day 23). A third woman returned to the clinic 10 days after her phone call (study day 24) and requested a surgical evacuation for management of ongoing bleeding.

Most women (98.8% [685/693]) who did not make an interim visit to the clinic and were successfully contacted by phone had a functional pregnancy test result recorded at the phone follow-up. In eight cases, the test line did not appear and the result was not readable. Among women with a functional pregnancy test (n=685), the sensitivity and specificity of the pregnancy test alone for the identification of ongoing pregnancy was 92.8% and 95.7%, respectively (Table 3). The specificity was slightly lower with the use of the pregnancy test and symptom checklist (90.6%) and the screen-positive rate slightly higher (11.1% for the combined symptom checklist and pregnancy test compared with 6.1% for the pregnancy test alone).

Fourteen women in the phone follow-up group who did not make an interim visit to the clinic were diagnosed with an ongoing pregnancy at or after the follow-up visit. The results of the two follow-up screening methods are shown in Table 4. The semiquantitative pregnancy test identified 92.8% (13/14) of ongoing pregnancies. The symptom checklist alone identified 71.4% (10/14) of ongoing pregnancies. One woman with an ongoing pregnancy was not identified by either the checklist or the pregnancy test.

We also examined the estimated hCG levels reported by women on the day of their follow-up call. More than one third of women (37.8% [259/685]) reported a result of less than 25 milli-international units/mL. Most women (94.7% [649/685]) reported an hCG level of less than 2,000 milli-international units/mL when they administered the second urine pregnancy test. Most women who were diagnosed with an ongoing pregnancy on or after the follow-up appointment (n=14) reported an hCG level of 10,000 milli-international units/mL or above (85.7% [12/14]). However, two women reported lower levels of at least 500 milli-international units/mL and at least 25 milli-international units/mL, respectively.

Women in the phone follow-up group were asked about the feasibility and acceptability of the pregnancy test and symptom checklist during their follow-up phone call (Table 5). Most participants completed the checklist (98.3% [681/693]) and the semiquantitative pregnancy test (99.1% [687/693]). Almost all women

Table 3. Sensitivity and Specificity and Positive and Negative Predictive Values of Phone Follow-up With Checklist and Semiquantitative Pregnancy Test for Detection of Ongoing Pregnancy After Medical Abortion

Screen	Sensitivity	Specificity	Screen-Positive	Positive Predictive Value	Negative Predictive Value
Phone follow-up with semiquantitative pregnancy test and symptom checklist* (n=684)	92.8 (66.1–98.8)	90.6 (88.1–92.7)	11.1 (8.9–13.7)	17.1 (8.9–13.7)	99.8 (99.1–99.9)

* Excludes women who made an interim visit to the clinic (n=16) or who the clinic was unable to contact (n=4) or who had an invalid pregnancy test (n=8) or incomplete checklist (n=1).
† Excludes women who made an interim visit to the clinic (n=16) or who had an invalid test (n=8).
‡ Excludes women who made an interim visit to the clinic (n=16) or an incomplete checklist (n=1).

reported that completion of the checklist and pregnancy test was easy or very easy (checklist: 97.3% [673/691]; semiquantitative pregnancy test: 97.5% [674/691]).

Women in both groups were asked about their preference for follow-up should they require another medical abortion in the future (Table 5). In the phone follow-up group, most women (88.3% [606/686]) indicated that they preferred to complete their follow-up at home with a phone call from the health care provider. In the clinic follow-up group, fewer women (39.9% [256/242]) reported that they would opt for phone follow-up at home in the future.

DISCUSSION

Phone follow-up after medical abortion is a safe and effective alternative to clinic-based follow-up after medical abortion. The data from this study show that phone follow-up with a semiquantitative urine pregnancy test and symptom checklist could enable 85% of women to avoid a routine follow-up visit without any decrease in safety. The semiquantitative urine pregnancy test and symptom checklist accurately screened for ongoing pregnancy and resulted in fewer women being lost to follow-up.

Women reported the hCG levels measured with the semiquantitative pregnancy test at 2 weeks after mifepristone administration. A follow-up system using only a high sensitivity pregnancy test at follow-up could successfully identify all ongoing pregnancies but would still require nearly two thirds of women to return to the clinic for follow-up. In contrast, only 5.3% of women reported a value greater than 2,000 milli-international units/mL at the follow-up call, but two women diagnosed with an ongoing pregnancy reported levels of at least 500 milli-international units/mL and at least 25 milli-international units/mL. A follow-up scheme using a single low-sensitivity pregnancy test would permit fewer women to return to the clinic but could still fail to identify cases of ongoing pregnancy after medical abortion.

The semiquantitative urine pregnancy test was more successful at screening for ongoing pregnancy earlier than high- and low-sensitivity urine pregnancy tests used in previous research.[9] In the present study, women were able to confirm their abortion outcome 2 weeks after mifepristone administration with repeat semiquantitative pregnancy tests with a higher sensitivity and specificity (92.8% and 95.7%, respectively).

Table 4. Identification of Ongoing Pregnancy (n=14) by Pregnancy Test and Symptom Checklist Among Women in the Phone Follow-up Group

		Ongoing Pregnancy Identified by Semiquantitative Pregnancy Test	
Ongoing pregnancy identified by symptom checklist		Yes	No
	Yes	10	0
	No	3	1

Women in the phone follow-up group with an ongoing pregnancy diagnosed at an interim visit to the clinic (n=4) were excluded from the analysis.

Table 5. Feasibility and Acceptability of Follow-up

	Phone Follow-Up	Clinic Follow-Up
Woman completed checklist* (n=693)	98.3 (681)	—
Ease of completion of checklist (n=691)		
Very easy	12.4 (86)	—
Easy	84.7 (587)	—
Neither easy nor difficult	2.2 (115)	—
Difficult	0.4 (3)	—
Woman completed pregnancy test	99.1 (687)	—
Ease of completion of pregnancy test (n=691)		
Very easy	14.4 (100)	—
Easy	82.8 (574)	—
Neither easy nor difficult	2.5 (17)	—
Preference for future medical abortion follow-up†		
At the clinic	10.5 (72)	60.0 (385)
At home with phone follow-up	88.3 (606)	39.9 (256)
No preference	1.2 (8)	0.2 (1)

* Excludes women who made an interim visit to clinic (n=16) or were lost to follow-up (n=4).
† Phone follow-up: n=686; clinic follow-up: n=642; five women in phone follow-up group did not respond to question.

Two previous studies have also documented that the semiquantitative pregnancy test effectively detects continuing pregnancy when performed 1–2 weeks mifepristone administration.[11,12]

Although the phone follow-up failed to identify one woman who was later identified with an ongoing pregnancy, she still returned to the clinic for follow-up but was not clear about why she had come. Counseling, together with the semiquantitative pregnancy test, may help to ensure that women can safely and effectively assess their postabortion status at home and identify when they need to return.

This study used both the semiquantitative pregnancy test and a symptom checklist to help women assess their postabortion status. The semiquantitative pregnancy test was highly effective at identifying ongoing pregnancies. When used with the semiquantitative pregnancy test, the symptom checklist appears to offer no additional value for identifying cases of ongoing pregnancy. Indeed, the one case of ongoing pregnancy missed in the phone follow-up group was not detected by either the participant's self-reported pregnancy test or symptom checklist (Table 4). The results from this study confirm previous reports that symptomatic assessment of ongoing pregnancy is not highly specific.[14]

The study has several limitations. The results obtained in a single country, Vietnam, may not be generalizable to other settings. The large majority of participants reported having completed at least secondary school education; results may differ among women with lower levels of educational attainment. It is possible, although highly unlikely, that some of the participants in the phone follow-up group may have sought additional abortion care elsewhere. Given that all outcomes, including the number of ongoing pregnancies, were similar in the two randomized study groups, we feel that ascertainment of ongoing pregnancy was equally good in both groups.

Additional research should seek to further simplify service delivery, perhaps with pictorial phone-based assessment of the pregnancy test results for various settings. It might also be possible to document the downward trend in hCG earlier than 2 weeks postmifepristone. If so, this would allow for more expeditious integration of other aspects of service delivery such as provision of postabortion contraception, which also deserves greater attention. More documentation about novel service delivery modalities such as the one described in this article should contribute to international efforts to encourage task shifting in medical care. In the case of medical abortion follow-up, this could mean giving women more of the responsibility to manage their follow-up at home.

The introduction of semiquantitative tests in lieu of universal clinic-based follow-up would simplify care and potentially reduce costs for women and the health care system by providing an alternative follow-up tool to confirm the absence of an ongoing pregnancy. Such efforts may be especially beneficial in resource-poor countries, where clinics may be overcrowded and understaffed with limited access to serum hCG testing and transvaginal ultrasonography.

Accepted 2 March 2021. Published Online 14 June 2021.

Objective To provide a descriptive overview and evaluate changes in the use and outcome of abortions provided worldwide by telemedicine in the past 10 years.

Design Retrospective cohort study.

Setting Multi-country.

Population/Sample 30 344 women who completed the follow-up survey of the telemedical abortion service Women on Web from January 2009 till January 2020.

Methods Analyses of follow-up surveys, binary logistic regressions to test the association between year and outcomes.

Main outcome measures Rate of complete abortions, surgical interventions, ongoing pregnancies, blood transfusions per year, socio-economic situation, knowledge on medical abortion, acceptability of receiving service, appropriateness of method and the likelihood of recommending the service to a friend.

Results Medical abortions were provided to 81 683 women, of whom 30 344 (37.2%) completed the follow-up survey. In total, 26 076 women reported doing the medical abortion, of whom 1.5% reported an ongoing pregnancy, 10.2% a surgical intervention and 0.6% a blood transfusion. Acceptability of the service was 99%, and 59.2% of the users reported previous knowledge of medical abortion. We found a significant increase in complete abortions in 2019 (odds ratio 1.92; 95% CI 1.59–2.31) and decrease in surgical interventions (odds ratio 0.49; 95% CI 0.40–0.60) compared with 2009.

Conclusion Low follow-up rates present a limitation in analysing trends in telemedical abortion usage. However, our findings suggest that it is a highly acceptable method around the world and that there has been an increase in complete abortions by telemedical abortions and a decrease in surgical interventions in the last 10 years.

Keywords medical abortion, mifepristone, self-managed abortion, telemedicine.

Tweetable abstract In the last 10 years, there has been an increase in complete abortions and decrease in surgical interventions of telemedical abortion.

Introduction

Around 44% of pregnancies worldwide are unintended and approximately half of these result in induced abortion.[1] Restrictive laws on access to abortion services do not decrease abortion rates but increase the likeliness of abortions to be unsafe.[2] Approximately 700 million women of reproductive age live in countries with restrictive abortion laws.[3] Additional barriers to access services, irrespective of legal setting, include long-waiting lists, long-distance, lack of transport, high costs and stigma.[4] Among the 56 million abortions that were estimated to take place yearly between 2010 and 2014, 25 million (45%) were estimated to be unsafe.[5] In 2014, at least 22 800 women worldwide died as a direct result of unsafe abortion.[1]

The increased access and use of medical abortion have been described as revolutionary, because they are believed to have helped to decrease abortion-related morbidity and mortality globally.[6–8] Medical abortion with a combination of mifepristone and a prostaglandin analogue was first

© 2021 John Wiley & Sons Ltd.

developed in the 1980s.[9] Subsequently, the method has been demedicalised while maintaining high efficacy, safety and acceptability. This development included home use of misoprostol, simplified follow up and task shifting to mid-level providers and to women themselves.[10–13]

Telemedicine in terms of abortion care refers to the use of telecommunications technology by healthcare professionals, to provide information, counselling, and provision and clinical guidance of medical abortion.[14] Telemedicine has become increasingly available and is a promising solution to make abortion services more accessible, particularly for those living in rural areas and legally restricted settings.[15,16] Studies of the use of medical abortion in the first trimester through telemedicine have found it to be non-inferior to the in-clinic provision of services.[17–19] Similarly, emerging evidence is showing that medical abortion in the first trimester through telemedicine is safe, effective and an acceptable method for women.[14]

However, gaps remain in evidence on medical abortion through telemedicine, and a comprehensive overview of trends in the usage is lacking.[20] Two recent reviews on self-managed abortion identified critical areas of future research, including further evidence on physical, social and emotional experiences, and that study settings include diversity in legal restrictions, geographic and social context.[15,20] Therefore, this study aims to provide a descriptive overview and evaluate changes in the use and outcome of abortion provided by the telemedical abortion service Women on Web (WoW) in the past 10 years.

Methods

Study design

This study was a retrospective cohort study, using a quantitative approach to evaluate the changes observed over time in the use and outcome of medical abortion by analysing the data of WoW.

Study setting

WoW is a non-profit organisation, providing telemedicine services since 2006. Services include the provision of information, medical guidance and medical abortion for women living in countries with restricted access to safe abortion.[21] WoW mainly provide their services through their website.[21] Women opting for a medical abortion complete an online consultation with a medical doctor. If they are <9 or 10 weeks pregnant (depending on the country of residence) and have no contraindications, abortion pills can be sent with detailed instructions for use. Gestation is established based on women's self-reported last menstrual period. Women are advised but not required to have an ultrasound to establish gestation and confirm completion. WoW requests a donation of between 70 and 90 euros, but the service is provided on a sliding scale or for free in case of financial hardship.

Study population

A total of 81 683 women were sent medical abortion medication between 2009 and 2019. To be included in the main data analysis, women had to report that they used the medical abortion medication in the follow-up survey. Women who did not go through with the abortion and did not return follow-up surveys were excluded for data analysis.

Patient involvement

There was no patient or public involvement in the design or conduct of the study. However, the service that WoW provides is designed to address the priorities and experiences of people who access the service. Hence, the research questions were informed by the needs of people who rely on WoW to access abortion. The Medical Abortion Reporting Efficacy (MARE) guidelines were followed for reporting the main outcomes.[22] Core outcome sets were not applicable. No funding was received for this study.

Data collection

Data including the consultation and follow-up survey were self-reported through the WoW website. Data were transported to an Excel file and anonymised. Follow-up surveys were sent via e-mail 5 weeks after the shipment of medication. If needed, a reminder was sent after another 2 weeks. Similar to follow-up instruments in clinical settings, the survey consisted of 30 questions that included information on completed treatment, how the pregnancy was confirmed, perceived adverse effects, any visits or contacts for medical care, any treatment received, how information was accessed and emotions after the procedure. Although WoW has been active since 2006, we included data from the year 2009 onwards because this was the year that WoW changed its data collection system.

Measurements

Main outcomes included: rate of reported ongoing pregnancy, surgical intervention, blood transfusions per year, socio-economic situation, knowledge on medical abortion, acceptability of receiving telemedical abortion service method, appropriateness of medical abortion method and the likelihood of recommending telemedical abortion service to a friend.[14,15] Ongoing pregnancy is defined as the failure of medical abortion.[22] MARE guidelines recommend defining a medical abortion to be successful when there is a 'successful expulsion of the intrauterine pregnancy without the need for surgical intervention', i.e. a complete abortion.[22] Lastly, a blood transfusion is an adverse event that is often measured as an indication of safety.[20]

© 2021 John Wiley & Sons Ltd.

Countries were initially divided into United Nations geographic regions and sub-regions.[23] As the frequencies of evaluations and representation of countries were shown to be extremely varied, this was considered to be a misleading classification. As a result, only the ten countries where most of the medical abortion services were provided were included for an overview, as they accounted for 84.3% of the total sample, and 84.9% after applying the inclusion criteria.

Statistical analysis

Data were cleaned using Microsoft Excel and further analysed in IBM SPSS 26 (IBM, Armonk, NY, USA). Invalid or missing answers were corrected or deleted by evaluating women's comments or subsequent responses throughout the follow-up survey. If contradictory information was provided in the survey, e-mail correspondence was checked in the WoW database for the original answer. Descriptive statistical analysis was performed on demographic information and main outcomes. For questions with multiple answers, new categories were created, and variables were re-coded into binary variables in accordance with previous studies.[14,19,22,24,25] Seven age categories were created; <20, 20–24, 25–29, 30–34, 35–39, 40–44, ≥45 years based on previous literature and for the purposes of summarising the data, but age was included as a continuous variable in logistic regression analysis.[24] Follow-up surveys from Ireland and Northern Ireland were grouped, in accordance with previous research using WoW data.[24] A binary logistic regression analysis was performed to test associations further. Four regressions were run for the total sample and year, adjusted for age. The year 2009 was set as the reference category.

Results

An overview of the study population is presented in Table 1. Abortion pills were provided to 81 683 women between 2009 and 2019. A total of 30 344 (37.2%) women from 183 different countries completed the follow-up evaluation between January 2009 and December 2019, of which 26 076 (85.6%) reported that they used the abortion pills and were included in the main data analysis. In all, 4268 (14.1%) were excluded because they did not report using the abortion pills, because they decided to continue the pregnancy (n = 737, 2.4%), had a spontaneous miscarriage meanwhile (n = 1839, 6.1%), decided to use another method (n = 1040, 3.4%), realised they were not pregnant after all (n = 39, 0.1%), did not receive the medicines (n = 121 0.4%), had an ectopic pregnancy (n = 4, 0.0%) or left the question blank (n = 488, 1.6%). The ten countries with the most follow-up surveys for each United Nations geographic region were included for an overview. Of these, the ten countries with the highest frequency of follow-up surveys were: Poland (n = 11 902), Ireland and Northern Ireland (n = 3059), Thailand (n = 1422), Chile (n = 1346), South Korea (n = 1155), Brazil (n = 1121), United Arab Emirates (n = 601), Philippines (n = 565), Japan (n = 486) and Malaysia (n = 470). The incidence of missing data in the completed follow-up surveys was relatively low, ranging from 0.5 to 0.7% and was deleted from the subsequent regression analysis.

A summary of the main outcome measures is presented in Table 2. Ongoing pregnancy was reported by 1.5% (n = 404) of women while 87.9% (n = 22 926) reported a complete abortion. The overall rate of blood transfusion was 0.6% (n = 155). As a proxy of economic situation, we found that 9175 (35%) who made a donation for the service reported that it was difficult to find the money. In 8.5% of cases (n = 2223), the service was fully donated. Just over half of the women reported previous knowledge of medical abortion. A large majority of women (96.6%; n = 25 178) found medical abortion to be the appropriate method for them, and 99% (n = 25 186) found it to be acceptable to have the telemedical abortion at home with WoW support. Overall, 96.1% (n = 25 071) would recommend WoW services to other women in a similar situation.

Results from logistic regression analyses are summarised in Table 3. Year of treatment was significantly associated with all outcomes, except for knowledge about medical abortion. Models were adjusted for age, which had an odds ratio and 95% CI close or equal to 1, indicating no association for each outcome. Overall, the chance of having a complete abortion increased with time, (odds ratio 1.92; 95% CI 1.59–2.31) in 2019 versus 2009. The risk of having surgical intervention significantly decreased from 2012 onwards, with an odds ratio of 0.49 (95% CI 0.40–0.60) in 2019 versus 2009.

Discussion

Main findings

This large study including 30 344 women from 183 countries using medical abortion provided by telemedicine identified several changes in the use and outcome of medical abortion provided by WoW over 10 years. A significant association was found between the year of treatment and outcome measures. There was a significant increase in reported complete abortions, a decrease in surgical intervention, and an overall low rate of ongoing pregnancy and blood transfusions. The service was highly acceptable and medical abortion was considered an appropriate method in almost all cases. There were significant fluctuations in financial hardship but these did not show a specific trend. There was no significant change in knowledge about medical abortion over the years.

*To facilitate overview, the ten countries with the highest number of evaluations for each UN geographic regions were included.

Strengths and limitations

A key limitation is the low response rate, which appeared to decrease over time. If the likelihood of responding was related to the patient's experience and outcome, then this would be a source of bias in our results. A high loss to follow up was to be expected and is a persistent challenge within abortion research given the high level of stigma associated, and in this case also included countries with legal restrictions to access abortion services.[11,26] In other studies, the follow-up rate was improved by analysing email correspondence and phone calls; however, it was not feasible to include these because of the high number of participants and language groups.[21] There is limited information about reasons for follow-up participation; however, a previous study suggests that those who have a complication or failure are more likely to report back than in the case of a successful abortion.[11] A limitation of self-managed medical abortions is that only self-reported data are available, and in a study like ours, we cannot be sure that women follow the instructions on intervals and dosage. Hence, there is a possibility that the continuing pregnancies are due to non-adherence to the regimen. Following the advice of the WHO, women are advised to administer one mifepristone orally and after 24 hours

*In years.

administer four misoprostol sublingually for 30 minutes, and repeat with two misoprostol every 3 hours until the abortion process starts.[27] However, given that the sample was located in several different countries with varying legal restrictions in abortion access, using self-reported data is the most feasible method.[24] It was not possible to adjust for known confounders, such as gestational age, as this information was not available in our data set.[25] Although WoW limits the availability of the service to women who are <9 to 10 weeks pregnant since last menstrual period at the time they complete the online consultation, between the online consultation and the actual use of the medication, there is a variable time lag, depending on shipping time and any delay in usage after receiving them. However, the majority of the abortions in this data set are expected to have taken place in the first trimester. To our best knowledge, this study provides the largest evaluation so far of the outcome of medical abortion provided by telemedicine. Furthermore, it includes the largest sample of women doing a medical abortion in a wide range of different legal settings. Outcomes are reported in consistency with previous studies for comparability. In addition, we included outcome measures that have never been looked at before, such as financial hardship and pre-existing knowledge about medical abortion.

Interpretation

As illustrated in Table 1, all of the United Nations main geographic regions were represented, with a highly variable frequency of countries. Country representation is also likely to have been affected by language translations and the censorship of the website. When WoW was launched in 2006, it was available in Polish, English, Spanish, French and Portuguese, whereas today it is available in 24 languages.[11,21] The age distribution for the total sample is as expected and in line with a previous report of 'Abortion Worldwide 2017' by the Guttmacher Institute, showing the peak for having an abortion is often around 20–24 years of age, but also common in the early thirties in many countries.[8]

The proportion of the total sample reporting that they knew about medical abortion before using the service was 59.2% and remained almost unchanged between 2009 and 2019. Given the advancements over the past years in use and acceptability among healthcare providers, the dissemination of knowledge about medical abortion by the WHO, local women's rights organisations and other international non-governmental organisations and the media, these results suggest that many women still only learn about medical abortion once they have an unwanted pregnancy, which has also been suggested previously.[28]

Our findings concerning the outcome of the medical abortion treatment are in line with previously published research. A recent systematic review of outcomes of

medical abortion through telemedicine reported a range of 0–1.9% for continuing pregnancy, 93.8–96.4% for complete abortion, 0.9–19.3% for surgical intervention and 0–0.7% for blood transfusion.[14] Our findings are also in line with reported complete abortion rates for in-clinic medical abortion treatment.[19] The slightly higher rate in surgical interventions in our study compared with other studies might be explained by the fact that almost half of women were living in Poland and the surgical intervention rate in this study was highest in Poland (13.2%) and Brazil (17.2%). High intervention rates in Poland and Brazil have also been reported in previous studies.[29–31] It has been suggested that this is caused by differences in local clinical practices and economic incentives, rather than treatment efficacy or gestational length.[31] We found an overall increase in the rate of complete abortion and a decrease in surgical interventions between 2009 and 2019. This may be caused by a combination of factors, such as a rise of medical treatment of incomplete abortion with the administration of repeat doses of misoprostol, improved training of health professionals and increased knowledge about the medical abortion process by women, as in countries with restricted abortion laws a decrease of follow-up visits after the medical abortion is likely to result in a decrease in surgical interventions.[31,32] Previous research has found a decreasing trend in gestational age at the time of abortion in countries with liberal abortion laws, which could lead to higher efficacy.[33]

These findings are particularly pertinent and relevant in the current situation of the coronavirus disease 2019 global pandemic, where measures implemented to prevent the spread of disease have hampered access to safe abortion care. Telemedical abortion care, which has been primarily outside the medical institutions, is now being further integrated, for example, the United Kingdom has permitted telemedical abortions.[34] This further highlights the potential and feasibility of telemedicine services to provide safe abortion access worldwide during the coronavirus disease 2019 pandemic and beyond.

Conclusion

The purpose of the current study was to evaluate the use and outcome in the telemedical provision of medical abortion over the past 10 years. We identified several promising trends over the past 10 years, including increasing rates of complete abortion and a decrease in surgical interventions. As indicated by a high rate of complete abortion, high acceptability, low rate of ongoing pregnancy and complications such as bleeding needing a blood transfusion, the study adds to the growing body of research suggesting that online telemedical counselling and provision and self-managed medical abortion are safe, effective and highly acceptable methods for women around the world. The varying surgical intervention rates between the different countries suggest that local post-abortion care can be improved and further research is needed to gain a better understanding of the different local post-abortion practices, especially in countries with a higher surgical intervention rate. While being of a descriptive nature, findings also suggest that there is

an unmet need for information about medical abortion provided by telemedicine.

Disclosure of interests

HN and IO have none to declare. JW is supported by a Wellcome Institutional Strategic Support Fund award (204796/Z/16/Z) outside the submitted work and declares that publishing research benefits his career. KGD has served as an ad hoc speaker and/or member of advisory boards for Exelgyn, Campus Pharma, HRA Pharma, MSD/Merck, Bayer AG, Exeltis, Mithra, Natural Cycles, Gedeon Richter and Azanta, and her clinic has received support for clinical trials from MSD/Merk, Bayer AG, Myovant, and Removaid outside the submitted work. RG is the founder and director of Women on Web. Completed disclosure of interests forms are available to view online as supporting information.

Contribution to authorship

HN was responsible for the conception, planning, carrying out, analysing and writing up of the work. JW was responsible for analysing and editing. OI was responsible for conception, planning and editing. KGD was responsible for conception and editing. RG was responsible for the conception, planning and writing up of the work.

Details of ethics approval

Ethical approval was given by the Karolinska Institutet (Dnr 2020-05406). During the original data collection, participants gave informed consent to their data being used for research purposes. All data were completely anonymised.

Funding

No funding was received for this study.

Acknowledgements

None.

Nurse versus physician-provision of early medical abortion in Mexico: a randomized controlled non-inferiority trial

Claudia Diaz Olavarrieta,[a] Bela Ganatra,[b] Annik Sorhaindo,[c] Tahilin S Karver,[c] Armando Seuc,[b] Aremis Villalobos,[a] Sandra G García,[c] Martha Pérez,[d] Manuel Bousieguez[c] & Patricio Sanhueza[d]

Objective To examine the effectiveness, safety, and acceptability of nurse provision of early medical abortion compared to physicians at three facilities in Mexico City.

Methods We conducted a randomized non-inferiority trial on the provision of medical abortion and contraceptive counselling by physicians or nurses. The participants were pregnant women seeking abortion at a gestational duration of 70 days or less. The medical abortion regimen was 200 mg of oral mifepristone taken on-site followed by 800 µg of misoprostol self–administered buccally at home 24 hours later. Women were instructed to return to the clinic for follow-up 7–15 days later. We did an intention-to-treat analysis for risk differences between physicians' and nurses' provision for completion and the need for surgical intervention.

Findings Of 1017 eligible women, 884 women were included in the intention-to-treat analysis, 450 in the physician-provision arm and 434 in the nurse-provision arm. Women who completed medical abortion, without the need for surgical intervention, were 98.4% (443/450) for physicians' provision and 97.9% (425/434) for nurses' provision. The risk difference between the group was 0.5% (95% confidence interval, CI: −1.2% to 2.3%). There were no differences between providers for examined gestational duration or women's contraceptive method uptake. Both types of providers were rated by the women as highly acceptable.

Conclusion Nurses' provision of medical abortion is as safe, acceptable and effective as provision by physicians in this setting. Authorizing nurses to provide medical abortion can help to meet the demand for safe abortion services.

Abstracts in عربي, 中文, Français, Русский and Español at the end of each article.

Introduction

In Mexico City, early elective abortion to terminate pregnancy was legalized in April 2007.[1–3] Up to June 2013, 100 000 abortions have been provided by trained physicians in Ministry of Health hospitals and clinics.[4] In 2009, it was estimated that 13.5% (16 475/122 455) of all abortions in Mexico City were safe and legal and provided by the public sector.[5] Even though some safe and legal abortions are done in private facilities,[6] most abortions are done outside sanctioned facilities and are potentially unsafe.[7] Despite Mexico City's efforts to expand services and increase the availability of the mifepristone-misoprostol regimen for medical abortion, patient demand is outpacing service capacity. Furthermore, conscientious objections from trained physicians[8] have further restricted service capacity.

To expand the capacity of the health workforce, task-shifting has been proven to be an important strategy.[9] Evidence from low-resource settings suggests that trained, mid-level providers can administer medical abortion with similar outcomes as physicians.[10–14]

In Mexico, nurses tend to have a subordinate role compared to physicians and have traditionally been excluded from decision-making.[15] Approximately one-third of the Mexico City Ministry of Health personnel are physicians and one-third are nurses.[16] Authorizing nurses to provide medical abortion could increase the potential capacity for provision of this service and help to address increasing demand.

We aimed to assess the effectiveness, safety and acceptability of nurses' versus physicians' provision of early medical abortion in facilities of the Mexico City Ministry of Health.

Methods

We conducted a randomized controlled non-inferiority trial between November 2012 and January 2013 at two Mexico City Ministry of Health abortion clinics and one hospital. Mean numbers of both medical and surgical abortions performed weekly are 137 and 27 at the clinics and 48 at the hospital, representing 50% of legal abortion provision in Mexico City, a city of 8 851 080 people.[17]

We assumed that physicians and nurses would achieve a 95% completion rate for medical abortions, based on a previous randomized controlled trial[11] and a meta-analysis on medical abortion efficacy which found successful medical abortion rates using the mifepristone-misoprostol regimen between 91% to 96% depending on gestational duration.[18] We assumed a 5% non-inferiority margin based on cost-effectiveness and clinical differences – such as the ability of nurses and physicians to determine gestational duration, screen for early medical abortion and determine incomplete abortion.[19] We used the PASS software version 11 (NCSS, LCC, Kaysville, United States of America) to determine that a sample size of 800 (400 per arm) would be sufficient to detect non-inferiority with 90% power and a one-sided significance level of 0.025, assuming 15% loss to follow-up per arm.

The study protocol was approved by the Mexico City Ministry of Health and Mexico's National Institute of Public Health institutional review boards. Ethical approval was obtained from the World Health Organization's (WHO's) ethics review committee. We invited experts in medical abortion, nursing, ultrasound training and health systems to participate in a scientific advisory and data safety monitoring committee.

The Mexico City Ministry of Health granted temporary permission for nurses to administer medical abortion for study purposes and providers were recruited from existing Ministry of Health personnel. We only recruited physicians who had recently joined clinic staff and who had never provided medical abortion or had only previously managed medical abortion under supervision to minimize unfair comparison between physicians with previous experience and nurses with no experience.

Physicians and nurses received separately one and a half weeks of training on medical abortion management. The training was provided by a certified ultrasonographer and one of the authors. To reach a professional level of ultrasound skill,[20,21] all physicians and nurses received 20 hours of abdominal and transvaginal ultrasound training using a Hitachi SSD-3500SX console.[22] The providers were certified by experienced obstetricians to have achieved required competency. At each site, an experienced obstetrician – not part of the study – was made available for providers to consult as needed.

Women visiting the facilities for an abortion were shown to a private space and screened for eligibility by a nurse participating in the study. Women were invited to participate if they: wanted a

medical abortion, were aged 18 years or older, reported a last menstrual period of less than 70 days previously and were willing to provide contact information for follow-up. They were excluded if they had a history of allergy to mifepristone or misoprostol, chronic systemic corticosteroid use, chronic adrenal failure, coagulopathy or current therapy with anticoagulants, inherited porphyria, chronic medical conditions including pre-existing heart, severe hepatic or renal disease and severe anaemia. They were also excluded if they had previously received a medical abortion as part of the Mexico City legal abortion programme. All women were given an opportunity to ask questions before providing written consent. Participants could voluntarily withdraw from the study at any time and for any reason without change to the care they received. Before randomization, enrolled participants provided contact and sociodemographic information via a structured interview.

We generated a list of consecutive identification numbers and randomly allocated a physician or a nurse that should provide medical abortion to each number using R 3.1.2 software for Windows (R Foundation for Statistical Computing, Vienna, Austria). As women were recruited, they were assigned an identification number. Allocation was concealed in a sealed envelope, which was only opened once the participant was considered eligible and consented to enrol.

All enrolled women received clinical care and medical abortion at their first visit. This included a vaginal and pelvic exam, and an abdominal ultrasound to confirm intrauterine pregnancy and gestational duration. According to Mexico City Ministry of Health guidelines, providers must confirm gestational duration via abdominal ultrasound. Providers followed the guidelines' standard of care regarding ultrasound image interpretation.[22] Women with an inserted intrauterine device (IUD) that could not be removed before administering mifepristone were excluded from the study. If providers could not confirm gestational duration or intrauterine pregnancy, women were referred to another facility for a β-hCG (human chorionic gonadotropin) fraction test. Since we could not ensure their return to the study, they were excluded.

We used the medical abortion regimen recommended by Mexico City Ministry of Health,[23] which differs from WHO's recommendation.[24] Pregnant women with a gestational duration determined as less than 70 days were given 200 mg of oral mifepristone under supervision followed by instructions to self–administer four tablets of misoprostol (200 µg each) buccally at home, 24 hours later.

All women received misoprostol, instructions for administration and contraceptive method counselling from their assigned provider. The study followed the standard of care in counselling and providers offered a mix of different contraceptive methods. Participants were also given an instruction card for contacting a study representative in the event of any questions or concerns and a pamphlet explaining expected side-effects and symptoms that may warrant prompt medical attention – such as

heavy bleeding, fever, headache and abnormal vaginal discharge. Women were instructed to return to the clinic for follow-up 7–15 days later.

At the follow-up visit, providers confirmed completed abortion based on a clinical symptoms checklist, bleeding history and ultrasound results. If the provider determined that the woman had an ongoing pregnancy or incomplete abortion –such as continued bleeding, tissue residue or cramps – participants were offered an additional 800 µg of misoprostol administered at the clinic or hospital, according to Mexico City Ministry of Health practice.[25] If women requested a manual vacuum aspiration or the provider felt it was warranted – due to remaining fetal tissue, persistent gestational sac or continuation of pregnancy – it was provided on-site by an obstetrician who was not part of the study. Participants who chose to take an additional 800 µg of misoprostol were instructed to return in 7–15 days. If these women still did not have a complete abortion at the second follow-up, a vacuum aspiration was performed on-site, that day.

During follow-up, providers asked participants if they had chosen a post-abortion contraceptive method based on the previous counselling. If available, the method was provided; if not, information on where to obtain it was given.

All adverse and serious adverse events were recorded by providers using a review form that had been reviewed by the scientific advisory and data safety monitoring committee. Events were recorded and analysed to allow for safety reporting.

To assess if there were any significant differences between the two study arms, student's *t*-tests and χ^2 tests for two independent samples were used. Non-inferiority was tested using intention-to-treat and per-protocol analysis. A 95% confidence interval (CI) for the difference between the physicians' and nurses' groups in completed abortion rates between study arms was computed and non-inferiority was accepted if this interval lay completely on the left of the non-inferiority 5% margin, that is, if the difference falls within the predefined equivalence range of 5%. Homogeneity of the three study sites was assessed using the Higgins & Thompson index *H*. Stratified analysis for potential site effects was not conducted because the complete abortion rate at one site was 100% for both study groups.

We conducted a sensitivity analysis to test two different outcome scenarios for women lost to follow-up. Based on observed success rates, we assumed a 100% success rate for women lost to follow-up in both scenarios in the physicians' group. For the nurses' group we assumed 78.6% and 71.4% success rates in the first and second scenario, respectively.

Once a complete abortion was confirmed and women were given a contraceptive method or information, a study coordinator not linked to clinical care administered a satisfaction survey that the participants completed on-site. An acceptability scale was constructed using responses to the 14 questions. Some answers were binary – yes or no – and others were categorical – e.g. range of satisfaction and expectation levels. We scored the responses for each question using a range between 0 to 1, where the responses with the lowest acceptability received 0 points and responses with the highest acceptability received 1. The points generated for each question were summed to create a provider acceptability score per participant ranging from 0–14. The mean overall acceptability scores for each provider group were compared to determine women's satisfaction.

All analyses were conducted using SPSS version 18.0 (SPSS Inc., Chicago, USA).[26]

Table 3. **Outcomes of medical abortion provided by nurses or physicians in Mexico City, 2012–2013**

Analysis	Physicians' group	Nurses' group	Difference, % (95% CI)
Intention-to-treat			
No. of women	450	434	–

GBP-PET00653

Results

Fifteen providers, seven nurses and eight physicians, participated in the study. There was one male nurse and five male physicians. There was no significant difference in homogeneity between the different study sites ($P = 0.07$).

Of 1028 women approached, eleven were excluded for not meeting eligibility criteria (Fig. 1). Of the eligible women, 503 were randomized to receive medical abortion from nurses and 514 women from physicians. Women in both groups had similar characteristics (Table 1).

In the nurses' group we excluded 12 women who required a β-hCG fraction test to confirm pregnancy and 28 women who had gestational durations longer than 70 days based on abdominal ultrasound examination. One woman was excluded because she changed her mind after randomization and requested manual vacuum aspiration. In the physicians' group, we excluded two women who decided to continue with the pregnancy, 11 who required a β-hCG fraction test and 28 who had gestational durations longer than 70 days based on abdominal ultrasound examination. One woman was excluded when opting for manual vacuum aspiration after randomization and one woman was not pregnant. The number of women excluded and reasons for exclusion were similar in both groups (Fig. 1).

Forty-nine women did not return for follow-up. Attrition was similar in both groups; 6.1% (28) for nurses and 4.5% (21) for physicians (Fig. 1). The characteristics of the women lost to follow-up were similar to those who remained; however, they were more likely to be married or cohabiting (46.9% [23/49] versus 39.5% [349/884]) and be employed (42.9% [21/49] versus 31.8% [281/884]). For the analyses, 434 women remained in the nurses' group and 450 in the physicians' group.

Women had on average a gestational duration of 53 days by last menstrual period and 50 days by ultrasound examination. There was no significant difference in gestational duration assessed by last menstrual period or ultrasound between providers (Table 2).

Successful medical abortions, without need for surgical intervention, were 97.9% (425/434) for nurses and 98.4% (443/450) for physicians – a result within our 5% a priori non-inferiority limit (Table 3). In 14 cases, abortion was completed after manual vacuum aspiration – nine in the nurses' group and five in the physicians' group. Four of the women who eventually underwent manual vacuum aspiration had initially received an additional buccal misoprostol dose at home, but at the second follow-up three still had embryonic tissue and one persistent gestational sac. The analysis also showed that providers administered an additional misoprostol dose in 68 cases. Nurses were sig-

nificantly more likely than physicians to administer an extra dose (45 doses versus 23 doses; $P < 0.05$). At one facility, nurses and physicians were more likely to administer an extra dose compared with providers at the other facilities (43 doses in the nurses' group $P < 0.05$; 17 doses in the physicians' group $P = 0.056$).

We conducted pre-protocol analysis excluding women with the following protocol violations: taking misoprostol later than 24 hours following mifepristone administration, returning to the clinic in less than 7 days or later than 15 days after their first visit or women not having an ultrasound examination. For the analysis, 395 women remained in the nurses' group and 406 women in the physicians' group (Fig. 1). The results of successful medical abortion were similar to the intention-to-treat analysis (97.7% [386/395] for nurses and 98.8% [401/406] for physicians; Table 3).

We conducted a sensitivity analysis to assess the robustness of our conclusion of non-inferiority among nurses providing medical abortion in relation to physicians.[27] We calculated two scenarios where we hypothesized the outcome for the women lost to follow-up and our results demonstrated that nurses were not inferior to physicians when providing medical abortion (Table 4).

There was no difference between physicians and nurses in post-abortion contraceptive counselling and method chosen by the women. Eight-hundred and seventy-four (98.9%) women requested and were prescribed a method and 97.0% (848/874) of these women left the clinic with at least one method (Table 5). Physicians were more likely to prescribe IUDs (312 in the physicians' group versus 267 in the nurses' group) and women seen by physicians were more likely to leave with an IUD (135 in physicians' group versus 100 in nurses' group). Women treated by nurses were more likely to leave with condoms and emergency contraception, 46 in physicians' group versus 80 in nurses' group and 0 in physicians' group versus 9 in nurses' group, respectively.

Consultation with an experienced obstetrician was done in 11 cases. Nurses consulted in six cases for administering an additional misoprostol dose, in two cases for manual vacuum aspiration and one case for a persistent gestational sac. Physicians consulted the obstetrician for interpreting ultrasound results in two cases.

On average, participants reported an acceptability score of 13.6/14 for both providers. Women in both groups reported feeling comfortable with their assigned provider (99.0% [430/434] for nurses and 98.7% [444/450] for physicians). Most women (685/884) treated by either provider reported feeling very satisfied with their service (Table 6).

Only one serious adverse event was recorded; a 26-year old woman at eight weeks' gestation randomized to receive care from a physician was hospitalized for 38 hours due to bleeding following misoprostol administration and underwent a surgical abortion under general anaesthesia without further complications.

Discussion

Our findings suggest that nurses were equal to physicians when providing medical abortion. Nurses were trained in ultrasound techniques, interpreted results and successfully managed early medical abortion up to 70 days of gestational duration as effectively as physicians. Compared with another study[11] on the same subject, our study had higher gestational duration limits and women self-administered misoprostol at home.

The efficacy of medical abortion does not depend on who provides the medication, but on providers' ability to correctly determine gestational duration and exclude women over 70 days' gestation. Effective counselling for misoprostol administration at home, appropriate responses to normal and adverse effects and correct clinical decisions during follow-up are also needed. In our study, nurses were twice as likely to prescribe an additional misoprostol dose. This may reflect differences in judgment of abortion completion. Nurses may have been less confident of their skills and therefore may have depended more on ultrasound findings of persistent tissue, which is not always a sign of an incomplete abortion.[28] At one facility, both nurses and physicians were more likely to administer an extra dose compared with providers at the other facilities. This might be explained by the higher caseload at that facility. In high-volume settings, where time is often limited, providers may give an additional misoprostol dose to be on the safe side and to use this dose as a substitute for spending more time obtaining a detailed history to assess abortion completion.

The need for an adequate learning curve for new medical abortion providers to build confidence is documented and should be given careful consideration when translating these research findings to task-shifting in programme settings.[29]

The Mexico City Ministry of Health's guidelines mandate the use of ultrasound to determine gestational duration. While not an explicit objective determination, our findings suggest that where ultrasound is used for pregnancy dating and assessing abortion completion, nurses can manage this skill as well as physicians. These findings support the feasibility of task shifting in Mexico City.

Participants rated the medical abortion services by physicians and nurses as highly acceptable. Moreover, both types of providers were equally effective in offering post-abortion contraceptive counselling and prescribing a method. We hypothesize that differences in methods provided is due to the fact that physicians, and not nurses, routinely fit IUDs. It is possible that nurses felt less confident counselling women about IUDs. In this setting, nurses are typically responsible for providing women with condoms and emergency contraception. Familiarity with these methods is thus a potential explanation for this difference in prescribing behaviour. Because long-acting contraceptive methods such as IUD's are more effective in reducing the likelihood of repeat unplanned pregnancy, nurses should be trained to insert them as part of routine medical care.[30,31]

A study limitation is that both types of providers practiced in the same facilities. The ethics committee of the Mexico City Ministry of Health required nurses to practice in the same facilities as physicians and would not allow the research team to alter service delivery by separating them. However, we took the necessary steps to reduce potential contamination and limited interaction by allocating different examination rooms for each provider type. This prevented them from observing or consulting with each other, although we understand this would not have prevented them from conversing in other locations. We believe these interactions would have been infrequent

Table 6. **Acceptability survey of women undergoing medical abortion provided by nurses or physicians in Mexico City, 2012–2013**

Question[a]	No. (%)		
	Physicians' group (*n* = 450)	Nurses' group (*n* = 434)	Total (*n* = 884)
Did the provider explain the procedure in a clear and easy way?			
Yes	448 (99.6)	434 (100.0)	882 (99.8)
No	2 (0.4)	0 (0.0)	2 (0.2)
Did the provider give you time to ask questions about the procedure?			
Yes	449 (99.8)	431 (99.3)	880 (99.5)
No	1 (0.2)	3 (0.7)	4 (0.5)
Did the provider discuss the symptoms you may experience during the procedure?			
Yes	447 (99.3)	433 (99.8)	880 (99.5)
No	3 (0.7)	1 (0.2)	4 (0.5)
Did the provider discuss the warning signs that may occur during the procedure?			
Yes	447 (99.3)	433 (99.8)	880 (99.5)
No	3 (0.7)	1 (0.2)	4 (0.5)
Did the provider discuss the return of fertility after the medical abortion procedure?			
Yes	395 (87.8)	394 (90.8)	789 (89.3)
No	55 (12.2)	40 (9.2)	95 (10.7)
Did the provider take action to manage your pain?			
Yes	449 (99.8)	434 (100.0)	883 (99.9)
No	1 (0.2)	0 (0.0)	1 (0.1)
Could the provider have done more to control your pain?			
Could have done more	53 (11.8)	43 (9.9)	96 (10.9)
Did enough	366 (81.3)	348 (80.2)	714 (80.8)
I did not experience pain during the procedure	31 (6.9)	43 (9.9)	74 (8.4)
Did you have confidence in the technical skills of the provider			
Yes	446 (99.1)	427 (98.4)	873 (98.8)
Sometimes	4 (0.9)	4 (0.9)	8 (0.9)
No	0 (0.0)	3 (0.7)	3 (0.3)
Did the provider make you feel comfortable?			
Yes	444 (98.7)	430 (99.1)	874 (98.9)
Sometimes	6 (1.3)	4 (0.9)	10 (1.1)
How satisfied are you with the provider?			
Very satisfied	342 (76.0)	343 (79.0)	685 (77.5)
Satisfied	106 (23.6)	90 (20.7)	196 (22.2)
Dissatisfied	1 (0.2)	1 (0.2)	2 (0.2)
No opinion	1 (0.2)	0 (0.0)	1 (0.1)
Would you recommend your type of provider to a friend if she needed the same procedure?			
Yes	444 (98.7)	427 (98.4)	871 (98.5)
Maybe	5 (1.1)	7 (1.6)	12 (1.4)
No	1 (0.2)	0 (0.0)	1 (0.1)
How was the medical care you received from the provider in this health centre or hospital?			
Better than you expected	431 (95.8)	408 (94.0)	839 (94.9)
As you expected	19 (4.2)	25 (5.8)	44 (5.0)
Do not know	0 (0.0)	1 (0.2)	1 (0.1)

[a] Information regarding type of contraceptive methods prescribed and taken is presented in Table 5.
Note: For some questions the percentage does not add up to 100 due to rounding

GBP-PET00656

and would not have affected the results. Instead, keeping the providers in the same facilities might have reduced the confounding factors, because different facilities could have had different characteristics – such as availability and type of equipment and operating procedures. Further research should investigate nurses' ability to provide medical abortion in an environment where a back-up physician may not be available.

Our study found that nurses can manage medical abortion care safely, effectively and with a high degree of patient acceptability, which is consistent with the systematic review on non-physician provision of abortion care.[32] Enabling nurses to manage medical abortion in public health facilities or in rural areas, where there is often unmet need and less infrastructure,[33,34] may address the high demand for safe abortion in Mexico. ■

ملخص

تقديم خدمات الإجهاض الطبي المبكر في المكسيك بواسطة الممرضات مقابل الأطباء: تجربة غير دونية في بيئة خاضعة للمراقبة على نحو عشوائي

الغرض دراسة فعالية ومأمونية ومقبولية تقديم خدمات الإجهاض الطبي المبكر بواسطة الممرضات مقارنة بالأطباء في ثلاثة مرافق في مكسيكو سيتي.

الطريقة أجرينا تجربة غير دونية عشوائية بشأن تقديم خدمات الإجهاض الطبي والاستشارات حول وسائل منع الحمل بواسطة الأطباء أو الممرضات. وكانت المشاركات نساءً حوامل يلتمسن الإجهاض في مدة حملهن التي بلغت 70 يوماً أو أقل. وكان نظام الإجهاض الطبي يتكون من 200 ملغم من ميفيبريستون الفموي الذي يتم تناوله في المرفق ثم 800 ميكروغرام من ميزوبروستول الذي تتناوله المشاركة في الدراسة بنفسها عن طريق الفم في المنزل بعدها بأربع وعشرين ساعة. وتم إرشاد النساء إلى العودة إلى العيادة للمتابعة لمدة تتراوح من 7 إلى 15 يوماً بعدها. وأجرينا تحليل نية العلاج لفروق الاختطار بين تقديم هذه الخدمات بواسطة الأطباء والممرضات بخصوص الاستكمال والحاجة إلى التدخل الجراحي.

النتائج تم إدراج 884 امرأة، من أصل 1017 امرأة مؤهلة، في تحليل نية العلاج وإدراج 450 امرأة في مجموعة تقديم هذه الخدمات بواسطة الأطباء و434 امرأة في مجموعة تقديم هذه الخدمات بواسطة الممرضات. وكانت نسبة النساء اللاتي استكملن الإجهاض الطبي، دون الحاجة إلى التدخل الجراحي 98.4 ٪ (443/450 امرأة) عند تقديم هذه الخدمات بواسطة الأطباء و97.9 ٪ (425/434 امرأة) عند تقديم هذه الخدمات بواسطة الممرضات. وكان فرق الاختطار بين المجموعة 0.5 ٪ (فاصل الثقة 95 ٪: من 1.2 – ٪ إلى 2.3 ٪). ولم توجد فروق بين مقدمي هذه الخدمات بالنسبة لمدة الحمل التي تم دراستها أو استعمال وسائل منع الحمل لدى النساء. وقيّمت النساء كلا نوعي مقدمي هذه الخدمات بوصفهما مقبولين بدرجة عالية.

الاستنتاج تقديم خدمات الإجهاض الطبي بواسطة الممرضات مأمون ومقبول وفعال بنفس قدر مأمونية ومقبولية وفعالية تقديم هذه الخدمات بواسطة الأطباء في هذه البيئة. ومن الممكن أن يساعد السماح للممرضات بتقديم خدمات الإجهاض الطبي في تلبية الطلب على خدمات الإجهاض المأمونة.

摘要

墨西哥护士与医生提供早期药物堕胎对比：随机对照非劣效性试验

目的 对比调查墨西哥城三个医疗设施的护士和医生提供的早期医疗堕胎服务的有效性、安全性和可接受性。

方法 我们对医生或护士提供的药物堕胎和避孕咨询服务进行了随机非劣效试验。参与者是寻求堕胎的 70 天或更短妊娠期孕妇。药物堕胎方案是现场服用 200 毫克口服米非司酮，接着是 24 小时之后在家口服 800 微克的米索前列醇。指导孕妇在后面的 7 – 15 天后回到医院接受检查。我们对医生和护士提供的完成堕胎服务之间的风险差异和外科干预的必要性执行意向性治疗分析。

结果 在 1017 名合格的女性中，有 884 名女性参与意向性治疗分析，其中医生服务组有 450 名，护士服务组有 434 名。完成药物堕胎且无需手术治疗的女性，医生服务组占 98.4%（443/450），护士服务组占 97.9%（425/434）。组之间的风险差异为 0.5%（95% 置信区间：-1.2% 至 2.3%）。经调查的妊娠期持续时间或使用避孕用具方法的提供者之间没有差别。将这两种类型的提供者均被女性评为高度可接受。

结论 在此设置中，护士和医生提供的药物堕胎服务具有同样的安全性、可接受性和有效性。授权护士提供药物堕胎服务有助于满足安全堕胎服务的需求。

Résumé

Comparaison de l'avortement médical précoce pratiqué par un infirmier et par un médecin au Mexique: un essai de non-infériorité randomisé contrôlé

Objectif Examiner l'efficacité, la sécurité et l'acceptabilité de l'avortement médical précoce pratiqué par un(e) infirmier(ière) par rapport au même acte réalisé par un médecin dans trois établissements de la ville de Mexico.

Méthodes Nous avons mené un essai de non-infériorité randomisé sur l'avortement médical et le conseil en matière de contraception pratiqués par des médecins ou des infirmiers. Les participantes étaient des femmes enceintes souhaitant avorter à un terme de grossesse de 70 jours ou moins. Le protocole de l'avortement médical était de 200 mg de mifépristone administrés sur place par voie orale, suivis de 800 µg de misoprostol auto-administrés par voie orale à la maison 24 heures plus tard. Les femmes avaient reçu comme consigne de revenir à la clinique pour y être suivies 7 à 15 jours plus tard. Nous avons effectué une analyse en intention de traiter pour les différences de risque entre l'avortement médical pratiqué par les médecins et par les infirmiers et le besoin d'une intervention chirurgicale.

Résultats Parmi les 1 017 femmes éligibles, 884 femmes étaient incluses dans l'analyse en intention de traiter, 450 dans l'acte d'avortement pratiqué par un médecin et 434 dans l'acte d'avortement pratiqué par un(e) infirmier(ière). Les femmes qui ont subi un avortement médical sans avoir eu besoin d'une intervention chirurgicale étaient de 98,4% (443/450) pour l'avortement pratiqué par un médecin et de 97,9% (425/434) pour l'avortement pratiqué par un(e) infirmier(ière). La différence de risque entre les groupes était de 0,5% (intervalle de confiance à 95%: de 1,2% à 2,3%). Il n'y avait pas de différence entre les professionnels de santé pour les termes de la grossesse examinés ou la prise de méthode contraceptive des femmes. Par ailleurs, les femmes acceptaient complètement les deux types de professionnels de santé.

Conclusion Dans ce contexte, l'avortement médical pratiqué par les infirmiers est aussi sûr, acceptable et efficace que celui pratiqué par les médecins. Autoriser les infirmiers à pratiquer l'avortement médical peut aider à répondre à la demande en matière de services d'avortement sécurisés.

Резюме

Выполнение раннего медикаментозного аборта фельдшерами и акушерами в Мексике: рандомизированное контролируемое исследование

Цель Изучить эффективность, безопасность и переносимость раннего медикаментозного аборта, выполняемого фельдшерами в сравнении с акушерами, в трех учреждениях Мехико.

Методы Было проведено рандомизированное исследование медикаментозных абортов и консультаций по контрацепции, выполняемых и предоставляемых фельдшерами на предмет их не меньшей эффективности по сравнению с выполнением данных абортов акушерами. В исследовании принимали участие беременные женщины, желающие сделать аборт на сроке беременности до 70 дней. Медикаментозный аборт заключался в приеме в исследовательском центре 200 мг перорального мифепристона с последующим приемом дома 800 мкг буккального мизопростола через 24 часа. Женщины были проинформированы о необходимости посещения клиники через 7-15 дней для проведения последующего наблюдения. Был проведен статистический анализ всех рандомизированных пациентов для определения разности рисков проведения медикаментозного аборта акушерами в сравнении с фельдшерами и необходимости хирургического вмешательства.

Результаты Из 1017 удовлетворяющих критериям включения женщин 884 были включены в статистический анализ, 450 – в группу выполнения аборта акушерами и 434 – в группу выполнения аборта фельдшерами. Согласно результатам исследования 98,4% (443/450) составляли женщины, которым медикаментозный аборт был выполнен акушерами без необходимости проведения хирургического вмешательства, и 97,9% (425/434) – женщины, которым медикаментозный аборт был выполнен фельдшерами. Разность рисков между группами составляла 0,5% (95%-ный доверительный интервал: −1,2-2,3%). Не были выявлены различия между исполнителями абортов в исследованных сроках беременности или методах контрацепции женщин. Оба типа исполнителей абортов были оценены женщинами как "в высшей степени приемлемыми".

Вывод В данных условиях медикаментозный аборт, выполненный фельдшерами, является столь же безопасным, допустимым и эффективным, как и аборт, выполненный акушерами. Допуск фельдшеров к выполнению медикаментозных абортов может помочь удовлетворить потребности в услугах по безопасному проведению абортов.

Resumen

Enfermeros frente a médicos en la asistencia en los abortos con medicamentos tempranos en México: un ensayo de no inferioridad controlado aleatorio

Objetivo Examinar la eficacia, seguridad y aceptabilidad de la actuación de los enfermeros en los abortos con medicamentos en fases tempranas de la gestación en tres centros de Ciudad de México en comparación con la actuación los médicos.

Métodos Se llevó a cabo un ensayo de no inferioridad aleatorio sobre la realización de abortos médicos y asesoramiento anticonceptivo por parte de médicos o enfermeros. Las participantes fueron mujeres embarazadas que buscaban interrumpir una gestación de 70 días o menos. El régimen para el aborto con medicamentos consistió en 200 mg de mifepristona por vía oral, administrados en el centro, seguidos de 800 µg de misoprostol autoadministrados por vía oral en casa 24 horas más tarde. Se indicó a las mujeres que acudieran a la clínica para realizar un seguimiento entre 7 y 15 días más tarde. Se realizó un análisis por intención de tratar de las diferencias de riesgo entre la asistencia de los médicos y los enfermeros para el término y la necesidad de una intervención quirúrgica.

Resultados De 1017 mujeres elegibles, se incluyeron 884 en el análisis por intención de tratar, 450 en el brazo atendido por médicos y 434 en el grupo atendido por enfermeros. De las mujeres que se sometieron al aborto con medicamentos, el 98,4 % (443/450) de las atendidas por

GBP-PET00658

médicos y el 97,9 % (425/434) de las atendidas por enfermeras no requirieron ninguna intervención quirúrgica. La diferencia de riesgo entre el grupo fue de 0,5 % (intervalo de confianza del 95 %: −1,2 % al 2,3 %). No hubo diferencias entre los proveedores para la duración de la gestación examinada o método anticonceptivo de las mujeres. Las mujeres calificaron ambos proveedores como muy aceptables.

Conclusión Los enfermeros son tan seguros, aceptables y eficaces como los médicos a la hora de asistir un aborto con medicamentos. Autorizar a las enfermeras a realizar abortos con medicamentos puede ayudar a satisfacer la demanda de servicios para un aborto seguro.

ABSTRACT

Objective: To evaluate the experience of women receiving mifepristone–misoprostol for early induced abortion in public sector facilities in the Federal District of Mexico City. *Methods:* An open-label prospective study was conducted with 1000 pregnant women who sought induced abortion with a pregnancy of up to 63 days of gestation, as measured from the date of their last menstrual period. The study was conducted in three public sector healthcare facilities: two secondary level hospitals and one primary care clinic. Women ingested 200 mg mifepristone on day 1, followed by 800 μg buccal misoprostol 24 hours later, and they returned for follow-up on day 8. The primary outcome was complete abortion without recourse to surgical intervention. *Results:* A total of 971 women received mifepristone–misoprostol and were included in the analysis for efficacy of treatment. The overall efficacy of the combined medical abortion regimen studied was 97.3% (n = 945); the success rate did not vary significantly by gestational age (95.9%–100%; $P = 0.449$). Most women (n = 922, 95.0%) had a successful induced abortion with only one dose of misoprostol. *Conclusion:* The combined mifepristone and buccal misoprostol regimen was found to be highly effective and acceptable among Mexican women. www.ClinicalTrials.gov: NCT00386282.

1. Introduction

Elective induced abortion during the first 12 weeks of pregnancy was legalized in April 2007 in the Federal District of Mexico. The new law prompted immediate action from the Secretariat of Health of Mexico City (SSDF) to provide legal induced abortion services in its facilities. Affiliated hospitals relied on dilatation and curettage (D&C) as the primary method of induced abortion, since obstetrician/gynecologists and general surgeons were already skilled in the procedure. The Secretariat recognized the potential of medical abortion technology to help meet the large demand for induced abortion services. To reduce the burden on the limited resources available for surgery, the SSDF started integrating medical methods of induced abortion. As of August 5, 2013, medical abortion accounted for 69% of elective induced abortions in the Secretariat system [1].

Combined regimens of mifepristone and misoprostol remain the preferred method of medical abortion [2–5], but as mifepristone was not registered or available for distribution in Mexico in 2007, a misoprostol-only regimen was introduced initially.

The present article describes an open-label study of mifepristone–misoprostol medical abortion in SSDF facilities in Mexico City, designed to evaluate the efficacy, safety, and acceptability in this setting; to garner data that could be used for local registration of a 200-mg mifepristone product; and to provide training, access, and experience to healthcare providers with the best known medical method of induced abortion before large-scale introduction occurred.

The primary objective was to evaluate the effectiveness of the regimen of 200 mg mifepristone followed by 800 μg buccal misoprostol for induced abortion of pregnancies of up to 63 days of gestation in women seeking induced abortions at SSDF facilities. The efficacy and safety of this medical abortion regimen have been documented in clinical trials and retrospective studies involving over 12 000 women [3,4,6–8]. Moreover, this regimen is the one most commonly used in the USA and is recognized by several health service delivery organizations and international guidance bodies including the National Abortion Federation [9], Planned Parenthood Federation of America (K. Shea, personal communication, May 16, 2012), the Royal College of Obstetricians and Gynaecologists [10], and WHO [5], among others. It was expected

that the transition for clinical staff to this regimen would be simple as they were already employing an 800-μg buccal misoprostol-only regimen prior to study implementation.

2. Materials and methods

This open-label prospective study evaluated a combined regimen of 200 mg mifepristone followed by 800 μg buccal misoprostol in women with pregnancies of up to 63 days of gestation, as measured from the date of their last menstrual period. The study was conducted between September 28, 2010 and May 31, 2011 in three SSDF public sector healthcare facilities in Mexico City: two secondary level hospitals (Hospital General Enrique Cabrera and Hospital Materno-Infantil Inguarán) and one primary care clinic (Beatriz Velasco de Alemán). The protocol was approved by the Ethics, Biosecurity, and Research Commission of the Secretariat of Health of Mexico City and the Federal Commission for Protection against Sanitary Risks, the national drug regulatory agency.

Women were enrolled in the present study if they were interested in and eligible for medical abortion established in accordance with clinical evaluation and ultrasound exam, if they were willing to undergo surgical completion of abortion if needed, if they were willing to provide an address and/or telephone number for follow-up purposes, if they had access to a telephone and transport in case of an emergency, and if they consented to comply with the study procedures and visit schedule. Exclusion criteria followed labeled contraindications for mifepristone and misoprostol products. Gestational age was assessed from the date of the woman's last menstrual period, clinical evaluation, and ultrasound.

On day 1, participants swallowed one tablet of 200 mg mifepristone (Miffee; Linepharma, France) in the study center. Women were given 800 μg misoprostol (Cytotec; Pfizer, USA) to administer buccally at home 24 to 48 hours after mifepristone ingestion. They were instructed to place two pills in each cheek pouch and hold them in place, swallowing any remaining fragments after 30 minutes. All women were also given four 500-mg tablets of acetaminophen to take for pain as needed; providers were free to prescribe or recommend other medications at their discretion or if the participant requested additional analgesia. Women were advised to call the study team in case of concerns related to their induced abortion at any time. Participants were asked to return to the health center 8 days after study enrollment for a clinical exam and ultrasound as is standard care to determine the status of the abortion. Women with continuing pregnancies underwent suction aspiration. Participants with nonviable pregnancies, such as persistent gestational sac, retained products of conception or bleeding, were offered a second dose of misoprostol, suction aspiration, or expectant management and were scheduled to return a week later for extended follow-up. Study participants who presented again with a persistent nonviable pregnancy at the extended follow-up visit underwent surgical completion. Suction evacuation was performed if the provider deemed it medically necessary, such as for problematic bleeding, or at the woman's request. Women completed an exit interview prior to study discharge, to provide data on adverse effects and treatment acceptability. They rated their experience of pain during treatment using a visual seven-point Likert scale [11] that depicted a series of faces ranging from sad to neutral to happy. Study staff explained to women that each face represented a grade of pain severity, with the happiest face representing no pain and the saddest face representing the worst pain imaginable. The primary outcome of the study was success of the procedure as defined by complete abortion without recourse to surgical intervention for any reason. In addition, secondary outcomes included adverse effects experienced and method acceptability.

The sample size was calculated based on the published efficacy of 96% of the study regimen [9]. A comparable success rate was expected and thus it was determined that a sample of 500 participants would suffice to document 95% efficacy with a 95% confidence interval of ± 2%. The sample size was increased to account for loss to follow-up (estimated at 15%) and heterogeneity in research sites, personnel, and patient populations. Frequencies and means (with standard deviations) were calculated using SPSS 19.0 (IBM, Armonk, NY, USA) and were evaluated by intention-to-treat analysis. Treatment adherence and abortion status were ascertained at follow-up in the study center or by telephone.

3. Results

One thousand women were enrolled in the study (Table 1). Twenty-nine (2.9%) women did not return for their follow-up visits and could not be reached by telephone by study personnel. Thus, 971 participants were followed up and their results were analyzed for efficacy. Two women were mistakenly enrolled with pregnancies of more than 63 days of gestation as measured from the date of their last menstrual period. In accordance with the intention-to-treat analysis, their outcomes (each had a successful induced abortion with study medications alone) were included in the analysis. The overall efficacy of the combined medical abortion regimen studied was 97.3% (n = 945); the success rate did not vary significantly by gestational age (95.9%–100%; $P = 0.449$) (Table 2). Most women (94.9%, n = 922) had a successful induced abortion with only one dose of misoprostol. There were a total of 26 surgical evacuations (2.7%); the reported reason for the majority of surgical evacuations was bleeding (n = 16, 1.7%). Few women experienced continuing pregnancy (n = 6, 0.6%) or persistent sac (n = 2, 0.2%); an additional two women (0.2%) received surgical intervention for pain.

A total of 858 (88.5%) women reported adverse effects (Fig. 1). Diarrhea and fever/chills were the most commonly reported adverse effects, followed by nausea and vomiting. Fever/chills (n = 86, 8.9%) and diarrhea (n = 76, 7.8%) were most commonly reported by participants as severe. The mean pain score reported was 5.1 (range 1–7).

Of the women who took the study regimen, 38 (3.8%) placed telephone calls to the study team during their participation in the study; of those, the vast majority (n = 34, 89.5%) called only once. Two women (0.2%) made unscheduled visits to the study centers. Seventeen study participants (1.7%) visited other health facilities, primarily for bleeding or pain or a combination of the two (n = 13), followed by anxiety (n = 2), and fainting or tachycardia (n = 2). Twelve women treated in non-study facilities underwent D&C, three were verbally reassured and received no additional treatment, and two women were offered but refused D&C and did not report any adverse effects. There were no serious complications as defined by any occurrence that was unexpected, serious, and related to the induced abortion.

Almost all women (n = 915, 94.4%) reported they were satisfied with their treatment, and most participants (n = 778, 80.3%) reported that the adverse effects were acceptable (Table 3). Women were able to report up to two positive and two negative aspects of the treatment. The most commonly mentioned positive aspects of the medical abortion procedure were the rapidity of the treatment (n = 410/1118, 36.7%) and its efficacy (n = 279/1118, 25.0%). About one-third of women (n = 337, 34.8%) did not report any negative aspect of treatment. Cramps and pain were reported as the worst aspect of this treatment

[c] Reason indicated was pain.

(n = 380/1054, 36.1%), with 46.0% (n = 446) noting that the pain was greater than expected (Table 4). Even so, 88.8% (n = 860) of all women reported they would have another medical abortion in the future if the situation arose. The vast majority of women (n = 700, 72.2%) perceived that bleeding was less than or as expected (Table 4).

4. Discussion

The effectiveness and acceptability of the medical abortion regimen used in the present study were consistent with those reported in the published literature [6,7]. Adverse effects were also comparable for most measures with those reported in other studies that used the same regimen [3,6]. Although women who undergo medical abortion are typically highly satisfied with the treatment and would recommend it to others, pain is often cited as the worst feature of the procedure, no matter what regimen of pain control is used [12]. This was also true for women in the present study. Women's analgesic use was not documented, however, so it was not possible to associate it with pain scores. Notwithstanding, the high level of pain reported on the visual analog scale and the relatively high proportion of women who reported pain being greater than they expected indicates that there may be room for improved pain management. There is little consensus about the most efficacious pain relief regimen for first-trimester medical abortion and research is continuing to inform service delivery practice on pain management [13].

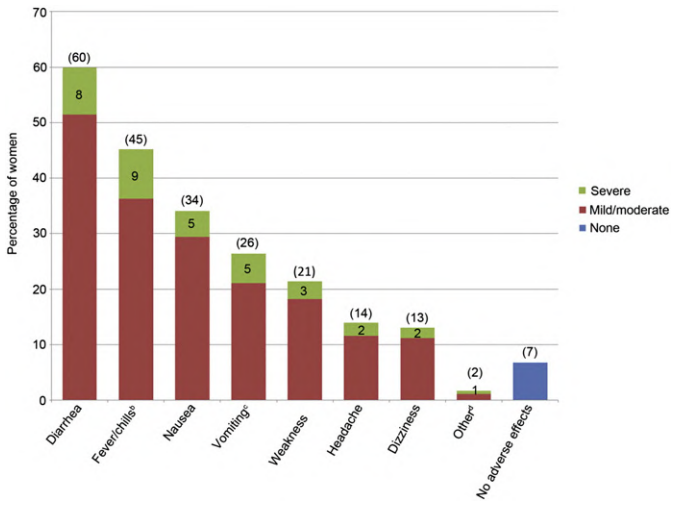

Fig. 1. Adverse effects and degree of severity reported by participants at follow-up (n = 969).[a]
[a]Two participants did not complete the exit interview.
[b]Missing level of severity for 1 participant.
[c]Missing level of severity for 1 participant.
[d]Other reported adverse effects included: anxiety/irritability/depression, dry throat, rash, hypotension, flu, difficulty breathing, hands fell asleep, and hunger.

The high level of satisfaction with the treatment reported by women in the present study is also strongly consistent with the published literature. Previous research has explored the acceptability of medical abortion by women, especially relating to aspects such as increased privacy and autonomy, and the less invasive nature of the procedure compared with surgical alternatives [14]. Satisfaction with these aspects of medical abortion treatment appears to be almost universal and has been reported for diverse populations [12]. Research has also documented that satisfaction is highly correlated with induced abortion success, which were both high in the present study [12].

It is possible that patient satisfaction may also be influenced by provider acceptability of medical methods. Within the first year of the legal induced abortion program in Mexico City providers made a swift transition to medical abortion. A qualitative study reported that healthcare professionals believed medical abortion resulted in a decrease in workload and possibly fewer conscientious objectors [15]. The very low number of calls and unscheduled visits to the study sites in the present study may reflect women's preparedness for what was to occur and their level of trust in the services. This phenomenon may also be indicative of the confidence that the study team had in the method, since these clinical providers and counselors already had previous experience with administering misoprostol-only regimens.

A mifepristone product was registered in Mexico in March 2011 and has been used in Secretariat facilities since December 2011. The mifepristone product currently available is relatively costly, however, the total cost of the drugs for the mifepristone and misoprostol regimen and misoprostol-only regimen previously used by the SSDF are essentially equivalent because of the high cost of misoprostol in Mexico. In reality, the combined regimen is less expensive than misoprostol-only regimens, however, as the method is more effective and therefore saves personnel and other treatment costs associated with aspirations for failed misoprostol-only procedures. In May 2013, a second mifepristone product was registered and it is hoped that this additional product will help to reduce costs further. Registration of additional mifepristone products can reduce the cost of mifepristone and thus increase access in both public and private sectors. Ideally,

combined mifepristone and misoprostol medical abortion regimens should be offered in all settings.

Since study completion, the SSDF has adapted its mifepristone abortion protocol to include recent documented innovations including home administration of mifepristone [16] and outpatient induced abortions with the same regimen during the first 10 weeks of pregnancy [17].

The liberalization of the induced abortion law in the Federal District of Mexico has created an unusual situation that has implications for all Mexican citizens. Any woman is legally allowed to receive an abortion in Mexico City, although limitations still exist for those who cannot afford the journey or the cost of services. Notwithstanding, for many women the ability to obtain safe and legal induced abortion reduces the risk of complications (including sepsis, perforated uterus, damaged cervix, death, among others) more often associated with the restricted legal context that exists in the rest of the country. The rapidity with which a medical abortion protocol was introduced into public sector services is a groundbreaking example for the region, benefitting the health system and women alike. The introduction of a medical abortion protocol has helped the Secretariat meet a growing demand that could not easily be accommodated by surgical abortion alone and has relieved the burden on the limited number of induced abortion providers operating during the first year after legalization. The present study helped prepare public health sector providers to transition from a misoprostol-only regimen to a combined regimen once mifepristone was registered and available on the market. Now more than two years since mifepristone was made available in Mexico, the gold standard of treatment using a combined regimen of mifepristone and misoprostol is firmly established as the primary method for induced abortion of early pregnancy.

Abstract

Background: This study was conducted to assess the feasibility of using telephone calls combined with high-sensitivity urine pregnancy testing as a primary method of follow-up after medical abortion.
Methods: We enrolled 139 women up to 63 days of gestation to receive mifepristone 200 mg orally and misoprostol 800 mcg vaginally or buccally, per their choice. Participants were contacted by phone one week after mifepristone administration and interviewed using standardized questions. If the subject or clinician thought the pregnancy was not expelled, the subject returned for an ultrasound examination. Otherwise, subjects performed high-sensitivity home urine pregnancy testing 30 days after the mifepristone and were called within 3 days of the test. Those with positive pregnancy tests returned for an ultrasound examination. Those with negative tests required no further follow-up.
Results: Six of the 139 (4.3%, 95% CI 1.6–9.1%) subjects presented prior to Phone Call 1 for an in-person visit. All 133 (100%, 95% CI 97.8–100%) subjects eligible for their first telephone follow-up were contacted. Eight of the 133 (6.1%, 95% CI 2.6–11.5%) women were asked to return for evaluation and all did so (100%, 95% CI 63.1–100%). Eight of the 133 women eligible for the 30 day phone call presented for an interim visit prior to the call. After 30 days, 116 of the 117 (99.1%, 95% CI 97.5–100%) eligible subjects were contacted. One subject was not reached for the day 30 phone call. Twenty-seven of the 116 (23.3%, 95% CI 15.6–31.0%) subjects had a positive pregnancy test and required follow-up. Two of these subjects (7.4%, 95% CI 1.0–24.2%) did not return for in-person follow-up. Two of the 116 (1.7%, 95% CI 0.2–6.1%) subjects had inconclusive pregnancy tests and were asked to return for follow-up. One of these subjects (50%, 95% CI 1.2–98.7%) did not return. Complete follow-up was achieved in 135 of the 139 subjects (97.1%, 95% CI 94.3–99.9%). None of the 26 women evaluated for a positive or inconclusive pregnancy test had a gestational sac or continuing pregnancy.
Conclusion: Telephone follow-up combined with urine pregnancy testing after medical abortion is a feasible alternative to routine ultrasonography or serial serum hCG measurements.

1. Introduction

The Food and Drug Administration guidelines for medical abortion with mifepristone and misoprostol recommend a pelvic examination approximately 14 days after medication administration to evaluate for complete expulsion and assess for complications [1]. Several studies have attempted to expedite follow-up after medical abortion through the use of vaginal ultrasonography [2,3], serial serum human chorionic gonadotropin (hCG) levels [4] and high- or low-sensitivity urine pregnancy testing [5].

With vaginal ultrasonography, investigators in the United States demonstrated that the follow-up examination can occur within the first week after treatment and accurately predicts clinical outcome [6]. The majority of clinicians providing medical abortion in the United States

doi:10.1016/j.contraception.2009.08.008

confirm completion by vaginal ultrasound [7,8]. With serum β-hCG evaluations, levels drop 60–66% from pretreatment levels within 24 h after misoprostol administration [9,10], and 80% by Days 6–18 [4]. Low levels of circulating β-hCG, however, can persist for a month or longer [11,12]. More importantly, both ultrasonography and serum hCG testing incur costs and require the patient to follow-up in-person for an evaluation. With urine pregnancy testing, both high-sensitivity (detection threshold 25–50 mIU/mL hCG) and low-sensitivity urine pregnancy testing (detection threshold 2000 mIU/mL hCG) have been evaluated at 7 and 14 days following medical abortion treatment [5]. More than 60% of both types of tests were still positive at 2 weeks. Although urine testing could be performed at home, the clinical utility to confirm expulsion shortly after treatment is limited.

Pymar et al. [13] first evaluated history alone as a predictor of medical abortion completion. In 40 women undergoing medical abortion with mifepristone and misoprostol up to 49 days gestation, clinicians accurately predicted pregnancy expulsion 95% of the time based on history alone. This prediction was confirmed using transvaginal ultrasonography. The ability of history alone to accurately predict pregnancy expulsion was confirmed in a planned secondary analysis of a large medical abortion study [14]. In 931 women who attended a follow-up visit 1 week after medical abortion, the clinician and subject both felt the pregnancy had expelled 95% of the time. Vaginal ultrasound confirmed passage of the gestational sac in 99.1% of those subjects in which pregnancy expulsion was predicted.

Thus, it appears that the ability of history alone to predict expulsion of the gestational sac is 95% in women treated with an effective medical abortion regimen. The ability of history alone to predict complete medical abortion is higher than that seen with urine pregnancy testing. However, these assessments were made in a setting where in-person follow-up still occurred and ultrasonography was going to be performed regardless of the responses of the patient and clinician regarding expulsion. With proper education at the time of mifepristone administration, women may recognize and understand if expulsion has occurred. If clinicians can reliably assess medical abortion outcome without a physical examination or sonography, re-evaluation of guidelines for medical abortion follow-up care would be indicated. This study was designed to evaluate whether a system of early follow-up by telephone to triage who requires in-person evaluation in combination with self-administered high-sensitivity urine pregnancy testing at 30 days is an accurate and feasible alternative to current clinical practice. If telephone follow-up after medical abortion is a feasible option it has the potential to increase access to medical abortion, particularly for women that have to travel long distances for abortion services. As a secondary objective, we offered women the choice of vaginally or buccally administered misoprostol to assess their preferences. Both options are widely used and are highly effective [2,15–17]. To our knowledge, no published studies have allowed women to choose the route of misoprostol administration.

2. Materials and methods

This prospective cohort study was performed at the University of Pittsburgh Center for Family Planning Research after receiving approval from the University of Pittsburgh Institutional Review Board. Healthy women 18 years old or older, up to 63 days of gestation, and desiring medical abortion were recruited from the community. Participants needed to be willing to comply with the visit schedules and undergo surgical abortion (suction curettage), if indicated. Potential subjects were excluded from the study if they were currently breastfeeding or had any of the following: no working telephone; a pregnancy with an intrauterine device in utero; ultrasound evidence of possible early pregnancy failure; a known clotting defect or receiving anticoagulants; a hemoglobin less than 10 g/dL; cardiovascular disease, including angina, arrhythmia, valvular disease, or cardiac failure; a contraindication to mifepristone, including adrenal disease or chronic systemic corticosteroid use; a contraindication to misoprostol, including glaucoma, sickle cell anemia, poorly controlled seizure disorder, allergy to prostaglandins; or had previously participated in this trial.

After obtaining written informed consent, the medical history and demographic information were reviewed. Subjects were asked to give every telephone number at which they could be contacted. They were asked to identify the telephone number they considered their primary telephone, and whether that telephone was a land line, a cellular telephone with a contract, or a prepaid cellular telephone (no contract). Subjects had blood drawn for hemoglobin and blood type, and underwent a pelvic examination and transvaginal ultrasonography to confirm gestational age of the pregnancy. The methods used to confirm gestational age have been previously described [15].

In accordance with the Pennsylvania Abortion Control Act, mifepristone administration was scheduled at least 24 h after abortion consent was obtained. Subjects were contacted between the screening visit and medication administration to confirm a working telephone number. A maximum of three attempts to contact the subjects at each telephone number was made. Women were excluded from the study if they could not be contacted.

On study Day 1, all subjects swallowed 200 mg of mifepristone. They were given the choice of self-administering 800 mcg of misoprostol vaginally or buccally. They were given an informational sheet which described the differences in timing and side effects between the two routes of administration based on the available literature (Appendix A) [16–18]. Women using vaginal misoprostol

were instructed to insert all four 200-mcg tablets as high up as possible into the vagina beginning anytime she chose up to 72 h after the mifepristone. Those selecting buccal misoprostol were instructed to place all four 200-mcg tablets in the buccal pouch (two on each side) from 24–72 h after use of the mifepristone and hold the tablets buccally for 30 min, after which the remaining tablets should be swallowed.

All subjects were given a prescription for 20 tablets of codeine (30 mg) or oxycodone (5 mg). They were instructed to take ibuprofen 800 mg or acetaminophen 1000 mg initially for pain and to add the narcotic medication as needed. Rh-immune globulin was given to all Rh-negative subjects. Sure-Vue™ urine pregnancy tests (Fisher HealthCare, Houston, TX) (sensitivity 25 mIU/mL) with instructions were given to all subjects, and all received contraception counseling. Women choosing oral, transdermal or vaginal hormonal contraception were given a prescription, and those choosing injectable, implantable or intrauterine contraception were given referral information. Subjects were given written instructions regarding pain medication use and bleeding parameters. Women were advised to contact the research office if they had any questions or if they experienced vaginal bleeding exceeding two soaked sanitary pads per hour for 2 consecutive hours, fever greater than 100°F, or other severe side effects.

Subjects were scheduled to be called by a clinician on study Day 8 (±2 days), 7 days after taking mifepristone. Up to three attempts at each telephone number were made to contact subjects. The subjects were asked how and when they used the misoprostol, and to provide a general description of what happened after using the misoprostol. In addition, they were asked a standardized set of questions for the clinician to use to assess for expulsion:

1. Did you have cramping and bleeding heavier than a period?
2. Did you pass clots or tissue?
3. What was the highest number of pads you soaked per hour?
4. Do you still feel pregnant now?
5. Do you think you passed the pregnancy?

If the subject or the clinician did not think the pregnancy had passed, the subject was asked to return to the research office within 7 days. An endovaginal ultrasound was performed to determine if the gestational sac was present within the uterus. If the gestational sac was absent, the subject was considered to have completed the study, and she was instructed to begin her contraceptive method or to schedule an appointment for intrauterine or implantable contraception. Women who wanted injectable contraception received the injection at that visit. If the gestational sac was present without a continuing pregnancy, she was given the option of an additional dose of vaginal misoprostol or dilation and curettage (D&C). If she chose an additional dose of misoprostol, she returned in one week for another ultrasound. A D&C was recommended for all women with a continuing pregnancy, defined as embryonic cardiac motion on ultrasound.

If both the clinician and the subject believed that the pregnancy had passed, the subject was instructed to begin her contraceptive method if applicable, or to schedule an appointment for injectable, implantable, or intrauterine contraception. The subject was told to perform the provided urine pregnancy test on study Day 30. She was told that she would be called within 3 days of taking the test, and the date and approximate time was scheduled. She was instructed to call at any time with problems or concerns.

All eligible participants were contacted by telephone as scheduled; if not initially reached, at least three attempts were made. The medical abortion was considered complete in participants with a negative urine pregnancy test, and no return visit was needed. Participants with a positive urine pregnancy test were scheduled for a return visit within 7 days of the telephone call. At the return visit, the urine pregnancy test was repeated with the Sure-Vue™ high sensitivity (sensitivity 25 mIU/mL) and the Clarity™ low sensitivity (Diagnostic Test Group, Boca Raton, FL, USA) (sensitivity 2000 mIU/mL) test. An endovaginal ultrasound was performed and the abortion considered complete in those subjects without a gestational sac visualized on ultrasound. If a gestational sac was present, the subject was offered an additional dose of misoprostol or D&C. Those subjects desiring an additional dose of misoprostol returned in one week for an ultrasound. The medical abortion was considered complete in those subjects choosing D&C. A D&C was recommended for all women with a continuing pregnancy.

At the final contact, either by telephone or in-person, subjects were asked if they would have preferred to take the misoprostol by a different route. The number of phone calls and length of the phone call each subject made to the research office was documented to gain insight into the amount of additional administrative time telephone follow-up may require.

The primary outcome of the study was successful follow-up per study protocol, defined as successful contact with subjects and in-person follow-up for those women asked to return to the office. For sample size estimation, we considered a 90% follow-up rate to be acceptable for this initial study of feasibility. To ensure a 95% confidence interval of no more than 5% (a lower 95% confidence interval of 85%), 139 subjects would be required with an alpha of .05 and beta of .2. We assumed that approximately 10% of subjects that screened for the study would not enroll, yielding a final sample estimate of 157 subjects. Statistical analysis was performed using Stata 10 (Stata, College Station, TX, USA; www.stata.com). Descriptive statistics and comparisons were calculated using chi-square and Fisher's Exact tests. The sensitivity, specificity, positive

and negative predictive value of the phone screen to predict pregnancy expulsion was calculated.

3. Results

Between March and October 2008, 157 subjects were screened and 139 subjects were enrolled in the study. Of the 18 screen failures only 2 subjects (11%, 95% CI 13.8–34.7%) were withdrawn because they did not have a working telephone. The remainder decided to continue the pregnancy, had hemoglobin levels less than 10 mg/dL or did not return to receive medications after screening. The characteristics of enrolled subjects are listed in Table 1.

Fig. 1 depicts the flow of the study. Six subjects returned to the office prior to Phone Call 1 for an interim visit and were not eligible for the first scheduled telephone call. All (100%, 95% CI 97.2–100.0) of the remaining 133 subjects were reached by telephone as scheduled, and all 8 subjects who were asked to return for a visit for unsure expulsion did so.

[a] A cellular telephone without an annual contract and minutes can be added to the phone as needed.

Eight subjects had an interim visit prior to Phone Call 2. Of the 117 subjects eligible to be contacted for the second scheduled phone call, 99.1% (95% CI 95.3–100.0) were contacted, with only one subject lost to follow-up. The pregnancy test results were negative in 87 (75%, 95% CI 66.1–82.6) women; 27 (23.3%, 95% CI 16.0–32.0) had a positive test, and 2 (1.7%, 95% CI 0.2–6.1) had problems reading the test. These latter 29 subjects all denied any ongoing pregnancy symptoms but, per protocol, were asked to return for an in-person visit. Of the 26 subjects that presented for this visit, none had a retained gestational sac or required D&C. The manufacturer of the Clarity™ low-sensitivity test discontinued production during the study, and only the first 15 subjects who returned after Phone Call 2 received the low-sensitivity test. Only one of the 15 was positive (6.7%, 95% CI 0.2–31.9). The repeat high-sensitivity pregnancy test was still positive in 21 subjects (80.8%, 95% CI 60.6–93.4). Of subjects completing Phone Call 2, 19.5% (95% CI 12.6–28.0) would have preferred to return for an ultrasound one week after medication to confirm pregnancy expulsion.

Successful follow-up per study protocol was achieved in 97.1% (95% CI 92.8–99.2) of subjects. A total of four subjects did not complete all follow-up (2.9%, 95% CI .08–7.2). One subject was never contacted by Phone Call 2, two subjects had a positive pregnancy test and one had an inconclusive test. None of these three returned for the in-person visit. Of the 135 women who completed follow-up, 64.4% (95% CI 55.8–72.5) never required an in-person visit.

Eight (6.7%, 95% CI 3.1–12.3%) D&C procedures were performed. Fig. 1 outlines the indications for the D&C procedures. Three subjects were diagnosed with a pelvic infection (2.2%, 95% CI 0.5–6.4%), with one requiring hospital admission and intravenous antibiotics. Two subjects (1.4%, 95% CI 0.2–5.2%) required blood transfusion for symptomatic anemia, one of whom underwent a D&C for bleeding. There were 4 continuing pregnancies (3.0%, 95% CI 0.8–7.4%); one was diagnosed prior to Phone Call 1, two were diagnosed at the follow-up visit after Phone Call 1, and the fourth was diagnosed at an interim visit prior to Phone Call 2.

The prediction by the subject and clinician that the pregnancy had been expelled had a sensitivity of 95.9%, specificity of 50.0%, positive predictive value of 97.5%, and negative predictive value of 37.5%. For this calculation, medical abortion was considered complete if there was ultrasound confirmation of pregnancy expulsion, or a negative high-sensitivity pregnancy test at Day 30. There were 129 subjects included in this analysis; the four subjects lost to follow-up were not included. The number of subjects without follow-up was too low to assess variables (such as type of telephone service or level of education) that were predictive of no follow-up. Fifty-two (37.4%, 95% CI 29.3–46.0) women contacted the research office for unscheduled calls; 57.6% (95% CI 43.2–71.2) called only once, while 42.3% (95% CI 28.7–56.8) called two or more times. The

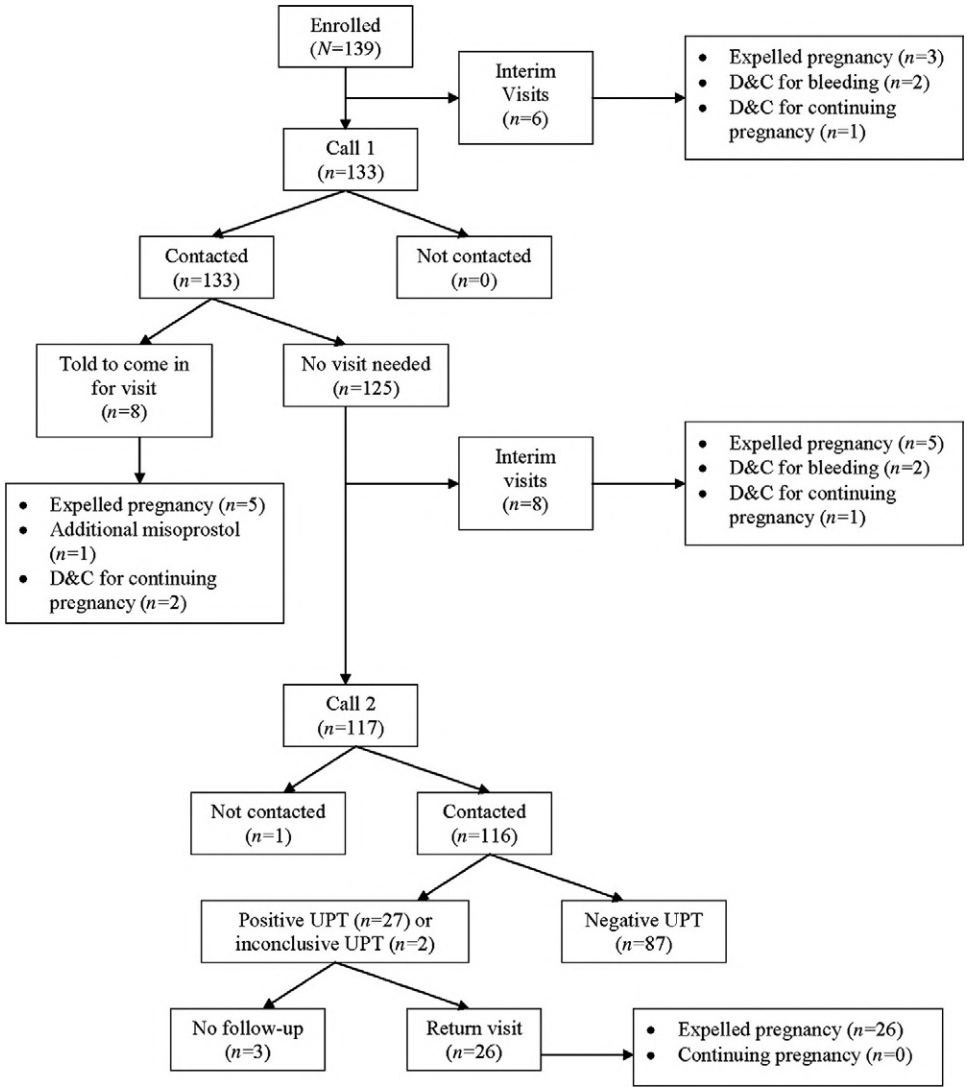

Fig. 1. Study flow. Call 1 scheduled 7±2 days after mifepristone use. Call 2 scheduled within 3 days of Day 30 pregnancy test. UPT, urine pregnancy test.

maximum number of phone calls by one subject was six calls. The mean length of each phone call was 2.5 min (95% CI 1.7–3.3, range 2–27 min).

Almost all women (94.2%, 95% CI 89.0–97.4%) chose vaginal misoprostol, with 74% using misoprostol within 6 h of mifepristone administration (Table 2). Only six women chose buccal misoprostol. When asked at the end of the study if they would choose to take misoprostol the same way, 96.4% (95% CI 91.8–98.8) of subjects would choose the same misoprostol route.

Table 2
Timing of misoprostol use (*n*, %)

Time since mifepristone (h)	Vaginal misoprostol *n*=127	Buccal misoprostol *n*=6
0–<2	32 (25.2)	0
2–<4	46 (36.2)	0
4–<6	16 (12.6)	0
6–<12	14 (11.0)	0
12–<24	9 (7.1)	0
≥24	10 (7.9)	6

4. Discussion

The primary aim of our study was to determine if it is possible to reach women by telephone, and based on a standardized set of questions, determine if an in-person visit is indicated. The intention of these standardized questions is to predict pregnancy expulsion so as to make appropriate recommendations to women about whether or not they should return to the office. In reality, the goal is to ensure that this method of follow-up avoided missing any continuing pregnancies by the final follow-up 30 days after treatment. Only 3% of women did not follow all instructions for follow-up. Given that complete loss to follow-up rates is at least 2%

in studies and clinical practice [19,20], our data show that it is very feasible to use the telephone as a primary method of follow-up after medical abortion.

The high sensitivity and positive predictive value of the standardized question set are reassuring such that when the clinician and subject both believe the pregnancy has passed, they are almost always correct. These results are not unlike those found in previous studies when questions have been used to assess medical abortion success [13,14]. This study was not powered to detect which questions were most predictive of pregnancy expulsion, and this information may warrant additional research. Importantly, all women who did not require a return visit after the phone screen but had problems such as bleeding or continuing pregnancy symptoms presented to the office on their own.

A prior evaluation of high-sensitivity urine pregnancy testing used the test within 2 weeks of treatment to confirm pregnancy expulsion [5], essentially using high and low-sensitivity urine pregnancy tests as a screening tool to diagnose successful medical abortion. In our study, we were using medical history as the screening tool, not the high-sensitivity urine pregnancy test. We only used the pregnancy test to rule out continuing pregnancies. While 25% of the high-sensitivity urine pregnancy tests were positive or inconclusive, none of those subjects that followed up for a positive pregnancy test had a continuing pregnancy. All four subjects with a continuing pregnancy presented on their own to the office prior to Phone Call 2, with only one continuing pregnancy being diagnosed between Phone Call 1 and Phone Call 2. While performing the urine pregnancy test 4 weeks after medication administration increases the number of women that must return for evaluation, it ensures that continuing pregnancies are diagnosed and that a D&C can be performed within the first trimester. We selected high-sensitivity urine pregnancy tests because they are available over the counter. If this method of follow-up is adopted, women could theoretically purchase their urine pregnancy tests in the pharmacy after receiving medical abortion medications.

In all medical abortion studies and in clinical practice, some women are lost to follow-up. The percentage of women with incomplete follow-up in our study was similar to the percentage of women that do not follow-up with the standard medical abortion follow-up protocol. It is impossible to know which women undergoing medical abortion will have a continuing pregnancy and/or will be lost to follow-up. Our data indicate that women with a continuing pregnancy develop pregnancy symptoms and schedule a follow-up visit.

Our 3% continuing pregnancy rate is somewhat higher than the 0–1% cited in other medical abortion studies [16,18,21]. Unlike these other trials, we did not allow an additional dose of misoprostol for subjects with continuing pregnancies. One of the four continuing pregnancies was diagnosed before Day 7 in a subject who presented for worsening pregnancy symptoms. It is still possible that she may have aborted prior to Phone Call 1 had she not had the D&C. All of the subjects with continuing pregnancies used vaginal misoprostol within 3 h of the mifepristone, and three of the four subjects had a gestation of 61 days. These factors may have contributed to the high continuing pregnancy rate.

This is the first published study that allowed women to select which route of misoprostol administration they would prefer. Women overwhelmingly chose vaginal misoprostol. While we did not specifically ask the reason they chose this route, 91.4% of subjects choosing the vaginal route used the misoprostol within 24 h after mifepristone administration. We infer that the ability to use the misoprostol sooner and thereby complete the medical abortion sooner is the reason the vaginal route of misoprostol was selected. While familiarity with a route can also be a contributing factor, only 13% of women had experienced a prior medical abortion, so this reason is unlikely in this case. Although some investigators have implied that women prefer an oral route, our findings suggest that, when all factors are considered, women may prefer the route that allows them to complete the abortion as quickly as possible [3].

We have found that telephone screening in combination with high-sensitivity urine pregnancy testing is feasible and believe that this method of medical abortion follow-up can be offered as an alternative to in-person evaluations for select patients. In our study, only one third of the subjects were required to return for a visit. Some women will feel more comfortable having a return visit and confirming pregnancy expulsion, while others find this additional visit inconvenient and would prefer telephone follow-up. Still, continued quality assessment will be required if such a program is implemented to determine if our findings are generalizable to other providers and settings. We are confident based on our data that women are very self-aware, and if they are having symptoms or problems after a medical abortion, they will return to the office for a visit despite the type of follow-up. This method of medical abortion follow-up provides women with more choices.

Appendix A. MEDICAL ABORTION with MIFEPRISTONE and MISOPROSTOL

Comparing misoprostol use options

Buccal=between your cheek and gums

Vaginal=in your vagina

	Buccal	Vaginal
MIFEPRISTONE	Swallow the tablet right away in the doctor's office	Swallow the tablet right away in the doctor's office

Appendix A (*continued*)

	Buccal	Vaginal
How you will use the MISOPROSTOL	Place all 4 of the tablets between your cheek and gum and allow them to dissolve for 30 minutes. After that time, you should swallow the rest of the tablets.	Place all 4 tablets in vagina
When you can use MISOPROSTOL	1-3 days later (whatever time works best for you)	Any time after you use the mifepristone, up to 3 days later (whatever time works best for you)
Where you will use the MISOPROSTOL	At home	In the office if you insert the pills immediately. At home if you use the pills later.
Chance of side effects	Nausea: 8 in 10 Vomiting: 5 in 10 Diarrhea: 4 in 10	Nausea: 4 in 10 Vomiting: 3 in 10 Diarrhea: 3 in 10
Likelihood of needing pain medication	Moderate to high	Moderate to high
Chance of needing a surgical abortion (because medicines didn't work)	4 out of 100	3 out of 100

opinions of partners, family members, friends, and later co-workers, especially with respect to later abortion and funding restrictions.

Conclusions: The NAF Hotline serves an important and transformative role in the lives of those who work for it. However, the NAF Hotline has the potential to play a much stronger role in shaping hearts and minds and social movement building in the US. Exploring ways to facilitate NAF Hotliners' engagement in ethical storytelling and advocacy appears warranted.

Transcutaneous electrical nerve stimulation (TENS) for pain control during first-trimester abortion: A single-blinded randomized controlled trial

K. Lerma *, L.M. Goldthwaite, P.D. Blumenthal, K.A. Shaw

Stanford University, Stanford, CA, USA

*Corresponding author. Email: klerma@stanford.edu

Introduction: High-frequency, high-intensity transcutaneous electrical nerve stimulation (TENS), pulsating electrical currents that activate underlying nerves, is an inexpensive and non-invasive pain control approach. We sought to compare TENS to intravenous sedation (IV) for pain control in first-trimester surgical abortion.

Method: We conducted a non-inferiority, single-blinded, randomized controlled trial of participants undergoing surgical abortion up to 11 weeks' gestation. Participants received TENS (electrodes parallel to the spinal cord at the T10-L1 and S2-S4 levels) or IV (100mcg fentanyl and 1mg versed). Providers administered the IV sedation and research staff administered the TENS and were therefore not blinded. The primary outcome was self-reported pain with aspiration (visual analogue scale, VAS 100mm, 0 "no pain" and 100 "worst pain imaginable"). Non-inferiority limit was defined as 15mm. We also assessed participant demographics and blinding.

Results: A total of 109 participants were enrolled (55 TENS, 54 IV) between January 2018 and October 2019. Participants had a mean gestational age of 56-days across groups (p = 0.88); groups were similar with regard to age, race and ethnicity, parity, and BMI. Nine (16%) in the TENS group were given IV sedation and excluded from the per-protocol analysis. 100 participants were included in the per-protocol analysis (46 TENS, 54 IV). Mean reported VAS for aspiration was 64.78 mm (SD24.16) and 60.35mm (SD26.06) in the TENS and IV groups, respectively, with a mean difference of 4.43mm (95% CI −5.6 to 14.47). One IV group participant received additional IV medications (2%). Post-procedure, in both groups the majority of participants identified their correct assignment (p = 0.96); one in five in both groups incorrectly identified their assignment (21.7%, n = 10 TENS; 22.2%, n = 12 IV). Intention-to-treat analysis (n = 109) yielded non-inferior results for the primary outcome.

Conclusions: TENS for pain control during first-trimester surgical abortion is non-inferior to IV sedation with respect to the primary outcome of pain with aspiration. TENS could be a pain control option for patients without access to IV sedation or for those who are ineligible to receive IV sedation due to additional cost, lack of sedation provider or restrictions, including the need for a designated driver. Expanding pain control options improves quality of care and access to abortion.

Advanced practice clinicians and medication abortion safety: A 10-year Retrospective Review

L. Porsch [a,*], M. Dragoman [a], H. Jones [b], K. Steinle [a], I. Dayananda [a]

[a] *Planned Parenthood of New York City, New York, NY, USA,* [b] *CUNY Graduate School of Public Health and Health Policy, New York, NY, USA*

*Corresponding author. Email: lauren.porsch@ppnyc.org

Introduction: Expanding the pool of trained, competent medication abortion providers is critical to filling gaps in access to safe abortion across the U.S. Despite a compelling public health argument for advanced practice clinicians (APCs) as abortion providers and the recent label change to mifepristone, 34 states currently mandate that clinicians providing medication abortion must be physicians.

Method: We performed a retrospective observational cohort study of medication abortion and clinician personnel data from the electronic medical record (EMR), quality management incident tracking, and human resources records at a large, urban-based sexual and reproductive health care provider between January 2009 and December 2018 to describe medication abortion outcomes when provided by APCs. We calculated descriptive statistics to assess overall abortion outcomes and complications. In order to assess complications by provider years of experience, we ran a negative binomial regression on total complications, using an offset term of the natural log of the total number of procedures with follow up to estimate a rate ratio.

Results: A total of 59,189 patients initiated medication abortion during the observation period under the supervision of 47 APCs. Among the 37,909 (64%) patients who completed follow up, outcomes included: 98.4% complete abortion, 1.1% failed abortion, 0.4% incomplete abortion, and 0.1% ectopic pregnancy. There were no meaningful differences in characteristics among patients who completed or failed to complete follow-up. 246 (0.6%) patients experienced complications requiring in-clinic management, ED referral, or hospital admission. .Most common interventions included aspiration (n = 112), blood transfusion (n = 36), and/or IV fluids (n = 34). We found no association between provider years of experience and complication rates (RR = 1.00, 95% CI 0.97, 1.04), restricting analyses to providers for whom there was follow-up data on at least 60% of cases in a given year.

Conclusions: Outcomes of medication abortion provided by APCs in our study are well within published benchmarks for medication abortion effectiveness (95–99%) and safety (<1% complications) when managed by physicians. Restricting provision to physicians serves only to impede access by excluding a large group of competent clinicians from offering this service.

Abstract: *Medical abortion was introduced in Nepal in 2009, but rural women's access to medical abortion services remained limited. We conducted a district-level operations research study to assess the effectiveness of training 13 auxiliary nurse-midwives as medical abortion providers, and 120 female community health volunteers as communicators and referral agents for expanding access to medical abortion for rural women. Interviews with service providers and women who received medical abortion were undertaken and service statistics were analysed. Compared to a neighbouring district with no intervention, there was a significant increase in the intervention area in community health volunteers' knowledge of the legal conditions for abortion, the advantages and disadvantages of medical abortion, safe places for an abortion, medical abortion drugs, correct gestational age for home use of medical abortion, and carrying out a urine pregnancy test. In a one-year period in 2011–12, the community health volunteers did pregnancy tests for 584 women and referred 114 women to the auxiliary nurse-midwives for abortion; 307 women in the intervention area received medical abortion services from auxiliary nurse-midwives. There were no complications that required referral to a higher-level facility except for one incomplete abortion. Almost all women who opted for medical abortion were happy with the services provided. The study demonstrated that auxiliary nurse-midwives can independently and confidently provide medical abortion safely and effectively at the sub-health post level, and community health volunteers are effective change agents in informing women about medical abortion.*

Keywords: medical abortion, auxiliary nurse-midwives, female community health volunteers, outreach health centres, Nepal

The abortion law was reformed in Nepal in September 2002 to improve the health status and condition of women. The law allows abortion up to 12 weeks of pregnancy at the request of the woman, up to 18 weeks if the pregnancy results from rape or incest, and at any time during pregnancy on the advice of a medical practitioner, if the physical or mental health or life of the woman is at risk, or the fetus is impaired or has a condition incompatible with life.[1] Previous laws did not allow abortion under any circumstances and many women who had had an abortion were imprisoned.[2] The introduction of legal abortion has been characterized by a committed effort by the Ministry of Health and Population and non-governmental organizations to rapidly scale up access to safe abortion. Manual vacuum aspiration services became available in 2004; second-trimester procedures were introduced in 2007; and senior nurses who had prior training in post-abortion care began providing services in 2008.[2] Manual vacuum aspiration was the only safe abortion method used until 2009 in Nepal. In line with the Safe Abortion Service Directives 2065 B.S. (2008), the Government of Nepal introduced medical abortion on a pilot basis in six districts through 32 accredited comprehensive abortion care centres for a period of one year in 2009, with a 96.1% success rate. The experience gained encouraged the Government to scale up medical

 Doi: 10.1016/S0968-8080(14)43784-4

abortion services in all accredited abortion clinics throughout the 75 districts of the country in a phased manner. However, medical abortion services are still limited to a relatively small number of accredited government and non-governmental centres, including selected primary health centres and health posts. No sub-health post was approved for medical abortion provision before this study.

Despite these efforts, knowledge and use of medical abortion has been discouragingly low. An evaluation study of medical abortion services in the six pilot districts, carried out by the Center for Research on Environment Health and Population Activities (CREPHA) in 2009, showed that only 15% of 1,093 married women of reproductive age had heard about medical abortion.[3] Government records from the six pilot districts revealed that of the women who had had an abortion in that period, only 6.1% had opted for medical abortion.[3] The study also found a number of other barriers:

- no full-time counsellor at the government facilities to provide information on medical abortion that would enable women to make an informed choice;
- negative attitudes on the part of providers towards medical abortion;
- a policy that barred women living more than two hours' distance from the health facility from using medical abortion;
- low confidence in medical abortion efficacy among the providers; and
- the requirement of repeat visits to the clinic.[3]

The findings contributed to elimination of the policy that stipulated that women living more than two hours from a health facility could not use medical abortion, and also helped provide a choice for women of home or clinic use of misoprostol.

Although medical abortion provision in recent years in Nepal has been expanding, restrictions on certification of facilities and provider provision remain in place. Rural women's access to medical abortion services remains limited due to the government's reluctance to expand the services to outreach health centres, particularly at the sub-health post level (the lowest level of health facility in the government health system) through auxiliary nurse-midwives.

Previous research in Nepal had demonstrated that medical abortion provision by doctors, nurses and auxiliary nurse-midwives is acceptable and feasible.[4,5] More recently, a World Health Organization study by CREHPA showed that mid-level providers could provide medical abortion from certified facilities with the same safety and effectiveness as doctors.[6] These findings were in line with research elsewhere indicating that non-clinicians can safely provide first-trimester abortion.[6–8]

Medical abortion has the potential to expand women's access to safe abortion in Nepal by overcoming the need for a skilled provider in a clinic setting, as needed with aspiration abortion.[8–10] It also increases affordability and privacy.[11,12] Most importantly, it offers the opportunity to decentralize provision of services away from traditional hospital and clinic settings.[13]

Increasing the utilization of medical abortion requires knowledge and motivation. Studies conducted elsewhere have shown that training and advocacy at different levels of the health system, use of mass communication channels, and mobilisation of community-based groups have been effective in increasing utilisation of contraception, HIV and child health services.[14,15] The grapevine is also very effective in spreading the word about misoprostol all over the world, in spite of laws against abortion and in the absence of formal information. However, the effectiveness of using community-based volunteers in increasing awareness about medical abortion and establishing referral systems in rural areas in countries like Nepal has not been studied.

The female community health volunteer programme in Nepal was introduced by the Ministry of Health and Population in 1988. Currently, over 50,000 women serve as an important source of information for communities in nearly all rural areas. They enjoy high respect and acceptability because they play an important role in contributing to key public health programmes, including family planning, maternity care, child health, vitamin A supplementation, deworming and immunization coverage.[15,16] However, they have not been trained or involved in providing information or referral for safe abortion care, including medical abortion.

This study, in two western districts of Nepal in 2011 and 2012, assessed the effectiveness of training 13 auxiliary nurse-midwives based in health posts and sub-health posts to provide medical abortion independently, and 100 female community health volunteers as communicators and referral agents for expanding medical abortion access to rural women.

GBP-PET00674

Data and methods

The study employed a non-equivalent comparison group design that compared the effect of training auxiliary nurse-midwives to provide medical abortion and female community health volunteers in the intervention group (Rupendehi district) against a similar, but not necessarily equivalent, comparison group located in the neighbouring district (Kailali). Rupendehi has 69 village development committees and two urban municipalities, two hospitals, five primary health care centres, six health posts and 57 sub-health posts. Prior to the implementation of the study, only two government hospitals, three NGO-managed clinics and three private clinics located in Rupendehi were offering medical as well as aspiration abortion services. The present study selected one primary health care centre, five health posts and two sub-health posts (approved as a birthing centre with the presence of at least one auxiliary nurse-midwife) and 120 female community health volunteers from 10 village development committees in the intervention district in consultation with the district health officials and stakeholders. The selection of the intervention area was based on the criteria that no outreach health centre was providing medical abortion services and that the district health officials were supportive of the study. In the comparison area, two primary health care centres and two health posts that had been offering medical abortion services since January 2009 and 96 female community health volunteers from ten village development committees were selected in consultation with district health officials. Both areas were very similar in terms of socio-economic and demographic indicators.

The interventions were carried out at two levels. At the community level, 120 female community health volunteers (a minimum of ten female community health volunteers per village development committee) were trained to communicate information about prevention of unintended pregnancy, abortion law and rights, safe (government-approved) health centres for abortion and legal abortion services, health consequences of unsafe abortion, safety and efficacy of medical abortion, importance of post-abortion/post-partum contraception, availability of medical abortion at health and sub-health posts through trained auxiliary nurse-midwives, and women's choice of place for misoprostol use (either self-administration at home or at the clinic). They were also trained to perform a urine pregnancy test and check eligibility criteria for women asking for medical abortion at health and sub-health posts. After training, the women were given ten sets of urine pregnancy test kits each so that they could maintain this skill and sustain this service by charging women a small amount (US$ 0.26) for a pregnancy test. They were also issued with special referral cards to give to women with a positive test result, either for antenatal care or abortion. Women receiving referral cards for abortion were later visited at home by the same female community health volunteer who had given them a referral card, to find out the outcome of the referral and for post-abortion or post-partum family planning advice.

All 13 auxiliary nurse-midwives working in the eight study health centres and who were already certified as skilled birth attendants were given comprehensive training on providing medical abortion, women's choice on misoprostol use either self-administered at home or in the clinic, management of minor complications and identification of complications requiring immediate referral. The training was conducted by three national trainers at the government's National Health Training Centre, following the national medical abortion training protocol, whose requirements included three days' training at the main Maternity Hospital in Kathmandu. All trained auxiliary nurse-midwives received government approval before starting medical abortion services in their health facilities.

In addition, the district health office supplied 300 sachets of medical abortion tablets (mifepristone 200 mg x 1 and misoprostol 200mcg x 4 in the same pack) and 300 copies of the self-assessment card to be used by women to the eight outreach health centres. No intervention was implemented in the comparison area.

The core study protocol and research instruments were approved by the Nepal Health Research Council (national ethical approval body) and the World Health Organization's Research Ethics Review Committees. Participants (female community health volunteers, women, and auxiliary nurse-midwives) involved in the study were fully informed about the nature of the study, research objectives, and confidentiality of the data. Participants' written consent (thumbprint if not literate) was obtained regarding their participation in the study. Confidentiality of information was ensured by removing personal identification from the data and by securing access to all data and information.

GBP-PET00675

We analyzed matched (paired data) pre- and post-intervention individual interviews with 110 female community health volunteers in the intervention area and similar interview data (but no intervention) with 79 female community health volunteers in the comparison area. Data at baseline and post-intervention were collected. The female community health volunteers were mainly asked about knowledge of existing abortion law, abortion-seeking behaviour of women in their communities, and their own knowledge and perceptions of medical abortion, involvement in urine pregnancy tests, referrals and providing abortion. Similarly, auxiliary nurse-midwives were asked about their training and skills on abortion, number of women whose abortions they managed, management of complications, and their knowledge and perceptions of medical abortion.

After the intervention, we also carried out semi-structured interviews with 13 auxiliary nurse-midwives (nine in the intervention area and four in the comparison area) who provided medical abortion services. Additionally, we carried out 241 exit interviews with women (124 in the intervention area and 117 in the comparison area) who had received medical abortion services from the 12 study facilities (eight in the intervention area and four in the comparison area) over a four-month period.

Interviews with women who had abortions were carried out between the sixth and tenth month of the intervention period. Along with their socio-demographic characteristics, women were asked what they knew about abortion clinics, abortion law, abortion experiences, and contraceptive counselling and use. Eight trained research assistants (four in the intervention area and four in the comparison area), stationed for four months at the study facilities, conducted the exit interviews. We also analyzed the 12 months of service statistics data maintained by the study health facilities.

As the female community health volunteers' interview data were matched, McNemar tests were used to examine whether the difference in knowledge of, and perception about, medical abortion and referral practices between pre-and post-intervention was greater in the intervention area than in the comparison area. Exit interview data were also compared to examine the differences in women's perceptions of medical abortion services intervention and the Chi-square test of association was also used to test whether the differences were independent.

Profile of study participants

Female community health workers

The mean age of female community health volunteers was slightly higher in the intervention area than in the comparison area (40.1 and 35.6 years, respectively) (Table 1). Their ages ranged from 18–60 years, with the great majority over age 25. A higher percentage were illiterate in the intervention area than in the comparison area. On average, they had served more than 13 years as community health volunteers (range 1–23 years).

Women who had a medical abortion during the study

The socio-demographic characteristics of the women who received medical abortion services and were interviewed (124 in the intervention area and 117 in comparison area) ranged in age from 15–53 years. A slightly higher percentage of women in the intervention than in the comparison area had never attended school (26.6% vs 21.4%). Over 70% of women in both areas had had at least two children.

Table 1. Profile of female community health volunteers, baseline interviews, June 2011

Characteristics	Intervention area n=110	Comparison area n=79
Mean age in years (standard deviation)	40.1 (8.8)	35.5 (7.7)

GBP-PET00676

Auxiliary nurse-midwives

Six out of nine auxiliary nurse-midwives who were interviewed in the intervention area were working at health posts, two at sub-health posts and one at a primary health care centre. Most of these auxiliary nurse-midwives had been working at these health centres for more than a year. In the comparison area, all four auxiliary nurse-midwives interviewed were working in the health posts for more than a year.

Findings

Female community health volunteers' knowledge of medical abortion

Table 2 shows a significant increase in female community health volunteers' knowledge about the legal conditions of abortion, government-approved health facilities for abortion, medical abortion medications and the correct gestational age for medical abortion at baseline and post-intervention in the intervention area as compared to the comparison area. For example, in the intervention area, knowledge about the legal grounds for abortion increased from 66% at baseline to 100% post-intervention, while remaining the same in the comparison area. Knowledge of the names of approved medical abortion drugs also increased from 1% at baseline to 97% post-intervention. Similarly, there was a sharp increase in knowledge about the upper time limit for home use of medical abortion (≤9 weeks) in the intervention area from 2% at baseline to 69% post-intervention.

There was also a significant increase in knowledge and use of urine pregnancy test kits, particularly in the intervention area. The comparison group also showed a significant increase in knowledge of medical abortion medications, correct gestation period and performing a urine pregnancy test, although the magnitude of change was lower than in the intervention group. Increases observed in the comparison area may reflect improvements as in other parts of the country.

Table 3 shows the changes in female community health volunteers' knowledge about the advantages and disadvantages of medical abortion between baseline and post-intervention. This included a significantly increased percentage at post-intervention who believed that medical abortion was safe (low risk), is an alternative to MVA, allows abortion to happen as a natural process, and ensures privacy, whether at home during the abortion process or in that nobody from her family knows about her abortion if in the clinic. Similar changes, particularly that they believe medical abortion is safe, requires no aspiration procedure and causes no physical trauma was also observed in the comparison area but the magnitude of changes was much lower than in the intervention area. For example, at baseline, about 12% of the female community health volunteers in the intervention group and 15% in the comparison group mentioned

Table 2. Increased knowledge and practice on abortion among female community health volunteers, baseline and post-intervention (%)

	Intervention area (n=110)		Comparison area (n=79)	
	Baseline	Post-intervention	Baseline	Post-intervention
Knows about legal grounds for abortion	66.3	100.0*	93.7	91.1^{ns}
Knows about safe (government-approved) places for abortion	89.1	100.0*	100.0	100.0^{ns}

a Percentage total may exceed 100 due to multiple responses.
p-values from McNemar-test: * p< 0.05, ** p< 0.01 and *** p<0.001. ns = non-significant

that one of the advantage of medical abortion was that it is a low risk method. At the post-intervention survey, these percentages increased by 70 percentage points in the intervention group and 39 percentage points in the comparison group. The percentage of female community health volunteers who reported lack of knowledge about the advantages of medical abortion significantly fell from 59% at baseline to 2% post-intervention in the intervention area.

In the post-intervention phase, in both the intervention and comparison areas, more of the female community health volunteers knew that there was a risk of incomplete abortion for a small minority of women and an even smaller risk of heavy bleeding. Changes in their knowledge of disadvantages of medical abortion – including issues related to pain, side effects from the misoprostol, and longer duration of the process than with aspiration abortion – were insignificant. This means that further information needs to be provided in future training.

Contribution of female community health volunteers and changes in practice due to the study

In the 12 months of the study, 584 urine pregnancy tests were performed by the female community health volunteers in the intervention area, of which 323 were positive. Of these 323 women, 209 were referred to antenatal care services (their pregnancies were desired) and the remaining 114 women opted for an abortion (108 for medical abortion and 6 for manual vacuum aspiration). Female community health volunteers referred the women opting for an abortion to the nearest health centres and issued 108 of them with referral cards for the medical abortion service. Of the 108 women referred, 80 actually attended the referral health centres, and all of the 80 had a medical abortion. The remaining 28 women either changed their minds and continued the pregnancy or were turned away from the abortion services due to higher gestational age (more than 9 weeks)* or had medical contraindications to abortion such as signs and symptoms of heart disease, for example, high blood pressure.

The female community health volunteers were asked where they referred women for abortion most often both at baseline and post-intervention interviews. Responses (Table 4) show that referral of women to health and sub-health posts increased significantly in the intervention area as compared to the comparison area. At baseline, almost none of the volunteers in the intervention area and 25% of those in the comparison area said they referred women opting for abortion to health and sub-health posts. Post-intervention, these percentages increased by 80 percentage points in the intervention area though only 5 percentage points in the comparison area. Similarly, referral to the primary health care centres also increased

*We do not know what happened to this group of women, but as a result of this happening we are exploring this problem in a new research collaboration.

GBP-PET00678

Table 4. Place of referral for abortion by female community health volunteers at baseline and post-intervention (%)

	Intervention area (n=110)		Comparison area (n=79)	
Place of referral for abortion	Baseline	Post-intervention	Baseline	Post-intervention
No referral	27.3	0.0*	7.6	6.3^{ns}
Governmental hospital	22.7	0.0*	10.1	6.3^{ns}
Primary health care centres	4.5	18.2*	45.6	48.1^{ns}
Health/sub-health posts	0.9	81.0*	24.1	30.4^{ns}
Private clinic	7.3	0.0^{ns}	3.8	2.5^{ns}
Pharmacy	37.3	0.9*	8.9	6.3^{ns}

p-values from McNemar-test: * p< 0.05, ** p< 0.01 and *** p<0.001. ns= non-significant

significantly in the intervention area at the post-intervention survey compared to the baseline (from 4.5% to 18.2%), whereas there was no significant change in the comparison area (from 45.6% to 48.1%). Referral to a pharmacy for abortion, which is not legal in Nepal, was reduced significantly in the intervention area (from 37.3% at baseline to 0.9% post-intervention) whereas in the comparison group the percentage (from 8.9% to 6.3%) did not change significantly.

Number of medical abortions and abortion success rate

Service statistics showed that 307 women in the intervention area and 289 women in the comparison area had received medical abortion services from auxiliary nurse-midwives in the one-year study period. Of the 307 women, there were five incomplete abortions (1.6%), four of which were treated with manual vacuum aspiration by the auxiliary nurse-midwives. Only one woman was referred to the nearest zonal hospital because it was a Saturday, and the outreach health centre was closed. Of the 289 women in the comparison area, there were seven incomplete abortions (2.4%), five of which were treated with manual vacuum aspiration and two were referred to the district hospitals. The difference in the number of incomplete abortions between the two areas was not statistically significant.

Confidence of auxiliary nurse-midwives providing medical abortion services

Interviews with the auxiliary nurse-midwives participating in this study in the intervention area revealed that all nine of them were confident about providing medical abortion independently, and they also expressed a strong desire to receive training in manual vacuum aspiration and additional skills, particularly in management of complications and clinical assessment. Auxiliary nurse-midwives working in the comparison area expressed similar views and interests.

"Initially I used to get worried about women who received medical abortion from me. I had to make frequent calls to them regarding their condition. I felt relieved only after they informed me that they were fine as the pills had worked well. Now I am more confident than before. I have provided medical abortion to a lot of women. So far none of these women has experienced incomplete abortion or a complication with medical abortion. I now realize that we are as capable of providing medical abortion as any other providers." (ANM working at sub-health post, intervention area)

"I feel that I have provided medical abortion services to many women successfully. My confidence to provide medical abortion service has increased over this period, and I think the government should train us [auxiliary nurse-midwives] to provide manual vacuum aspiration services also." (ANM working at health post, intervention area)

Women's experiences of medical abortion care from an auxiliary nurse-midwife

We conducted 241 exit interviews with women (124 in the intervention area and 117 in the comparison area) who received medical abortion care from an auxiliary nurse-midwife at one of the 12 outreach health facilities (eight in the intervention area

GBP-PET00679

and four in the comparison area). We learned that 96% of the women in the intervention area and 89% of the women in the comparison area reported that the services met their expectations (Table 5). About 97% of women in both intervention and comparison areas reported a complete abortion. The women reported only typical and well-known, short-term side effects such as nausea, vomiting, diarrhoea, abdominal pain, chills and fever.

In the intervention area, 82.3% of women opting for medical abortion chose self-administration of misoprostol at home, compared to 42.7% in the comparison area. The two main reasons for choosing home administration were: saving the time required to stay at the facility, followed by privacy and convenience. Those women who chose the clinic for misoprostol administration said they were scared, or felt safer and had more confidence at the clinic than at home. Almost all the women (96.8% in the intervention area and 97.4% in the comparison area) felt that they had received enough information about medical abortion from the counsellors/providers. Confidentiality, not requiring aspiration, less pain and less cost were perceived as the main advantages of medical abortion. In addition, all the women from both areas reported that they would recommend to their friends or others to attend the facility they visited for medical abortion services.

Discussion and conclusions

In this study, 307 women in the intervention area received medical abortion services from auxiliary nurse-midwives in a one-year period and had no complications that required referral to higher level facility except for one incomplete abortion. Auxiliary nurse-midwives showed that they were capable and interested in providing a good quality medical abortion service safely and effectively at outreach health facilities without the presence of physicians, and were confident of their ability to do so, with very limited clinical resources. This confidence was underpinned by the evidence, in that almost all abortions were complete, no serious adverse events were recorded, and women reported only typical and well-known, short-term side effects. Furthermore, interviews showed that the women who had had a medical abortion were happy with the service they had received and were willing to recommend this service to friends and other women.

Our study also found that female community health volunteers were capable of providing information to women and referrals to auxiliary

nurse-midwives with the aim of increasing access to medical abortion services among rural women. We therefore recommend that female community health volunteers should continue to play this role both for medical abortion and for manual vacuum aspiration, urine pregnancy tests, post-abortion/delivery contraceptive counselling and follow-up.

The safety, efficacy and acceptability of medical abortion provided by auxiliary nurse-midwives is now well established in Nepal,[6] and this study establishes it even further. To our knowledge, this is the first study to assess the possibility of introducing medical abortion services at the sub-health post level in Nepal.

There is no policy restriction on sub-health posts (if already approved as a birthing centre*) applying for government certification for providing abortion services. However, as of June 2013, no sub-health post (except for the ones in this study, who have continued to provide medical abortion services) had been accredited for providing medical abortion services in Nepal.

On the basis of our findings, we encourage the government to consider accrediting sub-health posts with a trained auxiliary nurse-midwife for medical abortion services in a phased manner, in order to increase access to medical abortion services for rural women. We also encourage the government to support scale-up of training for both female community health volunteers and auxiliary nurse-midwives.

*Only birthing centres will have the post of auxiliary nurse-midwives so as to make this possible.

Acknowledgments

We acknowledge the technical and financial support received from HRP (UNDP/UNFPA/UNICEF/WHO/World Bank Special Programme of Research, Development and Research Training in Human Reproduction). We would also like to thank the Family Health Division (Ministry of Health and Population, Nepal) and the District Public Health Office, Rupendehi, for encouraging us to conduct this study. We are grateful to all the study participants including female community health volunteers, abortion service providers and women, for their active participation in this study.

Résumé

L'avortement médicamenteux a été introduit en 2009 au Népal, mais l'accès des femmes rurales aux services est demeuré limité. Nous avons étudié les opérations au niveau d'un district pour évaluer l'efficacité de la formation de 13 infirmières sages-femmes auxiliaires comme prestataires de l'avortement médicamenteux, et de 120 femmes comme bénévoles de santé communautaire et agents d'orientation pour élargir l'accès des femmes rurales à l'avortement médicamenteux. Des entretiens ont été organisés avec des prestataires de service et des femmes ayant mené un avortement médicamenteux, et des statistiques de service ont été analysées. Par comparaison avec un district voisin où aucune intervention n'avait été réalisée, dans la zone d'intervention, on a constaté une hausse sensible de la connaissance des bénévoles de santé communautaire sur les conditions juridiques de l'avortement, les avantages et les inconvénients de l'avortement médicamenteux, les lieux sûrs pour l'avortement, les médicaments abortifs, l'âge gestationnel correct pour pratiquer un avortement médicamenteux à domicile et la réalisation d'un test de grossesse urinaire. Sur une période d'un an en 2011-2012, les bénévoles de santé communautaire ont effectué un test de grossesse pour 584 femmes et adressé 114 femmes qui voulaient avorter aux infirmières sages-femmes auxiliaires ; les infirmières sages-femmes auxiliaires ont prêté des services d'avortement médicamenteux pour 307 femmes dans la zone d'intervention. Aucune complication n'a exigé l'aiguillage vers un centre plus spécialisé, à l'exception d'un avortement incomplet. Presque toutes les femmes qui avaient opté pour l'avortement médicamenteux étaient satisfaites des services obtenus. L'étude a montré que les infirmières sages-femmes auxiliaires peuvent pratiquer efficacement, indépendamment et en confiance des avortements médicamenteux en toute sécurité au niveau des sous-centres de santé, et que les bénévoles de santé communautaire sont de précieux agents de changement pour renseigner les femmes sur l'avortement médicamenteux.

Resumen

Los servicios de aborto con medicamentos fueron introducidos en Nepal en 2009, pero el acceso de las mujeres rurales a dichos servicios continu,ó siendo limitado. Realizamos un estudio de investigación operativa a nivel de distrito para evaluar la eficacia de capacitar a 13 enfermeras-obstetras auxiliares como prestadoras de servicios de aborto con medicamentos, y 120 voluntarias comunitarias en salud como comunicadoras y agentes de referencia para ampliar el acceso de las mujeres rurales a dichos servicios. Se realizaron entrevistas con prestadores de servicios y mujeres que recibieron servicios de aborto con medicamentos y se analizaron las estadísticas de los servicios. Comparado con un distrito aledaño donde no hubo intervención, en la zona de la intervención se vio un considerable aumento en los conocimientos de las voluntarias comunitarias respecto a las condiciones para un aborto legal, las ventajas y desventajas del aborto con medicamentos, lugares seguros para tener un aborto, fármacos para inducir el aborto, edad gestacional correcta para el uso domiciliario de los medicamentos para inducir el aborto, y realizar una prueba de embarazo en la orina. En el plazo de un año, 2011-12, las voluntarias comunitarias en salud realizaron pruebas de embarazo en 584 mujeres y refirieron a 114 mujeres a enfermeras-obstetras auxiliares para aborto; 307 mujeres en la zona de la intervención recibieron servicios de aborto con medicamentos de enfermeras-obstetras auxiliares. No hubo complicaciones que necesitaron referencia a una unidad de salud de mayor nivel, excepto un aborto incompleto. Casi todas las mujeres que optaron por tener un aborto con medicamentos estuvieron contentas con los servicios que recibieron. El estudio demostró que las enfermeras-obstetras auxiliares pueden proporcionar servicios de aborto con medicamentos de manera independiente, confiada, segura y eficaz, en un nivel inferior al puesto de salud, y las voluntarias comunitarias en salud son agentes de cambio eficientes para informar a las mujeres acerca del aborto con medicamentos.

JAMA | Original Investigation

Comparison of No-Test Telehealth and In-Person Medication Abortion

Lauren J. Ralph, PhD, MPH; C. Finley Baba, MPH; M. Antonia Biggs, PhD; Colleen McNicholas, DO; Amy Hagstrom Miller, BA; Daniel Grossman, MD

IMPORTANCE In the US, access to medication abortion using history-based (no-test) eligibility assessment, including through telehealth and mailing of mifepristone, has grown rapidly. Additional evidence on the effectiveness and safety of these models is needed.

OBJECTIVE To evaluate whether medication abortion with no-test eligibility assessment and mailing of medications is as effective as in-person care with ultrasonography and safe overall.

DESIGN, SETTING, AND PARTICIPANTS Prospective, observational study with noninferiority analysis. Sites included 4 abortion-providing organizations in Colorado, Illinois, Maryland, Minnesota, Virginia, and Washington from May 2021 to March 2023. Eligible patients were seeking medication abortion up to and including 70 days' gestation, spoke English or Spanish, and were aged 15 years or older.

EXPOSURE Study groups reflected the model of care selected by the patient and clinicians and included: (1) no-test (telehealth) eligibility assessment and mailing of medications (no-test + mail) (n = 228); (2) no-test eligibility assessment and pickup of medications (no-test + pickup) (n = 119); or (3) in-person with ultrasonography (n = 238).

MAIN OUTCOMES AND MEASURES Effectiveness, defined as a complete abortion without the need for repeating the mifepristone and misoprostol regimen or a follow-up procedure, and safety, defined as an abortion-related serious adverse event, including overnight hospital admission, surgery, or blood transfusion. Outcomes were derived from patient surveys and medical records. Primary analysis focused on the comparison of the no-test + mail group with the in-person with ultrasonography group.

RESULTS The mean age of the participants (N = 585) was 27.3 years; most identified as non-Hispanic White (48.6%) or non-Hispanic Black (28.1%). Median (IQR) gestational duration was 45 days (39-53) and comparable between study groups (P = .30). Outcome data were available for 91.8% of participants. Overall effectiveness was 94.4% (95% CI, 90.7%-99.2%) in the no-test + mail group and 93.3% (95% CI, 88.3%-98.2%) in the in-person with ultrasonography group in adjusted models (adjusted risk difference, 1.2 [95% CI, −4.1 to 6.4]), meeting the prespecified 5% noninferiority margin. Serious adverse events included overnight hospitalization (n = 4), blood transfusion (n = 2), and emergency surgery (n = 1) and were reported by 1.1% (95% CI, 0.4%-2.4%) of participants, with 3 in the no-test + mail group, 3 in the in-person with ultrasonography group, and none in the no-test + pickup group.

CONCLUSIONS AND RELEVANCE This prospective, observational study found that medication abortion obtained following no-test telehealth screening and mailing of medications was associated with similar rates of complete abortion compared with in-person care with ultrasonography and met prespecified criteria for noninferiority, with a low prevalence of adverse events.

Case 6:25-cv-01491-DCJ-DJA Document 54-11 Filed 02/03/26 Page 117 of 140 PageID #: 3592

Medication abortion with mifepristone and misoprostol was first approved by the US Food and Drug Administration (FDA) in 2000 and is currently approved for use through 70 days' gestation in pregnancy.[1] In 2023, medication abortion accounted for 63% of abortions in the US, an increase from 53% in 2020 and 31% in 2014.[2-4] Multiple studies have firmly established the safety and effectiveness of the mifepristone and misoprostol regimen for medication abortion; the incidence of major complications or serious adverse events (SAEs) is less than 0.5% and overall effectiveness in ending the pregnancy without the need for a follow-up procedure is 95% to 97%.[5-10]

In recent years, access to various medication abortion models has expanded rapidly, including telehealth or virtual eligibility assessment and counseling, mailing medications directly to patients, and, in some instances, forgoing the requirement for an in-person ultrasonography or physical examination to establish location and duration of pregnancy prior to provision of medication abortion.[11] The FDA's removal of the in-person dispensing requirement for mifepristone, which had long been part of the drug's Risk Evaluation and Mitigation Strategy, facilitated this expansion. Emerging research evaluating the safety and effectiveness of telehealth and in-person, no-test models[12-14] builds on prior evidence demonstrating that provision of medication abortion by telemedicine (with ultrasonography and/or physical examination) has a comparable safety and effectiveness profile to in-person provision.[15-19] A 2022 retrospective cohort study of 2379 pregnant people accessing medication abortion using history-based (no-test) eligibility assessment in the US reported 94.5% effectiveness in ending the pregnancy and rate of SAEs of 0.42%.[20] Similarly, a large, retrospective cohort study of over 50 000 patients receiving medication abortion in the UK reported effectiveness rates of 98% to 99%, with no difference between those accessing care with and without routine pretreatment ultrasonography.[21]

Further evidence on the effectiveness and safety of telehealth and in-person, no-test (without ultrasonography or physical examination) medication abortion informs expansion of these models to all pregnant people seeking abortion, particularly those now living in the 21 states where abortion is banned or heavily restricted[22] or the 6 states where abortion remains legal but telehealth or mailing of medications is banned.[23] The present study compares the effectiveness and safety of medication abortion provided using 2 models of no-test, telehealth abortion care (mailed or pickup medications) with in-person care with ultrasonography.

Key Points

Question Is medication abortion provided using no-test eligibility screening and mailing of medications as effective as in-person care with ultrasonography and safe overall?

Findings This prospective, observational study found that medication abortion obtained following no-test telehealth screening and mailing of medications was associated with similar rates of complete abortion compared with in-person care with ultrasonography (94.4% vs 93.3%, respectively) and met the 5% noninferiority margin, with a low prevalence of adverse events.

Meaning The findings suggest that models of medication abortion care that rely on no-test eligibility assessment and mailing medications to patients are an option for individuals considering medication abortion.

Methods

This was an observational, prospective study comparing medication abortion effectiveness and safety using different methods of eligibility assessment (ultrasonography vs no-test) and dispensing of medications (mail vs in-person). The study protocol, including the statistical analysis plan, was published at Open Science Framework in April 2022 prior to initiating any analyses.[24]

Participants and Procedures

Participants were recruited from 4 abortion-providing organizations in 6 states (Colorado, Illinois, Maryland, Minnesota, Virginia, and Washington) between May 2021 and March 2023. We selected organizations that offered direct-to-patient telehealth or other no-test, history-based eligibility screening models that could dispense mifepristone using a mail-order pharmacy and, to allow for an appropriate comparison group, that also offered in-person provision at a facility within the same clinic network and state. One organization had facilities in 3 states and offered telehealth services to patients in those same states through a centralized call center. Thus, there were a total of 6 facilities, 1 in each state (eFigure 1 in Supplement 1). Eligibility was restricted to patients aged 15 years or older (3 facilities) or aged 18 years or older (3 facilities), English or Spanish speakers, seeking and eligible for medication abortion at that facility, and intending to take the medication up to and including 70 days' gestation. Participants were typically approached by facility staff during initial counseling; those interested in participating received a longer description of the study and then completed electronic informed consent and signed a Health Insurance Portability and Accountability Act waiver allowing clinic staff to review the patients' medical records with the study team. Patients then shared contact information for survey follow-up and received a $15 gift card for enrolling.

Data Collection

Study data were obtained from 2 sources. First, participants were asked to complete electronic surveys 1 day, 2 weeks, and 1 month after receiving the medications. Survey links were sent via text or email and included up to 5 reminders. Surveys were designed such that participants with an unclear abortion outcome (eg, who responded "I'm not sure" if the medications worked to end the pregnancy) were sent repeat surveys until an outcome was ascertained or the patient was considered lost to follow-up. Participants were remunerated with gift cards worth $25 for completing the first and third surveys and $15 for completing the second survey.

Clinics abstracted medical record data using a standardized tool[25] 6 weeks after the initial appointment. If care was

© 2024 American Medical Association. All rights reserved.
GBP-PET00684
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 04/24/2025

ongoing, clinics continued to abstract clinical data until the outcome of the abortion was known or adverse events (AEs) had resolved. In-depth, follow-up chart review was conducted for all cases with an unclear abortion outcome or potential AE.

Measures

The primary exposure was model of medication abortion care received. There were 3 groups: (1) no-test (telehealth) eligibility assessment by history and mailing of medications (no-test + mail); (2) no-test eligibility assessment (via telehealth or in-person) by history and pickup of medications (no-test + pickup); or (3) in-person assessment with ultrasonography and in-person dispensing of medications (in-person).

The primary outcome was effectiveness of medication abortion defined as a complete abortion without need for procedural abortion or repeating the mifepristone and misoprostol regimen.[26] We relied on a combination of patient self-report (survey) and clinic (chart-abstracted) data to determine effectiveness. Survey questions included patients' self-assessment of whether they "believe[d] that the abortion pills worked to end the pregnancy," had taken a pregnancy test and its result, "had a suction procedure (vacuum aspiration or dilation and curettage [D&C]) to complete the abortion," or had been "given another dose of the first abortion pill (mifepristone)" as part of follow-up care. Chart-abstracted data included the clinician's assessment of the medication abortion outcome at last contact with the patient (complete, incomplete, ongoing pregnancy, unknown), any tests performed to document pregnancy outcome (ie, ultrasonography, physical examination, review of symptoms, urine pregnancy test, serum human chorionic gonadotropin testing), and details on any follow-up care received or reported to the clinic. A flowchart was developed a priori to resolve discordant patient self-report and chart-abstracted outcomes (eFigure 2 in Supplement 1). Clinic staff completing abstraction were not blind to the study group because this information was in the patient's medical record.

A secondary outcome was safety, defined as reporting of any abortion-related SAE. This included overnight hospital admission, surgery, blood transfusion, or death. Surveys assessed whether patients had "go[ne] to a hospital, emergency department, doctor's office, or clinic (other than your regularly scheduled follow-up visit)" since taking the mifepristone and, if so, what type of care they received (including "I was given a blood transfusion" or "I stayed overnight in the hospital"). Chart-abstracted data included any documented care received at an outside facility as well as details on the care received. We searched across all chart-abstracted data fields for a list of terms related to the defined SAEs to ensure all potential cases were identified. All open-ended chart data fields were also reviewed by a physician (D.G.) to determine whether an SAE was reported.

We collected sociodemographic and pregnancy characteristics prespecified as potential confounders, including participants' age, race and ethnicity, gestational duration, parity, and prior abortion. Race and ethnicity data were based on 2 prespecified questions regarding Hispanic, Latine, or Spanish ethnicity (yes or no) and self-reported race (Asian, Black or African American, Middle Eastern or North African, Native American or Other Pacific Islander, White, or other), with the option to select all that apply and/or write in a response. Gestational duration at initial appointment collected by facility staff was estimated using date of last menstrual period for the telehealth groups and ultrasonography for the in-person with ultrasonography group. For race and ethnicity, prior abortion, and parity, we relied on participants' survey responses; when possible, missing responses were completed using medical record data.

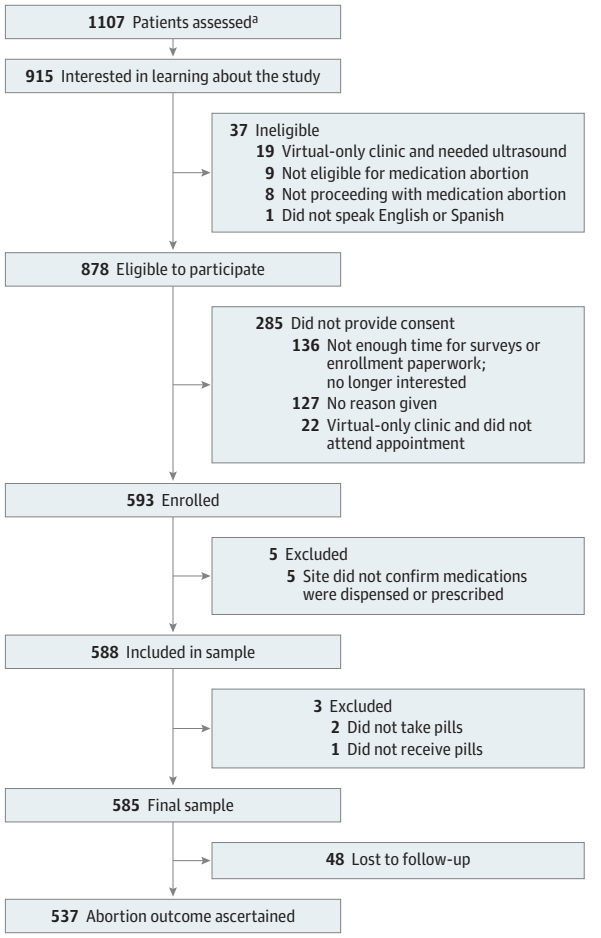
Statistical Analysis

We described the distribution of sociodemographic and pregnancy covariates in the study sample overall. We then tested for differences in the distribution of these covariates as well as the proportion with abortion outcome data by study group using bivariable mixed effects linear or multinomial regression models adjusted for clustering of observations by facility as well as standardized mean differences. Although our prespecified statistical analysis plan describes adjusting for clustering by *site*, our subsequent inclusion of facilities from the same organization but located in different states led to a preference for adjustment for clustering at the state and facility level, in the spirit of the prespecified plan. However, to ensure robustness of findings, we also included sensitivity analyses with random effects for organization (n = 4).

Among enrolled participants who took mifepristone or misoprostol and had abortion outcome data available, the unadjusted proportion (with 95% CI) with a complete abortion by study group was calculated. For the primary, prespecified analysis, we examined noninferiority of the telehealth (no-test) with mailed medications care group compared with the in-person care with ultrasonography group. From a logistic mixed effects model with a random effect for facility, we calculated the unadjusted risk difference (and 95% CI) in effectiveness between telehealth (no-test) with mailed medications and in-person care. We then reran the same model with the addition of prespecified confounders, including age and gestational duration, as well as any variables found to differ by study group in bivariable analysis. Telehealth (no-test) with mailed medications care was considered noninferior if the lower side of the 2-sided CI was above −5%, chosen to be consistent with prior research.[27-29] As secondary, prespecified analyses, we then repeated these steps to examine noninferiority of no-test + pickup (vs in-person) and either no-test (vs in-person with ultrasonography) care. We also descriptively examined the proportion (with 95% CI) in each study group that experienced an SAE and, when possible, differences in proportions by study group from adjusted models.

Prespecified analyses focused on a complete-case analysis. However, to ensure robustness of study findings, we repeated our primary, prespecified analysis using multiple imputation by chained equations. We imputed missing data for all covariates and the primary outcome (effectiveness) using all covariates in the original adjusted models as well as receipt of public assistance, educational attainment, and whether they completed a survey. We then used Stata's MI

© 2024 American Medical Association. All rights reserved.
GBP-PET00685
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 04/24/2025



estimate command and a logistic regression model using imputed values and the mimrgns command to estimate the risk difference between study groups (StataCorp). We utilized an inverse probability of treatment-weighted regression adjustment approach to balance covariates between study groups and re-estimate the risk difference. Specifically, logistic regression was used to calculate the propensity score or probability of treatment (telehealth + mail). We then calculated weights as 1/propensity score for the treated group and 1/1-propensity score for the untreated (in-person with ultrasonography) and reran a logistic regression model applying this weight. Finally, to allow for interpretation of marginal, population-level effects, we repeated the primary analysis using a logistic regression model with robust standard errors for facility.

Sample Size

We determined the minimum sample size required to establish noninferiority of telehealth (no-test) with mailed medications care to in-person care for the primary effectiveness outcome. Assuming 20% loss to follow-up, moderate correlation of observations by site (increasing sample size by an additional 15%), and effectiveness of 95%,[7,30] a sample size of 170 participants per study group, or 510 participants overall, gave 80% power with a 1-sided α of .025 to establish noninferiority of telehealth (no-test) with mailed medications care. The study was not powered to detect noninferiority of different models with respect to safety.

All study activities were approved by the University of California San Francisco institutional review board in January 2021 (#20-32514). This manuscript was prepared in accordance with STROBE guidance.[31]

Figure. Study Flowchart

[a]During initial telehealth or in-person appointment.

Results

A total of 1107 patients were approached, of whom 878 were eligible; 588 consented and enrolled (**Figure**). There were no differences in mean age (P = .38), appointment type (P = .72), or gestational duration (P = .51) between those eligible who enrolled vs did not enroll.

Among 588 enrolled patients, 3 were excluded from the analysis because they did not receive (n = 1) or take (n = 1) pills or because they sought emergency care for an ectopic pregnancy *before* picking up the pills (n = 1), resulting in a final sample of 585. Abortion outcome data were available for 537 of 585 (91.8%) of the participants; the proportion with abortion outcome data did not differ by study group (**Table 1**). Further, there were no differences by sociodemographic and pregnancy characteristics in the proportion missing abortion outcome data (eTable 1 in Supplement 1).

Median (IQR) participant age was 26 years (23-31). Nearly one-half (48.6%) were non-Hispanic White, with fewer non-Hispanic Black (28.1%), non-Hispanic other, or multiple races (12.1%) or Hispanic (9.6%). Approximately 4 in 10 participants reported a prior abortion (42.6%). Median (IQR) gestational duration at screening was 45 days (39-53) and did not differ by study group (P = .39). In the no-test + pickup medications study group, two-thirds (66%) completed eligibility assessment virtually and one-third (33%) completed no-test eligibility assessment in-person at a clinic.

Overall, 510 of 537 participants had a complete abortion without a procedure or repeating the mifepristone and misoprostol regimen, for an unadjusted effectiveness rate of 95.0% (95% CI, 92.8%-96.7%). Among the 27 participants classified as having an incomplete abortion, 18 had a follow-up procedure to complete the abortion, 6 reported a positive pregnancy test or uncertainty about whether the pills worked and were then lost to follow-up, 2 had a confirmed or suspected ectopic pregnancy, and 1 reported receiving outside care to complete the abortion to the study clinic. One ectopic pregnancy was confirmed by the patient, who reported to the clinic that they had sought care at an emergency department after taking the medications and had an operation to remove a fallopian tube. The other participant was referred to a hospital for evaluation and treatment of a suspected ectopic pregnancy after reporting no bleeding for more than 24 hours after taking misoprostol.

[a] N = 585; all values are No. (%) unless otherwise indicated.

[b] *P* value obtained from bivariable mixed effects linear or multinomial regression model adjusted for clustering of observations by facility.

[c] Relies on survey response first and on chart documentation if survey response was missing.

[d] Gestational duration was obtained from self-reported date of last menstrual period for both no-test study groups and from ultrasonography for in-person with ultrasonography group.

Unadjusted effectiveness was 94.1% (95% CI, 90.1%-96.8%) in the in-person group, 95.1% (95% CI, 91.2%-97.6%) in the no-test + mail group, and 96.5% (95% CI, 91.2%-99.0%) in the no-test + pickup group. After adjustment for covariates including age, race and ethnicity, and gestational duration, the risk difference between the in-person and no-test + mail groups was 1.2% (95% CI, −4.1% to 6.4%), above the limit of −5% and indicating noninferiority of telehealth (no-test) with mailed medications care. In this adjusted model, effectiveness was 94.4% (95% CI, 89.6%-99.2%) in the no-test + mail group and 93.3% (95% CI, 88.3%-98.2%) in the in-person group. Similarly, the adjusted risk difference between the in-person and no-test + pickup care groups was 1.7% (95% CI, −4.6% to 8.1%), indicating noninferiority of no-test + medications pickup care. In this adjusted model, effectiveness was 95.0% (95% CI, 88.8%-100.0%) in the no-test + pickup care group and 93.3% (95% CI, 88.8%-97.8%) in the in-person group (**Table 2**).

In sensitivity analyses, rerunning models with imputed missing observations, with application of inverse probability of treatment weights, and with adjustment for clustering of observations by organization (vs facility), results were consistent and demonstrated noninferiority of the no-test model (eTable 2 in Supplement 1).

Overall, 6 of 537 participants experienced an SAE, for a rate of 1.1% (95% CI, 0.4%-2.4%). Events included 4 overnight hospitalizations, 2 blood transfusions, and 1 surgery (for treatment of ectopic pregnancy). The unadjusted rate of SAEs was 1.5% (95% CI, 0.3%-4.2%) in the telehealth + mail group (n = 3) and 1.4% (95% CI, 0.3%-3.9%) in the in-person group (n = 3); no SAEs were reported in the no-test + pickup care group. In adjusted logistic models with robust standard errors for state, the adjusted risk difference between the in-person with ultrasonography and no-test + mail care group was 0.4 (95% CI, −1.0 to 1.7), indicating noninferiority of the no-test + mail model (eTable 3 in Supplement 1).

Table 2. Noninferiority of Different Models of Care on Effectiveness of Medication Abortion

	Unadjusted risk difference (95% CI)[a]	Adjusted proportion (95% CI) with complete abortion[b] (nonrandomized study groups)			Adjusted risk difference (95% CI)[b,a]
		No-test telehealth + medication by mail	No-test + medication pickup	In-person with ultrasonography	
Unadjusted No. with complete abortion/ No. with abortion outcome data		194/204	109/113	206/220	
In-person with ultrasonography vs no-test telehealth + medication by mail	1.6 (−3.5 to 6.7)	94.4 (89.6 to 99.2)	NA	93.3 (88.3 to 98.2)	1.2 (−4.1 to 6.4)
In-person with ultrasonography vs no-test + medication pickup	1.5 (−4.9 to 7.9)	NA	95.0 (88.8 to 100.0)	93.3 (88.8 to 97.8)	1.7 (−4.6 to 8.1)
In-person with ultrasonography vs any no-test (medication by mail or pickup)	1.5 (−3.1 to 6.1)	94.4 (90.1 to 98.6)[c]		93.2 (88.4 to 98.1)	1.1 (−3.6 to 5.9)

[a] All models include a random effect to account for clustering of observations by facility.

[b] Adjusted for age, race and ethnicity, and gestational duration at time of initial appointment.

[c] Study groups 1 and 2 combined to show contrast with study group 3.

Discussion

In this prospective, observational study of 585 people obtaining medication abortion, it was found that medication abortion following no-test telehealth screening and mail-order pharmacy dispensing of medications was associated with similar rates of complete abortion as in-person care with ultrasonography, met the prespecified threshold for noninferiority, and had a low rate of AEs overall. Further, medication abortion following no-test screening with pickup of medications was also associated with similar outcomes as in-person care with ultrasonography and had low rates of AEs overall. Levels of effectiveness with models of care incorporating telehealth and eligibility assessment in this study were comparable to large 2022 and 2024 studies of no-test telehealth patients.[20,32] This study contributes new evidence pertaining to no-test telehealth models in direct comparison with a concurrent control group of people receiving care from similar facilities through in-person care with ultrasonography. Taken together, these findings indicate that no-test and telehealth models with mailing of medications may be offered as an option to people seeking abortion. Although geographic and logistical barriers have always delayed and complicated pregnant people's access to abortion,[33,34] these barriers have become increasingly problematic following the Supreme Court's June 2022 decision revoking federal protections on abortion.[35,36] Thus, expansion of telehealth and no-test or history-based models offers a safe and effective, as well as urgently needed, way to overcome at least some of the logistical and geographic barriers to accessing abortion.[37]

Study findings may also be used to refute ongoing efforts to further regulate and restrict access to medication abortion, most notably in the *Alliance for Hippocratic Medicine v FDA* case currently before the US Supreme Court. One of the central issues being considered in this case is the quality of the evidence the FDA relied on when it removed the in-person dispensing requirement for mifepristone in 2021.[38] Although the data were robust in 2021 when the FDA performed its review, this current analysis, as well as other research published since then,[20,32] further strengthens the evidence documenting the safety and effectiveness of medication abortion provided using no-test telehealth screening for eligibility and dispensing the medications by mail.

Limitations

This study has limitations. First, approximately 8% of the participants were lost to follow-up and did not complete a survey or have any follow-up contact with the clinic. Although this follow-up rate represents an improvement over prior research that relied only on chart-abstracted outcomes,[12,13,19,20] the possibility that those who were lost to follow-up had worse outcomes remains. Second, only patient-reported outcomes up to 4 weeks after initiation of treatment were collected; it is possible that additional treatment could have been accessed after that point. Third, as an observational study in which patients could select which model of medication abortion care they received, some differences in the sociodemographic and pregnancy characteristics by study group were expected and therefore the study relied on adjustment for these characteristics to account for them in analyses. Reassuringly, differences were not observed in gestational duration by study group, which is likely most strongly correlated with outcomes of safety and effectiveness,[7] and models with imputed data produced comparable findings. However, confounding on unobserved covariates always remains a possibility in observational data. Fourth, this study sample size was not powered to detect noninferiority of, or differences in, safety of different models of care. Although few SAEs (n = 6 [1.1%]), including ectopic pregnancy, were observed, the estimate is qualitatively higher than a large 2022 retrospective study of patients receiving medication abortion through history-based screening, which found that 0.5% experienced an SAE.[20] Inclusion of patient self-reported outcomes, including overnight hospitalization, in defining SAEs likely contributed to this. Notably, the concurrent control group allowed direct comparison of the rate of SAEs between those receiving no-test telehealth medication abortion with mailing of medications vs in-person care with ultrasonography.

Conclusions

This prospective, observational study found that medication abortion following no-test telehealth screening and mailing of medications was associated with similar rates of abortion completion compared with in-person care with ultrasonography, meeting the prespecified threshold for noninferiority and with a low prevalence of adverse events.

Original Research

The Comparative Safety of Legal Induced Abortion and Childbirth in the United States

Elizabeth G. Raymond, MD, MPH, and David A. Grimes, MD

OBJECTIVE: To assess the safety of abortion compared with childbirth.

METHODS: We estimated mortality rates associated with live births and legal induced abortions in the United States in 1998–2005. We used data from the Centers for Disease Control and Prevention's Pregnancy Mortality Surveillance System, birth certificates, and Guttmacher Institute surveys. In addition, we searched for population-based data comparing the morbidity of abortion and childbirth.

RESULTS: The pregnancy-associated mortality rate among women who delivered live neonates was 8.8 deaths per 100,000 live births. The mortality rate related to induced abortion was 0.6 deaths per 100,000 abortions. In the one recent comparative study of pregnancy morbidity in the United States, pregnancy-related complications were more common with childbirth than with abortion.

CONCLUSION: Legal induced abortion is markedly safer than childbirth. The risk of death associated with childbirth is approximately 14 times higher than that with abortion. Similarly, the overall morbidity associated with childbirth exceeds that with abortion.

Decades of research have demonstrated that legal induced abortion is safe. Mortality and serious acute complications are extremely rare.[1–4] Recently, allegations of later sequelae—breast cancer and mental illness—were refuted.[5,6] However, laws in 22 states in the United States now require that before an abortion is performed, the patient must be given detailed, specific verbal or written information about potential risks. In some cases, this material is misleading or patently wrong.[7]

Health policy and medical practice should be based on the best available evidence. In the past 10 years, the introduction of new abortion methods may have affected the overall safety of the procedure. Notably, mifepristone was approved by the U.S. Food and Drug Administration for medical abortion in 2000; by 2008, approximately 17% of all nonhospital abortions were performed medically rather than surgically.[8] In addition, changes in the risk profile of pregnant women—for example, as a result of growing obesity[9] and an upward shift in the maternal age distribution[10]—as well as the rising cesarean delivery rate[10] may have enhanced the risks of the alternative to abortion, childbirth. The objective of this review is to provide an updated assessment[2] of the safety of abortion relative to delivery.

MATERIALS AND METHODS

We estimated mortality rates associated with live births and legal induced abortions in the United States in 1998–2005 by combining published data from several national data sets. For mortality related to live birth, we divided the number of pregnancy-related deaths among women delivering live neonates as reported by the Centers for Disease Control and Prevention's (CDC) Pregnancy Mortality Surveillance System[11] by the number of live births as reported on birth certificates.[10] The Pregnancy Mortality Surveillance System collects and reviews death certificates and other information from deceased women who were recorded as pregnant within a

Copyright© American College of Obstetricians and Gynecologists
GBP-PET00691

specified time period before death in all 50 states and Washington, DC. To estimate abortion-related mortality, we divided the number of legal abortion-related deaths from the 50 states and Washington, DC, reported by the CDC[12] by the number of legal abortions estimated by the Guttmacher Institute from its annual surveys of all U.S. hospitals, clinics, and physician offices known or suspected to have provided abortion services.[8] We did not calculate confidence intervals around mortality rates because these estimates are derived from the full population.

In addition, we searched PubMed for relevant studies for other population-based comparative data on mortality and morbidity of abortion and childbirth in the United States since 2000. We used the following search strategies: (maternal morbidity [MESH] OR maternal mortality [MESH]) AND pregnancy outcome AND United States [MESH] (73 results); pregnancy outcome AND (maternal morbidity [MESH] OR maternal mortality [MESH]) AND United States [tiab] (49 results); pregnancy outcome AND abortion, induced AND morbidity AND United States [MESH] (94 results). We limited our review to reports that included data on both pregnancy outcomes in a single population with contemporaneous, uniform ascertainment of outcomes.

Because women who choose abortion differ in underlying risk for adverse outcomes from women who opt to continue a pregnancy, we also compared the characteristics of each group. We obtained data about characteristics of U.S. women having abortions and live births in 2008 from the Guttmacher Institute 2008 Abortion Patient survey[13] and from birth certificate data[11] (www.cdc.gov/nchs/data_access/vitalstats/VitalStats_Births.htm. Retrieved 28 May 2011).

RESULTS

Between 1998 and 2005, the pregnancy-associated mortality rate among women known to have delivered live neonates in the United States was 8.8 deaths per 100,000 live births (Table 1). Of all pregnancy-associated deaths of women with known pregnancy outcome, 71% occurred after live births[11]; if 71% of women with unknown pregnancy outcome who died of pregnancy-associated causes are also assumed to have had live births, the mortality estimate increases to 10.4 deaths per 100,000 live births. The mortality rate related to legal induced abortion during that same interval was 0.6 deaths per 100,000 abortions. Thus, according to federal statistics, the risk of death associated with childbirth was approximately 14 times higher than that with abortion.

Table 1. Pregnancy-Related Mortality in Women With Live Births or Legal Induced Abortions in the United States, 1998–2005

	Deaths*	Pregnancies†	Deaths per 100,000 Pregnancies
Live birth		32,347,794	
Known live birth	2,856		8.8
Known live births+71% of pregnancies with unknown outcome	3,352		10.4
Legal abortion	64	10,185,100	0.6

* Number of deaths related to live births from Berg et al[11]; number of deaths related to abortion from Pazol et al.[12]

† Number of live births from Martin et al[10]; number of abortions from Jones et al.[8]

Only one recent study provided comparative data on morbidity associated with various pregnancy outcomes in the United States.[14] Epidemiologists at the CDC examined all International Classification of Diseases, 9th Revision, Clinical Modification diagnoses reported during or within 8 weeks after all 24,481 pregnancies among members of the Kaiser Permanente Northwest Health Maintenance Organization between 1998 and 2001. Of these pregnancies, 16,824 ended in live birth, 4,192 in induced abortion, and the rest in spontaneous abortions, stillbirths, or other outcomes. Common maternal morbidities were defined as conditions either unique to pregnancy or potentially exacerbated by pregnancy that occurred in at least 5% of all pregnancies.

Every complication was more common among women having live births than among those having abortions (Fig. 1). The relative risks of morbidity with live birth compared with abortion were 1.3 for mental health conditions, 1.8 for urinary tract infection, 4.4 for postpartum hemorrhage, 5.2 for obstetric infections, 24 for hypertensive disorders of pregnancy, 25 for antepartum hemorrhage, and 26 for anemia.

In 2008, the median age of women having abortions was younger than that of women having live births, but the proportion of women age 40 years or older was comparable (Table 2). Nearly half of women in each group had no education beyond high school. Patients undergoing abortion were twice as likely to be unmarried or non-Hispanic African American women. Nulliparity was equally common in the two groups.

DISCUSSION

Legal abortion in the United States remains much safer than childbirth. The difference in risk of death is approximately 14-fold. Abortion also is associated with substantially less pregnancy-related morbidity. These results are consistent with prior analyses of national data.[2] Indeed, the relative safety of abortion has increased substantially since the first decade after nationwide legalization, when child birth-related mortality was approximately seven times the mortality related to abortion.[15] Although we could not find data that allowed comparable calculations of mortality or morbidity associated with surgical and medical abortion, Danco Laboratories, the distributor of mifepristone in the United States, has identified only 11 pregnancy-related deaths among the estimated 1.6 million women who have used the drug in the United States since 2000, which is a mortality rate of 0.7 per 100,000 users (Abigail Long, Danco Laboratories, LLC, personal communication). Clearly, the growing use of medical regimens has not increased relative abortion risk overall.

The disparity between abortion and childbirth safety is not surprising. Pregnancies ending in abortion are substantially shorter than those ending in childbirth and thus entail less time for pregnancy-related problems to occur. Many dangerous pregnancy-related complications such as pregnancy-induced hypertension and placental abnormalities manifest themselves in late pregnancy; early abortion avoids these hazards. Moreover, in the United States in 2008, one third of births occurred by cesarean delivery, an abdominal operation with substantial morbidity.[10,16]

These results may underestimate the relative safety of choosing abortion over continuing a pregnancy for two reasons. First, our comparison was limited to live

Copyright© American College of Obstetricians and Gynecologists
GBP-PET00693

births; we omitted other pregnancy outcomes: spontaneous abortion, stillbirths, ectopic pregnancies, and gestational trophoblastic disease. The number of pregnancies ending in these outcomes was not available. Stillbirths and ectopic pregnancies are associated with higher risks of death than is live birth.[2] We likely therefore underestimated the mortality associated with opting for pregnancy continuation.

Second, patients undergoing abortion appear to be at higher underlying risk than women who opt for delivery. Women who had abortions were more likely to be African American or unmarried, demographic characteristics strongly associated with increased mortality.[11,17] In addition, because comorbidities are sometimes the motivation for abortion, the underlying medical risk of patients undergoing abortion may be higher than that of other pregnant women. Women in good health may be more likely to choose to continue their pregnancies than those who are ill (selection bias termed the "healthy mother" effect[18]). Thus, mortality among patients undergoing abortion may overestimate the mortality risk of the procedure itself.

This study has both strengths and weaknesses. Strengths include the use of the most recent CDC statistics on pregnancy-related mortality for the entire country. Similarly, the cohort study of morbidity had uniform, contemporaneous ascertainment of outcomes in a large health maintenance organization. We systematically reviewed the past decade of PubMed publications for relevant data. Weaknesses include the likely underreporting of deaths, possibly differential by pregnancy outcome (abortion or childbirth).[19] The analytic rules used by the original researchers to handle incomplete or inconsistent data on women's characteristics may have led to errors. Our assessment of women's underlying risk was necessarily incomplete. Moreover, both abortion and childbirth can cause mortality and morbidity long after the end of the pregnancy; these cases are not included in our analysis. However, these weaknesses are unlikely to account for the large differences in mortality and morbidity found in this analysis.

Pregnant women considering their options deserve accurate information about comparative risks. Currently, some state laws and policies violate this standard. In Texas, for example, the mandatory 23-page pamphlet, "A Woman's Right-to-Know," lists 12 potential complications of medical abortion with mifepristone and misoprostol, 12 of suction curettage, and 11 of dilation and evacuation. In contrast, the pamphlet names only six potential complications of vaginal delivery and eight of cesarean delivery.[20] To laypersons who have little understanding of medical risk[21] but can count complications, these tallies may imply that abortion has more complications than does childbirth. Similarly, the mortality statistics are presented as fractions with one in the numerator and with large denominators (eg, 8,475). Empiric evidence[22,23] has demonstrated that women with less formal education than a college degree have trouble comparing risks expressed in this manner. Mortality risk should be expressed as number of deaths per 100,000, which is an easier format to understand.[22,23]

Laws that compel exposure of women to such biased material thwart informed choice and contravene the ethical principle of autonomy.[24] Moreover, they put clinicians in the untenable position of having to be complicit in misleading their patients. Since the early 1970s, the public health evidence has been clear and incontrovertible: induced abortion is safer than childbirth.

BJOG
An International Journal of Obstetrics and Gynaecology

VACANCY: EDITOR-IN-CHIEF
BJOG is inviting applications for the position of Editor-in-Chief as Philip Steer comes to the end of his 7 year term in October 2012.

OVERVIEW OF ROLE

The Editor-in-Chief's role is to lead on the strategic direction of the journal. They must also supervise and coach an excellent team of scientific editors with the support of three deputy editors-in-chief and take final responsibility for all published articles. The role requires a high level of expertise to oversee new developments and to provide intellectual input and experience. The role also requires someone who understands the business side to the extent that they can appreciate the publishing business model and how it is developing. Editorial and strategic experience is essential.

The Editor-in-Chief would need to share the values of BJOG: journal quality (selection, validation and improvement), influence and reputation.

This is a professional role with an annual stipend of £40,000.

Closing date for applications: 17th February 2012
Shortlisted applicants will be invited for interview in March 2012
Start Date as BJOG Scientific Editor: May 2012
Start Date as Editor-in-Chief: November 2012

For more information on this role, a job description and person specification, please visit BJOG's website at **www.BJOG.org** or contact Elizabeth Hay, Managing Editor by email **ehay@rcog.org.uk** or telephone +44 (0) 20 7772 6440

[c]University of North Carolina at Chapel Hill, Department of Medicine, CB #7064, Chapel Hill, NC 27599–7064, USA

Received 1 March 2012; revised 15 June 2012; accepted 19 June 2012

Abstract

Background: The dose of mifepristone approved by most government agencies for medical abortion is 600 mg. Our aim was to summarize extant data on the effectiveness and safety of regimens using the widely recommended lower mifepristone dose, 200 mg, followed by misoprostol in early pregnancy and to explore potential correlates of abortion failure.
Study Design: To identify eligible reports, we searched Medline, reviewed reference lists of published reports, and contacted experts to identify all prospective trials of any design of medical abortion using 200 mg mifepristone followed by misoprostol in women with viable pregnancies up to 63 days' gestation. Two authors independently extracted data from each study. We used logistic regression models to explore associations between 15 characteristics of the trial groups and, separately, the rates of medical abortion failure and of ongoing pregnancy.
Results: We identified 87 trials that collectively included 120 groups of women treated with a regimen of interest. Of the 47,283 treated subjects in these groups, abortion outcome data were reported for 45,528 (96%). Treatment failure occurred in 2,192 (4.8%) of these evaluable subjects. Ongoing pregnancy was reported in 1.1% (499/45,150) of the evaluable subjects in the 117 trial groups reporting this outcome. The risk of medical abortion failure was higher among trial groups in which at least 25% of subjects had gestational age >8 weeks, the specified interval between mifepristone and misoprostol was less than 24 h, the total misoprostol dose was 400 mcg (rather than higher), or the misoprostol was administered by the oral route (rather than by vaginal, buccal, or sublingual routes). Across all trials, 119 evaluable subjects (0.3%) were hospitalized, and 45 (0.1%) received blood transfusions.
Conclusions: Early medical abortion with mifepristone 200 mg followed by misoprostol is highly effective and safe.

Keywords: Medical abortion; Mifepristone; Misoprostol; Systematic review

1. Introduction

Since mifepristone was introduced in France and China more than two decades ago, medical abortion with this antiprogestin has expanded rapidly throughout the world. Mifepristone is now registered in 50 countries (www.gynuity.org, accessed 14 December 2011). In the United States, about one fifth of all outpatient abortions are performed medically [1], and in several countries in Europe, the proportion exceeds 60% [2,3].

Although medical abortion regimens approved by most government regulatory agencies specify 600 mg mifepristone, in practice, a dose of 200 mg is standard worldwide [4–7]. A prostaglandin, misoprostol, is administered after the mifepristone to enhance success. The dose, route, and timing of administration of misoprostol are not standardized. In the United States, affiliates of Planned Parenthood Federation of America provide 800 mcg buccally 24–48 h after the mifepristone [4]. The International Federation of Obstetricians and Gynaecologists recommends either vaginal, buccal, or sublingual administration [5] as do the World Health Organization [6] and the United Kingdom Royal College of Obstetricians and Gynaecologists [7], which also recommend

oral dosing at gestational ages up to 49 days. Lower doses, divided doses, oral administration, and a shorter or longer interval between the two drugs also have been used clinically or evaluated in research studies.

The purpose of this review is to summarize published data on the effectiveness and safety of regimens including 200 mg mifepristone followed by misoprostol for early medical abortion. We also explore whether variation among studies in the frequency of medical abortion failure could be explained by characteristics of the study designs, treatment protocols, or study populations.

2. Materials and methods

We searched Medline using PubMed on 7 July 2011 for studies of medical abortion using mifepristone and misoprostol. Our search strategy was as follows: (abortion OR pregnancy termination OR termination of pregnancy) AND (mifepristone OR RU 486 OR RU-486 OR RU486 OR Mifegyne OR Mifeprex OR Medabon) AND (misoprostol OR prostaglandin). In addition, we reviewed the reference lists of relevant articles, and we contacted experts in the field for information about any published or unpublished trials not discovered in our search.

Two authors (E.G.R., C.S.) independently examined the search results (titles and as necessary abstracts and full publications) and other available information to identify all English language reports of prospective trials that included at least one group of women with viable first trimester pregnancies who were treated with a specified abortion regimen consisting of 200 mg mifepristone followed by misoprostol. These trials included randomized trials, cohort studies, and case series studies. For each group of interest in these reports, the same two authors separately abstracted data, including information about the study design and treatment protocol, the number and characteristics of women treated, and the numbers who had medical abortion failure, medical abortion failure with a diagnosed ongoing (viable) pregnancy, hospitalization, and blood transfusion. We contacted some authors to obtain additional data or to clarify details about the studies. We resolved discrepancies by discussion.

In some reports, the effectiveness analyses excluded subjects who initiated treatment but failed to complete the full prescribed medical abortion regimen. Our analyses included all pregnant women in each trial group who received at least mifepristone and who had a gestational age of 63 days or less, were not known to have an ectopic pregnancy, and had a reported abortion outcome. Most trials defined medical abortion failure as need for surgical intervention to complete the abortion, but a few used other definitions, such as failure to abort within 24 h after the misoprostol [8] and use of additional abortifacient drugs after the initially prescribed regimen [9]. Of necessity, we used the authors' definitions, but when possible, we also included as failures ongoing pregnancies that were continued at the patient's choice after ingestion of mifepristone.

In abstracting data about protocols and study populations, we combined the original authors' categories that were similar but not necessarily identical; for example, in recording gestational age ranges, we considered "<63 days", "≤63 days", "<9 weeks", and "≤9 weeks" all to be equivalent, and we considered subjects who had had no live births to be nulliparous if the report did not describe parity (including both live births and stillbirths). In recording parity and the gestational age distribution, we accepted figures for either the entire enrolled trial population or the analyzed population, as provided by the authors. We used our judgment to resolve internal inconsistencies and to correct frank errors noted in a few reports.

Our analysis considered each group from each trial (regardless of study design) as a separate case-series. We combined data across trial groups to calculate the proportion of subjects who had medical abortion failure and the proportion who had ongoing pregnancy. We used exact Pearson chi-square goodness-of-fit tests, calculated using StatXact, Version 8.0 (Cytel Inc., Cambridge, MA, USA), to assess heterogeneity across trial groups in both outcomes. To explore possible explanations for heterogeneity, we used logistic regression to examine associations between selected characteristics of the trial groups and, separately, medical abortion failure rate and ongoing pregnancy rate. The models controlled for nesting of groups within trial using generalized estimating equations with an independence working correlation matrix. The response for the models was the ratio of the number of events to the number of evaluable patients for each trial group (conducted in SAS, version 9.2, SAS Institute, Cary NC, USA); thus, model results were weighted by trial group sample size. We used "missing" categories to include trial groups with missing predictor data wherever relevant. The models included interaction terms for misoprostol dose and route of first dose. We excluded from both models one trial group of 4 women treated with 200 mcg misoprostol [10]. We excluded from the ongoing pregnancy model 3 trial groups in which ongoing pregnancy was not assessed [11–13], and to allow model convergence, we also excluded 4 groups in which women received misoprostol 600 mcg sublingual [14–17] because no ongoing pregnancies occurred in any groups with that dose/route combination. For one study in which the misoprostol dose was increased from 400 to 800 mcg partway through [18], we estimated the number of women and events in each of the two respective trial groups by assuming that the enrollment rate was constant over the course of the study. In reviewing the results, we focused on associations that were both substantial (odds ratio >1.5 or <0.67) and significant ($p<.05$).

A previously published protocol for this systematic review does not exist.

3. Results

The Medline search yielded 860 citations. Of these, 81 included at least one group of women who were treated with an abortion regimen that used 200 mg mifepristone followed by misoprostol in viable first trimester pregnancy [8–88]. In addition, we became aware of six reports of unpublished trials (M. Pena and S. Raghavan, Gynuity Health Projects, personal communication) that met these criteria.

The 87 trials included 36 randomized trials and 51 prospective cohort or case series studies conducted at 314 sites in 35 countries (Table 1). Sixty-three of the trials were performed between 1994 and 2011; the other 24 reports did not provide dates of data collection. Inclusion criteria for the trials were similar and broad: in general, any woman who requested medical abortion, did not have contraindications to the abortion drugs, and was within a specified gestational age range (determined by ultrasound or clinically) was eligible. Some trials had age restrictions and/or excluded women with multiple gestations.

The 87 trials included 120 groups of women treated with a regimen of interest: 62 trials studied a single such regimen, 18 studied two, six studied three, and one studied four (Appendix). The total prescribed dose of misoprostol in the regimens studied varied from 200–6400 mcg. In most trial groups, the misoprostol was delivered in one administration, but 13 groups received the total dose in divided increments over 1–7 days. Routes of administration included vaginal, oral, buccal and sublingual. The two most commonly studied regimens used 800 mcg misoprostol vaginally or 400 mcg orally. The interval between the mifepristone and the misoprostol ranged from 0 to 72 h. Some protocols required that all subjects receive the misoprostol in the clinic, whereas others allowed most or all women to take the misoprostol at home. In nearly half the groups, the treatment protocol specified that selected subjects who did not abort after the initial treatment should be offered one or more additional doses of misoprostol rather than immediate surgical evacuation.

The timing of the initial follow-up evaluation of abortion success varied from 1–21 days after mifepristone administration. In about half the trial groups, ultrasound was used routinely at the follow-up visit to determine whether the medical abortion regimen resulted in complete abortion and, if not, whether the pregnancy was ongoing. In other groups, outcome assessment, including the diagnosis of ongoing pregnancy, relied primarily or solely on patient symptoms and/or clinical examination. Some trials allowed collection of outcome information by telephone or by review of outside records. No trial had explicit criteria for hospitalization and transfusion of subjects.

The 120 trial groups included a total of 47,283 treated subjects, of whom 45,528 (96%) provided evaluable data for our effectiveness analyses (Table 1). The median proportion of treated subjects with missing outcome data was 1.3% (range 0–19%). The number of evaluable subjects in the 120 groups ranged from 4 to 4,132.

Among all evaluable subjects, 2,192 (4.8%) had medical abortion failure (Table 2). Across trial groups, the proportion with this outcome ranged from 0 to 40% (Fig. 1A). Half the groups had failure rates of 4.8% or less, and more than 90% of the evaluable subjects were in trial groups in which the failure proportion was 8.8% or less.

In 84 trials (117 groups), researchers noted whether or not each patient with medical abortion failure was diagnosed with ongoing pregnancy at the time of the failure ascertainment (Table 2). Of the 45,150 evaluable subjects in these trials, 499 (1.1%) had ongoing pregnancies. Across these groups, the median percentage of subjects with ongoing pregnancies was 0.7%, and 90% of the subjects were in groups in which less than 2.9% of subjects had ongoing pregnancy (Fig. 1B). The 499 ongoing pregnancies constituted 23% of the 1,976 medical abortion failures in these groups.

We found strong evidence of heterogeneity across trial groups in both the proportion of subjects who had medical abortion failure and the proportion who had ongoing pregnancy ($p<.001$ for both outcomes). Logistic regression models included as independent variables all the characteristics listed in Table 2. These models found few associations that were both substantial and significant. After adjustment for other characteristics included in the model, groups in which at least 25% of the women were in the ninth week of pregnancy had higher medical abortion failure rates than groups in which fewer women were so advanced in gestation (OR 1.5; 95% CI 1.1–2.0). Groups instructed to take the misoprostol <23 h after the mifepristone also had higher medical abortion failure rates than other groups (OR 2.1; 95% CI 1.4–3.2). At each total misoprostol dose level, oral administration was associated with higher medical abortion failure rates than each of the other three routes, but no substantial differences were noted among the other routes. Similarly, for each route, 400 mcg misoprostol was associated with higher failure rates than higher doses, although not all of these associations were significant.

Associations of misoprostol dose and route with ongoing pregnancy were mostly consistent with the associations with failure of all types; that is, both the oral route and the 400 mcg dose of misoprostol were generally associated with higher ongoing pregnancy rates than other doses and other routes. Ongoing pregnancy was twice as common in groups in which ultrasound was not routinely used to confirm success than in groups in which it was used in all women (OR 2.0, 95% CI 1.0–3.9). No notable associations were apparent between ongoing pregnancy rates and of any of the other group characteristics, however.

Across all trials, 119 of 45,528 evaluable subjects (0.3%) were hospitalized; of these, 46 hospitalizations (38%) occurred in a single trial [21] which included 4,132 treated women. Most of the hospitalizations were for vaginal bleeding, pelvic pain, or infection; some were for ectopic

pregnancy or other conditions unrelated to the abortion. Forty-five women (0.1%) received blood transfusions. Hospitalizations and blood transfusions were less common in trials in which women were permitted to take the misoprostol at home (0.15% and 0.08%, respectively) than in trials in which clinic administration was required (0.45% and 0.14%, respectively).

4. Discussion

Medical abortion using mifepristone 200 mg followed by misoprostol in the first 63 days of gestation is remarkably effective and safe. In trials that together included more than 45,000 women conducted in disparate settings over nearly two decades using a variety of regimens and treatment protocols, fewer than 5% of subjects required surgery to complete termination of the pregnancy. The proportion who had ongoing pregnancy at follow-up — the outcome of greatest concern to clinicians — was 1.1%. Serious complications requiring hospitalization or transfusion occurred in less than 0.4% of patients.

Some random variability in results is expected in any collection of research studies. However, our analysis found strong evidence of statistical heterogeneity across trials in both medical abortion failure rates and rates of ongoing pregnancy. This finding indicates that the non-uniformity in these outcomes was due to underlying differences among the studies rather than simply to chance. We identified a few practices that were associated with a lower risk of medical

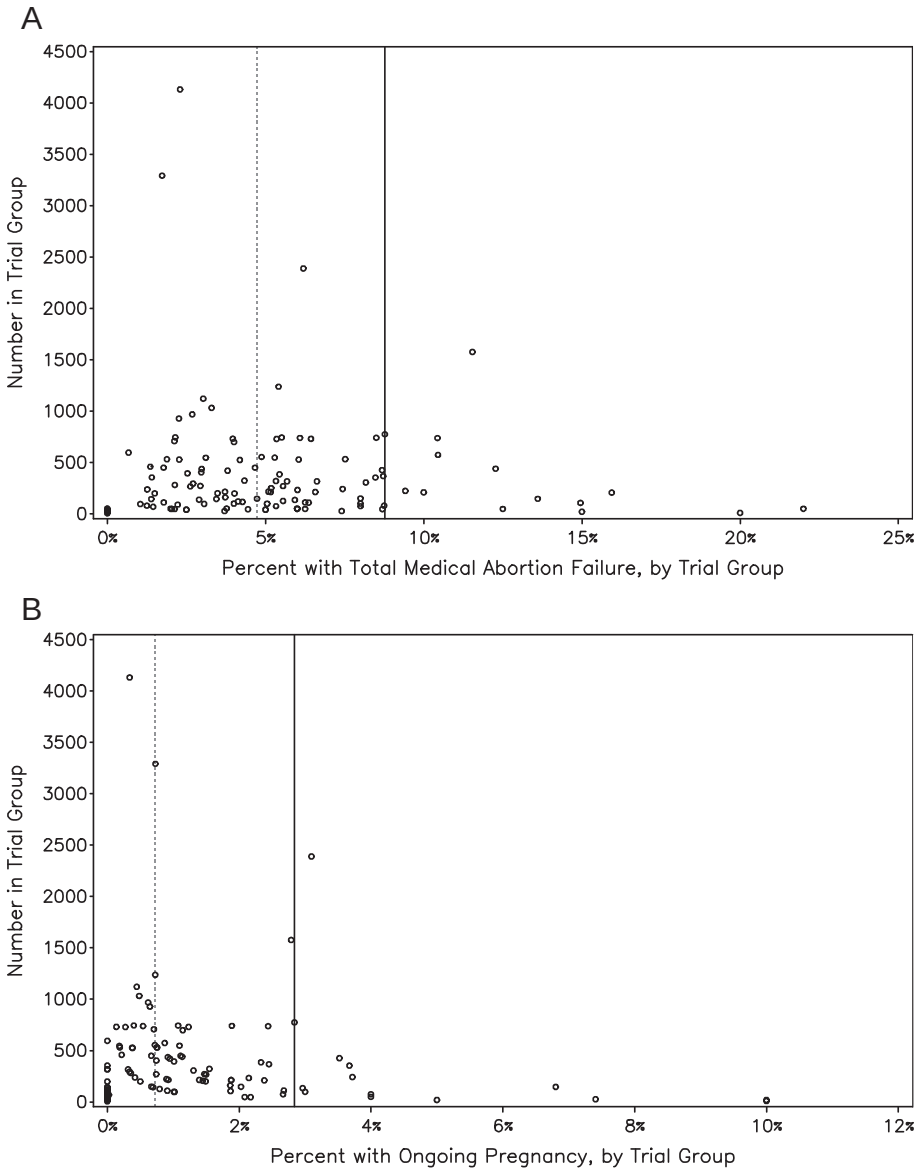

Fig. 1. Size of trial group by percentage of subjects with medical abortion failure and ongoing pregnancy at follow-up assessment. 50% of trial groups are to the left of dashed line; 90% of subjects are to the left of solid line. One group of 4 subjects with one ongoing pregnancy is omitted from both panels; panel A also omits one group of 20 subjects with 8 medical abortion failures. (A) Medical abortion failure. (B) Ongoing pregnancy.

abortion failure: an interval of at least 24 h between the mifepristone and misoprostol, use of misoprostol doses higher than 400 mcg and administration of misoprostol by a buccal, vaginal, or sublingual rather than oral route. The last of these is consistent with the conclusions of a recent Cochrane review of first trimester medical abortion, which included only randomized trials [89]. As cited previously, most current guidelines for medical abortion incorporate these practices.

We also found slightly higher risks of medical abortion failure in groups that had a high proportion (>25%) of women in the 9th week of pregnancy: after adjustment for other factors, these groups overall had a 50% higher odds of medical abortion failure. However, we did not find a higher risk of ongoing pregnancy in these groups. Given the low overall risk of medical abortion failure and the relative ease of treating failure using surgical evacuation (which would have been the treatment for all subjects had medical abortion not been attempted), offering medical abortion to women at this gestational age seems reasonable.

We observed no significant association between abortion failure rates and the timing of the follow-up evaluation. The data thus are inconclusive with respect to the theory that high surgical intervention rates are in part attributable to impatience among providers and patients [90]. Moreover, although routine ultrasound evaluation at follow-up was

associated with a lower risk of diagnosis of ongoing pregnancy, we found no evidence for or against an effect of this practice on overall medical abortion failure rates — that is, the need for surgical intervention. Prompt confirmation of completeness of the abortion and clinical assessment without routine ultrasound may enhance women's satisfaction with the procedure.

We found no evidence that allowing women to take the misoprostol at home increased the rates of abortion failure or serious complications. Most women prefer this option [90], and it is presumably substantially more efficient for the health care system than requiring patients to return to the provider for administration of the prostaglandin. This requirement, which is law in some countries such as the United Kingdom [7], thus is unjustifiable and should be abandoned.

This analysis has some limitations. Our data allowed us to explore heterogeneity across patient populations, not across individual patients; therefore, we may have missed some associations that would have been identified in an individual-level analysis. Missing data on some characteristics of some groups may have affected the direction or strength of associations, and we acknowledge that including "missing" categories for predictor variables would not have been preferred had we analyzed individual-level data [91]. Because none of the 540 women in the four groups that received misoprostol 600 mcg sublingual had ongoing pregnancies, these groups were excluded for technical reasons from our regression analysis of that outcome; this omission may have affected the apparent associations of other factors with ongoing pregnancy. Undetected publication bias is always possible; we attempted to minimize this problem by consulting experts likely to be aware of relevant unpublished studies through their many years of work in this field. We had information on only selected characteristics of the studies, and unmeasured confounding was not controlled by randomization. We evaluated many potential associations without any adjustment for multiple comparisons; however, we fit only a single model for each outcome. In 5 of the 120 trial groups, at least 10% of subjects were lost to follow-up. However, the overall follow-up success was high, and even if we made the extreme assumption that all the subjects who were lost had abortion failures, the overall medical abortion failure rate would still have been low (8.3%).

The large quantity of data presented in this review demonstrates that currently used medical abortion regimens are so effective and safe that additional research aimed at further clinical improvement will have little public health benefit. Future investigations should focus on service delivery issues: increasing access, reducing cost, enhancing patient comfort and ensuring availability of ancillary services such as contraception that can aid women in reaching their reproductive goals.

n/a: data not available.
Ref indicates reference number. U1-U6 are unpublished studies.
Date indicates dates of data collection.
Dose/route indicates dose and route of misoprostol. SL, sublingual; vag, vaginal; buc, buccal; q, every; h, hours; d, days.
Delay indicates prescribed interval between mifepristone and misoprostol, in hours.
Evaluable indicates number of subjects with known abortion outcome.
Failures indicates number and percent of evaluable subjects with abortion failure.
Ongoing pregnancy indicates number and percent of evaluable subjects with abortion failures that were ongoing pregnancies.

ABSTRACT

Objectives: To evaluate the safety, feasibility, and acceptability of a direct-to-patient telemedicine service that enabled people to obtain medical abortion without visiting an abortion provider in person.
Study design: We offered the service in five states. Each participant had a videoconference with a study clinician and had pre-treatment laboratory tests and ultrasound at facilities of her choice. If the participant was eligible for medical abortion, the clinician sent a package containing mifepristone, misoprostol, and instructions to her by mail. After taking the medications, the participant obtained follow-up tests and had a follow-up consultation with the clinician by telephone or videoconference to evaluate abortion completeness. The analysis was descriptive.
Results: Over 32 months, we conducted 433 study screenings and shipped 248 packages. The median interval between screening and mailing was 7 days (91st percentile 17 days), and no participant took the mifepristone at ≫71 days of gestation. We ascertained abortion outcomes of 190/248 package recipients (77%): 177/190 (93%) had complete abortion without a procedure. Of the 217/248 package recipients who provided meaningful follow-up data (88%), one was hospitalized for postoperative seizure and another for excessive bleeding, and 27 had other unscheduled clinical encounters, 12 of which resulted in no treatment. A total of 159/248 participants who received packages (64%) completed satisfaction questionnaires at study exit; all were satisfied with the service.
Conclusions: This direct-to-patient telemedicine abortion service was safe, effective, efficient, and satisfactory. The model has the potential to increase abortion access by enhancing the reach of providers and by offering people a new option for obtaining care conveniently and privately.

Implications: Provision of medical abortion by direct-to-patient telemedicine and mail has the potential to increase abortion access by increasing the reach of providers and by offering people the option of obtaining abortion care without an in-person visit to an abortion provider.

1. Introduction

Access to abortion is limited for many people in the United States. The number of clinics providing this service declined by 6% between 2011 and 2014 [1], and in 2017, 27 cities with populations of 50,000 or more had no abortion clinic within a 100 mile radius [2]. Even people who live near a clinic may have difficulty attending in person due to scheduling conflicts, long wait times for appointments, the high cost of travel, child care, and lost wages [3], concerns about confidentiality, and anticipated harassment at clinics [4].

In response to this problem, we launched the TelAbortion Project in 2016 to provide medical abortion using telemedicine. Unlike other telemedicine abortion services in our country [5–7], the TelAbortion model does not require the patient to present in person to a facility that provides abortion: rather, she obtains screening tests at laboratories and radiology offices and then communicates with the abortion provider by videoconference. If she is eligible for treatment, the provider dispenses the abortion medications by mail [8]. This direct-to-patient approach has been successfully instituted in international settings [9–15] but has been inhibited in the United States because the restriction on mifepristone distribution imposed by the Food and Drug Administration (FDA) is interpreted as prohibiting mailing [16]. Consequently, we implemented TelAbortion as a research study conducted under an Investigational New Drug application. The specific goals of the study are to assess the safety, acceptability, and feasibility of the service. Here, we provide data from the first 32 months of the project.

2. Methods

To date, the project has been conducted at five institutions: Choices Women's Medical Center in New York, the University of Hawaii (UH), Oregon Health & Science University (OHSU), Maine Family Planning (MFP), and Planned Parenthood Columbia Willamette (PPCW) in Oregon. These sites initiated enrollment in the order listed over 25 months. Choices stopped recruitment in mid-2017 due to slow accrual; the other sites are still enrolling. Each institution offered TelAbortions to people in its home state, and OHSU and MFP also served Washington and New York, respectively. We selected the six study states after confirming that they had no laws prohibiting the service.

We publicized the study using multiple approaches, including a study website (www.telabortion.org), outreach to clinicians, media reports, Google advertising, and strategically placed posters and pamphlets. In addition, sites provided information about the study to people contacting them for abortion appointments.

After a screening consultation with a study coordinator by telephone, each interested person had a "TelEvaluation" by videoconference with a study clinician who provided standard pre-abortion counseling and explained the study procedures, including expected costs. The participant signed the study informed consent form and other documents electronically using commercially available secure software. The clinician recorded relevant demographic and medical information. If the participant had not already had an ultrasound and Rh typing, the clinician assisted her in identifying facilities where she could conveniently obtain those tests and have the results sent to the study clinician. The participant and the clinician agreed on a plan for evaluating abortion outcome using ultrasound, serum HCG tests before and after mifepristone ingestion, or urine pregnancy test.

A person was eligible for medical abortion through the study if she was located in a project state where the study clinician was licensed, if she had no contraindications to medical abortion (intrauterine device in place, chronic adrenal failure, long-term corticosteroid therapy, allergy to mifepristone, misoprostol or other prostaglandin, hemorrhagic disorder, current use of anticoagulant therapy, or inherited porphyria), if her ultrasound showed an intrauterine pregnancy, and if the clinician judged that she would be able to receive and take the mifepristone at ≤70 days of gestation. Choices excluded people with negative Rh blood type because of concerns about ensuring provision of Rh immune globulin. OHSU and PPCW excluded people ≪18 years old and UH excluded people ≪14 years old.

If the participant was eligible and wished to continue with the abortion, the site sent to her by overnight or regular tracked mail a package containing one tablet of mifepristone 200 mg and eight tablets of misoprostol 200 mcg. Analgesics, antibiotics, anti-emetics, and contraceptives were included or prescribed at the discretion of the site clinician. The package also included an instruction sheet that described how to use the medications, expected symptoms and side effects, the follow-up plan, and emergency procedures. The abortifacient regimen was mifepristone 200 mg followed by misoprostol 800 mcg within 48 h administered buccally or vaginally per accepted practices at the sites. The participant was instructed to take the other four misoprostol tablets if no bleeding occurred within 24 h.

The site scheduled a follow-up contact with the study clinician for 7–14 days after the package was mailed. At this contact, the clinician interviewed the participant to assess symptoms, adverse events, and other relevant information. If further care was indicated, the clinician referred her to an appropriate facility. If a participant had not had the planned follow-up tests by 3–4 weeks after mifepristone ingestion, the clinician instructed her to obtain and perform a home urine pregnancy test. Once the clinician determined that the abortion was complete (i.e., she needed no further care related to the abortion), staff administered a satisfaction questionnaire by telephone.

Throughout the study, participants or their insurance were responsible for paying for tests and treatments obtained outside the study site. Initially, the study paid for all care and medications provided directly by the study sites; once we had gained some experience with the service, we amended the protocol to require that participants or their insurance pay standard charges for these services. Because sites initiated enrollment at different times, this amendment affected some participants at UH and all at MFP and PPCW; it was not implemented at Choices or at OHSU as of this analysis. Each participant at every site received $50 after completing the exit interview.

We initially planned to enroll a total of 50 participants, a number determined by funding considerations. When additional support became available we continued the project to obtain more generalizable data.

Sites sent paper data forms to Gynuity Health Projects for entry into a central database. The analysis was descriptive. We counted each enrollment as an independent participant. We defined an adverse event as serious if it was fatal, life-threatening or resulted in hospitalization, transfusion, or significant disability. An unplanned clinical encounter was any visit to a clinician that was not planned before the study package was mailed. We defined meaningful follow-up as ascertainment of ingestion of abortion medications, abortion outcome, or unplanned clinical encounters.

The UH Office of Research Compliance Human Studies Program, OHSU Institutional Review Board, and Advarra Institutional Review

Board all approved the protocol. We registered the study at clinicaltrials.gov (NCT02513043).

3. Results

Between May 2016 and December 2018 (79 site-months), we conducted 433 screenings (Fig. 1), including three with people who had enrolled in a prior pregnancy. Most screened people (187; 43%) had learned about the study from the study clinic itself through the clinic's website or appointments personnel; the rest were referred by other providers, internet searches, the study website, media articles, or friends. Of the 433 people, 363 (84%) scheduled TelEvaluations with study clinicians. Most (322; 89%) cited speed, convenience, lack of local options, or cost as reasons for interest, including 47 (13%) who specifically mentioned cost. Seventy-eight (21%) said that they wanted privacy or to avoid harassment.

A total of 165 people (38%) either declined to schedule TelEvaluations or did not present for the appointment. We ascertained reasons from 98 (59%). The most common were concerns about the logistics or time involved (46%), the decision to have a medical abortion (18%), or cost (14%); 23% were ineligible for medical abortion through the study. In Hawaii, implementation of the protocol amendment for billing had no apparent effect on uptake of TelEvaluations over time.

The 268 participants who had TelEvaluations were diverse (Table 1). In the continental states, 52% of participants lived ≥50 miles from their study site, and 29% lived ≥150 miles distant. Of 59 participants enrolled by OHSU, 27 (46%) lived in Washington state, and one of the 30 participants enrolled by MFP lived in New York. In Hawaii, ≫60% of participants lived on an island without an abortion clinic.

We sent study packages to 248 (93%) of the 268 participants who had TelEvaluations (Fig. 1). Of the other 20, seven miscarried shortly after their TelEvaluations, three decided against abortion, two would not have received the package by 70 days of gestation, seven had other reasons, and one did not provide a reason.

The characteristics of the 248 participants who were sent packages were similar to those of the screened population (Table 1). All met eligibility criteria, and all received the package sent. Of the 207 participants (83%) who reported having taken at least one abortifacient medication (Fig. 1), 187 reported the date of ingestion of mifepristone; all of these participants took that medication on or before 70 days of gestation except two who took it at 71 days.

We were unable to ascertain abortion outcomes for 58 package recipients (23%), and two participants decided to continue their pregnancies and did not take the mifepristone. Of the other 188, 177 (94%), including the three who had previously enrolled, aborted completely without a procedure. All but four of these 177 reported having taken at least one abortifacient medication. Tests used in assessment of completeness included ultrasound in 86 participants (49%), 80% decline in serum HCG concentration in 58 (33%), and urine pregnancy tests in 36 (20%). Five participants (3%) were assessed using only other means. Eleven participants (6%) had uterine evacuation procedures, of whom two had not taken the mifepristone, four had ongoing pregnancies after mifepristone ingestion as reported by the provider, and five had bleeding and/or incomplete abortions.

Eleven of the 16 Rh-negative participants who received packages obtained Rh immune globulin, three opted out of this prophylaxis before package shipment, one did not keep an appointment made for her to receive it, and one did not provide relevant information.

A total of 217 participants had meaningful follow-up after package shipment. Two of these (1%) reported serious adverse events. One was hospitalized because of a seizure after an aspiration performed for bleeding. The second was hospitalized because of severe anemia (hemoglobin of 6.3 g/dl) 7 days after mifepristone ingestion at 56 days of gestation; she was diagnosed with complete abortion but received a transfusion. We judged that neither event would have been averted had the abortion medications been provided in person. Sixteen other participants (7%) attended an emergency department or urgent care center: 14 for bleeding and/or pain, one for dizziness, and one to get Rh immune globulin. Two of these 16 participants had aspirations, one had products of conception manually removed from her cervical os, three received medication for pain and/or nausea, one was treated for a urinary tract infection, and the other nine received no medical treatment. Eleven participants (5%) had clinic or office visits: eight had outpatient aspirations, and three had no reported medical treatment. All 29 participants reported having taken at least one abortifacient medication except one who miscarried without taking it, one who decided to have a uterine evacuation procedure, one who decided to continue the pregnancy, and two who did not provide data on medication ingestion. The proportion of participants with any unscheduled encounter was significantly more common among participants who lived ≥50 miles from the providing study site than among participants who lived closer (18% vs. 6%; p=.01).

Implementation of the service was efficient (Table 2). The median duration of TelEvaluations as recorded in 180 cases was 24 min (range 8–70 min). Nearly all packages (91%) were mailed within 17 days after the participant's initial contact with the study site (median 7 days). Of the 177 participants who had complete medical abortion without a procedure, more than half had their last evaluation test within 17 days after the package was mailed.

The 159 participants who completed the satisfaction questionnaire were highly satisfied with the service (Table 3). The most valued aspects of the service cited by respondents were convenience (77%), privacy (45%), and communication with the study staff (39%). The most disliked aspect of the service, cited by 21%, was inconvenience.

4. Discussion

The TelAbortion Project is the first reported effort in the US to enable people to obtain abortion legally without an in-person visit to an abortion provider. The project has been highly successful. Participants received treatment appropriately and efficiently. Of participants with follow-up, 94% had complete abortion without a procedure, comparable to success rates of medical abortion provided in person [17]. No serious adverse events occurred that would have been avoided by an initial in-person encounter. All participants were satisfied with the service.

The proportion of participants who visited a hospital, emergency department, or urgent care center for abortion-related problems (8%) was higher than the proportion of 4% recently reported in an analysis of nearly 11,319 medical abortion patients in California [18]. Of note, our participants lived much farther from the abortion provider than did the California patients (≥100 miles: 38% in our continental states vs. 2.5% in California [19]), which has been associated with higher use of emergency departments following treatment [20]. In our study, half of these encounters did not entail any medical treatment. Their incidence could possibly be reduced by stronger encouragement to contact the TelAbortion provider for advice before seeking unplanned in-person care.

More than half of the participants lived more than 150 miles from the project sites or on a Hawaiian island without an abortion clinic, suggesting that the TelAbortion option filled an evident need. We were surprised to find, though, that many participants lived quite close: 14% of participants in the four continental states lived less than 10 miles from the site and nearly half within 50 miles. Most of our participants cited convenience or privacy as key reasons for interest in TelAbortion;

some specifically mentioned difficulties with scheduling and the importance of having the abortion quickly. Remote provision of the service is well suited to address these issues.

We encountered several challenges in implementing the service. Ensuring that people across entire states are aware of the service requires outreach beyond routine local advertising. Identifying facilities where people can conveniently get pre-abortion tests and retrieving results can be time-consuming. Establishing billing processes for off-label use of mifepristone has been complicated. Connecting people with local sources of Rh immune globulin is also problematic. We expect that these issues will resolve as the service expands.

Our data have some limitations. Most of our participants came from Hawaii, which has unique access barriers due to the absence of abortion providers on most of its islands. We did not ascertain abortion outcomes for 23% of participants treated; our estimates of the proportion with medical abortion failure or complications may thus be underestimated. Interest in TelAbortion may have been influenced by the financial support and compensation provided by the study. Notably, though, at the UH site, which was the only site in this analysis that enrolled people before and after we instituted billing for the service, we found no evidence of a decrease in uptake of or satisfaction with TelAbortion.

We believe that the TelAbortion model has the potential to substantially increase access to abortion in the United States by increasing the reach of providers and by offering a safe and legal option for obtaining the service outside of an established clinical setting. Currently, the FDA's restriction on distribution of mifepristone appears to preclude implementation of TelAbortion except in the context of a research study. However, this restriction is medically unwarranted [16], and advocates are working to convince FDA to withdraw it [21]. Meanwhile, we intend to continue to offer TelAbortion through an expanded study to evaluate its benefits, risks, feasibility, and acceptability in a more diverse population. We plan to examine the potential for simplifications of the study procedures to decrease cost and further enhance convenience, and we hope to explore the potential for the TelAbortion model to reduce out-of-pocket costs, particularly for people who have no insurance coverage for abortion but do have coverage for the required screening and follow-up tests performed outside a facility that provides abortion. We anticipate that our data will ultimately be useful for supporting policy advances at both state and federal levels.

1. Introduction

The COVID-19 pandemic is acutely threatening access to essential health services, including abortion [1]. Across all fields of medicine, changes in practice models are occurring rapidly. For patients seeking abortion, urgent modifications of current protocols are needed to ensure that patients can continue to obtain this time-sensitive treatment while limiting transmission of infection by maintaining distance between and among patients and providers. Remote delivery of care, which has recently been endorsed by local, state, and federal authorities as a key epidemic control measure [2], will be indispensable to accommodate patients and staff who are navigating quarantines, stay-at-home directives, lack of transportation, new family or work obligations, or other unavoidable circumstances that impede their ability to go in in person to a health facility.

Fortunately, medication abortion (MA) using mifepristone and misoprostol can address many of these challenges. At present, MA typically entails a visit to a clinician or facility that provides abortion where an ultrasound or pelvic examination and often blood tests are performed to evaluate eligibility before pills are dispensed. Many abortion providers require a follow-up ultrasound or blood test after treatment to confirm abortion completion. However, research and experience have demonstrated that these tests, which inherently involve physical contact between patient and health care worker, are usually unnecessary for safe and effective MA [3–7]. Indeed, over the past 15 years, international organizations have provided mifepristone and misoprostol by mail to tens of thousands of patients screened only by history [8–11]. A prospective study conducted in 2015–2016 in the United States, Mexico, and Moldova provided 406 MAs without screening ultrasound or pelvic examination [12]. No serious adverse events were reported that resulted from the omission of the tests, and participants were highly satisfied.

To assist abortion providers with the current crisis, we present a sample protocol (Box. 1) for providing a "no-test" MA that includes recommendations for patient selection, Rh status evaluation and management, the treatment regimen, and follow-up. Although FDA-imposed restrictions on mifepristone dispensing may require patients to go to the abortion provider or facility to obtain the drug [13], this protocol would enable every other part of the MA process to be implemented without any in-person encounter. The protocol is intended to serve as a guidance; abortion providers should use clinical judgment when adapting it for their practice settings and patient populations. Below we summarize the data that we considered in developing this protocol and our rationales for and comments on selected provisions.

Sample Protocol for No-Test Medication Abortion

PURPOSE

To enable safe and effective provision of medication abortion without a mandatory pre-treatment ultrasound, pelvic examination or laboratory tests when medically appropriate, given that these tests may be significant barriers to access and, in the setting of a pandemic, may increase transmission of infection to patients and health care workers.

CRITERIA

- Pregnancy confirmed by patient report of urine or serum test or prior ultrasound
- Last menstrual period started ≤77 days before anticipated date of mifepristone ingestion
- Certain of last menstrual period onset date ± 1 week
- None of the following symptoms or risk factors for ectopic pregnancy:
  - Vaginal bleeding or spotting within the past week
  - Unilateral pelvic pain or significant bilateral pelvic pain within the past week
  - Prior ectopic pregnancy
  - Prior permanent contraception or other tubal surgery
  - IUD in uterus at conception or currently
- None of the following contraindications to medication abortion, assessed by history:
  - Hemorrhagic disorder or concurrent anticoagulant therapy
  - Chronic adrenal failure
  - Concurrent long-term systemic corticosteroid therapy
  - Inherited porphyria
  - Allergy to mifepristone, misoprostol, or other prostaglandin
- No strong preference for pre-treatment ultrasound, pelvic examination or laboratory tests

RH TYPING AND ADMINISTRATION OF ANTI-D IMMUNOGLOBULIN

- Not needed if the gestational age on the anticipated mifepristone ingestion date will be <70 days or if the patient reports positive Rh type, wants no future children, or declines anti-D immunoglobulin.
- Should be considered for patients not meeting above criteria

TREATMENT

Provide the following:

- Mifepristone 200 mg orally
- Misoprostol 800 mcg x 2
- Analgesics, antiemetics per health facility protocol
- Patient instruction sheet and health facility emergency contact information
- Two high sensitivity pregnancy tests (HSPTs)

The patient should take mifepristone 200 mg orally followed by misoprostol 800 mcg buccally or vaginally 24-48 hours later. Patients with estimated GA >63 days should take a second dose of misoprostol 800 mcg 4 hours after the first. Patients with estimated GA ≤63 days should take the second dose if no bleeding occurs within the first 24 hours after the first misoprostol dose or if instructed to take it by a clinician. Review the instruction sheet with the patient.

FOLLOW-UP

1. Plan a follow-up contact with the patient one week after dispensing treatment.
2. If the patient reports indicators of continuing or ectopic pregnancy (e.g., any of the symptoms on the instruction sheet), evaluate with ultrasound or serum HCGs.
3. Otherwise, instruct the patient to perform the first HSPT 4 weeks after taking misoprostol (not earlier) and to contact the abortion provider if the result is positive.
4. If the patient has indicators of continuing or ectopic pregnancy, evaluate with ultrasound or serum HCGs
5. If the first HSPT result is positive but the patient has no such indicators, instruct the patient to perform the second HSPT in 1 week.
6. If second HSPT result is also positive, evaluate with ultrasound, serum HCGs, additional urine testing, or uterine aspiration.

Box. 1. Sample protocol for no-test medication abortion.

2. Patient selection

The three key goals of clinical evaluation before MA are (1) to confirm that the gestational age (GA) is within accepted limits for effective and safe outpatient treatment, (2) to identify ectopic pregnancy, and (3) to establish that the patient has no other contraindications to MA.

The sample no-test MA protocol specifies an upper GA limit of 77 days as estimated from the first day of the last menstrual period (LMP). The LMP-based GA should be ≤77 days on the day of mifepristone ingestion, which may be later than the day the drug is dispensed if the patient plans to take the pills home for later use or if the medication is mailed or dispensed to a patient intermediary. The patient should be certain within one week of the LMP onset date.

We chose a 77-day limit because recent data have indicated that outpatient MA is safe and effective through that GA [14,15] and because this limit is consistent with current guidelines of the National Abortion Federation [16] and Planned Parenthood Federation of America (personal communication, Gillian Dean, MD, MPH, Planned Parenthood Federation of America). We note, though, that 2014 guidelines issued by the American College of Obstetricians and Gynecologists (ACOG) and the Society for Family Planning [17] as well as the mifepristone label approved by the US Food and Drug Administration in 2016 specify a 70-day limit. In response to the pandemic, ACOG has recently issued a statement acknowledging that LMP-based gestational dating without ultrasound is acceptable, although no specific GA limit was specified [18].

Regardless of the precise GA limit selected, use of the no-test approach will inevitably result in treatment of some fraction of patients whose true GAs exceed 77 days. Data from studies that compared LMP-based GA estimates to ultrasound-based estimates suggest that this fraction tends to be higher in patient populations that include more patients with advanced GA [19,20] and that it may be reduced by decreasing the LMP-based GA cutoff [19]. Reassuringly, the largest study, which was conducted in the United States in 2005–2007 [21], found that only 31 (1%) of 3012 MA patients who were certain that their LMPs had started ≤77 days prior had GAs > 77 days by ultrasound examination. Furthermore, international studies that included more than 1600 patients treated with mifepristone and one or more misoprostol doses at 13–24 weeks of gestation reported efficacy and safety similar to that expected in earlier gestation: >93% of patients aborted without further intervention, 0.7–4% required transfusion, and no patient required hysterectomy or died [22]. Therefore, we expect that serious adverse health consequences of GA underestimation based on LMP will be rare. Nevertheless, clinicians using the no-test approach to MA should have a plan for managing or referring patients who may need a second trimester procedure to complete the abortion.

When assessing GA, providers may incorporate other historical information reported by the patient that, for simplicity, we do not mention in the sample protocol but that may indicate that the GA is greater than the proposed limit. For example, a patient who reports a positive pregnancy test >7 weeks before presentation is unlikely to have a GA of ≤77 days. The sample protocol does not exclude patients who report menstrual irregularity or recent use of hormonal contraceptives. Although these conditions may signal ovulatory dysfunction, we expect that they would more likely lead to overestimation of GA than to underestimation, which is the primary concern for MA eligibility, and excluding patients with these conditions may therefore unnecessarily limit access by eligible patients.

MA with mifepristone and misoprostol is contraindicated in patients with ectopic pregnancy not because the drugs are dangerous for such patients but because the regimen is not a proven treatment for this condition. The sample no-test protocol excludes patients with significant symptoms of or risk factors for ectopic pregnancy; recent vaginal bleeding or pelvic pain, prior permanent contraception, prior ectopic pregnancy, or intrauterine device in place at conception [23,24]. We do not exclude patients who report prior pelvic inflammatory disease because unconfirmed diagnoses of this condition are associated with only a mildly increased risk [24]. We recognize that the listed criteria will not identify every patient with ectopic pregnancy; an estimated half of all patients with this condition have no risk factors [25]. However, published and emerging data suggest that the incidence of ectopic pregnancy among patients seeking MA is very low, <1% [26,27]. Moreover, substantial data [28–32] and current clinical MA guidelines [16,33] support treatment of patients in whom ectopic pregnancy has not been definitively excluded because the condition can be detected and managed afterwards. Thus, this aspect of the protocol is consistent with the standard of care.

The medical contraindications in the sample protocol are those listed in the FDA-approved mifepristone label. Patient history is sufficient for assessing these conditions.

3. Rh typing and other pre-treatment laboratory testing

Recent research has suggested that the risk of Rh sensitization after early abortion is negligible [34–36]. Consequently, the National Abortion Federation has concluded that forgoing Rh typing and administration of anti-D immunoglobulin is reasonable for Rh-negative patients having aspiration abortion before 56 days of gestation and may be considered for all patients having MA at less than 70 days [16,37]. The sample protocol is consistent with this conclusion. In addition, it specifies that testing is unnecessary for patients who can report a Rh-positive blood type or who are certain that they want no future children after the planned abortion. Any patient may opt out of Rh typing; the recent statement from ACOG notes that Rh testing and RhD immunoglobulin administration should not be a barrier to the provision of medication abortion [18].

Hemoglobin/hematocrit and other laboratory tests are not routinely needed before first-trimester abortion but may be performed as indicated by medical history and patient symptoms [16].

4. Treatment regimen

The sample protocol specifies that patients should receive a standard regimen of mifepristone 200 mg orally and misoprostol 800 mcg vaginally or buccally [16]. In addition, each patient should be provided with an extra dose of misoprostol 800 mcg. Those with estimated GA > 63 days should be instructed to take this second misoprostol dose 4 hours after the first to improve effectiveness [16,38]. Patients with estimated GA < 63 days may be instructed to take the second dose if no bleeding occurs within the first 24 hours after the first dose or to retain it for use if recommended by the provider. Alternatively, all patients may be told to take two misoprostol doses 4 hours apart. Although this specific regimen has not been studied, trials of repeated doses of misoprostol in the first and second trimester suggest that it will be safe [39–43].

5. Scheduled follow-up

The primary goals of follow-up are to confirm absence of continuing pregnancy, to detect ectopic pregnancies not diagnosed before treatment, and to identify complications that need evaluation and treatment. To accomplish these goals, the sample protocol relies on patient symptoms and high sensitivity urine pregnancy tests (HSPTs) that the patient performs at home. This strategy has been validated in several studies [44,45], is consistent with current MA guidelines for follow-up of patients who have documented intrauterine pregnancies [16,17], and is increasingly used by MA providers.

The sample instruction sheet (Box. 2), which includes a list of symptoms that may need in-person evaluation, is derived from studies of symptoms used to assess outcomes in MA patients with intrauterine pregnancies documented by ultrasound [44–47] and from experience in managing patients with ectopic pregnancies. The instruction sheet directs patients to contact the abortion provider if specified symptoms occur or the HSPT result is positive. Research has shown that patients can safely use these tools on their own to recognize when follow-up is needed [48,49], and

Sample Instructions for Patients Receiving No-Test Medication Abortion

1. **Call your abortion provider** if:
   - ☐ You vomit within the first 30 minutes after taking mifepristone.
   - ☐ You have a fever of 100.4°F or higher more than 24 hours after you take the misoprostol.
   - ☐ One week after taking misoprostol, you have any of the following:
     - You have not had cramping and bleeding heavier than a period.
     - Your bleeding is not getting lighter.
     - You do not feel that you passed the pregnancy.
     - Your pregnancy symptoms (such as nausea and breast tenderness) are not resolving.
   - ☐ At any time, you have any of the following:
     - An increase in pain/cramps or bleeding more than 24 hours after taking misoprostol.
     - Severe pain or cramps that don't get better with pain medicine, rest, or heating pads.
     - Enough bleeding to soak 2 maxi pads an hour for more than 2 hours.
     - Dizziness or vomiting lasting more than 2 hours.
     - Weakness, nausea, or diarrhea lasting more than 24 hours.
2. Perform one urine pregnancy test 4 weeks after taking misoprostol (not earlier). **Call your abortion provider if the result is positive or invalid**. Use the second test if instructed to do so by your abortion provider.

Box. 2. Sample instructions for patients receiving no-test medication abortion.

indeed patient-controlled follow-up is widely used for MA follow-up by provider organizations in multiple European countries [50–52]. However, the sample no-test protocol recommends a planned follow-up contact with the provider one week after dispensing the abortifacient medications to confirm absence of symptoms of ongoing or undiagnosed ectopic pregnancy or other potential complications. This contact may be conducted by videoconference, telephone, patient portal, email, text, or other telehealth modalities [53,54].

MA failures are often detectable based on symptoms alone [6,44,47–49]. Nevertheless, the sample no-test protocol recommends a HSPT 4 weeks after misoprostol use to confirm pregnancy termination. Available data indicate that 5–25% of HSPTs performed about a month after MA treatment produce positive results, nearly all of which are "false positives" in patients who no longer have viable pregnancies [44,45]. Therefore, the sample protocol recommends that two HSPTs be provided initially to each patient. The patient should be instructed to contact the provider if the result of the initial 4-week test is positive. If the patient is asymptomatic, a repeat test one week later may be appropriate. If the patient has symptoms of ongoing or ectopic pregnancy or the second HSPT result is positive, further evaluation is indicated. The specific procedures for this evaluation should address the patient's individual clinical situation and may include ultrasound, serial serum HCG levels, additional urine pregnancy testing, or aspiration and tissue examination.

Patients receiving a no-test MA may remain at risk for having ectopic pregnancy until a negative HSPT result is obtained. Therefore, vigilant attention on the part of both provider and patients to symptoms such as increased pelvic or abdominal pain, continued vaginal bleeding, or dizziness is imperative.

6. Counseling

Patients requesting a no-test MA should receive standard pre-abortion counseling about pregnancy options, the risks and benefits of MA, expected results, side effects, and warning signs. In addition, each patient should be explicitly informed that LMP-based dating may underestimate GA, in which case efficacy may be lower than expected, bleeding and cramping may be heavier, and, rarely, fetal tissue may be visible. Moreover, patients should understand that without ultrasound, ectopic pregnancy will not be definitively excluded before treatment. To increase the chance of abortion success and reduce the time to diagnosis of ectopic pregnancy or MA complications, patients should be advised to diligently follow all instructions provided. However, patients should also be advised that serious adverse events of no-test abortion are expected to be rare and that side effects of MA can often be managed remotely. To avoid unnecessary infectious exposure during a pandemic as well as excess cost and inconvenience, patients should contact the abortion provider before seeking in-person care.

7. Conclusion

Although the COVID-19 crisis prompted the development of this sample protocol, we recognize that the pandemic is only one of many longstanding, serious impediments to abortion access in

the United States. Omitting unnecessary use of ultrasound, examination, and laboratory tests before MA can reduce barriers to this essential service by decreasing cost and enhancing convenience and comfort. The no-test approach can enable provision of abortion in new venues and by new categories of providers, and it can facilitate new service delivery models, such as synchronous or asynchronous telehealth, stationary or mobile "mini-clinics", pill pick-up arrangements, or dispensing via lockboxes or, potentially, by mail [7,54]. If the no-test strategy results in earlier treatment, it may increase MA success rates [14,43,55]. Details of the no-test MA protocol will certainly need to be revised as new evidence emerges, but we anticipate that this approach to providing the service will continue to be beneficial for both patients and abortion providers even after the current epidemic resolves.

Systematic review

Who can provide effective and safe termination of pregnancy care? A systematic review*

R-M Renner,[a] D Brahmi,[b] N Kapp[c]

[a] Department of Obstetrics and Gynaecology, Oregon Health & Science University, Portland, OR, USA [b] Ipas, Chapel Hill, NC, USA [c] UNDP/UNFPA/WHO/World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), World Health Organization, Geneva, Switzerland

Accepted 18 June 2012. Published Online 20 August 2012.

Background Unsafe termination of pregnancy is a major contributor to maternal morbidity and mortality. Task sharing termination of pregnancy services between physicians and mid-level providers, a heterogeneous group of trained healthcare providers, such as nurses, midwives and physician assistants, has become a key strategy to increase access to safe pregnancy termination care.

Objectives To systematically review the evidence to assess whether termination of pregnancy services by nonphysician providers can be performed safely and effectively.

Search strategy We searched the Cochrane Central Register of Controlled Trials, MEDLINE, MEDLINE in process and other nonindexed citations and POPLINE.

Selection criteria We included randomised controlled trials (RCTs), as well as clinical studies, using study designs that compared efficacy, safety and acceptability of termination of pregnancy services by physicians versus other provider groups.

Data collection and analysis Two reviewers independently extracted the data, and we performed a meta-analysis where appropriate using RevMan. Quality assessment of the data used the Grading of Recommendations Assessment, Development and Evaluation (GRADE) approach.

Main results We identified five controlled studies comprising 8908 women undergoing first-trimester surgical termination of pregnancy (one RCT and three prospective cohort studies) and medical termination of pregnancy (one RCT). The mid-level provider group included midwives, nurses, auxiliary nurse midwives and physician assistants trained in termination of pregnancy services. Safety and efficacy outcomes, including incomplete termination of pregnancy, haemorrhage, injury to the uterus or cervix, did not differ significantly between providers.

Author's conclusions Limited evidence indicates that trained mid-level providers may effectively and safely provide first-trimester surgical and medical termination of pregnancy services. Data are limited by the scarcity of RCTs and biases of the cohort studies.

Keywords Abortion, mid-level providers, midwives, nonphysician providers, nurses, physician assistants, provision, safety, termination of pregnancy.

Introduction

Multiple barriers may prevent access to safe abortion care (termination of pregnancy or management of miscarriage). Even when legal, access to safe services is often restricted by the lack of trained providers,[1] particularly in nonurban settings. Many countries have policies that limit the provision of services to physicians or physician specialists (obstetrician gynaecologists), thereby limiting the number of available providers and further restricting women's access.

Improving maternal health is one of the eight Millennium Development Goals,[2] and an estimated 13% of all maternal deaths are caused by unsafe termination of pregnancy.[3] Task shifting termination of pregnancy care services to mid-level providers (MLPs), a heterogeneous group of various nonphysician healthcare providers, such as nurses, midwives and physician assistants, has become a key strategy to achieve this goal.[4] Task shifting can broaden the provision of safe termination of pregnancy to the primary care level and thus has the potential to expand access to services.

To assess whether the provision of termination of pregnancy services by providers other than physicians could be performed with similar levels of safety, efficacy and acceptability as when performed by physicians, we undertook a systematic review of this topic.

Methods

The current review has been prepared in accordance with the PRISMA guidelines[5] and included a review protocol.

Criteria for considering studies for this review

Criteria covered the areas of participants, interventions, comparisons, outcomes and study design (PICOS) as outlined below.

Types of study

Randomised controlled trials (RCTs) on this topic were anticipated to be scarce and many of the safety outcomes are rare. In order to increase the evidence base addressing this issue and to increase the generalisability to various settings, we included clinical studies using the following study designs: RCTs, cluster RCTs, nonrandomised cluster-controlled trials, controlled before and after studies, interrupted time series[6] and cohort studies.

Types of participant

Women undergoing medical or surgical termination of pregnancy or receiving treatment for miscarriage at any gestational age of pregnancy.

Types of intervention

Termination of pregnancy or management of a miscarriage provided by either physician providers or MLPs. MLP for this review is defined as any formally trained nonphysician provider, and comprises a heterogeneous group depending on the cadre of provider, country and setting.

Types of outcome measure

The primary outcomes were: (1) efficacy: complete termination of pregnancy; correct assessment of gestational age; (2) safety: complications, their recognition and management. The secondary outcomes were: (1) training needed for competency; (2) acceptability and satisfaction; (3) costs.

Search methods for the identification of studies

Electronic searches

An electronic literature search of the Cochrane Central Register of Controlled Trials (third quarter, 2011), MEDLINE (1946 to October 2011), MEDLINE in process, other nonindexed citations (6 October 2011) and POPLINE (1927 to October 2011) without language preference and using terms that include abortion, termination of pregnancy services and healthcare providers.

Searching other sources

We contacted researchers in the field to seek information on unpublished or ongoing studies that we might have missed or that may have been unavailable with the electronic search. Reference lists of articles retrieved were hand searched.

Data collection and analysis

Selection of studies

The primary reviewer (RMR) evaluated the articles identified from the literature search. A second reviewer (NK) evaluated the articles in question for inclusion and, where needed, additional information was sought from the study's author. Studies under consideration were evaluated based on methodology without consideration of the results. We included studies examining manual vacuum aspiration, electric suction aspiration or dilation and curettage. We considered as medical termination of pregnancy those regimens that used mifepristone/misoprostol, misoprostol alone or methotrexate/misoprostol.

Data extraction and management

Two reviewers (RMR and NK) independently extracted data using standard extraction forms. Data collected included PICOS, funding information and, if applicable, randomisation, allocation and blinding and loss to follow-up. Participant characteristics included number, demographics and gestational age. Discrepancies were resolved by consensus of the reviewers.

Assessment of the risk of bias in the included studies

Two reviewers (RMR and NK) independently graded the quality of the included studies using the Grading of Recommendations Assessment, Development and Evaluation (GRADE) system that incorporates in its assessment the study design, limitations, inconsistency, indirectness and imprecision.[7] The quality of evidence was classified into one of four categories: high (further research is very unlikely to change our confidence in the estimates of the effects), moderate (further research is likely to greatly affect our confidence in the estimates of the effects and may change the estimates), low (further research is very likely to greatly affect confidence in the estimates of the effects and is likely to change the estimates) or very low (any estimate of effect is very uncertain).

For RCTs, we assessed bias by:

1 Assigning a quality score for concealment of allocation:[8]
(a) adequate concealment of allocation;
(b) unclear whether adequate concealment of allocation;

(c) inadequate concealment of allocation;
(d) allocation concealment not used.
2 Blinding of participants, clinicians and investigators.
3 Protection against exclusion bias.
4 Appropriate analysis of data.

Any discrepancies between reviewers were addressed by a joint re-evaluation of the original article. Funnel plots were used to assess publication bias.

Measures of treatment effect and assessment of heterogeneity

We used RevMan5.1 software for data analysis. Effects of dichotomous outcomes are presented as risk ratios with a 95% confidence interval, and were considered to be statistically significant if the confidence interval did not include 1.0. We examined for heterogeneity using the I^2 statistic.[9] If $I^2 > 75\%$ (considerable heterogeneity), we used a random effects model in the analysis.

Dealing with missing data

For RCTs, we aimed to use an intention-to-treat analysis. However, in one study,[10] the need for post-randomisation exclusion of women who turned out to be ineligible was part of the study design. We excluded these women from the analysis, but included women who were lost to follow-up after undergoing a termination of pregnancy. Depending on the study and outcome, the denominator of the cohort studies included women who underwent the intervention or only those who were followed up. We did not impute any outcomes, and thereby may have slightly mis-estimated the true proportion of complications. Loss to follow-up was considered in the GRADE assessment.

Data synthesis

Using RevMan5.1 software for data analysis, and consistent with our protocol, we divided the studies into two comparisons.

1 Comparison 1: surgical termination of pregnancy.
2 Comparison 2: medical termination of pregnancy.

Within each comparison, RCTs and prospective cohort studies were considered separately. The only RCT on surgical termination of pregnancy showed significant heterogeneity between the two countries in which it was performed. Therefore, we combined them in a meta-analysis using a random effects model. We summarised but did not perform meta-analyses of the cohort studies because of their heterogeneity and other limitations.

Results

Results of the search

Our search strategy (Appendix S1) identified a total of 806 articles (Figure 1).

Studies were excluded after screening the title and abstract or the full-text article ($n = 41$) based on study design, lacking a comparison group or not assessing the outcomes of interest. Ultimately, we identified five studies that met all inclusion criteria. Of note, we did not identify studies comparing the provision of active miscarriage management or costs of services. Each study investigated only one method of termination of pregnancy; there were no identified studies in which providers chose the method.

Included studies

Five studies with a total of 8908 subjects were included in this review with the following interventions and comparison groups.

Comparison 1: surgical termination of pregnancy. One RCT[11] (2894 women) compared MLPs, mostly midwives and one doctor assistant, with physicians performing surgical termination of pregnancy up to 12 weeks at various clinics in South Africa (mean gestational age, 7.7 weeks) and Vietnam (mean gestational age, 6.1 weeks). Three prospective cohort studies (4910 women) compared MLPs – nurses in India[12] (1089 women) and physician assistants in two US studies[13,14] (3821 women) – with physicians. In the Indian clinics, women with pregnancies up to 10 weeks of gestation (mean gestational age, 8.6 weeks) and, in the USA, up to 15 weeks of gestation (>80% <10 weeks) were included. All studies were conducted in a setting in which emergency care in the case of complications was accessible.

Comparison 2: medical termination of pregnancy. One RCT[10] (1104 women) compared nurses and auxiliary nurse midwives with physicians in several Nepalese hospitals using 200 mg mifepristone, followed by 800 μg vaginal misoprostol 2 days later. Women with pregnancies up to 9 weeks (mean, 6.6 weeks) were included. The study required that the women resided within 90 minutes of the study site to guarantee access to emergency care if needed.

The Indian study[12] compared newly trained MLPs with newly trained physicians. The other studies included previously trained pregnancy termination providers;[10,11,13,14] however, in Warriner et al.,[11] physicians had more years of experience than did MLPs. Table 1 presents the characteristics of the included studies.

Quality of evidence

The quality of evidence of all included studies was graded using the GRADE system.[7] A panel of international experts reviewed and prioritised our proposed outcomes of interest, and the critical outcomes are summarised in Table 1 (for complete GRADE tables, see Tables S1 and S2). We found no serious inconsistency or indirectness among the studies. RCTs were rated as low to moderate quality,

14710528, 2013, 1, Downloaded from https://obgyn.onlinelibrary.wiley.com/doi/10.1111/j.1471-0528.2012.03464.x, Wiley Online Library on [28/04/2025]. See the Terms and Conditions (https://onlinelibrary.wiley.com/terms-and-conditions) on Wiley Online Library for rules of use; OA articles are governed by the applicable Creative Commons License

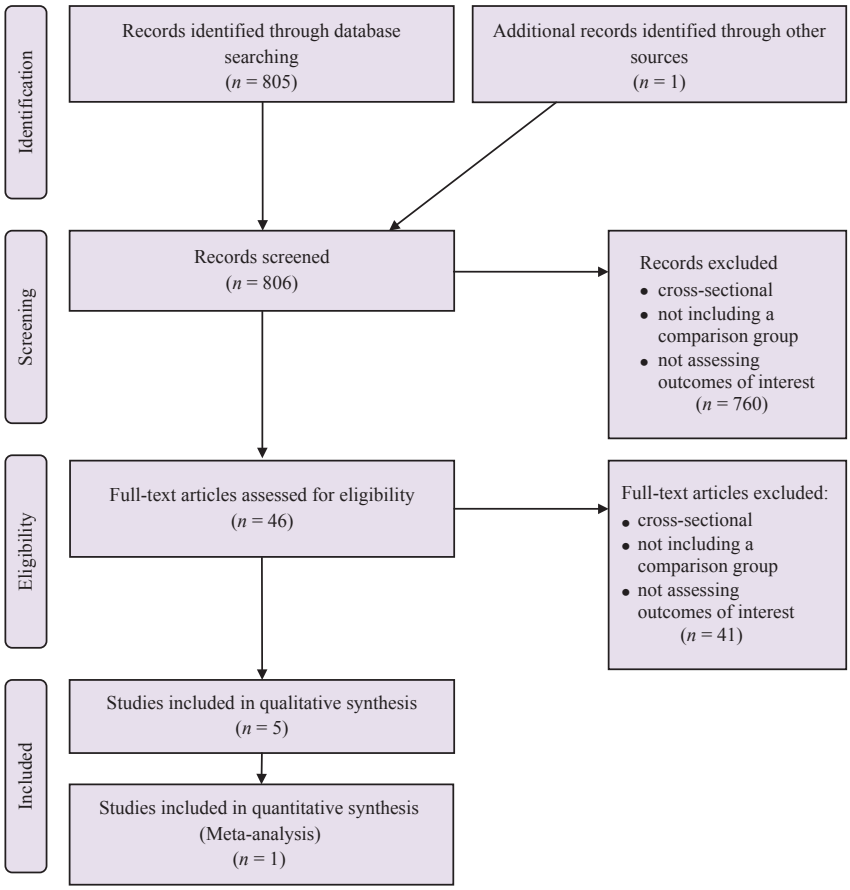

Figure 1. Study selection.

whereas prospective cohort studies ranged from very low to low quality for the outcomes of interest. The most frequent reason for downgrading the evidence was imprecision because of a wide confidence interval (related to the small number of studies or to the heterogeneity of the results[11]) and small number of events (related to the rare occurrence of complications). No studies met the criteria for upgrading. In cohort studies, high loss to follow-up also occurred.

Risk of bias in the included studies

Inclusion and exclusion criteria were clearly defined[10,11] for protection against exclusion bias.

Incomplete data occurred in 3.6% of women with surgical termination of pregnancy,[11] either because they withdrew before the procedure or because they were lost to follow-up after the procedure. In the RCT on medical termination of pregnancy by Warriner et al.,[10] 6.3% of women had incomplete data (including the women who were excluded post-randomisation as they were found to be ineligible based on the provider examination).

We did not find evidence of reporting bias. According to the funnel plots, studies included in this review are symmetrically distributed, indicating that publication bias is unlikely. Published results corroborate observational study results, such as programme evaluations on the safety and efficacy of MLPs providing termination of pregnancy services.

Effects of intervention

Results are stratified by surgical versus medical termination of pregnancy. All effect sizes are presented in Table 1 and in the forest plot of overall complications (Figure 2).

Comparison 1: surgical termination of pregnancy

RCT

None of the safety and efficacy outcomes (overall complications, incomplete abortion necessitating re-aspiration, haemorrhage (>500 ml), injury to the uterus, injury to the cervix or infection) occurred frequently or showed a statistically significant difference between provider groups (Table 1). Among the 2894 women randomised to MLPs (mostly midwives or doctor assistants) and physicians, 18 and 10, respectively, experienced complications [risk ratio (RR), 3.1; 95% confidence interval (95% CI), 0.2–59.3] (Table 1, Figure 2].[11]

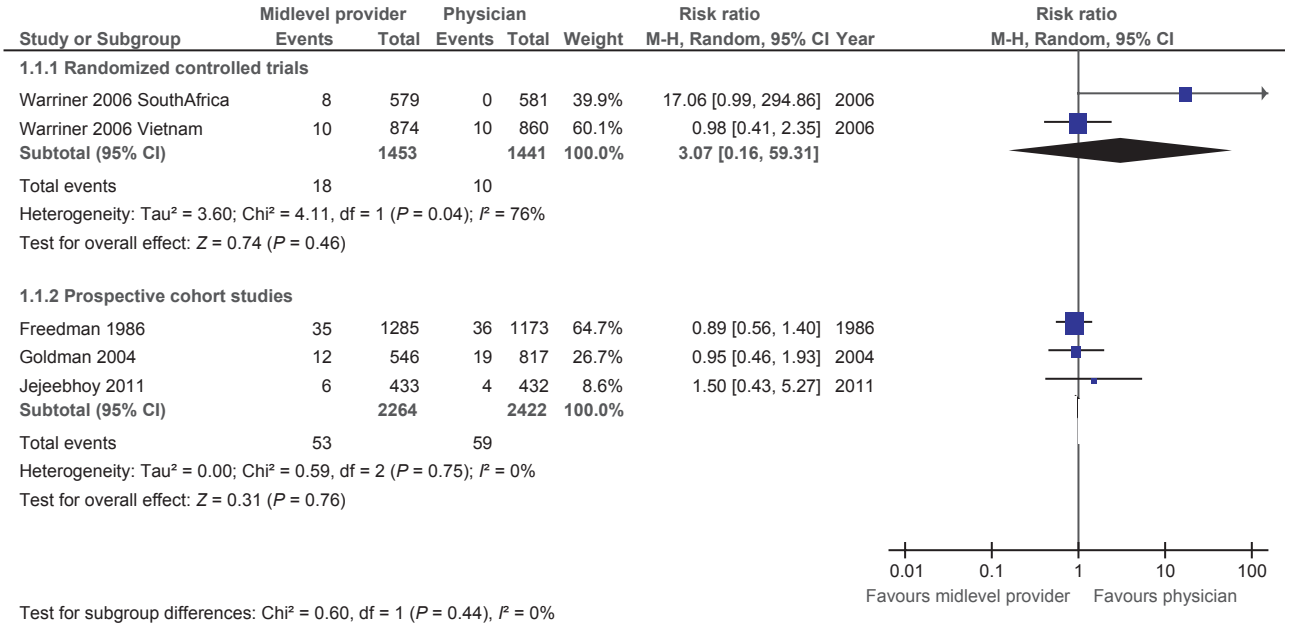

Figure 2. Forest plot of overall complications in surgical termination of pregnancy.

Prospective cohort studies

Overall complications, ongoing pregnancy, incomplete termination of pregnancy, haemorrhage, injury to the uterus, injury to the cervix and missed ectopic pregnancy showed no differences between provider groups in all studies (Table 1). Overall complications occurred in 112 (53 in the nurses and physician assistant group, 59 in the physician group) of 4686 women.[12–14] Only infection (18 of 1363 women) was less common among procedures performed by physician assistants than physicians (two versus 16).[14] In addition, one study compared the assessment of gestational age and completion of termination of pregnancy, both via bimanual examination by an experienced physician, who repeated the examination to verify the findings of the MLP, which did not differ between provider groups.[12]

Comparison 2: medical termination of pregnancy

RCT

Among 1077 women, none experienced a serious complication (haemorrhage requiring blood transfusion or condition necessitating hospitalisation).[10] None of the safety and efficacy outcomes [serious complication, ongoing pregnancy or incomplete abortion (retained products of conception possibly requiring aspiration)] showed a significant difference between provider types (Table 1). Of note, there were five ongoing pregnancies, all of which were in the physician group, and 29 incomplete abortions (14 in the MLP group [staff nurses and auxiliary nurse midwives] and 15 in the physician group). MLPs chose to discuss <2% of cases with a physician, and referred <1% for termination of pregnancy care elsewhere.

Discussion

Summary of main results

Two RCTs and three prospective cohort studies were included in this review which compared various formally trained provider groups with physicians providing surgical[11–14] and medical[10] termination of pregnancy.

Comparison 1: surgical termination of pregnancy

The RCT[11] and prospective cohort studies[12–14] showed that various MLP groups (nurses, midwives, doctor assistants, physician assistants) have effectively and safely provided surgical termination of pregnancy using manual or electric vacuum aspiration in clinic settings in South Africa, Vietnam, India and the USA. Overall complications in the RCT[11] resulted in RR = 3, favouring physicians, but the difference was not significant. The experience of physicians – 7 and 10 years in South Africa and Vietnam, respectively – compared with that of MLPs – 4 and 7 years, respectively, may have contributed to this finding, as a lack of experience is a known risk factor for complications.[15] The heterogeneity of the data is probably related to varying provider experience and the rarity of outcomes.

Complications were rare in all included studies; infection was the only complication that differed between provider groups, favouring the MLP group, in one study.[14] This

14710528, 2013, 1, Downloaded from https://obgyn.onlinelibrary.wiley.com/doi/10.1111/j.1471-0528.2012.03464.x, Wiley Online Library on [28/04/2025]. result is confounded by different practices in antibiotic prophylaxis: MLP patients routinely received 1 week of antibiotics, whereas physicians' patients received either the antibiotic medication or only a prescription.

Comparison 2: medical termination of pregnancy

One RCT[10] did not identify any significant differences between efficacy, safety outcomes or women's satisfaction when comparing nurses and auxiliary nurse midwives with physicians using mifepristone and misoprostol.

Overall completeness and acceptability of the evidence

Studies have been conducted in various countries and settings: developing and developed countries, clinics and hospitals. This is a strength of the data, as it increases the generalisability, as does the inclusion of various groups of MLPs, including nurses, midwives, auxiliary nurse midwives and physician assistants.

Limitations of the evidence include the scarcity of RCTs, making the data imprecise. Data of prospective cohort studies are limited by imprecision, as well as by biases inherent to the study design. Studies on the surgical termination of pregnancy included women up to 15 weeks of gestation; however, women actually recruited had an average gestational age of 7 weeks (RCT) and <10 weeks (cohort studies), leaving few data for the later first trimester. Mortality has been shown to increase with increasing gestational age, particularly above 8 weeks.[16] Women undergoing surgical termination of pregnancy had access to care for complications and women undergoing medical termination of pregnancy resided within 90 minutes of the study site. The extrapolation of these data to care in the second trimester (medical or surgical) or to settings without access and referral for emergency care options may not be appropriate. No comparative study assessed active management of miscarriage.

Agreement or disagreement with other studies or reviews

The incidence of complications observed in the included studies is uncommon and consistent with other publications.[15–17] MLPs have been evaluated in cross-sectional studies and programme evaluations, usually without direct comparison with physicians. Although the evidence of these reports is subject to even more bias and of lower quality than the evidence included in this review, our findings are consistent with the conclusion that trained MLPs can safely provide surgical and medical termination of pregnancy. Providers used manual or electric vacuum aspiration (as opposed to sharp curettage) as is recommended in the literature.[18,19] Access to emergency care was available in all studies, and has been generally recommended for termination of pregnancy services.[15,17,19]

Conclusions

Implications for practice

Limited evidence suggests that MLPs can be trained to provide first-trimester surgical (using vacuum aspiration) and medical (mifepristone and misoprostol) termination of pregnancy services as safely and effectively as physicians. A learning curve probably affects complication risk, particularly in the provision of surgical services.

Implications for research

This review highlights the importance of further studies to address task sharing in termination of pregnancy care, such as the safety of providing surgical termination of pregnancy beyond 10 weeks of gestation, the use of other medical termination of pregnancy methods in the first or second trimesters, the safety and efficacy of post-termination of pregnancy care and management of miscarriage, implications for training for competency for different groups of providers and the impact of increasing access to safe termination of pregnancy services.

Disclosure of interests

R-MR, DB and NK have nothing to disclose.

Contribution to authorship

R-MR developed the protocol for this review and conducted all steps of the review, including the development of the search strategy, identification of the studies for inclusion, data extraction, analysis and interpretation, as well as writing the manuscript.

DB contributed to data analysis and interpretation, as well as to the manuscript, during her time at the Department of Reproductive Health and Research, World Health Organization.

NK also contributed to all aspects of this review. She was the second author who independently extracted the data, contributed to the analyses and their interpretation, as well as to the manuscript.

Details of ethics approval

Ethics review and approval were not necessary for the appropriate conduct of this systematic review.

Funding

Resources from the Department of Reproductive Health and Research at the World Health Organization and from the Oregon Health & Science Family Planning Fellowship Fund supported the staff time for the completion of this review.

Acknowledgements

We thank Metin Gulmezoglu and Marit Johansen for support in the development of the search strategy.

ABSTRACT

Background In response to the COVID-19 pandemic, legislation and guidance were introduced in Scotland permitting medical abortion at home by telemedicine for pregnancies at less than 12 weeks' gestation. Women had a telephone consultation with a clinician. Routine ultrasound was not performed. Medications and a low-sensitivity pregnancy test to confirm success of treatment were collected by or delivered to the woman, with telephone support provided as needed.

Methods A prospective cohort study of 663 women choosing medical abortion at home via the NHS Lothian telemedicine abortion service between 1 April and 9 July 2020. Interviewer-administered questionnaires were completed 4 and 14 days following treatment. Regional hospital databases were reviewed to verify abortion outcomes and complications within 6 weeks. Outcome measures included efficacy, complications and acceptability.

Results Almost all (642/663, 98.2%) the women were under 10 weeks' gestation. For 522/663 (78.7%) women, gestation was determined using last menstrual period alone. Some 650/663 (98%) women had a complete abortion, 5 (0.8%) an ongoing pregnancy and 4 (0.6%) an incomplete abortion. No one was treated inadvertently beyond 12 weeks' gestation, but one woman was never pregnant. One woman who had a pre-abortion ultrasound was later managed as a caesarean scar ectopic. There were two cases of haemorrhage and no severe infections. Some 123 (18.5%) women sought advice by telephone for a concern related to the abortion and 56 (8.4%) then attended a clinic for review. Most (628, 95%) women rated their care as very or somewhat acceptable.

Conclusions This model of telemedicine abortion without routine ultrasound is safe, and has high efficacy and high acceptability among women.

Key messages

- Telemedicine medical abortion at home in the first trimester without routine ultrasound is effective, with low complication rates and high acceptability.
- Telemedicine service models need flexibility and resources to accommodate those women requiring clinical review post-abortion including ultrasound assessment.
- If given the choice, most women would choose a telemedicine consultation again rather than an in-person visit.

INTRODUCTION

Until recently, medical abortion care in Britain typically involved an in-person clinical consultation and a routine ultrasound scan to assess gestational age.[1 2] Women had to take mifepristone in a clinical setting but for those less than 10 weeks' gestation, there was the option to self-administer the second part of the treatment, misoprostol, at home. Women over 10 weeks' gestation were admitted to a clinical facility for misoprostol.[3]

In March 2020, the COVID-19 outbreak in the UK resulted in legislation being introduced permitting home use of mifepristone.[4] Recommendations from the Royal College of Obstetricians and Gynaecologists for the provision of abortion care were introduced that supported telemedicine consultations (telephone or video call), gestational assessment based on the date of last menstrual period (LMP) and delivery of medical abortion drugs to women eligible for this care at home.[5] In Scotland, additional clinical guidelines were introduced that supported

BMJ Sex Reprod Health: first published as 10.1136/bmjsrh-2020-200976 on 4 February 2021. Downloaded from http://jfprhc.bmj.com/ on April 28, 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

telemedicine provision of medical abortion at home up to 11 weeks and 6 days' gestation.[4]

NHS Lothian is the sole provider of abortion care in Edinburgh and the surrounding region. Just over 2600 women receive abortion care annually.[6] All abortion care including post-abortion contraception is provided at no cost to the patient, as is the norm in the National Health Service (NHS). As a result of the new legislation and clinical guidance,[4 5] the service moved wholly to provision of abortion care by telemedicine and without routine ultrasound on 1 April 2020.

Globally, telemedicine provision of medical abortion has largely been carried out in areas where abortion access is restricted, but existing evidence suggests that rates of complete abortion, emergency admissions to hospital and serious complication rates are similar to those after abortion care in a clinical setting and that acceptability for women is high.[7–11]

We initiated an evaluation of the NHS Lothian telemedicine medical abortion service, based at the Chalmers Sexual and Reproductive Health Centre in Edinburgh. The aims were to determine the number of women having medical abortion at home without routine ultrasound, the efficacy of the procedure when delivered by this model, safety based on serious complications after treatment, and women's acceptability of their care.

METHODS

The telemedicine model

Anyone aged 16 years or older who contacted the service to discuss an unwanted pregnancy was given an appointment for a telephone consultation with a clinician.[2] They were advised to visit the service website for more information on what to expect at the teleconsultation, including audiovisual resources.[12] Those aged less than 16 years were routinely offered an in-person appointment.

During the teleconsultation, women were assessed for the need for ultrasound (LMP uncertain or >12 weeks ago, pain, bleeding, or significant risk factors for ectopic pregnancy).[4 5] For eligible women (LMP <12 weeks ago, no contraindications to mifepristone and misoprostol) requesting medical abortion at home, informed consent was taken verbally, and arrangements made for collection of a medication pack from the service or for couriered delivery to the woman's home. In line with national guidance introduced in relation to COVID-19, anti-D prophylaxis was not provided or considered necessary for rhesus-negative women having medical abortion in the first trimester.[4 5] The contents of the medication pack included prophylactic antibiotics and are shown in online supplemental table 1. Post-abortion contraception was discussed during the consultation, and condoms and short-acting hormonal contraception were included in the medication pack if women wished.[13] Those who requested long-acting reversible contraception (LARC) were offered a clinic appointment 2 weeks later.

For women requiring an in-person consultation and/or ultrasound, this pack was provided at that visit. For women over 12 weeks' gestation or choosing surgical abortion, the existing arrangements for direct admission to the local hospital for this procedure were made.[14] An overview of the telemedicine care pathway can be seen in online supplemental figure 1.

Evaluation

We conducted a prospective observational study of women having medical abortion at home via telemedicine from its instigation on 1 April 2020 until 9 July 2020. We prospectively collected data on the numbers requiring a pre-abortion ultrasound, as well as routinely collected data on gestation, demographic characteristics, reproductive history and choice of post-abortion contraception. For the purposes of the evaluation only, women were contacted by telephone by a researcher for an interviewer-administered questionnaire on days 4 and 14 after misoprostol administration.

The day 4 questionnaire asked about acceptability of the care and preparedness for the procedure. The day 14 questionnaire recorded the result of the self-performed low-sensitivity urine pregnancy test (LSPT) to confirm the success of the procedure,[15] method of contraception provided and women's ratings on the importance of different parts of the telemedicine model for future service development. Responses were either binary (yes/no), rated on a five-point Likert scale (eg, very acceptable to very unacceptable) or by selection from a predefined list of possible options (online supplemental figure 2).

If research staff received a clinical query or elicited information about a possible complication, women were transferred to the abortion service clinical advice line for assessment and care as needed. All these calls for advice were recorded in patient electronic records.

The outcome of the pregnancy (complete abortion, incomplete abortion, ongoing pregnancy) and complications (haemorrhage defined as ≥500 mL blood loss, severe infection defined as requiring intravenous antibiotics) were verified at 6 weeks after abortion through a review of both the regional hospital electronic patient records (TRAK) and the sexual health service records (NaSH).

The primary outcome of the study was efficacy of medical abortion, with success of abortion defined according to the Medical Abortion Reporting of Efficacy (MARE) guidelines as successful expulsion of pregnancy without the need for surgical intervention.[16] Secondary outcomes were severe complications (haemorrhage and severe infection), adverse outcomes such as undiagnosed ectopic pregnancy, gestation beyond 12 weeks, unscheduled contact with the service, acceptability of the telemedicine service, and contraception uptake.

Statistics

A descriptive analysis has been presented: continuous data as mean and standard deviation (for example, age) and categorical data as numbers and percentages

BMJ Sex Reprod Health: first published as 10.1136/bmjsrh-2020-200976 on 4 February 2021. Downloaded from http://jfprhc.bmj.com/ on April 28, 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

of total responders. In some instances due to small numbers categorical responses may have been grouped; however, unless otherwise indicated we have treated all responses in the categories they were collected in. All statistical analysis was performed using SAS Enterprise Guide v 7.15 (SAS Institute Inc., Cary, NC, USA) and Microsoft Excel 2016 by an independent statistician.

Approvals

The project received approval from the NHS Lothian Sexual and Reproductive Health Service Quality Improvement Team and was not deemed to require ethical approval following review by the local NHS Research Ethics Committee scientific officer.

Patient and public involvement

Patients and members of the public were not directly involved in the design of this study.

RESULTS

During the study period, 826 women had a teleconsultation. Thirty-five (4.3%) women chose to continue with the pregnancy, 31 (3.8%) had a miscarriage diagnosed so did not proceed to abortion and the outcome was not known in 2 (0.2%) cases. Of the remaining 758 women who proceeded to abortion, 663 (87%) had a medical abortion at home and were included in the study cohort. The remainder had either a medical or surgical abortion in a hospital setting or were referred to an external provider in England for abortion as they were over 20 weeks' gestation and so the abortion care could not be provided at the local hospital.

Characteristics of women

Table 1 summarises the demographic information and gestational age data. The mean (SD) age was 27.6 (6.6) years (range 16 to 50 years). In 522/663 (78.7%) cases the gestation was determined using LMP alone. In 141 (21.3%) cases a pre-abortion ultrasound was performed for uncertain gestation (n=95; 14.3%) or to confirm that pregnancy was intrauterine (n=33; 5.0%). Thirteen (2%) women had already had an ultrasound at a different service before attending. Capturing gestation in weeks, 56% of women had a gestation of 5 weeks to 6 weeks and 6 days.

Table 1 Demographic characteristics of the telemedicine cohort.

*Scottish Index of Multiple Deprivation.[24]
†For 141 patients the gestational age was taken from an ultrasound result. For all the remaining patients the gestational age was taken from the last menstrual period (LMP).

Outcome of medical abortion

The outcomes of medical abortion are shown in table 2. A complete abortion took place in 650/663 (98%) cases. Eight of the nine failed abortions (ongoing or incomplete) were at gestations <10 weeks. No one was known to have been treated inadvertently beyond 12 weeks' gestation.

Complications and unscheduled care after abortion

Some 16/663 (2.4%) women made unscheduled attendances to the hospital. Two (0.3%) of these women were admitted with haemorrhage but neither required transfusion (both <10 weeks' gestation). A further 13 (2%) women attended hospital with pain and/or bleeding but required only observation (n=7) or intravenous fluids (n=3) or were sent home with oral antibiotics (n=3). One woman was admitted with an unrelated medical event. No one presented with severe infection requiring intravenous antibiotics.

Some 123/663 (18.5%) women telephoned the abortion service for clinical advice. In 67 (10.1%) cases only telephone advice was required. In 56 (8.4%) cases a clinic visit was subsequently scheduled because of a positive or invalid LSPT (n=34), symptoms of continuing pregnancy (n=18) or persistent pain (n=4). In total, a post-abortion

BMJ Sex Reprod Health: first published as 10.1136/bmjsrh-2020-200976 on 4 February 2021. Downloaded from http://jfprhc.bmj.com/ on April 28, 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

Table 2 .Efficacy of medical abortion

Outcome	Cohort (n=663)* n (%)
Complete abortion	650 (98.0)
Ongoing pregnancy	5 (0.8)
Incomplete abortion	4 (0.6)

*The remaining four outcomes were: n=2 (0.3%) did not proceed to take the abortion medication and self-referred for antenatal care to continue the pregnancy. n=1 was presumed to have a caesarean scar ectopic pregnancy. She had an ultrasound at the hospital early pregnancy unit before referral for abortion that reported a small sac low within the uterus with a possible fetal pole. She re-presented 1 week after medical abortion with persisting pregnancy symptoms. A further ultrasound had unchanged findings and given her history of caesarean delivery, it was considered as a likely caesarean scar ectopic. She was managed by the hospital and treated uneventfully with methotrexate. n=1 reported no bleeding after medical abortion. She had an empty uterus on ultrasound 4 days following misoprostol and a negative serum human chorionic gonadotrophin (hCG), suggesting that she was probably never pregnant.

ultrasound was conducted in 66 (9.9%) cases (hospital admissions and clinic visits combined).

Contraception

The method of contraception provided to women is shown in table 3. The the most common method was the progestogen-only pill (desogestrel 75 µg) provided to 423 (63.8%) women. Fifty-eight (8.7%) women received long-acting reversible contraception (LARC).

Acceptability

Almost all (n=652, 98.3%) the women provided responses to at least one follow-up questionnaire. Complete questionnaires at both day 4 and day 14 post-abortion were available for 605 (91.3%) women. Forty-five (6.8%) women responded to the day 4 contact only and 2 (0.3%) only responded to the day 14 contact.

Table 3 Contraceptive method supplied (based on day 14 questionnaire response and clinic records)

Contraceptive method	Cohort (n=663) n	%
POP	423	63.8
COCP	49	7.4
Condoms	62	9.4
Injectable*	19	2.9
Implant*	17	2.6
IUD*	19	2.9
IUS*	20	3
No method	40	6
Patch	14	2.1

*These methods were initiated if women attended clinic for a pre-abortion ultrasound appointment (injectable and implant only) or at a rapid access clinic at a later date.
COCP, combined oral contraceptive pill; IUD, intrauterine device; IUS, intrauterine system; POP, progestogen-only pill.

Some 627 (94.6%) women stated at day 4 that they were 'very' (n=516, 77.8%) or 'somewhat prepared' (n=111, 16.7%) for their treatment following the telemedicine consultation.

Similarly, 628 (94.7%) women rated the abortion experience as 'somewhat' (n=43, 6.5%) or 'very' (n=585, 88.2%) acceptable at day 4. Asked on day 14, 588 (88.7%) stated that they would opt to have treatment at home again if they needed another abortion.

Regarding acceptability of the remote consultation (day 14), 574 (86.6%) women rated it as 'somewhat' (n=24, 3.6%) or 'very' (n=550, 83%) acceptable. Some 473 (71.3%) women stated that they would opt for a telephone consultation again if they required an abortion in the future.

Features of importance in an ideal abortion care service

On day 14, women were asked to rate the importance of the features listed in table 4 for a 'perfect abortion service'. The feature rated by most respondents as 'important' or 'very important' was 'being able to collect all my medications from a pharmacy' by 366/567 (64.6%) women. Ultrasound was rated 'unimportant or very unimportant' by 302/569 (53.1%) women.

DISCUSSION

Telemedicine medical abortion at home was used by almost nine out of ten women and, of these, only two out of ten women required a pre-abortion ultrasound. The study showed high rates of complete abortion, low rates of complications and low rates of unscheduled contact. These findings are similar to previous cohort studies from this service of women who took misoprostol at home having had routine ultrasound and mifepristone in clinic.[14 15 17] Women reported high levels of preparedness to use the medications in their own homes. Indeed, acceptability of care was high, and the majority of women expressed a preference for choosing this model of care again in the future.

This study provides support for continuing this model of care beyond the current pandemic. There was one instance of unnecessary treatment, where the woman had probably never been pregnant. The only ectopic pregnancy in the cohort had a pre-abortion ultrasound and was initially thought to have an intrauterine pregnancy. This highlights how routine ultrasound can provide false reassurance of intrauterine pregnancy.[18] Indeed, the treatment failure and persistence of pregnancy symptoms may have expedited diagnosis and treatment of this ectopic.

Not requiring pre-abortion ultrasound potentially expands the range of healthcare providers who can offer medical abortion,[19] as recommended by the World Health Organization (WHO).[20] There is also existing evidence to support the safety of medical abortion provision without ultrasound based on LMP alone.[21] When asked, more than half of the women in our study considered the use of routine

BMJ Sex Reprod Health: first published as 10.1136/bmjsrh-2020-200976 on 4 February 2021. Downloaded from http://jfprhc.bmj.com/ on April 28, 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

Able to get the treatment from my general practitioner	112	19.8	160	28.2	294	51.8

Some women did not answer certain questions but responded to others and so the denominators and totals may vary slightly between variables.

ultrasound to be 'unimportant' and over half of the women also considered that general practitioners as abortion providers would be an important future development.

In our study, rates of telephone contact to the service for a concern related to the abortion were similar to our previous studies.[14 15] However, we did observe a higher proportion of women requiring a post-abortion clinic attendance (8.4%) compared with our former service model with routine pre-abortion ultrasound and clinic-administered mifepristone with misoprostol at home (2.7%).[14] The majority of the post-abortion clinic visits were to exclude continuing pregnancy following a positive or invalid LSPT. It is possible that the telephone contact from the researcher triggered more of these post-abortion visits since they actively questioned women about the pregnancy test result, rather than leaving them to call the service if they had a concern. It is also likely that without the knowledge of a pre-abortion ultrasound, staff have a lower threshold for arranging a clinic review post-abortion to minimise the chance of missing an ectopic or a pregnancy that may have been at a more advanced gestation. This need for post-abortion clinical support needs to be factored into provision of telemedicine abortion.

Most women received contraception, but this was mostly oral contraceptive pills, which are less effective than LARC methods[22] but can be initiated immediately if a woman has all her care by telemedicine. Fewer than one in ten women in this study received LARC in contrast to previous studies at our service where around one-third of women received LARC.[14] Although, strategies such as 'fast track' to post-abortion contraception clinics can facilitate access to LARC,[23] it is possible that the pandemic may have played a role in women's choice both to use contraception and also the method. Some women may have opted not to use LARC as it required a further visit to a clinic with risk of exposure to the virus, plus the convenience of receiving oral contraception in the treatment pack.

Our study also showed that there is support among women for several simple modifications to the service that could be developed in the future, including expanding the range of options for accessing medications such as postal delivery of medical abortion drugs or collection from a local pharmacy.

This study had an extremely high rate of follow-up for all outcomes. This may be in part because women were at home during the COVID-19 lockdown restrictions and so were easily contactable. Using the electronic patient record for the entire region, we were able to actively search for all serious complications within a 6-week timeframe, and verify abortion outcomes rather than relying on self-reporting at an earlier timepoint alone. Nevertheless, the study size, while considerable, is still too small to detect changes in rare events. While possible, it is extremely unlikely during this period when the study was conducted that many women will have travelled out of the region and suffered a complication. Of course, the telemedicine service was devised and evaluated during the COVID-19 pandemic and so is not yet embedded under 'normal' circumstances, where the proportion of women choosing or being invited for in-person care may be different. In addition, qualitative research is required to provide more nuanced information on women's views on the acceptability of the telemedicine medical abortion service.

CONCLUSIONS

This model of telemedicine medical abortion without routine ultrasound is safe, and has high efficacy and high acceptability among women. This study provides support for continuation of this model of care in this setting beyond the current pandemic.

Abstract

Background

Expanding access to medication abortion through pharmacies is a promising avenue to reach women with safe and convenient care, yet no pharmacy provision interventions have been evaluated. This observational non-inferiority study investigated the effectiveness and safety of mifepristone-misoprostol medication abortion provided at pharmacies, compared to government-certified public health facilities, by trained auxiliary nurse-midwives in Nepal.

Methods

Auxiliary nurse-midwives were trained to provide medication abortion through twelve pharmacies and public facilities as part of a demonstration project in two districts. Eligible women were ≤63 days pregnant, aged 16–45, and had no medical contraindications. Between 2014–2015, participants (n = 605) obtained 200 mg mifepristone orally and 800μg misoprostol sublingually or intravaginally 24 hours later, and followed-up 14–21 days later. The primary outcome was complete abortion without manual vacuum aspiration; the secondary outcome was complication requiring treatment. We assessed risk differences by facility type with multivariable logistic mixed-effects regression.

Results

Over 99% of enrolled women completed follow-up (n = 600). Complete abortions occurred in 588 (98·0%) cases, with ten incomplete abortions and two continuing pregnancies. 293/297 (98·7%) pharmacy participants and 295/303 (97·4%) public facility participants had complete abortions, with an adjusted risk difference falling within the pre-specified 5 percentage-point non-inferiority margin (1·5% [-0·8%, 3·8%]). No serious adverse events

(sarah.raifman@ucsf.edu) after obtaining the necessary ethical approvals.

occurred. Five (1.7%) pharmacy and two (0.7%) public facility participants experienced a complication warranting treatment (aRD, 0.8% [-1.0%-2.7%]).

Conclusions

Early mifepristone-misoprostol abortion was as effective and safe when provided by trained auxiliary nurse-midwives at pharmacies as at government-certified health facilities. Findings support policy expanding provision through registered pharmacies by trained auxiliary nurse-midwives to improve access to safe care.

Introduction

Unsafe abortion contributes substantially to maternal mortality and morbidity worldwide, accounting for approximately 18% of maternal deaths [1, 2]. Unsafe abortion occurs predominantly in lower-income countries where abortion is illegal or highly restricted, and in remote areas where trained providers and equipment are scarce [3]. In Nepal, where abortion was legalized in 2002 [4], unsafe abortion still accounted for 7% of maternal deaths in 2009, with access to safe and legal care particularly constrained in rural regions [5].

Efforts to improve access to safe abortion have focused on expanding the provider base, as well as decentralizing medication abortion (MA) provision beyond traditional hospital and clinic settings. On the World Health Organization (WHO) Essential Medicines List for developing countries [6], mifepristone and misoprostol abortion is approximately 95% effective in pregnancies under nine weeks, with a gradual decline in efficacy with increasing gestation [7]. The safety and effectiveness of MAB when provided by non-physician clinicians, including nurses and auxiliary nurse midwives (ANMs), has been well-established [8–11], and 2015 WHO guidelines on appropriate health worker roles in abortion care recommend implementing nurse/ANM provision at scale [12]. Accordingly, nurses and ANMs now regularly provide abortion care in Nepal, including in primary-level public health facilities in many districts [13].

Expanding access to MAB through regulated pharmacies may also be a promising avenue to reach women with safe care, though no interventions have been evaluated [14]. In many countries including Nepal, pharmacies are a common first contact point for women seeking abortion and serve as important sources of information and referral [14, 15]. They are more accessible than clinics, particularly in rural areas and for women who have limited autonomy and mobility, and may offer increased privacy compared to public facilities [14, 16, 17]. MAB can be provided without laboratory tests or ultrasounds, and women can safely self-administer misoprostol, complete the abortion, and self-evaluate completion at home [18–20]. In Nepal and elsewhere, however, unskilled and untrained pharmacy workers often provide inaccurate information and dispense unsafe or ineffective methods [21–26], and formative research training pharmacy workers on MAB eligibility and dosing has only been moderately successful [15, 27]. As such the WHO does not currently recommend pharmacist provision [12]. However, other cadres of trained health care providers, including nurses and ANMs, working in pharmacy settings could potentially incorporate MAB provision with clinical protocols into their services, expanding access points for safe services.

Nepal is a leader in innovating access to abortion. Since abortion was decriminalized in Nepal in 2002 [4], access to legal services has expanded to all districts [28, 29]. Abortion is legal for any reason up to 12 weeks' gestation, and second-trimester procedures, allowed under

certain circumstances, became available in 2007. Mifepristone-misoprostol became legally available in 2009, and Nepal is one of the few lower-income countries with national MAB practice guidelines. Provision by nurses and ANMs, who have a tenth grade education and 18 and 24 months' pre-service formal training, respectively, is permitted. Declines in the severity of abortion complications following legalization have been attributed in part to nurse/ANM service provision as well as the availability of MAB [12, 30]. In a 2013 pharmacy study in two Nepali districts, over 10% of pharmacy workers were trained as nurses or ANMs, and 85% of pharmacies had private spaces for client consultation [31]. Leveraging nurses and ANMs–a trained clinical workforce with a record of safe MAB–to deliver services in pharmacy settings, where women already seek care, could be an important next step toward increasing access to safe abortion.

In this observational demonstration study, we tested the hypothesis that the effectiveness and safety of mifepristone medication abortion provided by trained ANMs through pharmacies would not be inferior to provision through public health facilities that are government-certified to provide MAB. Empirical data on the effectiveness and safety of MAB provision from pharmacies by trained providers do not yet exist but are essential to inform evidence-based policy in Nepal and elsewhere.

Materials and methods

Study design and participants

This study was an observational, non-inferiority study comparing outcomes of medication abortion provided by trained auxiliary nurse-midwives in two settings: pharmacies and government-certified public health facilities. Sites were located in both semi-urban and remote regions of the Chitwan and Jhapa districts in the lower Terai region, bordering India. Twelve sites participated: six privately-owned pharmacies and six public health facilities, including four primary health care centers and two health posts. Primary health care centers provide basic health care services, minor surgeries, and aspiration and medication abortion; they are typically staffed by a physician, a few nurses/ANMs, and non-clinical staff. Health posts provide basic health care services and are staffed by a nurse/ANM, a health worker, and non-clinical staff; some are approved to provide medication abortion. Participating pharmacies had to be registered with the Department of Drug Administration, Ministry of Health and Population; have locked storage for data; and have a private space for patient examination, a typical set-up in Nepal [31].

Clinical study procedures were conducted by six ANMs. Each was trained as a skilled birth attendant, had required government training and certification to provide MAB at a public facility, and worked in a pharmacy. MAB outcomes can vary substantially between providers based on experience and tendency to intervene [32]. Because we were evaluating the effect of location of administration, not provider experience or ability, we designed the study such that the same ANM provided services from one pharmacy and one public health facility [31]. Study ANMs were identified in consultation with the District Public Health offices overseeing study sites.

ANMs completed a three-day training on study procedures, ethics and voluntary informed consent, and provision of MAB through the pharmacy, including ensuring confidentiality, storage of clinical case reports, and referrals. At training completion, each participating pharmacy received certification from the Ministry of Health and Population to provide MAB for the experimental demonstration study period. One ANM was relocated during the study; a replacement was trained on-site by a study investigator. Six female research assistants with nursing training were selected and trained to conduct non-clinical data collection.

GBP-PET00737

Women presenting at study sites seeking medication abortion were eligible to participate if they were aged 16–45 and had an established pregnancy of ≤63 days based on pelvic exam performed at the site. Women were excluded if they had already attempted abortion with the same pregnancy, lived outside of Nepal, had any medical contraindications to mifepristone-misoprostol, or were unable to provide consent or complete study visits.

Data were collected October 2014-September 2015. A pilot phase among 57 participants was conducted October-December 2014 to assess feasibility and test instruments. Results of an interim analysis were shared with two University of California, San Francisco (UCSF) obstetrician-gynecologists to determine that complications or incomplete abortions at pharmacy sites were not higher than expected. As pre-specified in the protocol, because no changes to the protocol were required, pilot data were included in analyses.

Ethical approval was obtained from the UCSF Committee on Human Research and the Nepal Health Research Council. The study was endorsed by the Family Health Division, Ministry of Health and Population, Nepal. We followed published guidelines for reporting of non-inferiority trials [33].

Procedures

For women presenting at all study sites requesting medication abortion, ANMs completed clinical screening for MAB eligibility, as is standard patient care. ANMs recorded last menstrual period and MAB contraindications. They conducted a pelvic exam to assess gestational length and identify signs of ectopic or adnexal mass or infection. Women meeting MAB eligibility criteria (both those enrolling and not enrolling) received MAB counseling, services, and information on when and where to seek care for complications.

Clinical procedures at all sites followed the standard Nepali medication abortion protocol [34], which is consistent with international safe abortion guidelines [18]. Ultrasound and pregnancy confirmation via urine pregnancy test are not part of routine care, but providers could use them or refer women at their discretion. Participants took 200 mg mifepristone orally in front of the provider, followed by 800 μg misoprostol sublingually or intravaginally 24 hours later, usually at home (Medabon®, Sun Pharmaceutical Industries Ltd., Gujarat, India). Due to shortages of Medabon® in study districts, and to eliminate pressure on women to enroll to obtain the drug, the study purchased and provided mifepristone-misoprostol to all women presenting to study sites, regardless of participation. All participants and non-participants were charged 500 Rupees ($5) for MAB care, standard price at public facilities at the time.

Women meeting eligibility criteria provided verbal informed consent. After taking mifepristone, participants completed interviewer-administered baseline questionnaires assessing sociodemographics, pregnancy and contraceptive history, pregnancy intentions, and experiences seeking services.

In the Nepali protocol, patients are provided context-appropriate instructions for when to seek care for a complication or incomplete abortion; follow-up visits are not mandatory [34]. However, to capture study outcome data, participants were asked to return after 14–21 days. At follow-up, ANMs completed a clinical interview about symptoms experienced and any medical care received since enrollment. They conducted a pelvic exam, providing or referring patients for care as needed, including for aspiration abortion for incomplete abortion; additional doses of misoprostol were not provided. Additional follow-up visits were scheduled at the ANM's discretion until all medical issues were resolved and abortions were complete. Finally, research assistants administered a follow-up questionnaire to capture participant satisfaction. All study procedures were conducted privately and confidentially. Participants received a gift worth 150 Rupees ($1.50) after each interview and 150 Rupees for travel costs at

follow-up. Costs of aspiration abortions and treatment for medical care received were covered by the study.

Data were managed by the Center for Research on Environment Health & Population (CREHPA). Research assistants secured data collection instruments at the study sites. Instruments were transferred to the CREHPA offices monthly.

Outcomes

The primary outcome was successful complete abortion (versus incomplete abortion or continuing pregnancy), without aspiration abortion, within 30 days of mifepristone [9]. Incomplete abortion was defined as the products of conception remaining in the uterus with continued bleeding, enlarged uterus, and open cervix. Continuing pregnancy was when symptoms of pregnancy continued and aspiration abortion was necessary to terminate the pregnancy. Aspiration abortions reported by participants and those determined as necessary by study ANMs at the follow-up visits were included.

The secondary outcome was experience of complications requiring treatment, including any case in which participants sought treatment or ANMs provided or referred for care at a follow-up visit. Serious adverse events, including hemorrhage needing blood transfusion and conditions requiring hospitalization, were captured. Finally, we assessed side effects experienced and satisfaction with services and MAB itself. Data for all outcomes were recorded on follow-up clinical case reports and questionnaires.

Statistical analysis

This non-inferiority study was designed to assess relative differences in complete abortion among women at pharmacies versus certified public health facilities. We conducted sample size calculations using an expected 97% complete abortions, based on a *Lancet* study of mid-level provider MAB provision [9]. The non-inferiority limit defined -5% as the acceptable difference in successful abortion proportions, based on prior research and feasibility [9, 33]. A sample size of 586 was calculated to be sufficient to establish non-inferiority of pharmacy distribution, with two-sided alpha of 5% and 80% power; an enrollment ratio of 1:1; and increases in the sample of 10% for attrition, 10% to control for sociodemographic differences by arm, and 40% to account for clustering. We based the intraclass correlation coefficient (ICC) on prior research (0.001) [9, 35], increasing it to 0.005 to be conservative. Calculations were replicated varying the expected outcome by 1%, and results did not change substantially.

To assess differences in participant characteristics by arm, we fit a series of bivariable mixed effects models, including random effects for provider and site for clustering. We calculated the proportions of women experiencing complete abortion overall and by arm. To assess non-inferiority of pharmacy MAB as compared to public health facility MAB, we fit a logistic mixed effects model with random provider and site effects. Based on this model, we calculated the crude risk difference by arm and 95% confidence intervals (CI). If the CI fell above -5%, the predetermined non-inferiority margin, we could conclude that pharmacy provision is not inferior to public health facility provision. We repeated mixed effects analyses adjusting for covariables found to differ between arms (education, parity, prior contraceptive use), as well as age and gestational length. We examined complications similarly. We conducted sensitivity analyses, assuming that the five participants who were lost-to-follow-up required aspiration abortions and had complications. Analyses were conducted using Stata v14 (College Station, TX). Results were reported at $p \leq 0.05$.

GBP-PET00739

Results

Participating ANMs were all female and a median of 37 years old (range 30–57). They had spent a median of 16 years (range 6–34) in medical practice and had five years' experience (range 3–5) providing medication abortion.

Overall, 660 women presented to study sites seeking MAB during the enrollment period (Fig 1), with 326 presenting at pharmacies and 334 at public health facilities. Of these, 50 did not meet eligibility criteria, with 47 >63 days gestation and three having medical contraindications (two chronic adrenal failure, one bleeding disorder). Two women at pharmacies and three at public health facilities were not enrolled for other reasons (concern of possible uterine infection, anemia, cholelithiasis, hypertension medication, and heart disease). Five of the 605 women enrolled into the study were lost to follow-up after treatment (<1%).

The 605 participants were on average 28 years old (Table 1). Almost all were married (99%), and 94% had children. A majority (61%) worked outside of the home, mostly in farming or livestock. About half had ever used an effective contraceptive method, and 62% wanted no more children. Participants presenting at pharmacies and public health facilities were similar by age, gestational length, prior abortion (33%), and knowledge of abortion legality (50%). However, pharmacy participants had more education (mean 8 vs. 7 years), lower parity (mean 1.7 vs. 2.1), were less likely to have used an effective contraceptive (40% vs. 57%), and were slightly less likely to desire no more children (55% vs. 67%, p = 0.06). Pharmacy participants experienced slightly shorter travel times to the facility than public facility participants (mean 28 vs. 34 minutes, p = 0.06).

The proportion of women having complete abortions overall was 98.0%, with 1.7% (n = 10) having an incomplete abortion and 0.3% (n = 2) having a continuing pregnancy (Table 2). By arm, the complete abortion proportions were 98.7% for pharmacy and 97.4% for public health facility, for a crude risk difference of 1.3% [-0.9%, 3.5%]. After adjusting for covariables, the risk difference was 1.5% [-0.8%, 3.8%], with the 95% CI well above the non-inferiority limit of -5%, indicating non-inferiority for abortion effectiveness. All participants with incomplete abortions and continuing pregnancies received manual vacuum aspiration from the study ANM or by referral.

* Assessed with 8 items asking whether participants' households had amenities such as electricity, radio, landline phone, and bicycle.

https://doi.org/10.1371/journal.pone.0191174.t001

No serious adverse events occurred. Seven participants experienced a complication that warranted treatment based on provider assessment (Table 2). By arm, 1.7% (n = 5) of pharmacy participants and 0.7% (n = 2) of public health facility participants required treatment, mostly antibiotics for fever and potential infection. The risk difference was not statistically significant (aRD = 0.8% [-1.0%, 2.7%]). Participants reported expected side effects, most commonly abdominal cramping (92%), nausea (61%), and chills (42%), with no differences by arm.

Proportions of complete abortions and complications for individual ANMs ranged from 95.6%-99.3% (ICC = 0.001) and 0–3.5%, respectively. Results were consistent assuming the five participants lost-to-follow-up had negative outcomes: complete abortion aRD = 0.4% [-2.2%, 3.1%]; complication aRD = 1.7% [-0.8%, 4.2%].

Acceptability of services was high across sites, with no differences by study arm (Table 3). Satisfaction with MAB as a method was high (64% satisfied, 34% highly satisfied), as was

Table 2. Medication abortion outcomes (n = 600).

	Pharmacy (n = 297)	Public Health Facility (n = 303)	Risk Difference (95% CI)	Adjusted Risk Difference* (95% CI)
Complete abortion (%)	98.7	97.4	1.3 (-0.9, 3.5)	1.5 (-0.8, 3.8)
Serious adverse event (%)	0	0		
Complication (%)	1.7	0.7	0.9 (-1.0, 2.8)	0.8 (-1.0, 2.7)

* Adjusted models control for age, education, parity, prior contraceptive use, and gestation.

satisfaction with services received (62% satisfied, 36% highly satisfied). Women experiencing an incomplete abortion, continuing pregnancy, or complication were less likely to report satisfaction with MAB (56.3% vs. 99.7%, $p<0.001$) or services received (78.6% vs. 99.7%, $p<0.001$). 95% of pharmacy participants and 98% of public health facility participants reported they would prefer to go to a pharmacy and public facility, respectively, if MAB services were needed again ($p<0.05$).

Discussion

In this observational non-inferiority study, the effectiveness and safety of early mifepristone-misoprostol medication abortion provided by auxiliary nurse-midwives at pharmacies was as effective and safe as compared to when provided by ANMs at government-certified health facilities. Our study showed ANM provision of MAB in both pharmacies (98.7%) and public facilities (97.4%) was as effective as has been demonstrated in other studies using the same regimen (91–99%) [7]. Our findings provide evidence that with minimal additional training, ANMs with previous experience providing MAB can administer services as effectively and

safely at a pharmacy as a government-certified facility in a low-resource setting, with high satisfaction across settings.

While nurse and ANM provision expands the abortion provider base, the potential of this trained workforce to reach women is limited by the requirement that services be provided from government-certified public health facilities. Pharmacies are more accessible than clinics, particularly in rural and mountainous areas, and are often the first contact point for women seeking services [14]. The leveraging of pharmacies to expand access to other reproductive health technologies, including injectable and emergency contraceptives, has already been successful in Nepal [36]. Although interventions to train pharmacy workers in harm reduction strategies in Zambia and Nepal have achieved moderate improvement in knowledge and referral practices [15, 27], pharmacists and pharmacy workers, often provide unsafe abortion care [14, 21–26], and the WHO does not currently recommend they provide care. Allowing nurses and ANMs with MAB training to deliver services from pharmacy settings may be the next step in an incremental approach to increasing access to care. Safe pharmacy care from nurses/ANMs may not only mitigate the unsafe or ineffective care women might otherwise receive, but could also expand safe provision beyond hospitals and clinics to a location where women already seek care, thereby reducing unsafe abortion-related morbidity and mortality.

This study has limitations. Public health facility participants returning to the facility for care may have been more likely to receive intervention due to the presence of other clinicians, thereby biasing results in favor of pharmacies; however, incomplete abortions and complications were infrequent in both facility settings in this study. The 14–21 day follow-up period might not have detected delayed complications or ongoing pregnancies. However, study ANM remained in touch with participants until any issues detected were fully resolved, and it is reasonable to believe that most participants who experienced a delayed complication would return to the study facility for care. Our measures of satisfaction did not capture the acceptability of specific aspects of care provided. Finally, given feasibility constraints for a government-approved demonstration project, we were limited to including twelve recruitment sites and six ANMs. We had planned originally for pharmacy providers to rely on self-reported date of last menstrual period for assessment of gestation. Study ANMs, however, were uncomfortable omitting the pelvic exam because they were accustomed to conducting it. Our findings are thus not generalizable to pharmacies without clinical exam space, nor do they apply to unregulated pharmacies or those without ANMs with abortion training. Research should examine whether removing the pelvic exam from the baseline clinical assessment affects abortion effectiveness and safety.

This study is the first to our knowledge to evaluate with a rigorous design and control group the effectiveness of medication abortion provision by trained clinicians in pharmacy settings. Our design isolated the effects of facility environment from the qualifications of providers on medication abortion outcomes. We had high (>99%) follow-up, supporting the internal validity of results. Importantly, this research with ANMs was clinically and ethnically appropriate, conducted in a manner consistent with World Health Organization guidelines, the scientific literature on ANM provision of abortion care, and current clinical practice and law in Nepal. Specifically, the safety and effectiveness of MAB when provided by non-physician clinicians, including nurses and ANMs, has been firmly established in peer-reviewed research [8–11]. The WHO has published evidence-based guidelines delineating the appropriate roles of different cadres of health providers in providing abortion care, recommending the implementation of nurse and ANM provision of first-trimester MAB care at scale as a safe and effective strategy for increasing access to safe pregnancy termination [12]. ANM provision of first-trimester MAB care is legal in Nepal for nurses and ANMs trained as skilled birth attendants and

GBP-PET00743

who have completed government training and certification. ANMs currently provide medication abortion care throughout Nepal [13, 29].

Conclusion

Despite improvements in access to safe abortion care in Nepal, women continue to face obstacles to safe abortion and to seek care from unskilled providers, with access to safe care particularly constrained in rural regions [5]. This study provides data supporting the expansion of medication abortion services to registered pharmacy settings when care is provided by an appropriately trained ANM. Future research should build on these findings by investigating ways to safely implement pharmacy ANM provision at scale and monitor quality of care provided.

Introduction to RCOG Best Practice Papers

The Royal College of Obstetricians and Gynaecologists (RCOG) Best Practice Papers are peer-reviewed, easy-to-use, adaptable documents that set out the essential elements for evidence-based clinical practice.

The best practices described are drawn from current evidence-based guidance produced by organisations such as the World Health Organization (WHO), the RCOG and the National Institute for Health and Care Excellence (NICE).

To be readable and useful to people providing healthcare on a daily basis, the papers have been deliberately kept short and succinct. Therefore, the primary evidence for recommendations and the strength of that evidence have been omitted but can be found in the original source documents. Very recently published evidence has been assessed to determine whether any recommendations from current guidelines should be amended.

The Best Practice Papers may also be used as a tool to assist policy makers in improving services.

While the Best Practice Papers may be used for reference in any country, local legal, regulatory, policy and service-delivery contexts may require adaptation of some recommendations; however, it is important to ensure that evidence-based practice is maintained.

For support on adapting the document while still maintaining good practice, please contact cfwgh@rcog.org.uk.

Acknowledgements

The original RCOG *Best Practice Paper on Comprehensive Abortion Care* was developed by Anna Glasier in close consultation with David Baird, Paul Blumenthal, Sharon Cameron, Alison Fiander, Ailsa Gebbie, Stefan Gebhardt, Natalie Kapp, Hawa Kawawa, Judy Kluge, Patricia A Lohr, Grace Magembe, Gileard Masenga, Projestine Muganyizi, Malika Patel, Gregory Petro, Lesley Regan, Sam Rowlands, Petrus Steyn and Zephne van der Spuy. It was peer reviewed by Kelly Culwell, Kristina Gemzell Danielsson and Angela Hyde.

This paper was updated in 2022 by Sharon Cameron, Jayne Kavanagh and Patricia A Lohr, and was peer reviewed by Roua Ahmed, Akinola B Ajayi, Sibongile Chikombore, Evangeline Dushimeyesu, Kristina Gemzell Danielsson, Salma A/Salam Gerais, Anna Glasier, Abbas Lawal Ibrahim, Jonathan Lord, Jerome Mfitumukiza and John Reynolds-Wright.

This paper was updated as part of the RCOG's Making Abortion Safe programme – a three-year programme working to increase healthcare providers' capacity to address the barriers to safe abortion care and/or post-abortion care, globally. For more information, visit www.rcog.org.uk/en/global-network/centre-womens-global-health/our-work/making-abortion-safe.

Language note

Globally, most abortions are provided to women; however, trans men and non-binary people also experience pregnancy and abortion. Therefore, this paper refers to 'women' and 'pregnant people' to reflect a range of identities.

RCOG guidelines disclaimer

The RCOG produces guidelines as an educational aid to good clinical practice. They present recognised methods and techniques of clinical practice, based on published evidence, for consideration by obstetricians/gynaecologists and other relevant health professionals.

The ultimate judgement regarding a particular clinical procedure or treatment plan must be made by the doctor or other attendant in the light of clinical data presented by the patient and the diagnostic and treatment options available. This means that RCOG guidelines are unlike protocols or guidelines issued by employers, as they are not intended to be prescriptive directions defining a single course of management.

Departure from the local prescriptive protocols or guidelines should be fully documented in the patient's case notes at the time the relevant decision is taken.

Background

An estimated 25 million unsafe abortions occur every year, making it one of the leading causes of maternal mortality and morbidity worldwide. Abortion-related deaths and morbidity are largely preventable by providing safe abortion care (performed in line with clinical best practice) and timely post-abortion care, as well as by access to contraception and comprehensive sexuality education (CSE). Denying, delaying or restricting access to safe abortion care may lead to violations of the right to life, the right to health and the right to privacy, and can in some cases amount to cruel, inhumane or degrading treatment.

Abortion need not be unsafe. Morbidity and mortality rates following abortion that is provided using best practice are lower than those that would be faced in an ongoing pregnancy and in childbirth. Surgical abortions provided according to evidence-based guidance are generally straightforward procedures and can be provided by a range of clinician groups in a variety of settings. In addition, with appropriate support, individuals can safely manage medical abortions at under 12 weeks of pregnancy themselves at home. As with many other medical procedures, adherence to best practice standards will ensure that the most effective and the safest services are delivered. This Best Practice Paper is designed to be used by health workers delivering abortion and post-abortion care.

The two methods of abortion are:

- **medical abortion:** the use of medications to end a pregnancy; the most commonly used medications are misoprostol alone or misoprostol in combination with mifepristone.
- **surgical abortion:** the use of transcervical procedures to end a pregnancy, including manual vacuum aspiration (MVA), electric vacuum aspiration (EVA) and dilatation and evacuation (D&E).

> All aspects of abortion care should be delivered in a respectful and sensitive manner that is person-centred and recognises women and pregnant people as the decision makers.

Information for individuals requesting an abortion

Women and pregnant people should be informed about their options so that they can make an informed choice about their preferred course of action. Their choice should be respected without any unnecessary delay, as the earlier in pregnancy an abortion is undertaken the safer it is likely to be.

> If performed in line with best practice, an abortion is safer than continuing a pregnancy and childbirth.

Whenever possible, offer individuals a choice of abortion method. Their choice will depend on their individual circumstances and how they feel about the different options.

The following information should be provided to those requesting an abortion, in a clear, understandable, non-judgemental and respectful way:

- Abortion is a safe procedure for which major complications are rare at all pregnancy durations.
- The choice of abortion methods available.
- What will happen during and after the abortion (see Table 1).
- What pain management options are available.
- Side effects, risks and complications of abortion methods (see Table 2).

- How to be sure the pregnancy has ended for those having a medical abortion at home.
- How to identify the need to seek urgent medical attention during or after the abortion.
- The range of potential emotions experienced after an abortion.
- Other available services, such as sexually transmitted infection (STI) screening, counselling for those who need it and support for those experiencing, for example, sexual coercion or domestic violence and abuse.
- What contraception options are available and how they can be accessed.

Those who are unsure about whether to continue the pregnancy or have an abortion should be offered counselling/decision-making support.

Table 1 What abortion methods entail; adapted from the WHO (2014) ***Clinical Practice Handbook for Safe Abortion*** and the NICE (2019) patient decision aids published with the ***Abortion Care*** guideline

Medical abortion	Surgical abortion
• Avoids surgery. • Mimics miscarriage. • May take place at home (depending on stage of pregnancy). • Takes time (hours to days) to complete and the timing may not be predictable. • The medications can cause nausea, vomiting, diarrhoea, chills and fever (1 in 10). • Will experience abdominal cramping and bleeding while passing the pregnancy (worse than during a period). • Abdominal cramping can last, on and off, for a week and bleeding for two to three weeks. • May see the pregnancy as it passes. • Serious complications are uncommon (see Table 2). • All contraceptive methods can be started at the time of the medical abortion, except intrauterine devices (IUDs), which can be inserted immediately after the pregnancy is expelled.	• Takes place in a healthcare facility. • Will experience some discomfort during procedures conducted with sedation and/or local anaesthetic. • Will experience no discomfort during procedures conducted under general anaesthetic. • The medications used to prepare the cervix cause cramps and bleeding and can cause nausea, vomiting, diarrhoea, chills and fever (1 in 10). • Will experience some pain and bleeding for one to two weeks afterwards. • Will not usually see the pregnancy, unless wishes to do so. • Requires a pelvic examination and insertion of surgical instruments into the uterus. • Serious complications are uncommon (see Table 2). • All contraceptive methods can be started at the time of the procedure, including the IUD.

Table 2 Complications and risks of abortion; adapted from the NICE (2019) ***Abortion Care*** guideline and the RCOG (2011) ***Care of Women Requesting Induced Abortion*** guideline

Complication/risk	Medical abortion	Surgical abortion
Continuing pregnancy	1–2 in 100	1 in 1000 Higher in pregnancies <7 weeks
Need for further intervention to complete the procedure	<14 weeks: 70 in 1000 >14 weeks: 13 in 100	<14 weeks: 35 in 1000 >14 weeks: 3 in 100
Infection*	Less than 1 in 100	Less than 1 in 100
Severe bleeding requiring transfusion	<20 weeks: less than 1 in 1000 >20 weeks: 4 in 1000	<20 weeks: less than 1 in 1000 >20 weeks: 4 in 1000
Cervical injury from dilation and manipulation**	–	1 in 100
Uterine perforation	–	1–4 in 1000
Uterine rupture	Less than 1 in 1000 for second-trimester medical abortions***	–

* Upper genital tract infection of varying degrees of severity is unlikely but may occur after abortion and is usually associated with pre-existing infection. Infection after surgical abortion is reduced with use of prophylactic antibiotics.
** Cervical injury is less likely if cervical preparation is undertaken in line with best practice.
*** The presence of a uterine scar (e.g. following a previous caesarean) is a risk factor.

Further treatment (e.g. blood transfusion, laparoscopy, laparotomy or hysterectomy) may be required, should any serious complications occur.

There are several myths about the consequences of abortion. Individuals who express concerns can be reassured that there are no proven associations between having an abortion and subsequent ectopic pregnancy, placenta praevia, infertility, breast cancer or mental health problems.

It is best practice to invite a discussion about contraception at the initial consultation. If a contraceptive method is chosen, that method should be provided, where possible, at the time of the abortion.

Young people
Adolescents deserve the same amount of respect as everyone else accessing abortion care. It's important to remember how vulnerable a young person might feel when requesting an abortion, especially if it's their first time seeking healthcare. If the law requires an adult to consent to their procedure, this should be clearly explained to the young person at the start of the consultation. While all adolescents should be encouraged to involve a trusted adult in their decision, if possible, do **not** insist on parents' authorisation unless it is a legal requirement.

Information for health workers assessing individuals prior to abortion

Communicate information in a clear, understandable way. Providers should not impose personal values or beliefs on clients but focus on their needs and show empathy and respect for their reproductive decisions.

Unless contraindicated, women and pregnant people should be offered a choice of abortion method.

Clinical history taking should identify any health conditions that might affect eligibility for a particular method of abortion and any extra considerations that might affect the location of care and/or pre-treatment planning, including individuals with serious medical conditions who need to be referred for specialist care.

Health workers should check that the person seeking an abortion is doing so voluntarily and is not being coerced into ending the pregnancy. They should also ask about sexual and domestic violence and abuse (physical and emotional) and be able to refer the person to appropriate support services. If the assessment is being conducted by telephone, video call or online, the provider should be confident that the person is able to speak privately without risk of being overheard.

Health workers should be aware of the anxiety that clients may have about perceived negative and judgemental attitudes from healthcare providers.

Health workers can help relieve anxiety, create a safe and respectful environment, and counteract abortion-related stigma by:

- using welcoming words when they first meet the patient (making eye contact and smiling in face-to face meetings)
- introducing themselves, explaining what the consultation will entail
- structuring the consultation so that there is time to build up a rapport before exploring feelings about the pregnancy
- giving clear, concise and accurate information and encouraging questions.
- trying not to make assumptions and by using value-neutral, unbiased language
- conveying how common abortion is.

> It is important that abortion eligibility by pregnancy duration is determined, that any contraindications to methods are identified and that post-abortion contraception is offered.

Determining pregnancy duration

The duration of the pregnancy will influence the method of abortion and whether the abortion can take place at home or should take place in a clinical facility. Pregnancy duration can be assessed from the first day of the last menstrual period (LMP). Most people can determine the duration of their pregnancy with reasonable accuracy by LMP alone.

Routine pre-abortion ultrasound scanning is unnecessary but, if available, should be used if there is clinically relevant uncertainty about the pregnancy duration or if there is a suspected ectopic pregnancy.

In circumstances where the pregnancy duration cannot be assessed by reliable LMP and where ultrasound scanning is not available, an abdominal examination can help determine pregnancy duration when it is over 12 weeks. A bimanual examination can be performed if the practitioner is still not sure of pregnancy duration after an abdominal examination and the information gained would change clinical management.

Contraindications and extra considerations

Medical abortion

There are few **contraindications** to medical abortion:

- known or suspected ectopic pregnancy
- previous allergic reaction to mifepristone or misoprostol
- severe uncontrolled asthma*
- chronic adrenal failure*
- inherited porphyria.*

* Mifepristone should not be used as there is a theoretical risk of exacerbation of the underlying condition, but use of misoprostol alone could be considered.

Extra consideration and additional care planning might be necessary for those:

- on **long-term steroid therapy** – theoretically, since mifepristone is a glucocorticoid receptor antagonist, it might inhibit the action of the steroid therapy and exacerbate the underlying condition; seek specialist input on whether dose adjustments to a corticosteroid regimen are required
- on **anticoagulant medication** – anticoagulants may need to be stopped before abortion medications are administered and then restarted after the abortion
- with a **bleeding disorder**, who may need care in a clinical setting rather than at home
- with **symptomatic anaemia**, where the haemoglobin concentration should be measured and who may need additional care in a hospital setting.
- with an **IUD in place** – the IUD should ideally be removed in advance of treatment; if the IUD cannot be retrieved, it is important to confirm that it is expelled during the procedure, by using imaging such as an abdominal X-ray after the abortion.

Surgical abortion

Surgical methods of abortion are contraindicated if the pregnancy cannot be removed through the cervix, for example due to an obstructing tumour.

In the very rare case that a medical abortion is also not suitable in these circumstances, hysterotomy or gravid hysterectomy may be undertaken.

Medical (or other) conditions and considerations can affect the choice of anaesthetic, indicate a need for the abortion to be undertaken in hospital, or require additional or specialised equipment. These include bleeding disorders and abnormal placentation, use of anticoagulant medication, and severe cardiopulmonary disease. A very high body mass index (BMI), distortion of the uterine cavity by fibroids or another anomaly, previous cervical surgery or type 3 female genital mutilation (FGM) can also make access to the cervix or pregnancy challenging. Procedure planning can include variations in patient positioning, use of longer instruments for evacuation, ultrasound guidance, and cervical preparation.

STI screening

It is best practice to undertake an STI risk assessment for everyone and conduct screening if appropriate, e.g. for chlamydia and gonorrhoea, which might be implicated in post-abortion infection, and for blood-borne viruses such as HIV and syphilis if such testing is available. This should be done without delaying the abortion.

Administer treatment doses of antibiotics to those with signs or symptoms of an STI. Partners of individuals with an STI also require treatment; ideally, a system for partner notification and follow-up or referral would be in place.

Prevention of post-abortion infection

Prophylactic antibiotics are not required for medical abortion but should be used for surgical abortion as they have been shown to reduce the risk of infection following the abortion. However, surgical abortion should not be delayed if antibiotics are not available.

The optimal regimen is not known but nitroimidazoles (e.g. metronidazole), tetracyclines (e.g. doxycycline) and penicillins have been shown to be effective.

The following regimen can be considered for surgical (or incomplete) abortion antibiotic prophylaxis:

- oral doxycycline 100mg twice a day for 3 to 7 days, starting within 2 hours of the procedure (there is evidence that a 3-day course is as effective as a 7-day course).

Blood tests

Pre-abortion assessment does not require routine blood tests. A determination of Rhesus blood status may be considered if the duration of pregnancy is over 12 weeks and anti-D is available. Measurement of haemoglobin concentration or other blood tests is not required unless there are good clinical indications for doing so, such as for those with symptomatic anaemia.

Contraception

Discussions about contraception should be sensitively initiated. Not all people will want to discuss contraception at the time of their abortion. Those who do should be offered information about all their contraceptive options, without any pressure to choose a particular method.

Advice can be given on the greater effectiveness and duration of long-acting reversible contraception (LARC) methods (implants and IUDs) and of their safety, but no pressure should be put on clients to accept these methods.

All contraceptive methods can be started at the time of a surgical abortion.

All contraceptive methods except for IUDs can be started at the time mifepristone and/or misoprostol is taken for medical abortion. An IUD can be inserted following expulsion of the pregnancy after a medical abortion.

Additional contraceptive precautions are not required if contraception is initiated immediately or within 5 days of an abortion.

If sterilisation is requested, this should ideally only be performed after some time has elapsed after abortion. Individuals who request that tubal occlusion be performed at the time of an abortion should be advised of the possible increased failure rate and risk of regret.

If a client's chosen method is not available, they should be provided with an interim, bridging method that they can start immediately and they should be referred to a service where the preferred method can be provided.

Telemedicine

Telemedicine (telephone, video call or online) can be used for consultations for any kind of abortion. Consultation by telemedicine also allows people to have a medical abortion (depending on stage of pregnancy) in their own home with remote support from the abortion provider. They do not need to see a healthcare provider in person or visit an abortion clinic, unless there is a reason to do so (e.g. unsure of date of LMP, ectopic pregnancy risk, complex medical conditions) or they prefer an in-person visit. This model of care for medical abortion at home has been shown to be safe, effective and acceptable to clients and it improves access to abortion care, enabling them to be treated earlier in their pregnancy. Where eligible, people should always be given the option to choose this model of care.

Information for health workers providing abortions

Medical abortion

Before 12 weeks of pregnancy

If mifepristone is available, it is best practice to use it in combination with misoprostol as it is more effective than misoprostol alone, shortens the time taken to complete the abortion (the induction-to-abortion interval), reduces side effects and decreases the rate of ongoing pregnancy. There is no lower limit of pregnancy duration at which medical abortion can be performed. Medical abortion in the first 12 weeks can be safely managed by most people at home, is as safe and effective as in-facility treatment, and can be more convenient and private for people.

The most effective regimen is mifepristone 200mg orally, followed 24–48 hours later by misoprostol 800 micrograms taken by the vaginal, buccal or sublingual route.

- If expulsion of the pregnancy has not occurred within 4 hours, a further 400 micrograms of misoprostol should be taken by the vaginal, buccal or sublingual route.
- If misoprostol is provided for use at home, additional doses should be provided in case they are required. This is especially important to consider for pregnancy durations of over 9 weeks as the effectiveness of a single dose of 800 micrograms of misoprostol starts to decline from then onwards.

If mifepristone is not available, use misoprostol 800 micrograms taken by the vaginal, buccal or sublingual route, followed by misoprostol 400 micrograms every 3 hours until the pregnancy has passed.

12–24 weeks of pregnancy

At 12 weeks or more, medical abortion is usually undertaken in a medical facility. However, there is no evidence indicating that out-of-facility medical abortion is unsafe.

If mifepristone is available, it should be used in combination with misoprostol as it shortens the induction-to-abortion interval, reduces side effects and decreases the rate of ongoing pregnancy.

The most effective regimen is mifepristone 200mg orally, followed 24–48 hours later by misoprostol 800 micrograms vaginally, buccally or sublingually, followed by misoprostol 400 micrograms vaginally, buccally or sublingually every 3 hours until abortion occurs.

Where mifepristone is not available, use misoprostol 800 micrograms followed by misoprostol 400 micrograms every 3 hours until abortion occurs.

The uterus is more sensitive to misoprostol as pregnancy advances, and therefore, in pregnancies over 24 weeks, lower doses of misoprostol should be used and increased intervals between misoprostol doses may be considered, especially for people with uterine scars.

Pain management for medical abortion

Analgesia (pain relief) should **always** be offered.

- Nonsteroidal anti-inflammatory drugs (NSAIDs) are recommended either prophylactically or at the time that cramping begins.
- Non-pharmacological pain management measures (e.g. hot water bottle/heat pad) may be helpful.
- Pain increases with pregnancy duration so narcotic analgesics may be required when other pain management measures are insufficient. Epidural anaesthesia can also be used, where available.

Surgical abortion

Before 14 weeks of pregnancy

Surgical abortion before 14 weeks can be performed using **vacuum aspiration** (electrical (EVA) or manual (MVA)).

Vacuum aspiration involves evacuation of the contents of the uterus through a plastic or metal cannula, attached to a vacuum source. EVA employs an electric vacuum pump. With MVA, the vacuum is created using a hand-held, hand-activated, plastic 60 ml aspirator (also called a syringe).

- MVA aspirators accommodate 4–12 mm cannulas.
- There is no lower limit of pregnancy duration for surgical abortion.
- It is best practice to inspect aspirated tissue at all durations of pregnancy, to confirm that the pregnancy has been fully removed.
- During vacuum aspiration, the uterus should be emptied using only a suction cannula (and forceps if required). The procedure should **not** be routinely completed by sharp curettage.

14–24 weeks of pregnancy

Surgical abortion between 14 and 24 weeks can be performed using dilatation and evacuation (D&E).

D&E requires preparation of the cervix using osmotic dilators or pharmacological agents, and evacuating the uterus using long forceps and vacuum aspiration with cannulas. It is the safest and most effective surgical technique after 14 weeks, as long as skilled, experienced providers are available.

Vacuum aspiration can be used up to 15–16 weeks of pregnancy with larger bore suction tubing and cannulas up to 16 mm in diameter.

> Dilatation and sharp curettage (D&C) is an obsolete method of surgical abortion and should not be used.

Cervical preparation before surgical abortion

Cervical preparation should be used for all patients as it reduces the risk of incomplete abortion and makes dilation easier. It may cause some bleeding and pain before the procedure. If osmotic dilators are used, consider inserting them the day before the abortion, especially if pregnancy duration is 19 weeks or greater.

Before 12 weeks of pregnancy:

- mifepristone 200mg orally, 24–48 hours before the procedure, or
- misoprostol 400 micrograms sublingually, 1–2 hours before the procedure, or
- misoprostol 400 micrograms vaginally or buccally, 2–3 hours before the procedure.

12–18^{+6} weeks of pregnancy:

- combination of mifepristone and misoprostol* (using above regimens), or
- osmotic dilators plus either mifepristone or misoprostol, or with both mifepristone and misoprostol (using above regimens in all cases).

19–24 weeks of pregnancy:

- osmotic dilators plus either mifepristone or misoprostol, or with both mifepristone and misoprostol (using above regimens in all cases).

Pain management for surgical abortion

Analgesia should **always** be offered.

- In most cases, analgesics, such as NSAIDS, local anaesthesia and/or conscious sedation, supplemented by verbal reassurance, are sufficient.
- General anaesthesia is not recommended for routine use in pain management for abortion procedures, as it has been associated with higher rates of complications, and with longer hospital stays, than local anaesthesia.
- Local anaesthesia, such as lidocaine given as a paracervical block, can be used to alleviate discomfort from mechanical cervical dilatation and uterine evacuation.
- Where conscious sedation is available, it should be offered with a cervical block.
- If general anaesthesia is used, consider intravenous propofol and a short-acting opioid (such as fentanyl) rather than inhalational anaesthesia.
- NSAIDS can be used to alleviate abdominal cramping caused by misoprostol given for cervical preparation.

Information for health workers providing care after abortions

People can experience a range of emotions after an abortion. Health workers should provide information on how to access emotional support after an abortion in case this is needed.

Health workers should ensure that individuals know what to expect following the procedure and where to get help if necessary. They should also ensure that everyone who wants a method of contraception is able to leave with their method of choice or know how and where to access it.

Information to provide after an abortion

Clients should receive instructions about signs and symptoms that might indicate a complication that requires urgent medical help, including if they:

- soak through two or more maxi-size sanitary towels per hour, for 2 hours in a row
- develop an unusual, unpleasant-smelling vaginal discharge
- develop a fever or flu-like symptoms after 24 hours
- develop worsening pain, including that which might indicate an undiagnosed ectopic pregnancy (for example, if lower abdominal pain is one-sided, under the ribs, or goes up to the shoulders).

* Sometimes more than one dose of misoprostol may be required to get adequate dilation.

Health workers should also provide information on signs and symptoms that might indicate an ongoing pregnancy for which clients should seek medical attention, including if they:

- have no bleeding or only spotting or smearing of blood on sanitary towel or underwear in the 24 hours after misoprostol for medical abortion
- still feel pregnant 1 week after the abortion.

Contraception

See above.

Anti-D

If available, anti-D should be offered to non-sensitised RhD-negative individuals from 12 weeks of pregnancy and provided within 72 hours of the abortion.

Follow-up

There is no need for routine follow-up nor for a routine post-abortion ultrasound. Rather, individuals should be given clear information on when to seek medical help, as outlined above.

For people having medical abortion at home

Confirming whether the pregnancy has ended can usually be determined by individuals from witnessing the pregnancy as it passes or from the amount and duration of bleeding experienced and the disappearance of pregnancy symptoms. If available, the success of the abortion can be confirmed with either a low-sensitivity urine pregnancy test (detection limit 1000IU hCG) from 2 weeks after treatment or with a high-sensitivity test (detection 50IU hCG or less) from 4 weeks after treatment.

Management of incomplete abortion

Post-abortion care can reduce the morbidity and mortality associated with complications of either miscarriage or incomplete abortion, including abortion that was performed unsafely. Options for management for incomplete abortion include surgical and medical methods of uterine evacuation.

For those who wish to avoid another pregnancy, a contraception discussion should be offered and the chosen method provided.

Assessment

Incomplete abortion should be suspected when a person of reproductive age presents with vaginal bleeding or abdominal pain after one or more missed menstrual periods. Ectopic pregnancy should be suspected if the uterus is small, the cervix is closed or there is an adnexal mass or tenderness.

Unsafe abortion

An abortion is unsafe when it is carried out either by a person lacking the necessary skills or in an environment that does not conform to minimal medical standards, or both.

In many settings it is important to distinguish between safe and unsafe abortion because the latter is much more likely to be associated with infection. Indications that an abortion has been attempted by unsafe methods include the presence of:

- vaginal laceration

- cervical injury
- uterine enlargement equivalent to a pregnancy of more than 12 weeks' duration
- products of conception visible at the cervix or in the vagina
- in patients with uterine injury, any of fever, significant lower abdominal pain, tenderness or abdominal distension
- the presence of a foreign body in the vagina or cervix.

Infection

It is vital to identify those who may have an infection and to manage this urgently. Infection is much more likely, and much more likely to be severe, if the abortion has been performed unsafely. Clinical features suggestive of infection include:

- temperature above 37.5°C
- localised or general abdominal tenderness, guarding or rebound
- unusual, unpleasant odour or pus visible in the cervical os
- uterine tenderness.

Features suggestive of sepsis and indicating the need for urgent intervention include:

- hypotension
- tachycardia
- increased respiratory rate.

Management

If there is no suspicion of infection and uterine size is less than 14 weeks

- Medical management with misoprostol 400 micrograms sublingually, buccally or vaginally or 600 micrograms orally:
  - for a missed abortion (retained non-viable fetus), mifepristone 200mg orally should be administered 24–48 hours before the misoprostol.

OR

- Uterine evacuation with vacuum aspiration and antibiotic prophylaxis (see above).

If there is no suspicion of infection and uterine size is 14 weeks or larger

- Medical management with misoprostol:
  - 14–24 weeks: misoprostol 400 micrograms administered sublingually, buccally or vaginally every 3 hours
  - the uterus is more sensitive to misoprostol as pregnancy advances, and therefore, in pregnancies over 24 weeks, lower doses of misoprostol should be used and increased intervals between misoprostol doses may be considered, especially for people with uterine scars
  - in order to align protocols, services may use the same dosing and intervals as recommended in regimens for induced abortion
  - for a missed abortion (retained non-viable fetus), mifepristone 200mg orally should be administered 24–48 hours before misoprostol.

OR

- Surgical management with antibiotic prophylaxis (see above):
  - vacuum aspiration for removal of retained tissue when the fetus has been expelled; blunt forceps may also be needed to remove a retained placenta
  - if the fetus is retained, vacuum aspiration is suitable before 14 weeks of pregnancy; from 14 weeks and up to 16 weeks of pregnancy, forceps removal of larger fetal parts may also be required; from 16 weeks of pregnancy, a dilatation and evacuation (D&E) may be performed
  - if removal of the pregnancy requires the use of forceps, either in combination with vacuum aspiration or for a D&E, this should only be carried out by a skilled provider; if not available, medical management is recommended.

If infection is present, the uterus should be evacuated urgently

- Start broad-spectrum antibiotics immediately – intravenously if infection is severe.
- Transfer to a unit with the facilities for undertaking surgical evacuation if it cannot be done in the facility to which the individual presents.
- If the patient is in septic shock, they should be transferred immediately to a specialist unit for surgical uterine evacuation – broad-spectrum antibiotics, such as a combination of ampicillin 0.5–1g every 6 hours, metronidazole 500mg every 8 hour and gentamicin 120mg daily (with appropriate monitoring), should be administered intravenously prior to transfer if available.
- If the skills necessary for urgent surgical uterine evacuation are not available, misoprostol can be administered using the dose regimens above.

Information to provide after an abortion

Service delivery

The provision of a safe and effective abortion care service depends on everyone involved in the service ensuring that everything can be done to achieve best practice for safe abortion care. It is not enough for doctors, nurses and midwives to perform effectively if the facilities and tools that they need are not reliably available and if the service is not organised in a way that ensures safe and effective abortion care. **Best practices for service delivery** are listed below.

Access to services

1. Abortion services should be available to the fullest extent that the law allows. Healthcare providers should know what the law *does* allow in their country and be clear about the circumstances for which abortion is legal.
2. If a person requesting abortion fulfils the legal criteria, there should be no further restriction of access on grounds such as age, marital status or the number of previous abortions.

3. Abortion is safer the sooner it is done. Services should be able to meet the local demand for abortion so that people can have their abortion as early as possible and as close to home as possible.
4. As the equipment and space required for a safe abortion service are similar to those needed for routine women's healthcare and contraception services, efforts should be made to provide safe abortion services in a wide range of health facilities and in an integrated manner.
5. All healthcare providers should be trained to provide safe abortion care in line with their skills and licences. This can help spread the workload and improve the skills of *all* providers of women's healthcare, thereby enhancing access to and increasing the safety of abortion care.
6. Integrating abortion services within mainstream maternity and women's health services minimises the stigma associated with abortion care for both patients and providers.
7. Where abortion services are provided but there is no provision for emergency or specialist care, there must be robust and timely pathways for referral.

Information provision

1. There should be local arrangements in place for providing information to women and pregnant people and to healthcare providers on routes of access to safe abortion care.
2. Services should ensure that written, objective, evidence-guided information is available in a way that is understandable to all people considering abortion. Information should be available in a variety of languages and formats.
3. Women and pregnant people should have access to objective information and, if required, counselling and decision-making support about their pregnancy options. However, there should be no requirement for compulsory counselling or mandatory time for reflection before an abortion.

Initial assessment

1. There should be a pathway to appropriate medical care for people with known significant medical conditions (e.g. heart disease) that require specialist abortion care in a hospital.
2. People presenting for abortion who are found to have a non-viable pregnancy also require contraception and sexual healthcare.
3. People requesting abortion but who subsequently decide to continue the pregnancy should be referred for antenatal care (together with all their relevant information).
4. Services should identify people who may be particularly vulnerable (e.g. some adolescents, those in controlling, abusive relationships, people addicted to drugs/alcohol, people with moderate/severe mental health problems) and refer/signpost them on to appropriate support services.

Arrangements for the procedure

1. To minimise delay, service arrangements should be such that an abortion can be provided as soon as possible, ideally on the same day as the assessment.
2. The setting for abortion services (consultation rooms, procedure rooms and recovery rooms) should respect the need for clients' privacy and dignity.

Appendix: Post-abortion contraception

Adapted from World Health Organization (2014) *Clinical Practice Handbook for Safe Abortion*

Method of post-abortion contraception	Medical eligibility criteria (MEC) category		
	First trimester	Second trimester	Immediate post-septic abortion
CHC	1	1	1
POP	1	1	1
Progestogen-only injectable	1	1	1
Progestogen-only implant	1	1	1
Cu-IUD	1	2	4
LNG-IUD	1	2	4
Condom	1	1	1
Spermicide	1	1	1
Diaphragm	1	1	1

CHC = combined hormonal contraception (pill, patch, ring, injectable).
POP = progestogen-only pill.
Progestogen-only injectable = depot medroxyprogesterone acetate or norethisterone enanthate.
Progestogen-only implant = levonorgestrel or etonogestrel.
Cu-IUD = copper-bearing IUD.
LNG-IUD = levonorgestrel-releasing IUD.
Condom = male latex condom, male polyurethane condom or female condom.
Diaphragm = diaphragm (with spermicide) or cervical cap.

MEC categories for contraceptive eligibility	
1	A condition for which there is no restriction for the use of the contraceptive method.
2	A condition where the advantages of using the method generally outweigh the theoretical or proven risks.
3	A condition where the theoretical or proven risks usually outweigh the advantages of using the method.
4	A condition which represents an unacceptable health risk if the contraceptive method is used.

Recommendations for contraceptive use among women at high risk of HIV infection

- Women at high risk of HIV infection are eligible to use all hormonal contraceptive methods without restriction (MEC category 1), including combined hormonal contraception, progestogen-only pills, and progestogen-only injectables and implants.
- Women at high risk of HIV infection are also eligible to use Cu-IUD and LNG-IUDs without restriction (MEC category 1).

Contraception for individuals on antiretroviral therapy for HIV

There are potential drug interactions between some antiretroviral drugs and hormonal contraception that may affect efficacy of some methods of hormonal contraception. Providers should advise clients on the risk so that they can make an informed choice of method.

Background: In the site-to-site telehealth for medication abortion model, patients visit a health center to meet with a remote clinician using telehealth technology. This model is safe, effective, and acceptable to patients and providers. The objective of this study was to document the experiences of patients and providers using telehealth for medication abortion in Planned Parenthood health centers across different geographical contexts in the United States.

Methods: We conducted in-depth interviews with Planned Parenthood medication abortion patients who either met with a clinician at the clinic via telehealth or in-person about their experiences receiving care. We also interviewed Planned Parenthood staff members about their experiences implementing telehealth for medication abortion at their health center.

Results: We interviewed 29 patients who received care at Planned Parenthood health centers in five states. Both telehealth and in-person patients described positive interactions with health center staff and clinicians. The vast majority of telehealth patients said that they felt comfortable speaking with the clinician over telehealth and had no trouble using the telehealth technology. We interviewed 12 providers, including clinicians and administrative staff, who worked in seven states. Providers largely thought that telehealth for medication abortion expanded access to medication abortion.

Conclusions: Across different locations, our findings indicate that patients found telehealth for medication abortion services to be highly acceptable and providers found that telehealth services may help improve medication abortion access. As the use of telehealth for medication abortion expands, future research should include additional measures of quality to ensure that services are acceptable across different identities and experiences, including age, race, gender, and income level.

Keywords: Telehealth; medication abortion; patient experiences; provider experiences

Introduction

Abortion can be difficult to access in the United States for many reasons, including state and federal regulations that restrict how a pregnant person can access abortion care (1-3); decreasing numbers of abortion providers (4,5); the need to travel long distances to reach an abortion-providing facility (6-8); and costs associated with the procedure and/or travel to the facility (9,10). Over the past decade, abortion providers have implemented site-to-site telehealth for medication abortion (referred to here as "site-to-site TeleMAB") services to allow health centers that do not have a clinician onsite to provide medication abortion services remotely. Similar to in-person medication abortion care, site-to-site TeleMAB patients visit a health center where they meet with staff to receive pregnancy options counseling and diagnostic testing, such as an ultrasound. Instead of meeting with the clinician in-person, patients meet with the clinician via online videoconference platform on a clinic computer in a private room. Prior to the clinician-patient encounter, clinic staff set up the videoconference platform and ensure that the audio and video functions are working. If the patient is eligible for medication abortion, the clinician will answer questions and give the patient information about how to take the medication and when to seek follow-up care. The site-to-site TeleMAB model can mitigate some obstacles to accessing abortion care by increasing the availability of medication abortion in facilities that would otherwise not have services or have only limited availability (11,12), thereby enabling some patients to obtain care closer to home (12).

Site-to-site TeleMAB is safe, effective, and comparable to in-person care (11,13-17). However, quality abortion care must be more than just safe and effective; Price and Hawkins' social analysis framework for reproductive health services defines quality as the social experience of services and includes the extent to which a program "is responding to the perceived needs and demands of patients and potential patients" (18). They suggest that assumptions about quality do not always align between patients and providers, and therefore patient and provider interactions are an important—and often neglected—aspect of quality, which can provide critical insights into how to improve quality of care (18). Price and Hawkins' approach to evaluating reproductive health services provides an important basis for examining the acceptability of the site-to-site telehealth model for patients and providers. Ibis Reproductive Health (Ibis) has partnered with Planned Parenthood Federation of America (PPFA) to assess the acceptability of the site-to-site TeleMAB services for patients and providers and identify areas for improvement. In 2011, an evaluation of site-to-site TeleMAB services in Iowa demonstrated that both patients and providers found the service to be highly acceptable and most patients reported feeling positive or indifferent about meeting with the provider over videoconference (14). In addition, a 2013 study of provider experiences with a site-to-site TeleMAB service at Planned Parenthood health centers in Alaska found that the service allowed the clinic to increase the number of medication abortion appointments, which supported patients in receiving care sooner and at earlier gestational ages (13).

As the use of site-to-site TeleMAB services continues to expand, it is important to examine providers' and patients' experiences to ensure that these services meet the needs and expectations of both groups. This study sought to document the experiences of patients and providers using site-to-site TeleMAB with a focus on acceptability and perceptions of access. The findings presented below fill a gap in the literature by providing evidence about experiences using the site-to-site TeleMAB model across multiple locations in the United States. We present the following article in accordance with the Standards for Reporting Qualitative Research (SRQR) reporting checklist (available at https://mhealth.amegroups.com/article/view/10.21037/mhealth-22-12/rc).

Methods

Patient interviews

We conducted in-depth interviews with 29 abortion patients as part of a larger study that aimed to evaluate patient acceptability of medication abortion services received at Planned Parenthood affiliate health centers in five states: Alaska, New York, Maryland, Montana, and Nevada. Participants received medication abortion care by visiting a health center and meeting with the clinician either in person or via telehealth technology. When patients contacted Planned Parenthood, they received information about their abortion care options (i.e., medication or aspiration) and were offered appointment options based on the option they preferred.

Patients seeking abortion were eligible to participate in the study if they obtained a medication abortion (i.e., were ≤70 days' gestation and did not have other medical contraindications), were at least 18 years of age, were able to read and speak English, and were able to give informed consent. The gestational age limit for medication abortion

© mHealth. All rights reserved.

was set by the Planned Parenthood health centers. As part of the larger medication abortion acceptability study among Planned Parenthood patients, eligible patients were invited to complete an online survey two weeks after the appointment where they received the medication abortion pills. We recruited interview participants from the pool of patients who completed the online survey; upon completing the survey, participants interested in interviewing were redirected to an anonymous online interview interest form where they could provide their contact information. We did not link participant survey responses to the interview interest form or subsequent interview responses to ensure confidentiality and to increase the candidness of the interviewee's responses. Patients who expressed interest in participating in the interview by completing the online interest form were contacted by phone and screened by study staff to determine eligibility.

We initiated recruitment for interviews on a rolling basis as site-to-site TeleMAB services were introduced across different health centers between August 2016 and January 2019. Patient interviews were conducted by telephone using a semi-structured interview guide adapted from a previously published study assessing patient acceptability of site-to-site TeleMAB services in Iowa (14). We aimed to assess acceptability of services by asking participants about various aspects of perceived quality of care (19), such as how they were treated in the clinic and if they felt comfortable in the exam room. We also asked site-to-site TeleMAB patients about their comfort level meeting with the doctor remotely, if they had all of their questions answered, the level of privacy, the sound quality of the videoconference, and things they liked and disliked about the experience. We also asked both site-to-site TeleMAB and standard in-person medication abortion (MAB) patients whether they would recommend site-to-site TeleMAB services or the standard in-clinic MAB services to a friend. Patient interviews lasted from 15 to 50 minutes. Patients received a $40 electronic Amazon gift card upon completing the interview.

Provider interviews

We also conducted in-depth phone interviews between June 2017 and July 2019 with 12 providers who were involved with both in-person and site-to-site TeleMAB services. Providers were eligible to participate if they were a doctor, advanced practice clinician, nurse, medical assistant, health center manager, counselor, or other administrative personnel on staff involved in the implementation or administration of site-to-site TeleMAB. We included a broad range of providers, both clinical and administrative staff, in order to capture a holistic and nuanced perspective of the impact and acceptability of site-to-site TeleMAB services. Study team members from PPFA screened for initial interest among eligible providers, and Ibis study team members conducted the interviews by telephone. Prior to the interview, participants were read the study consent form and informed that participation in the study was voluntary and confidential. The provider interview guide was adapted from a previously published study examining provider acceptability and perspectives of a site-to-site TeleMAB model in Alaska (13). In order to capture provider acceptability of the site-to-site TeleMAB services, we asked providers to share their opinions about the services, including benefits and challenges. We also asked providers to share their perspectives of the site-to-site TeleMAB services, including its impact on abortion access, who benefitted the most from the site-to-site TeleMAB services, and if there were patients who might be better served by an in-person visit. Provider participants did not receive compensation. Provider interviews lasted from 30 to 60 minutes.

All study participants, patients and providers, provided verbal informed consent to participate in the study and to be audio recorded. For those who did not want their interview recorded (n=1 patient), study staff took handwritten notes. Audio files were transcribed verbatim by a third-party transcription company and study staff performed quality assurance checks on all transcriptions. De-identified transcriptions were analyzed qualitatively with inductive coding using modified grounded theory methods (20). A modified grounded theory approach was applied to our analysis to assess the factors that impacted participants' perspectives of acceptability and impact on access (21,22). Analyses were facilitated by the use of Dedoose to identify themes related to acceptability of medication abortion and site-to-site TeleMAB by study staff. The study was conducted in accordance with the Declaration of Helsinki (as revised in 2013), and was approved by Allendale Investigational Review Board (No. IRB00005829).

remote provider via site-to-site TeleMAB. Thirteen of the 29 participants met with the provider in-person at the health center ("MAB" patients). Patients received care at Planned Parenthood health centers in five states, including Alaska, New York, Maryland, Montana, and Nevada. Patient demographics are summarized in *Table 1*. Patient participants ranged in age from 19 to 41 years old, with a median age of 25. Nearly 80% of participants reported having at least some college education, and roughly a third (38%) were students. About half of the participants (52%) were in a relationship or married and most participants identified as White (45%) or Black (24%). Seven participants reported having had a previous abortion.

Site-to-site TeleMAB and MAB patients' health center experiences

Both site-to-site TeleMAB and MAB patients were required to visit the health center in order to receive the medication abortion pills. When asked about their experiences in the clinic, the vast majority of participants reported that they had positive experiences with staff and were comfortable in the health center including one site-to-site TeleMAB patient who said, "*[The staff] were very nice, not judgmental. It was just—I felt like a regular patient coming in for something very regular and normal, and there's not—it didn't seem like a taboo situation*". Two participants described mixed feelings about their comfort level in the health center; one said they were "fairly" comfortable, but felt a little awkward because of the medical illustrations of reproductive anatomy on the wall. One participant's negative interactions with staff resulted in an uncomfortable health center experience.

Patient experiences with telehealth platform

Site-to-site TeleMAB patients were asked to describe their experience using telehealth to meet with the provider. Many participants reported feeling comfortable during the telehealth visit, including one person who said that they felt more comfortable than they would have in an in-person visit, "*I think I felt more comfortable speaking to her on the screen than I would be in person*". Several participants reported that they would have felt more comfortable during an in-person visit, and of those participants, some reported a preference for in-person care. However, the telehealth participants who reported a preference for in-person care reflected that they still felt comfortable during the site-to-site TeleMAB visit. In addition, all reported having had an opportunity to have their questions answered, though some didn't have specific questions to ask. One participant said, "*[the doctor] answered any questions I had. It's just as much as—I mean it's not the same as a doctor next to you, but it's just as much the same. I mean I thought it was very good. I look at it as good technology*".

© mHealth. All rights reserved.

Site-to-site TeleMAB participants were also asked to describe what they thought about the privacy in talking with the doctor by videoconference, including whether they thought that the level of privacy was different from an in-person visit. Of the 13 participants who were asked about privacy, most thought that the privacy in a site-to-site TeleMAB visit was no different from how it would be during an in-person visit. Some described their appointment as private, including one participant who said, "*I wasn't worried about anybody over-hearing or—it felt comfortable with the confidentiality that Planned Parenthood provided in the first place, so that privacy wasn't an issue when it came to the telemedicine*". However, some participants said that they would have preferred a greater level of privacy, including two people who noted that a door was left ajar while they were waiting to meet with the doctor, and two others who reported that they would not have known if there was anyone listening in on the doctor's end. In addition, one person said the level of privacy felt different and they would have preferred to meet with the doctor in-person, and another said they were not sure if the visit would have been any different. An additional person said that they were not concerned with privacy.

The majority of site-to-site TeleMAB participants said that the sound quality was good, and one person said there was a slight delay in the audio. Many noted that they did not encounter any technical difficulties throughout their appointment, however, four participants mentioned that they experienced minor technical glitches, such as their internet connection briefly cutting out, or a wait for the teleconference system to load prior to meeting with the doctor. Only one person reported experiencing a connectivity issue that delayed their appointment by about two hours.

When asked to describe anything they liked about the site-to-site TeleMAB appointment, participants identified positive aspects of their visit, including liking their interaction with the provider via telehealth. Of these, one participant said, "*I was expecting it to be awkward, but it wasn't. And the nurse practitioner was kind and I thought that maybe it would be [rushed]—or my concerns would be [rushed] over, but they were not. She still listened and addressed my concerns just as if she was in the room with me*". Patients also reported that they liked that telehealth increased the availability of medication abortion and abortion care generally, including one person who said, "*Being able to be seen sooner than later, obviously, because I was really adamant about doing the pill abortion. So they did mention that they're starting this [telehealth] program to be able to see more patients a day, which I was extremely grateful for*", and another who said that they would otherwise not have been able to access care. Other positive aspects of the site-to-site TeleMAB visit described by patients included that it was a more personal experience than an in-person visit with a shorter wait time for meeting with the physician, and that the virtual waiting room gave them time to acclimate to the visit.

Some participants highlighted things they disliked, or perceived to be negative, about the site-to-site TeleMAB visit itself. Some participants who indicated a preference for in-person care also reported that they disliked the remote aspect of the visit or that the visit would have been improved by having an in-person encounter with the doctor. One participant expressed a negative experience discussing birth control options, and two participants, as mentioned above, shared concerns about privacy because of a door left ajar. Another person, also mentioned above, had technical issues that resulted in a longer-than-anticipated wait time. In contrast, four participants reported that there were no aspects of the site-to-site TeleMAB visit that they disliked.

Lastly, site-to-site TeleMAB participants were asked if they would recommend that a friend receive the medication abortion in the same way they did, via telehealth. Of these, the majority said that they would. Some participants said that they would recommend site-to-site TeleMAB if their friend was comfortable meeting with a doctor over videoconference. Of those who said they would recommend the service, some said they would make sure their friend understood that they would be meeting with the clinician remotely. In contrast, one participant said that they "*didn't really mind the web cam. I really don't care either way. So I don't even think I would bring that up to a friend, really. I don't think that was anything to change my mind about anything*".

We also described the site-to-site TeleMAB system to MAB participants and asked if they would recommend site-to-site TeleMAB to a friend; some said site-to-site TeleMAB sounded like it could be a good option, and others said they would recommend site-to-site TeleMAB based on their friend's preferences or situation. Of those MAB patients who said they would recommend an in-person visit over a site-to-site TeleMAB visit, some thought an in-person visit seemed more personal and comforting than a site-to-site TeleMAB visit, one stated a personal preference for in-person care based on their medical history, and one participant said that, if they were already in the health center, they would prefer to see the clinician in-person; however, this participant added that if they could avoid going into the health center at all, they would meet with the clinician over telehealth from their home.

Providers

Participant characteristics

We interviewed 12 clinicians and/or administrative staff from Planned Parenthood affiliates, including eight health center managers/directors, two medical directors, one nurse, and one administrator. Of these, two held clinical positions, eight held administrative positions, and two split their time between clinical and administrative tasks. Providers worked in four of the same states as the patients, including Maryland, Montana, New York, Nevada, while others worked in Oregon, Idaho, and Washington.

Improving access to medication abortion via telehealth

Participants were asked whether they thought the introduction of site-to-site TeleMAB services had an impact on abortion access. The majority said that the service had increased access to abortion. One manager said that site-to-site TeleMAB increased the availability of medication abortion appointments: "*So I think that women have been able to have a medication abortion either closer to the timeline that they would prefer or closer to home, and I think that that's a really good thing*". In addition, when asked what they liked about the telehealth service, the majority of participants said that they liked that the telehealth service expanded access to abortion, especially in areas where there are few abortion providing facilities. One administrator said, "*[Telehealth]… improves access to our patients and provides an opportunity for patients to receive their healthcare in a more localized way… just seven years ago, there were many more abortion facilities and abortion providers but due to increased state regulation… we've gone in this state from having 13 abortion providers to now I believe the number is down to five or six*". One participant said that they thought the implementation of telehealth would impact access to abortion once word spread, but that many people were still unaware of the service.

Some participants also commented on whether the site-to-site TeleMAB service impacted how soon pregnant people were able to access abortion care. Of these, some thought that people were able to access care earlier in a pregnancy, including one participant who also added that site-to-site TeleMAB provided an additional care option for patients: "*I mean, some patients like to do the in-clinic procedure regardless of how far along they are. Having the option to do the telemed, they have the option of [experiencing the abortion] at home if they choose so*". Another participant said that they thought telehealth increased availability, but did not necessarily impact how early in pregnancy people were able to access care.

Some participants described whether they thought there was any particular population or type of patient who benefited the most from site-to-site TeleMAB. Of these, some said that patients whose pregnancy was at the upper gestational limit for medication abortion, prefer medication abortion over aspiration abortion, need to travel long distances to care, and those who may need to take time off of work for the procedure would benefit from telehealth. Another participant thought telehealth benefited all patients.

Additionally, some participants discussed whether certain types of patients might be better served by an in-person visit than a telehealth visit. Of those, five reported that the majority of patients would not necessarily be better served by an in-person visit unless they had a medical condition that would put them at risk for complications or if they were uncomfortable being on video. One participant said in-person visits may be better for those who prefer a face-to-face visit. Another participant, a clinician, said that they were able to provide the same level of emotional support over videoconference as in-person: "*I actually got to do a counseling session like that through telemedicine where a patient was just crying and it went really well… And so, I kind of felt really comfortable with that. I felt like I was able to do the same level of counseling that I do with people in person, and it was fine*". One participant, an administrator, said they were not sure if patients might be better served by an in-person visit with the clinician physically present in the room.

Provider experiences delivering telehealth care

Providers were asked to share their experiences using site-to-site TeleMAB, including things they liked and challenges they encountered. One director said they liked that the telehealth service enabled teamwork among the remote clinician and the health center staff. Another director said that the telehealth service was "great" but more marketing was needed to get the word out. In addition, a nurse practitioner said that they were looking forward to adapting telehealth services for other family planning services. Some participants said they encountered technical problems, such as issues with connectivity or equipment, system outages, and a lack of technical familiarity among staff. The vast majority of these participants, however, also noted these issues did not prevent the delivery of care. One person said they had not encountered any technical problems.

Discussion

Our findings indicate that most site-to-site TeleMAB patients felt comfortable using the telehealth service, and that providers thought that site-to-site TeleMAB made medication abortion more accessible. Although the majority of the site-to-site TeleMAB patients reported feeling comfortable, some respondents reported a preference for meeting with the clinician in-person, rather than over videoconference. A few site-to-site TeleMAB patients discussed concerns around privacy during their conversation with the clinician, and some patients reported encountering technical difficulties. Two participants noted negative interactions with staff.

These findings align with previous evidence on patient acceptability of site-to-site TeleMAB services, and add new evidence of high acceptability for site-to-site TeleMAB across a range of different geographic settings. Consistent with previous findings, the majority of site-to-site TeleMAB and MAB patients reported positive interactions with clinic staff (13,14). Our results are also consistent with earlier findings on patient-provider interactions, as the majority of site-to-site TeleMAB patients felt comfortable with their conversation with the clinician, and, in some cases, were more comfortable meeting with the clinician via telehealth than in-person (14,23). In addition, the reasons why some site-to-site TeleMAB patients would have felt more comfortable with an in-person visit align with previous qualitative studies that have found that some people prefer in-person care (14,15). Reasons for privacy-related concerns, including not being able to tell if anyone else was in the room with the remote physician, have been documented in a previous study (14). Results from provider interviews add to existing evidence demonstrating that providers perceive that site-to-site TeleMAB services expand access to abortion care by increasing the availability medication abortion closer to where patients live, and that they are able to provide the same level of care regardless of whether they are in-person or on videoconference (13,14).

Providers in this study highlighted the ways in which the site-to-site TeleMAB model could address some of the disparities in abortion access in the United States. They reported that site-to-site TeleMAB benefited people who lived far away from the clinic, and that the services helped increase medication abortion availability in states where abortion care options are limited. Their experiences align with findings from a recent study that found that the introduction of site-to-site TeleMAB in Montana and Nevada led to an increase in the uptake of medication abortion in both states (11). Providers also reported that the site-to-site TeleMAB model may have helped patients get to the health center earlier, and that the populations who may benefit the most from the site-to-site TeleMAB services include those who prefer medication abortion over aspiration abortion and are close to the gestational age limit for medication abortion. Current evidence suggests that many abortion patients who express a preference for medication abortion encounter delays in accessing care and are beyond the gestational age limit for medication abortion, making them ineligible for the procedure (24). This underscores the importance of increasing overall availability of medication abortion, as well as reducing delays in access.

There are several limitations to this study. First, the qualitative findings from this study do not allow us to assess whether site-to-site TeleMAB services are meeting the needs of different groups equally. In addition, the vast majority of patients were not told ahead of their abortion appointment that it would be conducted via telehealth and, as a result, we were not able to assess whether knowledge of site-to-site TeleMAB services impacted patients' decision making when scheduling an appointment. Lastly, the small number of participants per state did not allow us to immediately identify any trends or differences in experiences across states. Despite these limitations, this study fills a gap in the literature by documenting the use of site-to-site TeleMAB across different geographical settings, and by providing additional data on site-to-site TeleMAB patient and provider experiences.

These findings also provide a strong foundation for further telehealth for medication abortion evaluations. Future studies of telehealth for medication abortion services should incorporate additional quality of care measures to gain deeper insight into how telehealth for medication abortion is meeting the care needs of patients. Researchers should also include measures such as accessibility of accurate and unbiased information about abortion care and telehealth in order to better understand care decision-making. In addition, future quality of care measures should also assess how patients from groups that are targeted by systems of oppression experience telehealth for medication abortion; for example, how provider use of gendered terminology and other cultural competencies can impact patient-provider interactions. Lastly, our study did not evaluate differences in feelings about privacy for site-to-site TeleMAB and MAB patients, however this information would be valuable for

© mHealth. All rights reserved.

identifying ways to ensure patient confidence in the privacy and security of TeleMAB and MAB appointments, especially for those who are experiencing intimate partner violence, which is common among people seeking abortion (25).

All of the participating sites in this study provided site-to-site telehealth, such that patients still had to travel to a health center. During the onset of the COVID-19 pandemic, in-clinic requirements for medication abortion were lifted in some countries, including the United States, in order to mitigate the risks of contagion associated with in-person care. As a result, abortion providers were able to implement direct-to-patient medication abortion using telehealth. Studies in the United States found that the direct-to-patient models implemented during the pandemic were safe, effective (26,27), and acceptable to patients (27). These findings were also echoed in studies examining patient experiences using direct-to-patient models during the pandemic in 2020 in the United Kingdom (28-30) and France (31). Given the recent change in mifepristone's Risk Evaluation and Mitigation Strategy (REMS) (32) more US providers will be able to implement direct-to-patient telehealth for medication abortion provision services. Additional research on direct-to-patient telehealth models for medication abortion is needed to support broadening the use of telehealth to further increase access to medication abortion.

Although both the direct-to-patient and the site-to-site model offer opportunities to expand access to abortion care in the United States, more work is needed to dismantle the structural systems that prevent access to telehealth (33). Digital redlining, for example, has resulted in a lack of internet access for communities of color compared to wealthier white communities (34). Studies evaluating the use of telehealth during the COVID-19 pandemic also demonstrated that the use of telehealth was lower among communities of color, rural populations, and those using Medicare or Medicaid (35,36). These findings underscore the need to address inequitable policies and practices in order to maximize the potential of telehealth. Additionally, some patients may prefer the direct-to-patient model because they do not want to (as one participant in our current study suggested) or are not able to visit a health center to obtain abortion care.

The high quality of care provided in-person and via telehealth suggests that Planned Parenthood health centers should continue to offer and seek ways to improve and expand telehealth services. The high-level of acceptability for the site-to-site TeleMAB services demonstrated in this study and others, suggests that this service model should be offered as part of a range of safe and acceptable service models available to patients to ensure they receive care the way they prefer. More context is still needed to better understand how telehealth for medication abortion services is experienced by different groups. Further research should aim to broaden the aspects of perceived quality assessed in this study to ensure that telehealth for medication abortion services is acceptable and accessible to patients with a range of identities and experiences across age, race, gender, and income levels.

Ectopic Pregnancy and Medical Abortion

Caitlin Shannon, MPH, L. Perry Brothers, MPH, MSW, Neena M. Philip, MPH, and Beverly Winikoff, MD, MPH

OBJECTIVE: **Medical abortion regimens have become more widely used to terminate early pregnancies. Medical abortion providers are concerned to diagnose and exclude women with ectopic pregnancy before initiating treatment, as with any early pregnancy termination. Yet, there is little information about whether the various pretreatment screening methods used are adequate. We reviewed published literature to determine the overall success of screening for ectopic pregnancy before medical abortion treatment.**

DATA SOURCES: **We searched MEDLINE for articles on medical abortion regimens published before July 2003.**

METHODS OF STUDY SELECTION: **We selected English language articles of studies of medical abortion with sample sizes greater than 100, which reported on ectopic pregnancy diagnosed after medical abortion treatment. Fifty-seven of 85 prospective studies and randomized trials (69%) met these inclusion criteria. We also included data from 2 unpublished studies because they were large and well-controlled and because they included serious adverse events known to us, which we did not deem fair to exclude from our analysis.**

TABULATION, INTEGRATION, AND RESULTS: **Each article was reviewed by one author. Data from selected studies were compiled, and the frequency of ectopic pregnancy diagnosed after medical abortion treatment was calculated. Ectopic pregnancy was diagnosed very infrequently following medical abortion procedures, occurring in only 10 of 44,789 (0.02%) women.**

CONCLUSION: **The very low frequency of ectopic pregnancies diagnosed after medical abortion treatment demonstrates that the various pretreatment screening methods that providers use to exclude patients with ectopic pregnancies are successful. Further, there is no evidence to suggest that medical abortion treatment leads to unusual complications for women with ectopic pregnancies. (Obstet Gynecol 2004;104:161–7. © 2004 by The American College of Obstetricians and Gynecologists.)**

From Gynuity Health Projects, New York, New York.

The authors thank Mary Fjerstad of the Planned Parenthood Federation of America for her contribution of clinic data and the Packard Foundation for their support.

Excluding women with ectopic pregnancies before abortion induction is a concern for early abortion providers—surgical and medical—because women are treated before an ectopic pregnancy is easily detectable by ultrasonography and before it causes symptoms or ruptures. Ectopic pregnancy is the leading cause of pregnancy-related death in the first trimester,[1] with an overall incidence of 19.7 per 1,000 pregnancies (1.97%)[2] in the United States, 11.5 per 1,000 pregnancies (1.15%)[3] in the United Kingdom, and 16 per 1,000 pregnancies in France (1.6%).[4] Approximately 22–34% of ectopic pregnancies rupture,[5] usually by 10 weeks of gestation at the latest,[6] and a history of ectopic pregnancy is associated with infertility and repeat ectopic pregnancy.

Over the past decade, medical abortion regimens have become more widely used to terminate early pregnancies. These procedures are often completed at home in the United States, so providers do not have the opportunity to examine expelled tissue in the same way they do for products of conception removed during surgical procedures. Therefore, providers remain concerned about failing to detect an ectopic pregnancy in patients undergoing medical abortion treatment. Additionally, although methotrexate medical abortion regimens may terminate an ectopic pregnancy, mifepristone-based and misoprostol-alone regimens do not. However, there is little published literature on the frequency of ectopic pregnancies diagnosed after medical abortion treatment, and consequently, little information on the success of pretreatment screening protocols used by clinicians to exclude women with ectopic pregnancies from treatment.

Based on U.S. Food and Drug Administration (FDA) adverse-event reports related to the use of mifepristone (Mifeprex; Danco Laboratories, LLC, New York, NY), a 2003 review by Hausknecht[7] noted 5 reported cases of ectopic pregnancy after the use of mifepristone-misoprostol regimens for medical abortion between late 2000 and May 2002. Because approximately 80,000 women in the United States are estimated to have undergone treatment in that period, the estimated frequency of ectopic pregnancy diagnosed after mifepristone-misoprostol medical abortion is 0.006%. Among the 5 cases reported

© 2004 by The American College of Obstetricians and Gynecologists.
Published by Lippincott Williams & Wilkins.
0029-7844/04/$30.00
doi:10.1097/01.AOG.0000130839.61098.12

by Hausknecht, one patient died as a result of a tubal rupture after refusing hospitalization and treatment the day before her death. Two additional patients had ruptured ectopic pregnancies but were treated successfully with surgery, and the remaining 2 cases also were treated successfully before rupture. (For more detail on outcomes, refer to regulatory agency reports for Mifeprex between September 28, 2000, and September 28, 2001, and for Mifegyne [Exelgyn, Oxon, UK] between December 1, 1999, and May 31, 2001.)

Data based on regulatory reports, however, are generally presumed to underestimate the true incidence of an event, because reporting is voluntary and unsolicited. To analyze the success of pretreatment screening methods more systematically, we conducted a literature review of medical abortion studies.

SOURCES

We searched the MEDLINE database for articles published before July 2003, written in English, and with the following indexing terms: "medical abortion," "mifepristone," "misoprostol," "methotrexate," "abortion," and "pregnancy termination."

STUDY SELECTION

We used the following selection criteria for study inclusion: 1) sample size greater than 100 (although for randomized trials, the sample size for a particular study arm could be less than 100), 2) data on the frequency of ectopic pregnancy following the medical abortion procedure by treatment group, and 3) gestational age for enrollment less than 12 weeks, and 4) English language. Articles selected included reports of prospective, retrospective, and randomized studies. The population for all studies was women of reproductive age who received medical abortion treatment in the first trimester. The frequency of ectopic pregnancy diagnosed after medical abortion treatment was the outcome of interest for our review. Using this methodology, we retrieved 85 articles, 57 of which met the inclusion criteria for our review (69%).[8–64] We also included data from 2 studies being prepared for publication (unpublished data from a study in Canada, 2001; unpublished data from study in United States, 2002). The review encompassed regimens using mifepristone and gemeprost, mifepristone and oral misoprostol, mifepristone and vaginal misoprostol, methotrexate and vaginal misoprostol, and vaginal misoprostol only, including a total of 44,789 women undergoing medical abortion procedures, almost all of whom had early gestations (less than 9 weeks of amenorrhea). Five studies included women with gestations of up to 12 weeks of amenorrhea.[18,22,32,34,55]

Each article was reviewed by one author. Data from selected studies were compiled, and the frequency of ectopic pregnancy diagnosed after medical abortion treatment was calculated.

RESULTS

In the aggregated sample, diagnosis of an ectopic pregnancy after medical abortion treatment was rare, occurring in only 10 of 44,789 women (0.02%). Among women treated with mifepristone and gemeprost (Table 1), 4 women were diagnosed with ectopic pregnancy (0.04%, n = 10,348). Three cases required surgical intervention, and the treatment of one case was not detailed. Among those treated with mifepristone and oral misoprostol (Table 1), 2 women were diagnosed with ectopic pregnancies (0.01%, n = 13,377). In one case, tubal rupture occurred 2 days after administration of misoprostol; both patients recovered fully. Of 15,172 women who received mifepristone followed by vaginal misoprostol (Table 1), 3 (0.02%) women had an ectopic pregnancy after the procedure. Treatment for one case was not detailed. The other 2 women were successfully treated–one with surgical intervention, one with methotrexate.

Although intramuscular methotrexate is a standard treatment for ectopic pregnancy, one woman had an ectopic pregnancy after treatment with methotrexate and vaginal misoprostol (Table 1; 0.03%, n = 3,893). The woman required laparotomy and transfusion. In this case, an intrauterine gestational sac was reportedly visualized by ultrasonography at intake, and it is uncertain whether the ectopic pregnancy was misinterpreted as intrauterine or was part of an unrecognized heterotopic twin pregnancy.[16]

Finally, among the 1,999 women who underwent medical abortion procedures with vaginal misoprostol alone, there were no cases of ectopic pregnancies diagnosed after treatment reported in the literature. However, there is limited use of vaginal misoprostol-only regimens and a correspondingly small sample of such patients. This finding is not unexpected, based on the overall frequency of ectopic pregnancy diagnosed after medical abortion.

CONCLUSION

Results from previous clinical trials and this literature review demonstrate that medical abortion is a safe and effective method for terminating early pregnancies and may actually contribute to women's health through the early screening, detection, and treatment of ectopic preg-

GA = gestational age; MP = mifepristone; GP = gemeprost; WHO = World Health Organization; UK = United Kingdom; MS = misoprostol; ICMR = Indian Council of Medical Research; IM = intramuscular; and MT = methotrexate.

* Gestational age based on first day of last menstrual period.

† Received full regimen; no comments on outcome.

‡ Required surgical intervention following regimen.

§ Received full regimen; given surgical intervention.

‖ Ruptured 2 days after misoprostol; treated with salpingectomy.

¶ Population Council, unpublished data.

Case 1: Had aspiration curettage; treated with methotrexate. Case 2: Adnexal mass treated with salpingectomy.

** Received full regimen; no details on treatment or treatment outcome.

†† One woman had undiagnosed ectopic pregnancy requiring laparotomy and transfusion; it is uncertain whether this was due to misdiagnosis or twin pregnancy.

nancy. Indeed, since ectopic pregnancy is a contraindication for medical abortion treatment (except for methotrexate regimens), if providers use adequate methods to screen patients before treatment, we would expect that ectopic pregnancy would be diagnosed after medical abortion treatment only very rarely. Further, because medical abortions are performed early in gestation, frequently before 7 weeks of gestation, providers are given an earlier-than-normal opportunity to screen and treat women for ectopic pregnancy.

In the studies reviewed here, the frequency of ectopic pregnancy diagnosed after medical abortion procedures was very low (0.02%), significantly lower than the incidence of ectopic pregnancy among all pregnancies (approximately 1–2%).[2–4] A review of data from the Planned Parenthood Federation of America confirms our finding that ectopic pregnancy is very rarely diagnosed after medical abortion treatment (0.01%, 7 of 58,950 cases treated with mifepristone and misoprostol between January 1, 2001 and June 30, 2003) (Mary Fjerstad, Planned Parenthood Federation of America, personal communication, January 13, 2004). This very low frequency suggests that, indeed, providers are successfully screening women for ectopic pregnancy before medical abortion treatment. These screened women thus avoid the risks inherent in later detection and treatment of ectopic pregnancy, including a higher risk of death, severe hemorrhage, and salpingectomy. In fact, of the 10 reported cases in this review, all were successfully treated. There was no evidence suggesting that medical abortion treatment led to unusual complications for women with ectopic pregnancies.

Despite the successful use of various screening approaches for ectopic pregnancy by early abortion providers (which may include use of some or all of these methods: bimanual examination, dating of the last menstrual period, β-hCG levels, and vaginal ultrasonography), even the most precise method, ultrasonography,

cannot be expected to detect all cases. The 2 primary reasons for failing to detect an ectopic pregnancy despite use of an ultrasound screen are that the pregnancy is so early it cannot be visualized and that clinicians can err in interpreting ultrasound images. Clinicians should therefore always be vigilant about the possibility of undiagnosed ectopic pregnancy and provide women with information about ectopic pregnancy and its symptoms to further increase the likelihood of early detection and successful treatment.

Systematic Review

No-Test Medication Abortion

A Systematic Review

Marit Pearlman Shapiro, MD, MPH, Divya Dethier, MD, Melissa Kahili-Heede, MLIS, MEd, and Bliss Kaneshiro, MD, MPH

OBJECTIVE: To summarize the effectiveness and safety outcomes of medication abortion performed without prior pelvic examination or ultrasonogram ("no-test medication abortion").

DATA SOURCES: We searched the MEDLINE, Scopus, Web of Science, Cochrane (including ClinicalTrials.gov), CINAHL, Global Index Medicus, and CAB Direct databases to identify relevant studies published before April 2022 using a peer-reviewed search strategy including terms such as "medication abortion" and "ultrasonography." We contacted experts in the field for unpublished data and ongoing studies.

METHODS OF STUDY SELECTION: We reviewed 2,423 studies using Colandr. We included studies if they presented clinical outcomes of medication abortion performed with mifepristone and misoprostol and without prior pelvic examination or ultrasonogram. We excluded studies with duplicate data. We abstracted successful abortion rates overall, as well as rates by gestational age through 63 days, 70 days and past 84 days. We abstracted complication rates, including the need for surgical evacuation, additional medications, blood transfusion, and ectopic pregnancy.

TABULATION, INTEGRATION AND RESULTS: We included 21 studies with a total of 10,693 patients with outcome data reported. The overall efficacy of no-test medication abortion was 96.4%; 93.8% (95% CI 92.8–94.6%) through 63 days of gestation and 95.2% (95% CI 94.7–95.7%) through 70 days of gestation. The overall rate of surgical evacuation was 4.4% (95% CI 4.0–4.9), need for additional misoprostol 2.2% (95% CI 1.8–2.6), blood transfusion 0.5% (95% CI 0.3–0.6), and ectopic pregnancy 0.06% (95% CI 0.02–0.15).

CONCLUSION: Medication abortion performed without prior pelvic examination or ultrasonogram is a safe and effective option for pregnancy termination.

(Obstet Gynecol 2023;141:23–34)

DOI: 10.1097/AOG.0000000000005016

The use of medication abortion is increasing. In 2018, half of all pregnancy terminations at less than 9 weeks of gestation were medication abortions.[1] This number is likely even higher today, because the coronavirus disease 2019 (COVID-19) pandemic triggered rapid shifts in abortion provision to minimize physical contact between patients and health care professionals and to reduce the time spent in medical facilities. Along with increasing use of telemedicine, health care professionals pivoted toward providing medication abortions without previously routine ultrasonograms or clinical examinations. Leading national professional organizations, including the American College of Obstetricians and Gynecolo-

gists, Planned Parenthood Federation of America, and the National Abortion Federation, as well as the World Health Organization, published recommendations supporting this practice.[2–4] The practice of providing a medication abortion without a prior pelvic examination or ultrasonogram has been described as "low-test medication abortion" or "medication abortion with history-based screening." In this review, we describe this model as no-test medication abortion.

Abortion care globally is typically provided without a prior ultrasonogram.[5] The two benefits of an ultrasonogram are accurate estimation of gestational age and exclusion of ectopic pregnancy. Research has shown that, with appropriate counseling, a patient's certain last menstrual period can be accurately used for determining gestational age without the use of ultrasonography.[6,7] One study demonstrated that gestational age dating using patient reported estimates of last menstrual period resulted in 0.8% of patients being provided a medication abortion beyond 70 days of gestation, the U.S. Food and Drug Administration–approved limit on the use of mifepristone for medication abortion.[8] Improved accuracy and sensitivity of self-assessment of gestational duration can be achieved by broadening the screening questions, including date of conception and number of weeks pregnant.[9] Another potential concern is a missed diagnosis of ectopic pregnancy. Ectopic pregnancy rates in patients seeking abortions are lower than the general U.S. population. A study of 16,369 patients choosing medication abortion with pregnancies less than 49 days demonstrated an ectopic pregnancy rate of 1.3 per 1,000 pregnancies,[10] lower than the U.S. rate of ectopic pregnancy of 8.3 per 1,000 pregnancies.[11]

The shift to using telemedicine and no-test medication abortion during the initial lockdown for COVID-19 was critical to removing older practices that created barriers to safe early medication abortion. Experts in the field advocated for this approach for several years before the pandemic.[12] The no-test medication abortion approach eliminates significant barriers to abortion access, increases convenience for patients and health care professionals, and reduces cost. No-test medication abortion further promotes different models for patients to access the medications including mailing, pharmacy dispensing, and asynchronous visits. Before the COVID-19 pandemic, the published literature on no-test medication abortion was limited to a few small research studies and abortion provision outside the United States. In the context of changing practices due to COVID-19, increasing numbers of health care professionals worldwide have adopted these innovative practices and published their results. In this systematic review, we summarize the efficacy and safety outcomes of medication abortion performed without prior pelvic examination or ultrasonogram.

SOURCES

This systematic review follows the PRISMA (Preferred Reporting Items for Systematic Reviews and Meta-Analyses) guidelines, including registration in PROSPERO (registration number CRD42021240739). A health sciences librarian developed the literature search strategy (M.K.-H.). A second librarian outside of our institution peer-reviewed the search strategy. We searched the following electronic databases: PubMed, MEDLINE, EMBASE (Elsevier), Scopus, Web of Science, and CINAHL (EBSCOhost). The search employed a combination of keywords and controlled vocabularies related to abortion ("no test medical abortion," "medication abortion"), abortion medication ("mifepristone", "misoprostol"), and pretreatment methods ("ultrasound", "telemedicine") with no date or language restriction (see Box 1 for the PubMed search strategy and Appendix 1, available online at http://links.lww.com/AOG/C955, for complete search strategy). To identify any ongoing or recent clinical trials, we searched registries through Cochrane Central Register of Controlled Trials, which included ClinicalTrials.gov and the International Clinical Trials Registry Platform. We also searched grey literature databases, Google Scholar, Global Index Medicus, and CAB Direct. We scanned the reference lists of included studies or relevant reviews identified through the search to ensure literature saturation. Additionally, we contacted experts in medication abortion to identify studies currently undergoing peer review. Before publication, we again searched databases to include any relevant studies newly published since the initial search. No terms were added or deleted from the search strategy.

STUDY SELECTION

Only studies discussing the provision of medication abortion without prior pelvic examination or ultrasonogram were eligible for inclusion. We included randomized control trials, as well as prospective and retrospective comparative cohort studies. We excluded case studies, commentaries, letters and editorials, as well as any manuscripts where clinical outcomes were not reported. The included studies employed any abortifacient medication regimen, including mifepristone and misoprostol combined

regimens, as well as misoprostol alone regimens of any dosages.

Two authors (M.P.S. & D.D.) independently screened the results of the search based on titles and abstracts against the inclusion criteria using Colandr. We used EndNote reference management software to assess for duplication of articles. To determine whether multiple reports of the same study were published, we juxtaposed author names and indicated if all reports of the study were considered. We obtained full reports for all titles that appeared to meet the inclusion criteria or where there was uncertainty. The reviewers then screened the full text reports and determined whether they meet the inclusion criteria. Google Translate was used for articles in languages not spoken by the authors and two articles that were unable to be entered into the online translation service were translated by native speakers. If more information was needed, we contacted the study authors to resolve eligibility questions. The reviewers then independently and in duplicate extracted data from the reports. Study information included number of patients enrolled and with follow-up, regimen used, efficacy rates, and complication rates. Any disagreement was resolved through discussion with the full systematic review team.

Our primary outcome was *successful medication abortion*, defined as a complete abortion without the need for surgical management to complete the termination, as per MARE (Medical Abortion Reporting of Efficacy) guidelines.[13] *Failure* was defined as the need for further surgical intervention at either planned or unscheduled follow-up visits to complete the abortion. Adverse events are of primary interest for decision-making on the safety of no-test medication abortion. The following were abstracted, when reported: unscheduled emergency department or urgent care visits, hospital admissions, blood transfusions, additional unplanned medication treatments, additional unplanned surgical treatments, ectopic pregnancies including those requiring emergent surgical treatment, and death. If study results were not presented in these categories, we recalculated the data based on tables and text within the manuscript for no-test medication abortion. If no follow-up was documented, we excluded those patients from our summary statistics to ensure the most conservative estimations. We then combined outcomes across studies to produce summary statistics for efficacy and safety.

RESULTS

We identified 2,423 records in the literature search and reviewed 190 full-text articles for eligibility. We contacted 26 authors for additional information about their studies, as well as the primary investigators of seven ongoing studies identified in ClinicalTrials.gov and the Clinical Trial Register at the International Clinical Trial Registry Platform of the World Health Organization. Three unpublished studies were identified by experts in the field, though at the time of publication of this review two were subsequently accepted to peer reviewed journals. After full-text review and discussion with authors, 150 studies were excluded because an ultrasonogram or pelvic examination was obtained before provision of medication abortion. Twelve studies were excluded because of study design. Seven studies were excluded because we did not have adequate information and authors did not respond to queries. We included four studies that published aggregated results for patients who had no-test medication abortion with those who had an ultrasonogram after authors responded to our query and sent disaggregated data sets. The 21 studies in this review include medication abortions performed without prior pelvic examination or ultrasonogram (Tables 1 and 2). The results include no-test medication abortion performed in at least 24 countries. We followed PRISMA guidelines for reporting of study selection (Fig. 1).

We excluded six of the studies from the final summative analysis (Table 2). Three of the studies were published in the 1970s and 1980s and used medication regimens that are not current standard of care for medication abortion, including intramuscular carboprost and sulprostone.[14–16] Two of the studies included participants from the TelAbortion study

hCG, human chorionic gonadotropin; NR, not reported.
* Defined as completed abortion or ongoing pregnancy confirmed at least by patient report.
† Marval-Peck L, Izaguirre S, Yanow S, Jelinska K, Comendant R, Foster AM [abstract]. Self-administration of very early medication abortion provided through a global online telemedicine service. Contraception 2019: 319. doi: 10.1016/j.contraception.2019.07.051
‡ Additional unpublished data provided by authors.
§ Patients reported information to Women on Web; however, 30 confirmed by ultrasonography, 21 observed expelled fetus, 18 had resolution of pregnancy symptoms, eight had a negative pregnancy test result, and four had resumption of normal menses.
‖ Includes 395 patients at more than 10 weeks of gestation but does not give an upper limit.

and University of Hawai'i patients who were potentially included in a third manuscript.[17–19] Although this excludes some participants from the Kerestes et al and Anger et al studies not represented in the larger Upadhyay et al study, we excluded these two studies from the summary statistics to avoid duplicate data and ensure the most conservative estimates. Lastly, clinical outcome data were not available for the majority of the participants in the U.K. national cohort study published by Aiken et al.[20] Although this study included more than 18,000 participants, we excluded these data from the summary statistics.

We determined the remaining 15 studies to be sufficiently homogeneous in terms of design and comparator to create summary statistics for the primary and secondary outcomes. All of the studies reported the number of abortions completed without the need for surgical evacuation for any reason. Studies reported complete abortion through a variety of methods, including patient self-report, physician or nurse report including direct visualization of products of conception, reduction in quantitative serum β-hCG levels, negative urine pregnancy test several weeks after ingesting abortifacient medications or absence of a gestational sac on follow-up ultrasound evaluation.

Several of the studies note that patients may have obtained an ultrasonogram at a different clinic than the one providing the abortifacient medications. We confirmed by direct contact with authors that, for all of these studies, clinicians did not have access to the ultrasonogram reports or images in making management decisions before dispending medications.

The overall efficacy rate of no-test medication abortion is 96.4% (95% CI 96.0–96.7%) in the 10,693 patients included in this systematic review (Table 3). For patients with pregnancies at less than 70 days of gestation (n=8,166), the efficacy rate was 95.2% (95% CI 94.7–95.7%). For patients with pregnancies at more than 84 days of gestation (n=432), the efficacy rate was 83.8% (95% CI 80.0–87.2%).

IM, intramuscular.

Adverse outcomes after no-test medication abortion are reported in Tables 4–7. The rate of surgical evacuation at less than 70 days of gestation was 3.8% (95% CI 3.3–4.3); for all participants it was 4.4% (95% CI 4.0–4.9). Of 7,987 patients for whom outcome data were available, only five ectopic pregnancies were

identified, for a total ectopic pregnancy rate of 0.06% (95% CI 0.02–0.15). For patients with pregnancies at less than 70 days of gestation (n=4,210), the rate of ectopic pregnancy was 0.02% (95% CI 0.0–0.13). There were no deaths reported. Blood transfusion was uncommon, with rates ranging from 0% to 0.7%.

DISCUSSION

This systematic review of 21 studies, which includes 10,693 patients, shows that no-test medication abortion is effective and safe. The cumulative efficacy rate of no-test medication abortion is 96.4% (95% CI 96.0–96.7%) confirmed completed abortions with only

observed are lower than similar complications during delivery in the United States.[21] Further, complication rates are far lower than the rates of complications seen with unsafe methods of abortion.[22] This systematic review further supports the abortion care guidelines from national and international organizations that ultrasonogram should not be a requirement for abortion provision.

No-test medication abortion is becoming increasingly common, as evidenced by the large increase in the number of studies on the subject published within the past few years. Eleven of the studies included in our analysis were published in 2021 or 2022. With legal restrictions on abortion, more patients will find themselves without access to abortion with considerable, unfeasible travel distances and expenses to the nearest abortion clinic. With the COVID-19 pandemic, telemedicine abortion care is already dramatically increasing, and no-test protocols will be crucial for the provision of abortion care to these patients. No-test protocols can be used to provide safe abortion care without a pretreatment ultrasonogram and, thus, with no in-person requirement for the vast majority of patients. There is ample evidence regarding the safety and acceptability of remote or telemedicine follow-up for medication abortion.[23]

One strength of our study is the size and makeup of patients included with documented efficacy and safety outcomes. Methodologically, we sought to include as many studies as possible. We did not impose a language limitation on study inclusion. We extensively corresponded with authors to clarify any questions about studies with the potential for inclusion and to inquire about de-aggregated data for studies in which patients who underwent no-test medication abortion were combined with patients with pretreatment ultrasonograms, and we included grey literature. More than 10,000 patients were included from countries across the world and in a variety of health care systems. Some patients from countries such as the United Kingdom sought care through the National Health Service, whereas others from the United States were from university hospitals or smaller abortion clinics. Some patients in Cambodia received care from pharmacies. Many sought care through online platforms outside traditional health care systems. The diversity of patients and variety of methods of abortion provision in these studies suggests our conclusions are generalizable to most populations.

Each individual study has the potential for bias, as described in Table 1. As in all pooled estimates, there is potential selection bias, particularly as not all of the included studies reported rates of all adverse events. Studies with a paucity of outcome data possibly have attrition bias, though this reflects evidence-based routine clinical practice of patients determining whether a medication abortion is successful rather than a true loss to follow-up. Many of the outcomes included in this review are self-reported by patients, introducing reporting bias, though research has shown that patients are very reliable at assessing the efficacy of medication abortions.[24]

In our analysis, efficacy and safety rates remained high despite using the most conservative estimates in our analysis. We only included patients in our analysis that had documented complete follow-up data. We deliberately made this decision to get the highest rate of known complications, and the lowest rate of complete medication abortion. Our rates likely underestimate the efficacy and safety of medication abortion as many patients who have a successful medication abortion forgo further follow-up as they understand they are no longer pregnant and do not require

further medical care. Many studies included were from countries with national health care systems or in places with shared medical record systems. However, patients lost to follow-up may have experienced complications that were not captured within the medical records used for these studies. The success rate of 96.4% is potentially an underestimate of completion, and this analysis may even overestimate complication rates, further supporting the safety and efficacy of no-test medication abortion.

Although the studies lack uniformity in methods of reporting completed abortion, this reflects the current medical practice and expands the generalizability of our outcomes. Patients often do not return to the clinic or are lost to follow-up after medication abortions. Further, with increasing legal restrictions on abortion, we anticipate increasing numbers of abortions outside the formal health care setting. Self-assessment of the outcome of medication abortion completed at home has been shown to be noninferior to routine clinic follow-up.[24]

There are several limitations to our analysis. We excluded Aiken's 2021 study with the largest cohort of more than 18,000 patients from the British Pregnancy Advisory Service given the minimal number of confirmed patient outcomes available.[20] The study relied on data from a public, universal health system and offers a compelling case for not requiring follow-up for medication abortion. However, for this systematic review we included only cases in which the outcome data were available to avoid any underestimation of adverse events. Another limitation is that some patients may have had ultrasonograms or physical examinations performed by health care professionals other than those they were seeing for abortion care and that patients used this to inform their stated gestational age. However, in these cases, we confirmed with the study authors that the health care professional providing the abortion did not have access to the ultrasonogram report or use it to inform their management.

Another important limitation is the inability to determine whether the treatments patients received were necessary or appropriate for potential adverse events. Rates of surgical intervention after medication abortion are variable depending on clinical setting and regional differences in practice. Most of the studies, particularly those using self-report for follow-up, were unable to determine whether a surgical procedure was performed for an ongoing pregnancy or for adverse events relating to the abortion itself, such as retained products of conception, or if further complications resulted from the surgical management rather than the abortifacient medications themselves. Additionally, there are notable practice differences in medicine between countries that may have contributed to higher rates of interventions. For example, Endler's 2019 study suggests that the high rates of surgical evacuation found in Poland reflected either clinical practice or perhaps, "financial incentives to performing surgical procedures, rather than clinical indications."[25]

Directions for future research include finding ways to remove the last in-person requirement of blood typing for patients at more than 70 days of gestation and exploring the safety and efficacy of asynchronous medication abortion provision. Based on the available data presented in this review, health care professionals can feel confident in the safety and efficacy of no-test medication abortion. This large body of evidence should empower physicians to incorporate no-test medication abortion into their practices. Policies that mandate an in-person visit for abortion care stand in direct opposition to evidenced-based medicine. This review affirms our responsibility as physicians to advocate for the availability of this service to ensure access to basic reproductive health care for our patients.

Abstract: *Extensive evidence exists regarding the efficacy and acceptability of medical abortion through 63 days since last menstrual period (LMP). In Mexico City's Secretariat of Health (SSDF) outpatient facilities, mifepristone-misoprostol medical abortion is the first-line approach for abortion care in this pregnancy range. Recent research demonstrates continued high rates of complete abortion through 70 days LMP. To expand access to legal abortion services in Mexico City (where abortion is legal through 12 weeks LMP), this study sought to assess the efficacy and acceptability of the standard outpatient approach through 70 days in two SSDF points of service. One thousand and one women seeking pregnancy termination were enrolled and given 200 mg mifepristone followed by 800 µg misoprostol 24–48 hours later. Women were asked to return to the clinic one week later for evaluation. The great majority of women (93.3%; 95% CI: 91.6–94.8) had complete abortions. Women with pregnancies ≤8 weeks LMP had significantly higher success rates than women in the 9th or 10th weeks (94.9% vs. 90.5%; p = 0.01). The difference in success rates between the 9th and 10th weeks was not significant (90.0% vs. 91.2%; p = 0.71). The majority of women found the side effects (82.9%) and the use of misoprostol (84.4%) to be very acceptable or acceptable. This study provides additional evidence supporting an extended outpatient medical abortion regimen through 10 weeks LMP.* © 2015 Reproductive Health Matters

Keywords: medical abortion, mifepristone, misoprostol, Mexico

Medical abortion using mifepristone and misoprostol is a safe and effective method of pregnancy termination that has been used by millions of women worldwide over the past 25 years. Extensive evidence regarding both efficacy and acceptability supports the outpatient use of medical abortion through 63 days since the last menstrual period (LMP).[1–6] In this pregnancy range, among the World Health Organization's (WHO) recommended regimens is 200 mg mifepristone followed by 800 µg buccal misoprostol;[7] this protocol is routinely used for legal abortion in the outpatient facilities of the Secretariat of Health of Mexico City (SSDF),[6,8] where approximately 71% of women who obtain services have a medical abortion.[9]

In Mexico, abortion is legal in the first trimester of pregnancy, and the first mifepristone product was registered there in 2011. At around the same time, a study of medical abortion through 63 days LMP was conducted among 1,000 women who sought services in several SSDF outpatient facilities, confirming the high efficacy and acceptability of the mifepristone–misoprostol regimen.[6] The findings facilitated the SSDF in establishing medical abortion with mifepristone and misoprostol as its first-line approach for abortion care. Due to the

high demand for medical abortion and the advantages to service delivery it offers over aspiration (including reduced cost and in-clinic time), the Secretariat strives to offer outpatient medical abortion services to as many women seeking first trimester pregnancy termination as possible. A previous study of the characteristics of the women who have sought legal abortions in SSDF facilities found that they are diverse in age, marital status, and parity, and that a high percentage are Catholic.[10]

A 2012 study in the United States using 200 mg mifepristone + 800 µg buccal misoprostol demonstrated that the same regimen can be used in women at 64–70 days LMP as in women at 57–63 days LMP, with comparable efficacy (92.8% and 93.5%, respectively) and satisfaction (88.3% vs. 87.4% satisfied or very satisfied).[11] In addition, the US National Abortion Federation guidelines now include outpatient mifepristone-misoprostol medical abortion through 70 days LMP.[12] As a next step in the process of extending the clinical protocol for legal abortion in SSDF facilities, this study sought to assess the efficacy and acceptability of medical abortion through 70 days (the 10th week) provided as part of routine clinical services.

Methodology

This was an open-label clinical study (both clinicians and participants knew the treatment being provided). Women seeking pregnancy termination were enrolled at two study sites: the outpatient service at the Hospital Materno Infantil Inguarán and the reproductive health clinic of a primary care clinic, Centro de Salud Beatriz Velasco de Alemán. Women were invited to join the study if they were eligible for medical abortion and had pregnancies up to 70 days LMP. Women interested in participating had to agree to undergo a surgical intervention (vacuum aspiration) if necessary, be willing to provide contact information for purposes of follow-up, have easy access to both a telephone and emergency transportation, and comply with the study protocol. All participants gave written informed consent. Ethical approval was granted by the Ethics, Biosecurity and Research Commission of the Secretariat of Health of Mexico City.

All participants were given the same regimen of 200 mg mifepristone (Zacafemyl, Intelligence Pharmaceutical Network) to swallow in the clinic followed by 800 µg misoprostol (4 × 200 µg; either Cytotec [Pfizer] or Cyrux [Llama Serral]) to take at home 24–48 hours later. Women were instructed to retain the misoprostol buccally (two pills inside each cheek) for 30 minutes before swallowing any remains. Analgesics were prescribed according to the standard of care at each facility, and participants were told to call the clinic with any questions or concerns. Each participating clinic was provided a mobile phone to facilitate communication with study participants.

Participants were asked to return to the clinic seven days after taking the mifepristone to assess abortion status. Women with ongoing pregnancies were recommended vacuum aspiration. Women with non-viable pregnancies, including persistent gestational sac, retained products of conception or bleeding were given the choice between an additional dose of 800 µg buccal misoprostol, expectant management, or vacuum aspiration. Those choosing either of the first two options were asked to return one week later for further follow-up. At that time women with a persistent non-viable pregnancy or substantial debris were offered vacuum aspiration. Prior to exiting the study, all women were asked a series of questions by a member of the on-site study team regarding their experiences with medical abortion.

The primary outcome of the study was method efficacy, defined as complete abortion without vacuum aspiration at any point. Additional outcomes included extent of bleeding, extent of pain and other side effects, rate of abortions needing further treatment, and acceptability. Based on the success rates in studies by Winikoff in 2008 (≤ 63 days LMP: 96.2%)[2] and in 2012 (57–63 days LMP: 93.5%; 64–70 days LMP: 92.8%),[11] a sample size of 456 women was deemed sufficient to show overall success of 95% +/− 2%. The sample size was increased to 1,000 to account for high rates of expected loss to follow-up and homogeneity between sites. Data were analysed using SPSS version 19 (IBM, Armonk, NY, USA) and STATA version 11 (StataCorp, College Station, TX, USA).

Findings

Between January and March 2012, 1,001 women were enrolled in the study. Of these, forty-one women were lost to follow-up and no follow-up data could be collected; therefore, they are only included in the analysis of participant characteristics and are excluded from further analyses. One woman with a pregnancy 73 days LMP was

GBP-PET00798

Table 1. Participant characteristics (N=1,001)

Age in years: median (range)	24 (13–45)
Gravidity: median (range)	2 (1–8)
Reported previous abortion: n (%)	181 (18.1%)
Reported previous medical abortion: n (%)	124/181 (68.5%)
Duration of pregnancy LMP, in days: median (range)	52 (25–73)
Days since last menstrual period (LMP): n (%)	
≤56 days	654 (65.3%)
57–63 days	196 (19.6%)
64–70 days[a]	151 (15.1%)

a One woman was 73 days' LMP.

mistakenly enrolled in the study; her data are included in the analyses. Participant characteristics are presented in Table 1. Around two-thirds (65.3%) of women in the study were ≤56 days LMP, one-fifth (19.6%) were 57–63 days LMP, and 15.1% were 64–70 days LMP.

All but one study participant reported taking mifepristone and misoprostol as instructed; one woman said she took the misoprostol five days after the mifepristone. The great majority of women (93.3%; 95% CI: 91.6–94.8) had complete medical abortions without vacuum aspiration (Table 2). The reasons for the 64 vacuum aspirations included ongoing pregnancy (n = 15), bleeding problem (n = 17), persistent sac (n = 14), incomplete at study end (n = 15), clinically indicated intervention (n = 2) and psychological/emotional reasons (n = 1). Rate of complete abortion varied by study site: 98.5% vs. 92.0%.

Women at ≤8 weeks LMP (≤56 days) had significantly higher complete abortion rates than women in the 9th week (94.9% vs. 90%, p = 0.02), but statistical significance did not hold when comparing women ≤8 weeks LMP to those in the 10th week (94.9% vs. 91.2%, p = 0.12). The difference in complete abortion rates between the 9th and 10th weeks did not differ significantly (90.0% vs. 91.2%; p = 0.85). Twenty women (2.1%) attended another (non-study) medical facility for abortion-related care during the study after having received the two medications; these women were more likely to undergo surgical intervention than women who only received care at the study clinics (70.0% vs. 5.3%; p < 0.001). Seventy participants (7.0%) called the clinic with questions or concerns about the abortion process; women 10 weeks LMP were no more likely to call than women 9 weeks LMP (8.6% vs. 11.2%; p = 0.48; data not shown).

The most common side effects experienced during the abortion process included fever/chills (46.0%), diarrhoea (44.6%), nausea (27.0%), and vomiting (23.0%) (Table 3). Severity of side effects is presented in Figure 1. Slightly over half of the women (56.2%) reported that the pain they

As expected	182 (30.2)	55 (30.2)	51 (35.4)	288 (31.0)
More than expected	254 (42.1)	87 (47.8)	66 (45.8)	407 (43.8)
Bleeding during treatment	**(n=609)**	**(n=183)**	**(n=144)**	**(n=936)**
Less than expected	195 (32.0)	45 (24.6)	32 (22.2)	272 (29.1)
As expected	275 (45.2)	84 (45.9)	67 (46.5)	426 (45.5)
More than expected	139 (22.8)	54 (29.5)	45 (31.3)	238 (25.4)

a One woman was 73 days LMP.

experienced was less than or as expected, and three-fourths (74.6%) found the bleeding to be less than or as expected. Approximately the same proportion of women in the 10th week as in the 9th week reported having more pain than expected (45.8% vs. 47.8%, p = 0.74). Reported mean pain level (on a scale from 1–7) did not differ between women in the 9th and

Figure 1. Side effects and severity

10th weeks (5.59 vs. 5.55. p = 0.79) but was statistically significantly higher when women 9 and 10 weeks LMP were compared to those ≤56 days LMP (5.57 vs. 5.26; p = 0.003; data not shown).

Three-fourths of the women (76.6%) found the medical abortion process to be not at all difficult or only slightly difficult, while 9.5% thought it was very difficult (Table 4). The majority of women (86.9%) found the side effects to be very acceptable or acceptable; only 2.4% thought they were unacceptable or very unacceptable. Most participants (84.4%) also found the mode of misoprostol administration to be very acceptable or acceptable, with only 1.2% finding the mode of administration unacceptable or very unacceptable. If another abortion is needed in the future, 77.8% of the women would again choose medical abortion; only 2.9% would choose vacuum aspiration and 19.3% had no preference. Best aspects of medical abortion as reported by participants included ease or convenience (26.0%), efficacy (24.4%), the quality of care received (11.7%), and privacy (8.5%). For 16.3%, there was no best aspect. Cramps/pain were the most commonly reported worst feature (28.8%). Over half (52.7%) of the women said that there was no worst aspect (data not shown).

Discussion

This study demonstrated that outpatient medical abortion protocols can be extended through 70 days LMP with rates of efficacy and acceptability within the range seen in other studies with similar protocols.[11,13,14] The overall ongoing pregnancy rate of 1.6% in this study that included women through 70 days LMP was slightly higher than the 0.5% typically seen in studies among women ≤63 days.[2,6] However, a higher rate of ongoing pregnancies in the 9th week (3.2%) and 10th week (3.4%) was expected and concurs with the Winikoff et al. 2012 study, which reported ongoing pregnancy rates of 3.1% and 3.0%, respectively.[11] Compared to women with earlier pregnancies, the chance of an ongoing pregnancy following use of the medical abortion regimen among women in the 9th and 10th weeks increases from less than 1 woman per 100 to less than 4 women per 100. While the slightly higher rate of ongoing pregnancy might discourage some women from selecting this method of abortion,

GBP-PET00801

other women do not consider the drop in success to be a limiting factor. Outpatient medical abortion with this regimen for women 9 weeks LMP is recommended by the World Health Organization[7] and commonly used. That there is no incremental difference in the ongoing pregnancy rate when used by women 10 weeks LMP supports the expansion of outpatient medical abortion services to include this additional week of pregnancy. Each woman should be able to make an informed choice to select whichever method she thinks is best for her.

The overall success rate in this study is lower than in previous studies in Mexico City,[6] but it does not appear to be due to the inclusion of women with pregnancies of 64–70 days LMP since success dropped sharply in the 9th week. This may be due to chance, or in part to provider management, specifically non-study clinicians at other facilities. Clinical providers who do not offer medical abortion services will typically follow standard management of non-complicated incomplete abortion; in Mexico, these women are often hospitalized and treated with dilatation and curettage even if not clinically indicated. Among study clinicians, we cannot rule out the possibility of behavioural bias, as providers were not blinded to pregnancy duration. Heterogeneity among providers, that is, the differences in the way individual providers clinically manage a case, might also have contributed to site differences in success rate.

Women with pregnancies in the 9th and 10th weeks reported significantly higher mean pain scores than other study participants. However, the scores are so similar that they may not be clinically meaningful, that is, they may not call for different strategies in pain management. More importantly, the mean pain score of women in the 10th week was almost identical to that of women in the 9th week, further supporting the routine offering of outpatient medical abortion to women with pregnancies 64–70 days.

This study provides additional evidence to the published literature that supports extending outpatient medical abortion through 70 days (10th week) of pregnancy. In fact, based on these study results and the experience obtained through participating in this study, the SSDF has expanded outpatient care through 70 days as a part of routine care. Offering outpatient medical abortion as a treatment option for this population would further expand access to women, and if participation in this study is any indication, women 64–70 days LMP could represent as much as 15% of medical abortion users. In turn, this would be time- and resource-saving for providers and the health care system. It is possible that this medical abortion regimen could be an option for women beyond 70 days LMP as well, as it is unlikely that the rate of success would sharply plummet at 71 days LMP. Further research is necessary to explore efficacy later in the first trimester. In addition, as the pregnancy develops and becomes more recognizable upon expulsion at 11 and 12 weeks, it would be important to assess simultaneously the acceptability of outpatient medical abortion for women, as well as providers' comfort with providing it, to determine the feasibility of this service delivery option.

Acknowledgments

The authors thank the staff at C.S. Beatriz Velasco Alemán and at H.M.I. Inguarán for their important work on this study, as well as the participants who made this analysis possible. We also thank Jennifer Britton for her invaluable assistance with data management and analysis.

Résumé

De nombreuses données existent sur l'efficacité et l'acceptabilité de l'avortement médicamenteux jusqu'à 63 jours depuis la date des dernières règles (DDR). Dans les centres ambulatoires du Secrétariat de la santé de Mexico (SSDF), l'avortement médicamenteux sous mifépristone et misoprostol est la méthode de première intention pour l'interruption de grossesses de cet âge gestationnel. Des recherches récentes montrent des taux élevés d'avortement complet jusqu'à 70 jours après la DDR. Pour élargir l'accès à des services d'avortement légal à Mexico (où l'avortement est autorisé jusqu'à 12 semaines après la DDR), cette étude a tenté d'évaluer l'efficacité et l'acceptabilité de la méthode ambulatoire standard jusqu'à 70 jours dans deux centres du SSDF. Mille et une femmes souhaitant avorter ont été recrutées et ont reçu 200 mg de mifépristone suivis de 800 µg de misoprostol 24–48 heures plus tard. Elles ont été invitées à revenir au centre une semaine après pour évaluation. Chez la grande majorité des patientes (93,3% ; IC 95% : 91,6–94,8), l'avortement était complet. Les femmes enceintes ≤8 semaines après la DDR avait des taux de réussite sensiblement plus élevés que les femmes à 9 ou 10 semaines (94,9% contre

Resumen

Existe extensa evidencia respecto a la eficacia y aceptabilidad del aborto con medicamentos hasta los 63 días desde la fecha de la última menstruación (FUM). En las unidades de salud ambulatorias de la Secretaría de Salud del Distrito Federal de México (SSDF), el aborto con medicamentos inducido con mifepristona-misoprostol es el enfoque de primera línea en los servicios de aborto para esta etapa de la edad gestacional. Recientes investigaciones demuestran continuas altas tasas de aborto completo hasta concluidos los 70 días desde la FUM. Con el fin de ampliar el acceso a los servicios de interrupción legal del embarazo en el Distrito Federal (donde el aborto es legal hasta las 12 semanas desde la FUM), este estudio buscó evaluar la eficacia y aceptabilidad del enfoque ambulatorio estándar hasta los 70 días en dos puntos de entrega de servicios de la SSDF. Mil y una mujeres que buscaban interrumpir su embarazo fueron inscritas y administradas una dosis de 200 mg de mifepristona seguida de 800 µg de misoprostol, 24 a 48 horas después. Se les pidió a las mujeres que regresaran a la clínica una semana después para la evaluación. La gran mayoría de las mujeres

90,5% ; p = 0,01). La différence dans les taux de réussite entre la 9e et la 10e semaine était non significative (90,0% contre 91,2% ; p = 0,71). La majorité des femmes ont jugé les effets secondaires (82,9%) et l'utilisation du misoprostol (84,4%) très acceptables ou acceptables. Cette étude fournit des données supplémentaires soutenant un régime étendu d'avortement médicamenteux en ambulatoire jusqu'à 10 semaines après la DDR.

(93.3%; 95% IC: 91.6–94.8) tuvo un aborto completo. Las mujeres con embarazos ≤8 semanas desde la FUM tuvieron tasas de eficacia significantemente más altas que las mujeres en la novena o décima semanas (94.9% vs. 90.5%; p = 0.01). La diferencia en las tasas de eficacia entre la novena y décima semanas no fue significante (90.0% vs. 91.2%; p = 0.71). La mayoría de las mujeres encontraron que los efectos secundarios (82.9%) y el uso de misoprostol (84.4%) eran muy aceptables o aceptables. Este estudio ofrece evidencia adicional que respalda un régimen de aborto con medicamentos extendido hasta concluidas las 10 semanas desde la FUM para usuarias ambulatorias.

The Safety and Efficacy of a "No Touch" Abortion Program Implemented in the Greater Toronto Area During the COVID-19 Pandemic

ABSTRACT

Objectives: To evaluate the safety and efficacy of first-trimester "No Touch" medication abortion programs at 2 clinics in Toronto, Ontario during their early implementation in response to the COVID-19 pandemic.

Methods: This retrospective study included all patients who underwent virtual consultation for mifepristone-misoprostol medication abortion between April 2020–August 2022 at 2 reproductive health clinics. In response to the pandemic, "No Touch" abortion protocols have been developed that align with the Canadian Protocol for the Provision of Medical Abortion via Telemedicine. Records were reviewed for demographic information, clinical course, investigations required, confirmation of complete abortion and adverse events. The primary outcome was complete medication abortion, defined as expulsion of the pregnancy without requiring uterine aspiration.

Results: A total of 277 patients had abortions initiated in the "No Touch" or "Low Touch" care pathways and had sufficient follow-up to determine outcomes. Of these patients, 92.8% (95% CI 89.7%–95.8%) had a complete medication abortion (n = 257) and 76.1% (n = 159) remained "No Touch" throughout their care. Investigations were performed for 102 participants before or after their abortion, classifying them as "Low Touch". Nineteen patients (6.9%) underwent uterine aspiration. The rate of adverse events was low, with 1 case of a missed ectopic pregnancy and 1 patient requiring hospitalization for endometritis.

Conclusions: "No Touch" provision of mifepristone-misoprostol medication abortion care was safe and effective with outcomes comparable to previous studies. These results provide evidence for the efficacy and safety of a "No Touch" approach in the Canadian context, which has the potential to reduce barriers to accessing abortion care.

RÉSUMÉ

Objectif : Évaluer l'innocuité et l'efficacité des programmes d'avortement médicamenteux sans contact au premier trimestre dans deux cliniques de Toronto, en Ontario, au début de leur mise en œuvre en réponse à la pandémie de COVID-19.

Méthode : Cette étude rétrospective porte sur toutes les patientes ayant obtenu une consultation virtuelle pour un avortement médicamenteux par mifépristone-misoprostol entre avril 2020 et août 2022 dans 2 cliniques de santé reproductive. En réponse à la pandémie, des protocoles d'avortement sans contact ont été mis au point en s'alignant sur le Protocole canadien de prestation de l'avortement médical par télémédecine. Les dossiers ont été examinés pour extraire les données sur les caractéristiques démographiques, l'évolution clinique, les examens réalisés, la confirmation de l'avortement complet et les événements indésirables. Le critère de jugement principal était l'avortement médicamenteux complet, défini comme l'expulsion de la grossesse sans nécessiter d'aspiration utérine.

Résultats : Au total, 277 patientes ont subi un avortement dans le cadre d'un protocole à faible ou sans contact et ont fait l'objet d'un suivi suffisant pour déterminer les résultats. De ce nombre, 92,8 % (IC à 95 % : 89,7–95,8 %) ont obtenu un avortement

médicamenteux complet (n = 257), et la totalité de la prise en charge s'est déroulée selon le protocole sans contact pour 76,1 % des patientes (n = 159). Des examens ont été réalisés auprès de 102 participantes avant ou après l'avortement, ce qui les classe dans la catégorie à faible contact. En tout, 19 patientes (6,9 %) ont subi une aspiration utérine. Le taux d'événements indésirables s'est avéré faible (1 grossesse extra-utérine non diagnostiquée et 1 hospitalisation pour une endométrite).

Conclusion : La prestation de l'avortement médicamenteux sans contact par mifépristone-misoprostol était sécuritaire et efficace, les résultats étant comparables à ceux d'études antérieures. Ces résultats démontrent l'efficacité et l'innocuité de l'approche sans contact dans le contexte canadien, laquelle pourrait réduire les obstacles à l'accès aux soins d'avortement.

INTRODUCTION

The COVID-19 pandemic posed several risks to the reproductive health of people globally.[1,2] In Canada, abortion remained an essential and time-sensitive service during this period of social disruption.[3] Traditionally, medication abortion care in Canada has required in-person clinical assessment, ultrasound dating of the pregnancy and in-clinic follow-up. However, evolving clinical practice guidelines during the pandemic have eliminated the requirement for in-person care and routine testing in some cases.[4]

There is increasing evidence that medication abortion delivered through a "No Touch" approach, where patients who meet clinical criteria have only remote contact with the health system, is safe and acceptable to patients.[5,6] This "No Touch" format of care delivery, also described as "virtual" or "telemedicine" throughout the existing literature, has been shown to be non-inferior to standard in-person care.[7] Within Canada, telemedicine has been used successfully to provide abortion care in British Columbia since 2012.[6] In the context of the COVID-19 pandemic, studies on "No Touch" abortion care have been conducted in other high-income countries,[8-10] demonstrating high patient satisfaction and low complication rates that are comparable to standard in-person care. No similar research has occurred in Ontario, Canada with our unique publicly funded health care system and geographic barriers to abortion care.

The goal of this study was to assess the safety and efficacy of virtual first-trimester "No Touch" abortions provided at 2 clinics in Toronto, Ontario. Both clinics offer comprehensive reproductive health services, including medication and procedural abortion. In response to the COVID-19 pandemic, these clinics developed "No Touch" abortion protocols that align with the Canadian Protocol for the Provision of Medical Abortion via Telemedicine.[4] As described, the COVID crisis has placed additional barriers to accessing safe abortion care and "No Touch" medication abortion could alleviate some of those barriers. Beyond the pandemic, this approach to abortion care has the potential to improve access, require fewer resources, and increase patients' satisfaction with their care.

METHODS

This was a retrospective study of all patients who underwent consultation for a "No Touch" abortion between 1 April 2020 and 31 August 2022, at the Bay Centre for Birth Control (BCBC) or Choice in Health Clinic (CIHC). BCBC, an academic clinic affiliated with Women's College Hospital, serves 1300 patients and provides 500 medication abortions annually. CIHC is a community-based clinic that serves approximately 2230 patients and provides 670 medication abortions per year. Both clinics have been offering mifepristone-misoprostol medication abortions since 2017. Prior to April 2020, both clinics required that patients have an ultrasound-confirmed intra-uterine pregnancy of less than 70 days and attend the clinic for abortion consultation. In response to the COVID-19 pandemic, BCBC and CIHC adopted "No Touch" abortion protocols for abortions up to 10 weeks gestational age.[4] Only patients seen virtually for consideration of "No Touch" abortion were evaluated in our study. This study was approved by the research ethics boards at the University of Toronto (REB #41859) and Women's College Hospital (REB #2021-0071-B).

"No Touch" Abortion Protocol

Similar protocols for "No Touch" abortion were adopted by both clinic sites. The purpose of the initial virtual consultation is to assess eligibility for a "No Touch" abortion. A physician or nurse practitioner assesses the patient for contra-indications to mifepristone/misoprostol medication abortion and determines if ultrasound or laboratory investigations are required before proceeding (Table 1). For those who are eligible, the following medications are prescribed: mifepristone 200 mg orally, 2 doses of 800 mcg misoprostol (taken buccally or vaginally), analgesics and anti-emetics. The first dose of misoprostol (800 mcg) is to be taken buccally or vaginally 24–48 hours after mifepristone. Patients with an estimated gestational age >63 days are counselled to take the second dose of misoprostol 4 hours after the first dose. In accordance

Table 1. Eligibility for first-trimester "No Touch" medication abortion

Ultrasound required if:	Laboratory investigations required if:	Contra-indications to mifepristone/ misoprostol medication abortion
• LMP uncertain • LMP >70 days ago • Signs or symptoms of ectopic pregnancy • Risk factors for ectopic pregnancy • Presence of an intra-uterine device	• Hemoglobinopathy or severe anemia suspected • Rhesus (Rh) status not previously documented and patient would want Rh immune globulins • Patient has risk factors for STIs (*optional*)	• Confirmed or suspected ectopic pregnancy • Chronic adrenal failure • Inherited porphyria • Uncontrolled asthma • Long-term use of corticosteroid therapy • Hemorrhagic disorder or anticoagulation therapy • Severe anemia

LMP: last menstrual period; STI: sexually transmitted infection.

with national guidance at the time, Rho(D) immuno-prophylaxis (for Rh-negative patients) was not routinely required at less than 8 weeks gestational age. For those between 8 and 10 weeks gestational age, the evidence for Rho(D) immune globulin prophylaxis is discussed with the patient. After this discussion, patients opting not to receive Rho(D) immuno-prophylaxis sign an additional consent form stating that they understand the possible risk to future pregnancies if Rh sensitization occurs. The physician or nurse practitioner then conducts a virtual follow-up visit via phone at 7 days and 4 weeks post-medication abortion. The patient is instructed to complete a home urine pregnancy test (UPT) at the 4-week visit. Both clinic sites had electronic messaging systems to facilitate clinician-patient communication between scheduled visits. A more detailed description of the clinical protocol can be found in online Appendix.

Data Collection and Analysis

We collected the following data from the patients' records: patient age, estimated gestational age, postal code (first 3 digits), gravidity, parity, complete abortion, repeat misoprostol, uterine aspiration (for ongoing pregnancy, incomplete abortion, or persistent bleeding), attendance at follow-up visits and how abortion was deemed complete. Safety outcomes included the number of emergency department visits, hospitalizations, hemorrhage requiring blood transfusion, and infections (defined as any treatment with antibiotics for uterine pain or tenderness). These were determined through patients' reports at the time of scheduled or subsequent clinical follow-up up to 6 weeks after administration of the medication abortion. Continuous data were recorded as median ± SE, and categorical data were recorded using counts and percentages.

Definitions

For the purposes of categorizing the clinical care pathways of the patients in this study, we applied the following definitions: A complete "No Touch" abortion was defined as expulsion of the pregnancy without the need for investigations or in-person care.[11] A "Low Touch" abortion was defined as requiring investigations at any point before, during or after expulsion of the pregnancy. Doing a home UPT did not qualify the care as "Low Touch" because there was no contact with the health care system. Investigations may have been required to confirm eligibility for a medication abortion, to investigate a potential complication and/or to confirm completion of the abortion. Some patients may also have chosen to receive investigations as reassurance, therefore categorizing their care as "Low Touch". Lastly, a "Full Touch" abortion was defined as requiring in-person clinical assessment related to the abortion at any point during the medication abortion process. This included clinic visits, emergency department visits, family physician visits, hospitalization and/or procedural management. A complete abortion was ascertained through a reassuring clinical history, negative UPT, negative quantitative beta-human chorionic gonadotropin, resumption of normal menses or procedural abortion. Patients who attended only the 7-day and not the 4-week follow-up appointment but provided clinical history consistent with passing the products of conception, were included in our evaluation as complete medication abortions.

RESULTS

Between 1 April 2020 and 21 August 2022, 327 patients had a virtual consultation for medication abortion through BCBC or CIHC. After initial consultation, 29 patients did not proceed, leaving 298 patients aged 14–48 years who continued with virtual, first-trimester medication abortion care. Demographic and pregnancy characteristics are reported in Table 2.

Of the 298 patients who proceeded with medication abortion, 209 (70.1%) were eligible for a "No Touch" approach (Figure). These were patients who met the

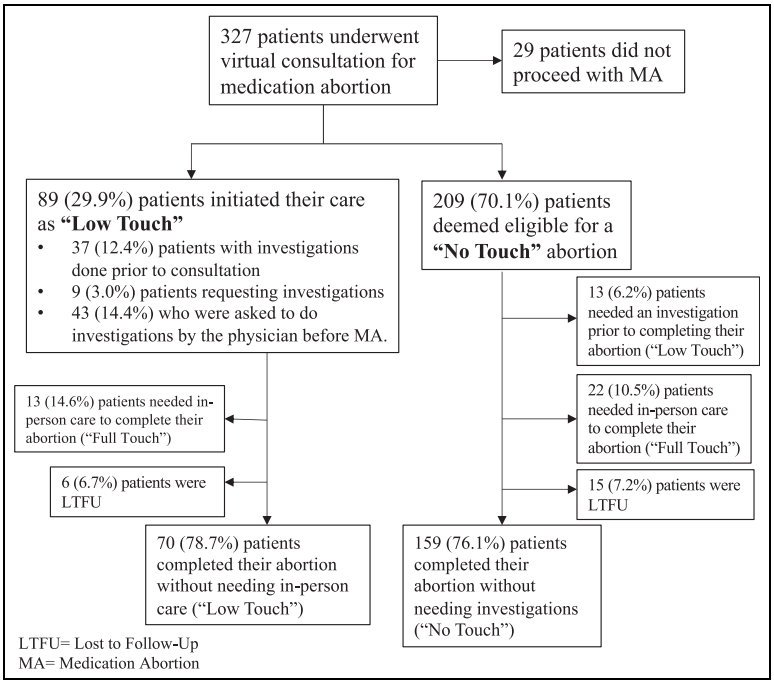
GTA: Greater Toronto Area (Etobicoke, North York, Scarborough, York, East York, Brampton, and Mississauga); SVD: spontaneous vaginal delivery.

eligibility criteria (Table 1) and so were prescribed mifepristone and misoprostol without requiring any investigations beforehand. The patients who had investigations were classified as initiating their care in the "Low Touch" pathway (N = 89, 29.9%). All patients who were not initially eligible for "No Touch" abortion were able to proceed with medication abortion once their investigations were complete. The most common reasons why patients were asked to do investigations were pain or vaginal bleeding (possible symptoms of ectopic pregnancy), history of anemia and uncertain last menstrual period. The most commonly performed investigation prior to medication abortion was an ultrasound, but other investigations included hemoglobin level, Rhesus status or testing for sexually transmitted infections. Figure displays the patient care pathways based on any interventions or investigations that were required before their abortion was complete.

A total of 277 patients had sufficient follow-up to determine the outcome of their abortion. Overall, 257 patients (92.8%, 95% CI 89.7%—95.8%) had a complete medication abortion. In Table 3, the medication abortion completion rate is reported by gestational age and whether the patient initiated their care in the "No Touch" or "Low Touch" pathway.

The rate of adverse events was low with only 1 case of an ectopic pregnancy and 1 patient requiring hospitalization for intravenous antibiotics. The patient with the ectopic pregnancy called the clinic about her pain and was advised to present to the emergency department. She delayed presentation until a few days later and was found to have a ruptured ectopic pregnancy requiring emergent laparoscopy. The patient who required hospitalization presented to the emergency department with fever 2 weeks after her abortion. She was admitted for 3 days for endometritis and was managed with intravenous antibiotics. There were no patients who required blood transfusion. A total of 13 patients (4.7%) presented to the emergency department during the process of their abortion. The reasons for and outcomes of these visits are displayed in Table 4.

Sixteen patients (5.8%) underwent a procedural abortion for incomplete medication abortion and 3 patients (1.1%) underwent a procedural abortion for an ongoing viable pregnancy. Nine patients (3.2%) required additional doses of misoprostol to complete their abortion.



DISCUSSION

This is the first evaluation of a "No Touch" medication abortion protocol in Ontario, Canada. The overall efficacy rate was high, with 92.8% (95% CI 89.7%—95.8%) of the patients who initiated their care in the "No Touch" or "Low Touch" care pathways having a complete medication abortion. Of these patients, 159 (76.1%) had complete "No Touch" medication abortions without any investigations or in-person care. Although our rates of complete medication abortion were lower than the 95.2% (CI 94.7%—95.7%) rate reported in a recent meta-analysis looking at telemedicine-based abortion outcomes globally, the confidence intervals overlap.[12]

Rates of adverse events were low in this study. Thirteen patients (4.7%) presented to the emergency department, however, only 2 (0.7%) experienced serious adverse

GBP-PET00808

Figure. Care pathways of patients undergoing first-trimester virtual medication abortion (MA).

LTFU: loss to follow-up.

events. One patient (0.4%) required laparoscopy for an ectopic pregnancy. In a large meta-analysis, the reported rate of ectopic pregnancy was 0.06%.[12] Another patient required admission to hospital for management of endometritis with intravenous antibiotics. In a United States-based study of telemedicine abortion outcomes, 0.5% of patients had an infection requiring intravenous antibiotics.[13] Adverse events in this study were documented based on patient reports and thus may have been underreported, particularly in the minority of patients who were lost to follow-up. We similarly relied on patient report of passing the pregnancy for those who attended the 7-day follow-up, but not the 4-week follow-up visit for categorization of complete abortion. This may have contributed to overestimation of the complete medication abortion rate. However, evidence suggests that patients can reliably assess the efficacy of medication abortion.[14]

Intervention rates for incomplete or failed abortion were overall low. Nineteen patients (6.9%) had a procedural abortion and 9 patients (3.2%) required additional doses of misoprostol. In the systematic review by Shapiro et al.[12] rates of procedural abortion and need for additional misoprostol were similar at 4.4% and 2.2%, respectively. There are several factors that may have contributed to our procedural intervention rates, in addition to usual indications such as patient preference or failed repeat misoprostol doses. First, uterine aspiration was relatively accessible same-day in the out-of-hospital clinic involved

Table 3. Complete medication abortion (MA) rate by gestational age (GA) and care pathway

GA (days)	Patients with follow-up (n)	Complete MA, n (%)	Complete MA among those initiated as "No Touch", n (%)	Complete MA among those initiated as "Low Touch", n (%)
All GA	277	257 (92.8%)	182 (93.8%)	75 (90.4%)
≤ 49	207	192 (92.8%)	146 (93.6%)	46 (90.2%)
50+	70	65 (92.9%)	36 (94.8%)	29 (90.6%)

Complete MA is defined as expulsion of the pregnancy without need for procedural abortion.

Table 4. Emergency department visits and outcomes

Emergency department visit reason	Cases (n)	Rate (%)
Patients initiating care as "No Touch" (n = 194)	8	4.1%
Bleeding, requiring D&C	1	0.5%
Bleeding, requiring misoprostol	3	1.5%
Bleeding, requiring reassurance	1	0.5%
Pain, requiring analgesia	2	1.0%
Pain, requiring laparoscopy for ruptured ectopic	1	0.5%
Patients initiating care as "Low Touch" (n = 83)	5	6.0%
Bleeding, requiring D&C	3	3.6%
Bleeding, requiring misoprostol	1	1.2%
Fever, requiring admission for endometritis	1	1.2%
Total serious adverse events	2[a]	0.7%
Total emergency department visits	13	4.7%

[a]The patient who presented with pain and required laparoscopy for a ruptured ectopic was included as a serious adverse event. The patient who presented with fever and required admission for endometritis was also included as a serious adverse event.

in our study. Additionally, mifepristone has only been available in Canada since 2017, and all physicians participating in this pilot were new to a "No Touch" approach. Therefore, physicians may have been more likely to intervene (convert to "Full Touch") or order investigations (convert to "Low Touch") to avoid a possible complication. We observed that the rate of procedural intervention trended downward after our first year of providing "No Touch" medication abortions, possibly indicating increased provider comfort levels with this protocol. In 2020, the procedural abortion rate after starting as a "No Touch" or "Low Touch" medication abortion was 7.7%. The procedural abortion rate was 4.2% and 5.7% in 2021 and 2022 respectively.

COVID-19 acted as the impetus for the pilot of this care protocol in many settings and served as justification for easing regulatory barriers to telemedicine-based care.[15] Globally, this approach has enabled physicians to provide care across states and districts, improving access to timely abortion care, and enhanced care in rural areas.[16,17] Findings from previous Canadian literature have suggested "Low" or "No Touch" medication abortion as a mechanism to improve geographic equity.[18] Indeed, 51 patients (17.1%) in our study were from regions outside the Greater Toronto Area and otherwise would have needed to travel many hours to present to these same clinics in person. "No Touch" care also plays a crucial role in improving the personal safety of those seeking abortion care. It enables those seeking abortion to do so from their homes or other secure locations, with potential for reduced risks to physical and emotional safety, and reduced risks of COVID-19 transmission associated with their abortion.[19] However, "No Touch" abortion alone does not remove all barriers to accessing care, where insurance status, access to phone or Wi-Fi, and supportive pharmacies to dispense the medications[20] are only some of the ongoing challenges.

This study has some limitations. First, this is exploratory data from a new care pathway, which was delivered during a period of tremendous strain related to the pandemic. It is unclear whether practice patterns, outcomes or patient preferences will change in more "normal" times. Similarly, a significant limitation of this study is its small sample size. A larger study including multiple clinics across a wider geographic area would more accurately determine the medication abortion completion rate and rate of adverse events. Importantly, this study did not include patients' perspectives on this mode of care delivery, which we plan to assess in future studies. Projects that have explored patient experiences found that a "No Touch" approach is highly acceptable among patients for a variety of reasons, including improved privacy, convenience, accessibility, home comforts and reduced stigma.[8,21-23] Some studies even demonstrated preference and perceived benefits of "No Touch" over in-person abortion care.[8,21,23]

Ample data has proven the safety of a "No Touch" approach to abortion care when offered in the context of a strict eligibility assessment. Despite this, many patients globally face challenges in accessing abortion including stigma, policy, cost, safety, and travel. This mode of delivery has the potential to reduce these barriers, particularly in legally restrictive, rural, and resource-constrained settings.

CONCLUSION

"No Touch" provision of mifepristone-misoprostol medication abortion care in this cohort was safe and effective with outcomes comparable to previous studies. These results provide evidence for the efficacy and safety of a "No Touch" approach in the Canadian context, which has the potential to reduce barriers to accessing abortion care. Future directions of this study will include a 2-phase qualitative evaluation of patients' perspectives on and experiences of "No Touch" abortion, including consideration for its role beyond the COVID-19 pandemic.

EARLY PREGNANCY TERMINATION WITH MIFEPRISTONE AND MISOPROSTOL IN THE UNITED STATES

IRVING M. SPITZ, M.D., D.SC., C. WAYNE BARDIN, M.D., LAURI BENTON, M.D., AND ANN ROBBINS, PH.D.

ABSTRACT

Background Mifepristone and a prostaglandin have been used successfully to terminate pregnancy in Europe and China. We report the results of a large U.S. study of mifepristone and misoprostol in women with pregnancies of up to nine weeks' duration.

Methods We administered 600 mg of mifepristone and then 400 μg of misoprostol two days later to 2121 women seeking termination of their pregnancies at 17 centers. The women were observed for four hours after the administration of misoprostol and returned on day 15 for final assessment.

Results Two thousand fifteen women completed the final assessment. Among them, pregnancy was terminated in 762 of the 827 women pregnant for ≤49 days (92 percent), 563 of the 678 women pregnant for 50 to 56 days (83 percent), and 395 of the 510 women pregnant for 57 to 63 days (77 percent) ($P<0.001$). Termination occurred within 4 hours after the administration of misoprostol in 49 percent of the women and within 24 hours in 75 percent. Failures, defined as cases requiring surgical intervention for medical reasons or because the patient requested it, the abortion was incomplete, or the pregnancy was ongoing, increased with increasing duration of pregnancy. The largest increase was in failures representing ongoing pregnancy, which increased from 1 percent in the ≤49-days group to 9 percent in the 57-to-63-days group ($P<0.001$). Abdominal pain, nausea, vomiting, diarrhea, and vaginal bleeding also increased with advancing gestational age. Two percent of the women in the ≤49-days group, as compared with 4 percent in each of the other two groups, were hospitalized, underwent surgical intervention, and received intravenous fluids ($P=0.008$).

Conclusions This mifepristone–misoprostol regimen is effective in terminating pregnancies, especially in women with pregnancies of 49 days' duration or less. (N Engl J Med 1998;338:1241-7.)

©1998, Massachusetts Medical Society.

THE antiprogestin mifepristone (RU 486) causes abortion by competitively blocking progesterone receptors.[1-3] For maximal effectiveness, a prostaglandin should be given 48 hours after mifepristone.[1,3,4] The rates of termination of pregnancies 49 days old or less are similar, ranging from 96 to 99 percent, whether mifepristone is used with gemeprost or misoprostol, both prostaglandin E_1 compounds.[1,3,5-7] Gemeprost is expensive, requires refrigeration, and is not widely available, but misoprostol is inexpensive, stable at room temperature, and obtainable in many countries, including the United States.

Many American women do not have access to abortion,[8] and in developing countries up to 200,000 women die annually of complications after illegal abortions.[9] The availability of medical abortion in the United States and elsewhere could lead to greater access to safer abortion services. We conducted a multicenter trial of mifepristone and misoprostol to determine whether this combination could be used to terminate pregnancies of up to 63 days' duration.

METHODS

Participating Centers

From September 1994 to September 1995, we enrolled 2121 women, each with a documented pregnancy of 63 days' duration or less, requesting termination of pregnancy. Women with liver, respiratory, renal, adrenal, or cardiovascular disease, thromboembolism, hypertension, anemia, insulin-dependent diabetes mellitus, coagulopathy, or known allergy to prostaglandins were excluded, as were women less than 18 years of age or those more than 35 years of age who smoked more than 10 cigarettes per day and had another cardiovascular risk factor. Women were also excluded if they had in situ intrauterine devices, were breast-feed-

ing, were receiving anticoagulation or long-term glucocorticoid therapy, had adnexal masses, had ectopic pregnancies, or had signs or symptoms suggesting they might abort spontaneously. All the women agreed to undergo surgical termination of pregnancy if the medical method failed. Among the 2121 women, 915 were enrolled at eight Planned Parenthood clinics, 538 at four university-hospital clinics, and 668 at five free-standing abortion clinics. The protocol was approved by the human investigational review board at each participating institution, and all the women gave informed consent.

Study Design

Pregnancy was measured from the first day of the last menstrual period according to menstrual history, pelvic examination, and vaginal ultrasonography. On the basis of the investigator's final assessment of these three measures, the women were assigned to the following arbitrarily defined gestational-age groups: the ≤49-days group (859 women); the 50-to-56-days group (722); and the 57-to-63-days group (540).

Three clinic visits were scheduled. At visit 1 (day 1), the women were assessed clinically and took 600 mg of mifepristone orally. At visit 2 (day 3), they took 400 μg of misoprostol orally unless a complete abortion had already occurred. After taking misoprostol, the women were monitored for four hours for adverse events, such as nausea, vomiting, diarrhea, and abdominal pain. These events were rated by the women and recorded as mild (felt but easily tolerated), moderate (uncomfortable enough to interfere with usual activity), or severe (incapacitating, preventing usual activity). Vaginal bleeding was recorded on a diary card and rated by each woman on days 1 through 15 of the study as spotting (less than normal menstrual bleeding), normal (similar to normal menstrual bleeding), or heavy (more than normal menstrual flow). During this period, the women were also monitored for expulsion of the conceptus. At visit 3 (day 15), the treatment outcome was assessed.

Efficacy was defined as the termination of pregnancy with complete expulsion of the conceptus without the need for a surgical procedure. The need for a surgical procedure (either vacuum aspiration or dilation and curettage) constituted a failure, and such a procedure was performed at any time if the investigator believed there was a threat to a woman's health (medically indicated), at a woman's request, or at the end of the study for an ongoing pregnancy or incomplete abortion. Follow-up was extended beyond visit 3 if there was uncertainty about the completeness of the abortion or if bleeding persisted.

A total of 106 women were excluded from the efficacy analysis because they did not return for visit 3. Evidence suggesting a successful outcome was available for 92 of these women, and evidence of failure for 1. The remaining 13 women were lost to follow up; 5 had continuing pregnancies when last seen at visit 2. The analyses of efficacy therefore included 2015 women.

Statistical Analysis

Statistical analysis was performed with the use of Statistical Analysis System software (SAS Institute, Cary, N.C.). One-way analysis of variance and Kruskal–Wallis tests were used to compare mean values in the gestational-age groups, and Pearson's chi-square tests were used to compare the distributions of categorical variables. Fisher's exact test was used to compare rates in the gestational-age groups. Stepwise logistic-regression analysis was used to evaluate the relation between success or failure and various base-line patient characteristics; the significance level required for a variable to stay in the model was 0.10. All statistical tests were two-tailed.

RESULTS

There were 859 women in the ≤49-days group, 722 in the 50-to-56-days group, and 540 in the 57-to-63-days group. The three groups were similar with respect to age (mean, 27 years; range, 18 to 45), gravidity, parity, number of spontaneous or previous elective abortions, and ethnic or racial distribution (white, 71 percent; black, 15 percent; Hispanic, 9 percent; Asian, 5 percent). Seventy-three percent of the women had had previous pregnancies, 51 percent elective abortions, and 15 percent spontaneous abortions.

Efficacy

Among the 2015 women who returned for the third visit, the rates of pregnancy termination were 92 percent in the ≤49-days group, 83 percent in the 50-to-56-days group, and 77 percent in the 57-to-63-days group ($P<0.001$) (Table 1). Of the 59 women who did not receive misoprostol, 56 had termination of their pregnancies after mifepristone alone. In the remaining three women, it subsequently became apparent that their pregnancies had not been terminated after mifepristone and they should have been given misoprostol; they later underwent surgical termination. The rate of termination after mifepristone alone also decreased significantly with increasing gestational age, from 5 percent to 0.8 percent (Table 1).

The rates of incomplete abortion were 8 percent in the 50-to-56-days group and 7 percent in the 57-to-63-days group, as compared with 5 percent in the ≤49-days group (Table 1). The failures for all other reasons were significantly higher in both the 50-to-56- and 57-to-63-days groups than in the ≤49-days group. The largest increase was in failures representing ongoing pregnancy, which rose from 1 percent in the ≤49-days group to 9 percent in the 57-to-63-days group. Ninety percent of the surgical terminations performed for medical reasons were for vaginal bleeding. A patient's request was the reason least often cited for surgical termination.

Although the study design called for analysis according to the three discrete gestational-age groups, there was in fact a steady decline in the frequency of termination of pregnancy with increasing duration of gestation (Fig. 1). Logistic-regression analysis indicated that the rates decreased with increasing gestational age, from more than 95 percent before day 40 to less than 90 percent after day 47 and to less than 80 percent after day 59. The only other factor that was related to outcome was the number of previous elective abortions (Fig. 1); the termination rates were higher for women with no previous abortions than for those with previous abortions. The differences in rates were less than 2 percent up to day 35, 2 to 3 percent from days 36 to 42, 3 to 4 percent from days 43 to 48, 4 to 6 percent from days 49 to 55, and 6 to 10 percent from days 56 to 63. The outcomes were unrelated to other base-line characteristics, including age, race, body weight, gravidity, and previous spontaneous abortions.

‡0.001≤P<0.03 for the comparison with the ≤49-days group.

§P<0.001 for the comparison with the 50-to-56-days group.

Complete expulsion of the conceptus occurred before the administration of misoprostol in 76 women (4 percent). This group included the 56 women who received only mifepristone and an additional 20 women who received misoprostol because their expulsion status was considered uncertain at the beginning of visit 2. It was subsequently determined that these 20 women had had complete expulsions before they took misoprostol. During the four hours of observation after the administration of misoprostol, 49 percent of the women expelled the conceptus, and during the fifth hour an additional 11 percent expelled the conceptus. By 24 hours after misoprostol administration, 75 percent of the women had expelled the conceptus (Fig. 2).

Figure 1. Logistic-Regression Analysis of the Predicted Probability of Successful Pregnancy Termination, According to the Duration of Pregnancy for All the Women and for the Women Who Had and Those Who Had Not Had Previous Elective Abortions.

Vaginal Bleeding

Vaginal bleeding is a natural consequence of the abortion process, and it occurred in all the women whose pregnancies were terminated medically. The median duration of bleeding or spotting was 13 days in the ≤49-days group and 15 days in the other two groups (P<0.001). The proportions of women who reported heavy bleeding did not differ significantly in the three groups, were highest on day 3, and then decreased steadily. By day 15, 77 percent of all reported bleeding was considered spotting (Fig. 3). Nine percent of the women reported some type of bleeding after 30 days, and 1 percent after 60 days.

Excessive bleeding necessitated blood transfusions in four women and accounted for 25 of 27 hospitalizations (including emergency-room visits), 56 of 59 surgical interventions, and 22 of 49 administrations of intravenous fluid. Hospitalizations, surgical interventions, and intravenous-fluid administration were reported for 2 percent of the women in the ≤49-days group and for 4 percent of those in each of the other groups (P=0.008). Bleeding was managed by the administration of uterotonic agents, such as oxytocin, methylergonovine, or vasopressin, in 41 women (5 percent) in the ≤49-days group, 50 (7 percent) in the 50-to-56-days group, and 55 (10 percent) in the 57-to-63-days group (P<0.001).

Other Adverse Events

Almost all the women (99 percent) reported at least one adverse event during the study period (Ta-

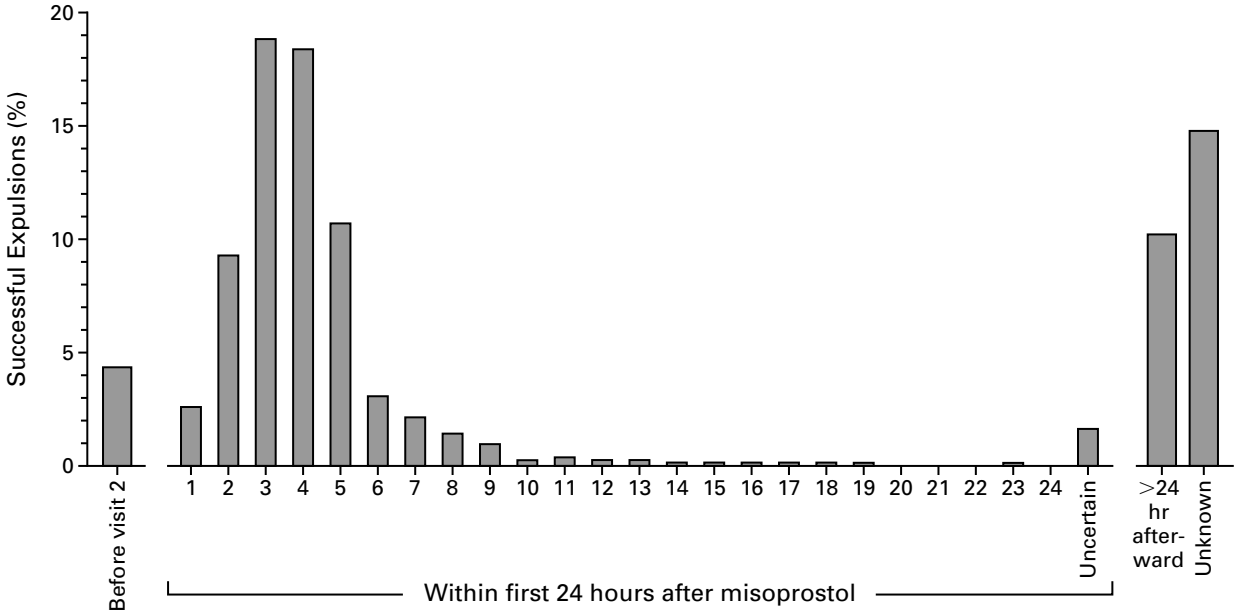

Figure 2. Times of Expulsion of the Conceptuses in 1720 Women with Successful Termination of Their Pregnancies.
The women received mifepristone at visit 1 and misoprostol two days later (visit 2). "Uncertain" indicates that expulsion occurred within the first 24 hours after misoprostol was given, but the exact time was not known. "Unknown" indicates that expulsion occurred more than 24 hours after misoprostol was given, but the exact time was not known.

ble 2). Nearly all had abdominal pain; its overall incidence did not differ among the three groups. However, 53 percent of the women in the 50-to-56-days group and 54 percent in the 57-to-63-days group had abdominal pain reported as severe, as compared with 43 percent in the ≤49-days group ($P<0.001$). Sixty-eight percent of the women received at least one medication for abdominal pain (usually acetaminophen), and 29 percent also received opiates (usually acetaminophen with hydrocodone or codeine). The women in the 50-to-56- and 57-to-63-days groups received significantly more analgesia and opiates than the women in the ≤49-days group ($P<0.001$). Abdominal pain resulted in one hospitalization and was the reason for two medically indicated surgical interventions.

As compared with the ≤49-days group, the 50-to-56- and 57-to-63-days groups had significantly more nausea and vomiting, and diarrhea was more frequent in the 57-to-63-days group. The overall percentages of events reported as severe were 3 percent for diarrhea, 10 percent for vomiting, and 20 percent for nausea. Medications for these adverse events were taken by 1 percent, 4 percent, and 19 percent of the women, respectively, with no differences among the gestational-age groups. Severe vomiting resulted in one hospitalization and was the reason for one medically indicated surgical intervention.

In the four-hour observation period after the administration of misoprostol, the number of adverse events and the percentage classified as severe were similar to those reported during the entire study period. During these four hours, nausea ($P<0.001$) and vomiting ($P<0.001$) were significantly more frequent in the 50-to-56- and 57-to-63-days groups than in the ≤49-days group, and abdominal pain ($P=0.009$) and diarrhea ($P=0.006$) were more severe in the 57-to-63-days group.

The frequency of adverse events declined significantly with increasing gravidity and parity (Table 2). Nulliparous women received significantly more analgesia ($P<0.001$), opiate analgesia ($P<0.001$), and medications for nausea ($P<0.001$) and diarrhea ($P<0.001$) than parous women. Chronologic age was not consistently related to the frequency of adverse events.

Other adverse events reported included headache (32 percent); dizziness, encompassing light-headedness and faintness (12 percent); back pain and fatigue (9 percent each); fever, vaginitis, and viral infections (4 percent each); rigors and dyspepsia (3 percent each); and asthenia, leg pain, anxiety, insomnia, anemia, syncope, leukorrhea, and sinusitis (2 percent each). Endometritis occurred in 19 women; it was considered study-related in 10, in 1 of whom it was severe.

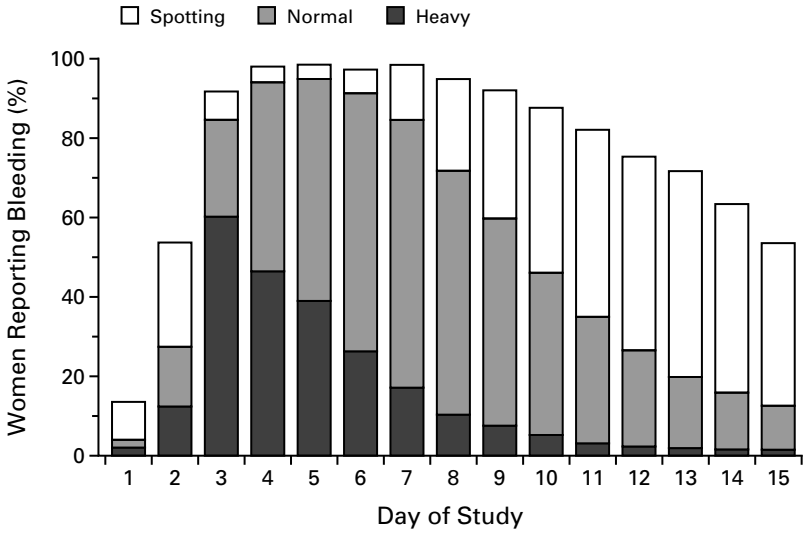

Figure 3. Types of Vaginal Bleeding as Recorded by the Women from Day 1 (Administration of Mifepristone) to Day 15.

The data are from 1506 women who did not undergo surgical termination of pregnancy and who recorded the types of bleeding they had from study day 1 to day 15 on menstrual-diary cards. Bleeding was characterized as spotting, as similar to normal menstrual bleeding (normal), or as heavier than normal menstrual bleeding (heavy).

DISCUSSION

In this large, multicenter U.S. trial, the success of medical termination of pregnancy decreased gradually with advancing gestational age. We confirmed the international experience that mifepristone and misoprostol can terminate pregnancies of up to 49 days' duration, although the success rate was lower than previously described.[7,10-12] As noted in other countries,[13] this lower success rate may be related to the lack of experience with medical abortion in the United States as well as to the design of our study. We considered the need for surgical intervention on day 15 as representing failure, but abortion might have occurred later.[13,14] Also, a surgical termination performed at the woman's request was classified as a failure instead of being excluded from the efficacy analysis.[10,12,13] Unexpectedly, success was also less frequent among women who had previous elective abortions. Although the reason is unknown, this factor could also have contributed to the differences, because 51 percent of the women in our study had had previous elective abortions, as compared with 25 to 27 percent in two British studies.[12,13]

Efficacy decreased after 49 days' gestation. A similar trend has previously been reported with misoprostol but not with gemeprost.[10-15] Thus, the lower success rates later in gestation are probably related to the prostaglandin component of the regimen. Such lower rates were not found when misoprostol was given by the vaginal route,[16,17] presumably because of greater tissue bioavailability.[18] Higher doses of oral misoprostol increase uterine contractility[19] and are also associated with improved results.[11,12,15] Efficacy is not, however, related to differences in the dose of mifepristone, and similarly good results have been reported with single doses as low as 200 mg.[11,14,20]

The incidence of adverse events rose with the duration of pregnancy.[7,10,13] These events included both subjective symptoms (abdominal pain, nausea, and vomiting) and more objective markers (hospitalizations and surgical interventions). The majority of hospitalizations and surgical interventions were for vaginal bleeding. With advancing pregnancy, the duration of bleeding increased, as did the administration of uterotonic drugs and intravenous fluids. Despite the increases in the numbers of failures and adverse events, the majority of the women in this study reported that they were satisfied with their medical abortions, regardless of whether the outcome was successful (Winikoff B, et al.: unpublished data).

One drawback of this method of pregnancy termination is the inconvenience of the four-hour clinic stay after the administration of misoprostol. In its favor is the fact that many adverse events, including those rated as severe, occurred during this period, as did almost half the expulsions, and some women may prefer to be in the clinic during these events. Moreover, in the women with pregnancies of longer duration, the majority of the hospitalizations or surgical interventions occurred on day 3, whereas in the women with pregnancies of shorter duration, these events were evenly distributed throughout the 15-day study period. Thus, the four-hour visit may be most appropriate for women with pregnancies of longer duration. Nonetheless, on the basis of the results of a small study, mifepristone combined with home application of vaginal misoprostol is a safe alternative in women with pregnancies of up to 56 days' duration.[17]

Careful medical follow-up is essential to ensure that surgical termination is performed in cases of failed medical abortion. In this study, 5 percent of the women did not return for final confirmation of the outcomes of their pregnancies, and five of these women had continuing pregnancies when last seen at visit 2. The ultimate outcome of these pregnancies is unknown, despite our repeated attempts to contact the women. In other studies, the loss to follow-up has ranged from 3 to 11 percent.[5-7,10,12,21] Although mifepristone is not teratogenic in rats, mice, or monkeys,[22,23] skull deformities attributed to uterine contractions occurred in rabbits.[24] Misoprostol, on the other hand, has been reported to be teratogenic in humans.[25,26]

Recently, other methods of medical abortion have been evaluated. Oral misoprostol alone is not effective.[19,27] The efficacy of vaginal misoprostol in the first trimester varies widely, from 47 to 94 percent,[28,29] but it is highly effective in the second trimester.[30] Success rates with methotrexate and vaginal misoprostol range from 83 to 98 percent.[31-35] As compared with mifepristone, this latter regimen has the advantage of being an effective treatment for ectopic pregnancy.[36] However, misoprostol has to be given three to seven days after methotrexate, delaying the abortion process.[35] Unlike mifepristone, methotrexate is cytotoxic to proliferating trophoblast tissue, and persisting pregnancies may represent a greater teratogenic risk.[28,32,33,35]

In conclusion, the regimen of mifepristone and misoprostol is safe and effective for women seeking medical abortions of pregnancies of 49 days' duration or less. With longer durations of pregnancy, the regimen is less effective and the incidence of adverse events is higher.

We are indebted to Dr. Elof Johansson for his helpful advice and continuing support; to Dr. Brigid M. O'Connor, Dr. Charlotte Ellertson, Dr. Beverly Winikoff, and Ms. Batya Elul for their contributions to the data analysis; to Mr. Evan Read for preparation of the figures; and to Mr. Peter Conlon and Ms. Irina Shmerlin for preparation of the manuscript.

BRIEF REPORT

Telehealth Medication Abortion in Primary Care: A Comparison to Usual in-Clinic Care

Silpa Srinivasulu, MPH, Deyang Nyandak, MD, Anna E. Fiastro, PhD, MPH, MEM, Honor MacNaughton, MD, Amy Tressan, MD, and Emily M. Godfrey, MD, MPH

Introduction: **Providing abortion in primary care expands access and alleviates delays. The 2020 COVID-19 public health emergency (PHE) led to the expansion of telehealth, including medication abortion (MAB). This study evaluates the accessibility of novel telehealth MAB (teleMAB) initiated during the PHE, with the lifting of mifepristone restrictions, compared with traditional in-clinic MAB offered before the PHE at a Massachusetts safety-net primary care organization.**

Methods: **We conducted a retrospective electronic medical record review of 267 MABs. We describe sociodemographic, care access, and complete abortion characteristics and compare differences between teleMAB and in-clinic MABs using Chi-squared test, fisher's exact test, independent *t* test, and Wilcoxon rank sum. We conducted logistic regression to examine differences in time to care (6 days or less vs 7 days or more).**

Results: **184 MABs were eligible for analysis (137 in-clinic, 47 teleMAB). Patients were not significantly more likely to receive teleMAB versus in-clinic MAB based on race, ethnicity, language, or payment. Completed abortion did not significantly differ between groups ($P = .187$). Patients received care more quickly when accessing teleMAB compared with usual in-clinic MAB (median 3 days, range 0 to 20 vs median 6 days, range 0 to 32; $P < .001$). TeleMAB patients had 2.29 times the odds of having their abortion appointment within 6 days compared with in-clinic (95% CI: 1.13, 4.86).**

Conclusion: **TeleMAB in primary care is as effective, timelier, and potentially more accessible than in-clinic MAB when in-person mifepristone regulations were enforced. TeleMAB is feasible and can promote patient-centered and timely access to abortion care. (J Am Board Fam Med 2024;37:295–302.)**

Introduction

The *Dobbs v Jackson Women's Health Organization* US Supreme Court decision (*Dobbs*) ended the federal protection to abortion, curtailing access for more than 35 million women and pregnancy-capable people who now live in 18 states that have banned or severely restricted provision.[1,2] Decades of research demonstrates that when abortion is restricted, those seeking care experience significant delays due to challenges navigating limited appointment availability and increased travel distances.[3–5] Medication abortion (MAB) in primary care has the potential to meaningfully increase access to care.[6–8] Early abortion is within the scope of primary care, and family physicians routinely provide safe and effective medication and aspiration abortion in outpatient settings.[9–13] Some patients prefer obtaining abortion care with primary care because of the trust, privacy, and continuity of care it affords and are

GBP-PET00819

highly satisfied with this care.[14,15] Yet, as of 2018 only 3% of family physicians reported providing abortion, although before its Food and Drug Administration (FDA) approval, 45% of family physicians anticipated offering MAB in their practices.[16,17] Despite its proven safety, since its approval the FDA has restricted mifepristone, the first of a 2-drug MAB regimen, under a "Risk Evaluation and Mitigation Strategy" (REMS), requiring clinicians to physically assess patients' pregnancies and dispense the medication in-clinic, until the COVID-19 Public Health Emergency (PHE).[18]

The PHE led to sustained changes in health care delivery, expanding telehealth services, including in primary care.[19] A temporary injunction on the FDA REMS and dissemination of evidence-based protocols supporting remote clinical assessment of patients allowed for telehealth MAB (teleMAB).[18,20,21] Although some clinics successfully adapted to the changing environment, few safety-net primary care clinics transitioned from in-clinic MAB to teleMAB with medication delivery. Barriers to novel abortion provision include unsupportive leadership, community or professional stigma, and burdensome systems, federal, and state regulations, including pre-*Dobbs* restrictions on teleMAB in 19 states.[22–24]

Although teleMAB can alleviate geographic barriers to abortion, medically underserved communities are impacted by harmful economic and social policies and conditions—poor broadband infrastructure, low access to education and job opportunities, residential segregation, and more—that impede their abilities to use telehealth, resulting in further inequities.[7,25] The extent to which primary care settings can meet the needs of diverse populations by offering teleMAB compared with usual in-clinic MAB is unclear. This study evaluates the accessibility of novel primary care teleMAB, initiated during the PHE with the lifting of mifepristone FDA restrictions, compared with traditional in-clinic MAB offered before the PHE.

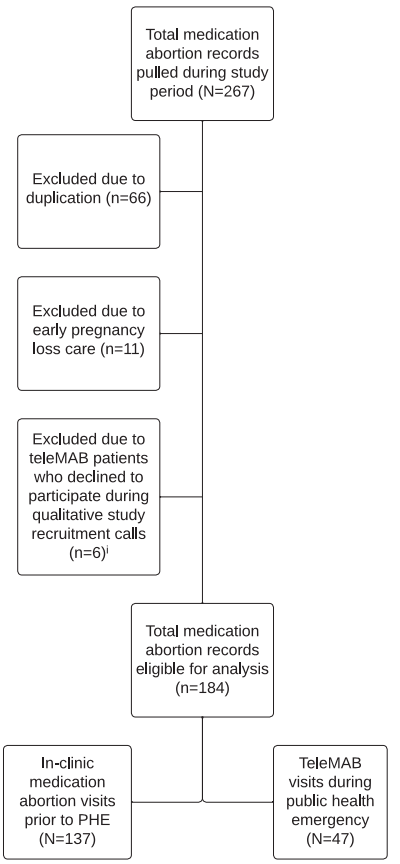
Methods

Study Design and Setting

We conducted a retrospective electronic medical record (EMR) review at a large primary care safety-net health system in Massachusetts. This organization serves an economically and culturally diverse population of 120,000 patients across 15 primary care clinics. Many identify as immigrants, the majority hold public or subsidized insurance, and 42% have limited English proficiency requiring professional interpretation in more than 60 languages. The organization has routinely provided MAB since 2003, providing on average 14 MABs per month (2019) and does not publicly advertise their abortion services.

In response to the PHE and temporary lifting of FDA restrictions, the organization expanded MAB to offer synchronous telehealth consultations, remote consent signing, and medications delivered to patients via courier from July 28, 2020 to present, except from January to April 2021 when the Supreme Court reinstated FDA enforcement of the in-person requirements (Figure 1).[18] Patients up to 11 weeks' gestation could choose between in-person and teleMAB appointments, though access to in-person appointments was severely curtailed during the PHE due to temporary clinic closures, staffing changes, and backlogs of appointments leading to health care delays for an extended time. Still, in-clinic visits were required for patients with contraindications to remote care, like symptoms of potential ectopic pregnancy. The in-clinic pre-PHE sample best represents the organization's abortion-seeking patient population during the same months as examined for teleMAB to account for seasonal tendencies in abortion.[26,27] MAB protocols changed in March 2020; first requiring ultrasound and recommending lab work, then only requiring ultrasound and labs when indicated, consistent with published standards of care.[21]



We extracted EMR data for eligible patients (n = 267): in-clinic MAB (April 12, 2019-January 12, 2020) and teleMAB (July 28, 2020-December 31, 2021). Figure 2 illustrates exclusion criteria.

Data Collection

DN, HM, and AT developed an encrypted Google Forms chart abstraction tool to systematically summarize sociodemographic, care access, and relevant medical information in a deidentified dataset. Sociodemographics included race (self-report, predetermined categories), ethnicity (self-report, open-ended), form of payment (private, public, missing), language of care, and whether a patient was an established patient at time of MAB. Race, ethnicity, payment, and language were included to explore racial, ethnic, and income-related differences in teleMAB access and serve as proxy measurements for systemic social, economic, and political barriers to accessing care.[28]

Care access measures included gestational age at time of MAB appointment and time to MAB appointment, calculated in days from when a patient first requested MAB (phone call or visit) to their MAB appointment date. We dichotomized time to MAB appointment as 6 days or less versus seven days or more based on an analysis of the 2014 Abortion Patient Survey, which found an average abortion

Figure 2. Flow diagram of inclusion criteria into study.

[i]Due to institutional review board requirements, eligible patients who declined to participate in an complementary qualitative study were excluded from this chart review (n= 6)

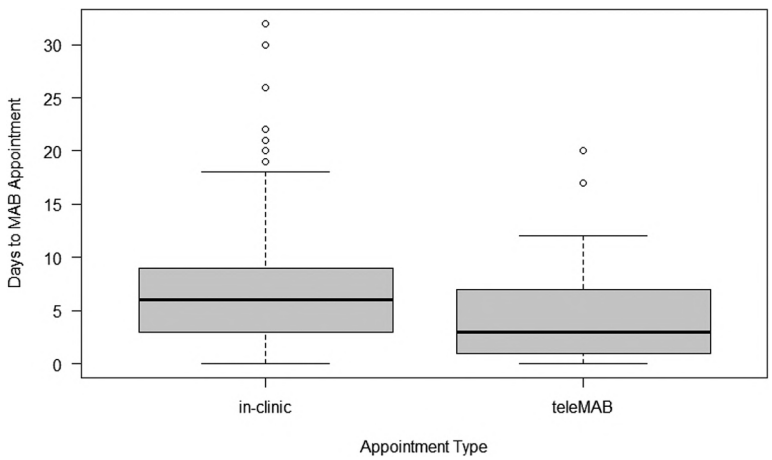
appointment delay of 7.6 days.[29] Complete abortion was dichotomized to describe MAB completions per protocol 1 to 28 days after abortion.

Data Analysis

We reported sociodemographic, care access, and complete abortion measures using descriptive statistics and compare differences between in-clinic and telehealth groups using c^2, fisher's exact test, independent *t* test, and Wilcoxon rank sum. We conducted logistic regression to examine time to care differences. We used R (4.1.1, R Core Team 2022) to conduct analyses. We set significance at $P = .05$; unknown responses were assigned missing. This study was approved by the two organizations' institutional review boards.

Results

Of 267 medical records extracted, 184 were eligible for analysis, of which 137 (74.5%) MABs occurred in-clinic pre-PHE and 47 (25.5%) were teleMAB encounters during the PHE (Table 1). The vast majority in both groups (91%) were established patients. Patients were not significantly more likely to receive teleMAB versus in-clinic MAB based on race, ethnicity, language, or form of payment. Completed abortion did not significantly differ between teleMAB and in-clinic MABs ($P = .187$).



In-clinic visits had a mean gestational age at time of appointment of 48.1 days compared with 45.3 days for teleMAB ($P = .049$). Patients received care more quickly when accessing teleMAB compared with in-clinic services (median 3 days to teleMAB, range 0 to 20 days vs median 6 days to in-clinic, range 0 to 32; $P < .001$, Figure 3). TeleMAB patients had 2.29 times the odds of having their abortion appointment within 6 days compared with in-clinic (95% CI: 1.13, 4.86).

Discussion

In a safety-net primary care system we found that teleMAB was as effective, timelier, and potentially more accessible than in-clinic care (when the FDA enforced in-person assessment and medication acquisition). This demonstrates the feasibility of primary care organizations to integrate novel abortion services to meet their patients' needs. In addition, timely clinical visits is an important indicator of quality abortion care.[30,31] Reducing delays enhances patient-centeredness, reflecting a health system's responsiveness to patients' preferences, needs, and values.[30] Increasing access in primary care is critical as *Dobbs* and other abortion restrictions have increased demand at remaining facilities, contributing to delays and prolonged care.[4,32–35]

We found no differences in sociodemographic characteristics or complete abortion between in-clinic and teleMAB patients. Although we cannot draw conclusions regarding MAB safety due to the study's small sample, our findings are within the range of other studies evaluating complete abortion after MAB in primary care.[36–38] And, although not statistically significant, we found a smaller percentage of teleMAB patients were Black, Haitian, and non-English speaking. Studies during the PHE have found racial, ethnic, and language inequities in broad telehealth utilization.[39–42] Structural barriers drive these inequities, including challenges integrating interpretation into video visits, reimbursement for audio-only visits, and systematic disinvestment in predominantly Black and/or low-income communities and consequences on access to and comfort using digital health infrastructure.[41] Like other telehealth services, teleMAB may not be as accessible due to this digital divide.[25,42] Employing strategies to increase abortion access in community-based settings where and how underserved communities obtain their usual health care is critical. Beyond telehealth, primary care organizations should prioritize access to timely in-person

Figure 3. Days between first contact for medication abortion and appointment between in-clinic pre-PHE visits and teleMAB visits during the PHE. *Abbreviation:* PHE, public health emergency.

appointments for patients who cannot or do not want to use telehealth. Research is needed to ensure introducing teleMAB does not exacerbate access disparities.

This study has limitations. We sought to collect comprehensive demographics but were limited by IRB requirements that restricted collecting age, parity, and other clinical data. Although time-related factors comparing in-clinic pre-PHE MAB with teleMAB during the PHE may have created systematic differences in the study's abortion-seeking population, this comparison is appropriate given the reduced in-person appointment and staff availability during the PHE, and the need to compare newly introduced teleMAB to usual in-clinic care. As the FDA permanently revised the mifepristone REMS in December 2021 by removing in-person requirements and allowing a pharmacy certification process, future research should compare access to and timeliness of primary care teleMAB to in-clinic MAB, as both are now similarly available in unrestricted states. Further study of the feasibility and effectiveness of primary care teleMAB may motivate more clinics to offer this care, thus reducing delays and improving access. And although the Supreme Court prepares to hear *Alliance for Hippocratic Medicine v FDA*, which may reverse the FDA's REMS modifications that enabled remote mifepristone dispensing, misoprostol-only teleMAB protocols will still be available.[43,44]

Novel teleMAB was comparable to in-clinic services historically provided in a primary care safety-net health care system. TeleMAB seems feasible and can promote timely access to abortion care. Primary care settings should consider implementing teleMAB provision to facilitate timely, patient-centered access to care.

Received 26 June 2012; revised 15 September 2012; accepted 19 October 2012

Abstract

Background: Most medical abortion protocols require women to take mifepristone in the doctor's office. We assessed the acceptability of home use of mifepristone among women and their providers.
Study Design: In this multicenter trial, eligible women requesting termination of early pregnancy (n=301) chose whether to take mifepristone in the office or at home. Data on safety, efficacy, acceptability and disability were collected.
Results: One hundred thirty-nine women (46%) chose to take mifepristone at home, and 162 (54%) chose office administration. Ninety-five percent of home users said that they would take the mifepristone in the same place in the future. Home users were not more likely to call the doctor's office or make an unplanned visit, and providers would recommend home use again for 95% of patients who chose home use.
Conclusions: Home administration of mifepristone was safe and acceptable to women and providers in our study. Women should be offered this choice to allow more flexibility, comfort and privacy in their abortion experiences.

Keywords: Medical abortion; Mifepristone; Home use

1. Introduction

Due to the politicized nature of abortion in the United States, mifepristone is distributed and dispensed in a highly unusual manner. Mifepristone is supplied only to physicians who sign an agreement with the distributor and is not available in pharmacies. In addition, mifepristone is generally administered under the direct observation of a physician or nurse. These conditions are specified in the manufacturer's label approved by the Food and Drug Administration [1]; however, there is a long history of off-label use in the US for other aspects of mifepristone provision where supportive data exist. Despite the fact that mifepristone has few to no side effects for most women, no data have been gathered on mifepristone use outside the constraints of office provision in the US. A descriptive study of women overseas who acquired both mifepristone and misoprostol from the Women on the Web website and self-administered the tablets reported a success rate similar to rates reported for other outpatient settings (93%) [2].

Women considering medical abortion may assume incorrectly that the abortion will occur on the day of their appointment and accordingly plan their visit around the demands of childcare, work and school. However, the most severe bleeding and cramping usually occur 1 to 3 days after the appointment, after the woman takes the misoprostol. Therefore, requiring women to take mifepristone in the doctor's office can interfere with patients' ability to plan how the abortion will fit into their lives because it forces them to

initiate the bleeding process at a time when it may be costly or inconvenient. Appointments are often not available at the most convenient times for patients. By contrast, if a woman were sent home with both medications, she could plan to experience bleeding over the weekend or at another time that is suitable for her so that she can avoid schedule disruption or loss of income. Offering women the option to take mifepristone at home may also enhance patient choice for those women who come to the doctor's office intending to have a medical abortion but ultimately choose to have a surgical abortion because of scheduling issues. Lastly, home use of mifepristone has the potential to increase patient satisfaction for those women who wish to start the medical abortion process in the privacy of their homes, with their partners or families.

Many studies of medical abortion have sought to increase acceptability by giving women greater flexibility and autonomy [3–21]. Similarly, the objective of this study was to assess the acceptability of home use of mifepristone for termination of pregnancy among women who choose it and their providers. We also aimed to compare the experiences of women using mifepristone at home to those of women taking mifepristone in the doctor's office and to estimate the proportion of women who might be interested in this new option.

2. Methods

Women presenting for termination of pregnancies up to 63 days of gestation were recruited for this prospective, nonrandomized multicenter trial. The study was conducted from May 2009 through November 2010 at four urban, demographically diverse clinical sites in New York City, Philadelphia and Atlanta. Ethical approval for the study was obtained from the Allendale Institutional Review Board, as well as the institutional review boards of the Montefiore Medical Center, the Institute for Family Health and the University of Pennsylvania. All participants gave written informed consent.

Study participation was generally offered to women after they had made the decision to have a medical abortion, although at three of the sites, the study was mentioned to some women during options counseling. Gestational age was determined according to clinical protocols (two sites by transvaginal ultrasound, one site by first day of last menstrual period (LMP) plus bimanual examination and one site by either or both methods). Participants were given a choice between taking the mifepristone at home or in the office setting. Since one of our primary objectives was to evaluate the acceptability of home use of mifepristone, participant preference was important.

At enrollment, study staff completed a questionnaire with each participant, which included questions about mifepristone administration location choice, pregnancy history and employment status. Women were also asked open-ended questions about their reasons for choosing to take the mifepristone where they did. Those who chose home use were asked to provide a date and time for when they planned to take the mifepristone. Providers counseled women to select a date within the 63-day gestational limit and within 1 week of their abortion appointment. Participants were then given 200-mg mifepristone to take orally either at home or in the doctor's office, depending on their stated choice. Each participant was given four 200-mcg pills of misoprostol to be taken 6 to 48 h after mifepristone per their site's medical abortion protocol. Women also received a home study card with instructions to record the time and date of mifepristone and misoprostol administration, number of missed days of work and/or school and hours of paid childcare needed due to the abortion. Pain, antidiarrheal and antinausea medications were recommended according to each site's standard clinical protocol.

Participants returned to the doctor's office 1 to 2 weeks after mifepristone administration for a follow-up visit. If a clinician determined that the abortion was complete (based on clinical history, examination and/or vaginal ultrasound, as per clinical protocol), an exit interview was administered to collect data on aspects of participant satisfaction. Responses on the home study card regarding time of medication administration and days of missed work, school or childcare needed due to the abortion were also reviewed with the participant during the follow-up visit. If the participant was unable to return for her follow-up visit, this information was obtained over the phone by study staff when possible. For participants requiring additional follow up or a surgical completion, the exit interview was conducted once the abortion was complete. After a participant was discharged from the study, providers answered a hypothetical question about whether or not they would recommend this participant take mifepristone at home in the future.

Studies have demonstrated that 87–97% of women find home use of misoprostol acceptable [7,22,23]. We wished to show that the satisfaction rate for home use of mifepristone is comparable to reported satisfaction rates for home use of misoprostol, which is now standard in the US. We chose 87% as the minimum value that would be regarded as consistent with the conclusion that home use of mifepristone is as acceptable as standard care. Enrolling 114 women in the home-use group would allow us to estimate an acceptability rate of 92% with a confidence interval of ±5%. Since the study was not randomized, we could not know a priori what proportion of women were going to choose the home-mifepristone regimen. Therefore, we planned to enroll participants until at least 114 women were followed up in the home-use group and at least 100 women in the office-use group so as to be able to provide adequate descriptive data for women in both groups.

When analyzing our results, we used Fisher's Exact Test to determine differences in proportions, and for continuous variables, we used the Student's *t* test to assess differences in means. In our analysis of primary and secondary outcomes,

we considered two-tailed p values of less than .05 to be statistically significant. We calculated 95% confidence intervals for rates as exact binomial confidence intervals. We analyzed data using Statistical Package for the Social Sciences (SPSS) 17.0 (SPSS, Chicago, IL, USA).

3. Results

Between May 2009 and November 2010, the study sites enrolled 301 women, 139 (46.2%) who chose home use of mifepristone and 162 (53.8%) who chose office use. The proportion of women who chose home use ranged from 41%–54% among the four study sites. Thirteen women (9.4%) in the home-use group and 25 women (15.4%) in the office-use group were lost to follow up (p=.11). Outcome data were available for a total of 260 participants, and success rates did not differ between groups (96.7% for home users vs. 95.6% for office users, p=.75). Four women in the home-use group and five women in the office-use group reported visiting the emergency room (ER) for care related to their abortion. Only one of the women who visited the ER received a surgical completion as part of her care; she was also the only one who was subsequently admitted to the hospital (the other women received fluids, pain and antinausea medication). Besides that case, no serious adverse events occurred among the study participants.

Despite the nonrandomized sample, baseline characteristics, including age, gravidity and employment status, were similar for the two groups (Table 1). Home users were more likely to have had a previous abortion, but this difference was not statistically significant. Women were asked to provide reasons for their choice of where to take the mifepristone; more than half of home users cited the flexibility in schedule, and more than one fourth felt that it would be more comfortable (Table 2). Office users also reported comfort as a common reason for their choice; 28% reported that they wanted to start the process immediately, and 26% answered that they had already planned their schedule accordingly, reflecting the extensive phone counseling that precedes many medical abortion appointments.

Table 1
Participant characteristics

	Home mifepristone users n=139	Office mifepristone users n=162	p value
Age, years (mean, range)	28.0 (16–42)	27.4 (14–48)	.51
Gravidity, mean (range)	2.5 (1–9)	2.5 (1–9)	.93
Gestational age, days (mean, range)	47.3 (28–64)	47.4 (28–66)	.85
Had previous abortion, %	51.4	40.1	.06
Had previous medical abortion, %	25.5	26.1	1.0
Doing paid work, %	68.3	69.8	.80
Student, %	31.9	35.8	.54
Part-time student, %	9.4	9.9	1.0
Full-time student, %	22.5	25.9	.50

Table 2
Top five reasons for choosing mifepristone location

Home mifepristone users, n=139	Office mifepristone users, n=161
More flexibility in schedule (62%)	More comfortable (35%)
More comfortable (28%)	Want to start abortion
More private (17%)	immediately (28%)
Miss less work/school (15%)	Already planned timing (26%)
More compatible with household duties (14%)	Less anxiety (16%)
	Like provider presence (14%)

Women could give more than 1 answer.

Among participants in the home user group who returned for follow up and recorded a date and time of mifepristone administration, 74% took mifepristone at the scheduled time (defined as within a window of 12 h around the time they had recorded with the provider). Three women decided to keep the pregnancy and opted not to take the mifepristone. Of the 31 women who took the mifepristone at a time different from what they scheduled, 9 took it before, and 22 took it after their scheduled time (Table 3). For those women who delayed taking the mifepristone, the median delay was 25 h. Reasons women provided for not taking the mifepristone at the scheduled time included work/school conflicts, family schedule conflicts, wanting more time to consider the abortion and greater convenience. No participant took the mifepristone after 63 days' LMP.

Over 90% of women in both groups took the misoprostol at the scheduled time (Table 3). Participants in the home-use group were slightly more likely to take the misoprostol on a Saturday or Sunday (41% vs. 35%), but this difference was not significant. All participants took the misoprostol within 72 h of taking the mifepristone, including those women who did not take mifepristone at the scheduled time.

Nearly all women who chose home use said that they would choose to take the mifepristone at home again if they needed another abortion (95.0%), whereas 81.7% of office users said that they would choose office use again (p=.001) (Table 4). Most home users (97.5%) and 75% of office users would recommend home use to a friend (p=.001).

Participants in both groups were asked to report the best and worst features of taking the mifepristone where they did (Table 4). Home users most valued being able to schedule the bleeding around their responsibilities and found home use comfortable. Almost three fourths of home users could not cite a single worst feature; however, 11% did report feeling anxious. Office users also reported comfort as a key best feature, and about a third valued the presence of a provider when they administered the mifepristone. Four in five office users

Table 3
Timing of mifepristone and misoprostol administration

	Home mifepristone n=117	Office mifepristone n=124	p value
Mifepristone administration[a]			
Took mifepristone at scheduled time, % (n)	73.5 (86)	n/a	n/a
Took mifepristone before scheduled time, % (n)	7.7 (9)	n/a	n/a
Took mifepristone after scheduled time, % (n)	18.8 (22)	n/a	n/a
Median delay, h (range)	25 h (7 h–9 d)	n/a	n/a
Misoprostol administration			
Took misoprostol at the scheduled time, % (n)[b]	94.2 (81/86)	91.1 (113/124)	.59
Took misoprostol on the weekend, % (n)	41.0 (48/117)	35.4 (45/127)	.43
Median mifepristone–misoprostol interval, h (range)[c]	24 (6–49 h)	24 (5–69 h)	n/a

n/a=not applicable.
[a] Among women who returned for follow up and completed a patient diary.
[b] Excludes women who did not take mifepristone at the scheduled time.
[c] Clinical protocols at two sites allowed for mifepristone–misoprostol intervals as short as 6 h. Home mifepristone group is n=117 and n=125 for office mifepristone group.

could also not cite a worst feature of taking the mifepristone in the doctor's office.

There were no significant differences in the mean number of days of work missed, school missed and hours of paid childcare needed due to the abortion between study groups, although the associations are in the hypothesized directions (Table 5). Most women made no additional calls (85% for home users and 90% for office users) or unscheduled visits to the doctor's office (96% for home users and 99% for office users). Providers recommended home use in the future for over 90% of participants in both groups (95.1% for home users and 90.2% for office users).

4. Discussion

Our study shows that women are able to administer mifepristone safely and properly outside of the doctor's office and that administration under direct medical supervision is unnecessary. There were no differences in rates of efficacy or complications between participants who took the mifepristone at home or in the office. All women who opted for home use of mifepristone took it within 63 days' LMP, which is the current evidence-based gestational age limit for use, and all study participants took the misoprostol within 72 h of mifepristone administration, regardless of mifepristone

Table 4
Participant satisfaction and best/worst features of taking mifepristone at the chosen location

	Home mifepristone	Office mifepristone
Would take mifepristone in same place again, % (n)[a]	95.0 (114/120)	81.7 (103/126)
Would recommend home use to a friend, % (n)[b]	97.5 (115/118)	75.0 (93/124)
Best features (%):	n=120	n=132

[a] Participants who were not employed, not in school or did not have children were excluded from the respective analyses.

administration location. Women who took the mifepristone at home were very satisfied with their experiences, and offering this option did not result in increased burden on clinical services in the form of calls and extra visits.

Regardless of where participants chose to take the mifepristone, many reported that the ability to plan when the abortion would occur was important to them. The option of home use enhances women's ability to plan their abortion experiences. Although it is reassuring that 74% of the participants in the home-use group took the mifepristone when they said they would during their initial visit, those women who took the mifepristone at a different time made good use of their greater autonomy; some took it earlier, some later, and several women used the flexibility as an opportunity to reflect further on their abortion decision. None of these women took the mifepristone and misoprostol in a nontherapeutic manner or in a way that was inconsistent with current guidelines.

A strength of our study is that our results are readily applicable to current clinical practice. Because our study design permitted participants to choose the place of mifepristone administration, we are able to report acceptability based on choice of where to initiate the abortion. Had we randomized participants to office versus home use, we would not have been able to describe this important outcome. Some providers reported improved counseling as an unanticipated benefit of the study. The process of talking through when and where women would take the abortion pills led to a greater understanding of the participants' privacy issues and support networks.

Our study has several limitations. We cannot predict with accuracy the future uptake of home use of mifepristone among all women seeking abortion because our study sites mainly offered the option of home use to those women who had already expressed interest in medical abortion. In addition, some women may have been interested in the option of home use but did not want to enroll in a research study to be able to have the opportunity. However, as almost half of participants chose home use, it is a fair conclusion that a substantial number of women would be interested in this option if it were incorporated into regular clinical practice.

Another potential limitation of our study is that more than half of our cases came from sites that offered medical abortion on Fridays and Saturdays. Because of the large number of participants who could take mifepristone in the office and still have weekend bleeding, we were likely unable to describe adequately the potential of home use for reducing childcare costs and the number of missed days of work or school for women undergoing medical abortion.

Home use of mifepristone is an innovation that stands to improve women's abortion experiences. In states where laws require women to receive inperson counseling 24 h or more before their abortion, home use has the potential to make medical abortion more accessible to women by eliminating a doctor's visit. Women who chose home use overwhelmingly approved of it, and taking the mifepristone at home did not result in increased complications or burden on clinicians. Our results support the use of home use of mifepristone, and this option should be offered to all women who undergo medical abortion.

ABSTRACT

PURPOSE The purpose of the study was to explore patients' experiences and perspectives obtaining telemedicine medication abortion (TeleMAB) through their primary care health system.

METHODS We conducted in-depth telephone interviews with 14 English-, Spanish-, and/or Portuguese-speaking patients who received a TeleMAB between July 2020 and December 2021, within a large primary care safety-net community health system in Massachusetts. We created and piloted a semistructured interview guide informed by patient-clinician communication frameworks and prior studies on patient experiences with TeleMAB. We analyzed data using reflexive thematic analysis and summarized main themes.

RESULTS Overall, participants found TeleMAB services in their primary care health system acceptable, positive, and easy. Participants discussed how TeleMAB supported their ability to exercise control, autonomy, and flexibility, and decreased barriers experienced with in-clinic care. Many participants perceived their primary care health system as the place to go for any pregnancy-related health care need, including abortion. They valued receiving abortion care from their established health care team within the context of ongoing social and medical concerns.

CONCLUSIONS Patients find TeleMAB from their primary care health system acceptable and beneficial. Primary care settings can integrate TeleMAB services to decrease care silos, normalize abortion as a part of comprehensive primary care, and improve access through remote care offerings. TeleMAB supports patients' access and autonomy, with the potential to benefit many people of reproductive age.

INTRODUCTION

Decades of abortion restrictions decrease equitable access to care, contribute to America's growing maternal mortality crisis, and exacerbate abortion stigma.[1-5] State-specific restrictions have singled out abortion providers and patients, enacting laws that are medically unnecessary and politically motivated. Laws include complete abortion bans, gestational duration limits, waiting periods, insurance coverage, unnecessary ultrasounds, need for specialized ambulatory surgical centers, and restrictions on telemedicine.[6] Restrictions further marginalize underserved communities, disproportionately affecting people who identify as Black, Indigenous, and people of color (BIPOC) who make up about 70% of those who obtain abortion services.[7,8] These inequities have worsened since June 2022 with the U S Supreme Court decision in *Dobbs v. Jackson Women's Health Organization* (*Dobbs*) with almost one-half of all US states subsequently severely restricting or banning abortion care altogether.[9]

Primary care plays a critical role caring for the most underserved populations in the US health care system.[10-12] Yet, before the *Dobbs* ruling few primary care practices offered abortion; 95% of abortions occurred in stand-alone clinics outside of where patients get their usual medical care.[13-16] Importantly, abortion in primary care settings has been shown to be safe, feasible, and effective.[17-20] In addition, some patients prefer abortion within primary care, compared with independent abortion clinics, for reasons of trust, familiarity, privacy, and provider comfort.[21-23]

During the 2019 coronavirus pandemic (COVID-19), several primary care practices initiated direct-to-patient telemedicine medication abortion (TeleMAB)

and mailed pills to patients.[24] Research shows that TeleMAB by primary care is feasible and efficient.[25,26] To date, however, no studies have evaluated patients' experiences regarding obtaining TeleMAB through their regular primary care health system.[27,28] Patient experience is an important aspect of patient-centered care and to thus understanding their perceptions enhances the delivery of care.[29] Therefore, we interviewed patients who completed TeleMAB through their primary care health system to understand their experiences.

METHODS

Study Design, Setting, and Sample

From March-May 2022, we interviewed a convenience sample of patients who received TeleMAB within a large primary care safety-net community health system in Massachusetts. This health system cares for a culturally diverse patient population of approximately 120,000 patients who mostly hold public or subsidized health insurance. Eligibility criteria included patients who received a TeleMAB between July 28, 2020 and December 31, 2021, had medications delivered, and spoke and understood English, Spanish, and/or Portuguese (n = 47). Using electronic medical records, D.N. generated a list of eligible participants. Interviewers called patients via encrypted teleconferencing software up to 5 times over 2 weeks and shared study information. Consent forms were e-mailed in the participant's language or patients provided verbal consent. D.N. did not call any patient for whom she had provided care and only identified as a researcher and not a physician. The 2 Institutional Review Boards of the involved institutions, University of Washington and Cambridge Health Alliance, approved this study. We followed the Consolidated Criteria for Reporting Qualitative Research (COREQ) reporting guidelines.[30]

Telemedicine Medication Abortion Workflow

Primary care clinics in this health system began providing in-clinic medication abortion (MAB) in 2003. In July 2020 the health system implemented direct-to-patient, TeleMAB services, which entailed the use of video visits or synchronous telephone calls between the clinician and patient. When patients expressed the need for a medication abortion, the health system offered them in-clinic or TeleMAB appointments. For patients who chose TeleMAB, the clinician assessed eligibility for remote care including patient location in Massachusetts at time of visit and assessment of gestational dating and ectopic pregnancy risk based on clinical history. The clinician counseled eligible patients on expected process, e-mailed consent forms for electronic signature, and placed a pharmacy order to send a package which was delivered by the health system's courier with mifepristone, misoprostol, anti-nausea medications, analgesics, a urine pregnancy test, and an instruction printout. The clinic scheduled each patient for a 1- to 2-week follow-up telemedicine appointment. Patients could choose to have any or all aspects of care via telemedicine or in-clinic.

Data Collection

We created a semistructured interview guide (Supplemental Appendix, 1.0 - 2.0) informed by the Miller patient-provider communication framework, prior studies on patient experiences with TeleMAB, and the research team's ongoing work exploring patients' experiences with TeleMAB at a primary care–based reproductive health clinic.[31-34] We chose Miller's framework because it includes key components of patient-centered communication and the medium of communication used, ie, telemedicine. Interviewers (D.N., S.S., A.E.F.) each pre-tested the guide with people of reproductive age and refined the questions based on their feedback (Supplemental Appendix, 3.0). All interviews were audio recorded, transcribed, and quality checked.[35,36] After the interview, participants self reported sociodemographic characteristics (Supplemental Appendix, 4.0) and received a $50 gift card.

Analysis

S.S. and A.E.F. performed the study analysis using reflexive thematic analysis.[37] They read transcripts, made conceptual notes, met to discuss potential codes, developed a codebook, and considered how the constructs related to a broader framework of patient experience. S.S. and A.E.F. used Dedoose software (SocioCultural Research Consultants) to manage, sort, and code data. They simultaneously coded 4 transcripts, discussed discrepancies in coding after each one, and refined the codebook accordingly. They coded the remaining transcripts independently (5 each) and met to refine study findings. The analytic team reached data saturation on key themes.[38]

Research Team and Reflexivity

D.N., A.T., and H.M. are family physicians who provided primary care including abortion at the study site. H.M. spearheaded TeleMAB implementation at the study site in June 2020. H.M., A.T., and D.N. were mentored and trained in key concepts of qualitative research by A.E.F. at the beginning of this study. S.S. is an MPH graduate and is a PhD student with a focus on reproductive health research with 4 years of experience conducting qualitative research. A.E.F. is a PhD graduate in public health with experience working in abortion policy and qualitative research. E.M.G. is a complex Family Planning Fellowship–trained practicing physician with master-level training in qualitative research. In terms of reflexivity, the team used Miller's framework which is based in patient-centered communication to shape the collected data and analysis. The analysts incorporated a reflexive process that deepened interpretations of the data and helped build cohesive and structured findings while reflecting on their own biases. A.E.F. is pro-telehealth and medication abortion, and A.F., D.N., H.M., and E.M.G. are pro-primary care, which may have influenced our interpretation of the data and the summary of findings.

RESULTS

Of 47 eligible patients, 14 (30%) agreed to an interview, 9 declined, 9 hung up after our introduction, 1 did not remember their appointment and was not interviewed, and 14 did not respond. One participant did not provide demographic information due to limited time. The other 13 participants identified as female, aged 26 to 42 years, and 10 (71.4%) were parents to children aged 8 months to 15 years. Six (42.8%) identified as African American/Black, 3 (21.4%) as Asian/Pacific Islander/Native Hawaiian, 2 (14.3%) as White and Black, 1 (7%) as White, and 1 as Hispanic/Latino. Eleven were interviewed in English, 2 in Portuguese, and 1 in Spanish.

Ease of Process of Obtaining TeleMAB in Primary Care

Overall, participants found TeleMAB in primary care acceptable, beneficial, and straightforward (Table 1). Participants felt provider counseling prepared them well and expressed confidence in having necessary information to successfully complete their abortion. One noted, "I was very confident and relaxed that everything was going to go right. They made me feel good about it. I wasn't scared" (ID 10, age unknown). They received clear instructions regarding medication use, expected side effects, and contact information for questions. Additionally, participants highlighted how caring interactions with staff amplified the ease of the process. For example, one participant, who initially felt overwhelmed by their pregnancy-related decisions, ultimately felt the experience was easy because of the support they received from their clinician and support staff.

Participants felt comfortable calling the health system or using their online patient portal to contact their providers to schedule appointments or ask questions. They shared having positive experiences with the medication delivery system, noting the simplicity and reliability of the service: " [The

Table 1. Excerpts Illustrating Patient Experience With TeleMAB Within Primary Care

Theme	Description	Illustrative Quotes
Ease of process of obtaining telemedicine medication abortion in primary care		
Patient-centered counseling and preparation	Participants reflected on having effective, patient-centered counseling throughout their TeleMAB experience and having clearly communicated instructions on how to use the medications and what to expect. Clinicians were also perceived as kind and non-judgmental. This enhanced participants' comfort and confidence with their TeleMAB.	#1 "Everything went well, the support they gave me, the information they gave me was complete and the process was exactly like the doctor told me it was going to be and everything turned out fine." (ID 3, age 28) #2 "She called again, [after the initial consultation], offered me support and she guided me through the steps on how to take medicine, what I'd feel, any side effects, if there were any issues - that they're just a phone call away… Very friendly. And again, they were great as far as support and everything." (ID 10, unknown age) #3 "Just dealing with people, making medication easy and making it simple to understand how to take it, the whole experience for me, someone who didn't plan to be pregnant, it was the most easy experience I've ever been through. And I would never have ever expected to go through an abortion experience like that, to be so simple." (ID 33, age 26)
Simplicity of the service	Participants found the process of scheduling appointments, contacting providers, and using the medication delivery system familiar, simple, easy, and reliable.	#4 "So, every time I needed to speak to her or set up an appointment, I was able to get a hold of either her or the other doctor that was in my case. They were there when I needed help." (ID 48, age 31) #5 "They set up a date to send the medication to my home, and a person delivered it to my hand. I had to sign the form, and I did the procedure at night." (ID 15, age 31) #6 "I trusted [the primary care system] and I knew how the process went, and I knew some of the people, and how things would go… I know how to message them and how to call them. Things like that made it feel familiar and easy to engage in. … Versus, I've never actually talked to anyone at [an abortion clinic] ever. So I'd have to figure out how to even set it up. So, I didn't have to go through that process." (ID 46, age 34)
Familiarity and trust in primary care system	Existing relationships and familiarity within one's primary care system made participants feel more comfortable navigating their abortion care.	#7 "Yeah, so prior to my first pregnancy, [my primary care doctor is] who I see for everything. So I didn't have to worry about finding new doctors for anything. She's who I go to." (ID 48, age 31) #8 "I felt more comfortable because I've been here for a minute, it's not my first pregnancy scare [with this clinic], so I knew that I could trust in them and rely on them." (ID 33, age 26) #9 "I've always had my PCP [in the health system] and that's where I had my baby and got all my care around that pregnancy and had really great experiences." (ID 46, age 34)

Note: Fourteen Massachusetts women of reproductive age were interviewed in 2022. Excerpts have been edited for clarity.

Table 1. Excerpts Illustrating Patient Experience With TeleMAB Within Primary Care *(continued)*

Theme	Description	Illustrative Quotes
Advantages of telemedicine		
Flexibility over where and when to take the appointment	Telemedicine allowed participants to take appointments in places and times that fit into their lives, reducing logistical, financial, health, and time-related burdens.	#10 "The televisit is convenient. It saves you time to move around. For instance, I have kids, so honestly, everywhere I will be going, I will be going with them, because I have no one to stay with them… And also the transport fare. I don't drive, so I have to transport myself to the hospital. Then the stress of looking after the kids, while I, at the same time, see the doctor, and all the examination processes. So [telemedicine] was quite convenient for me." (ID 53, age 34) #11 "It was fine. It was actually a slow day [at work], so thankfully I was able to talk to my doctor and get everything that I needed… I had my headphones in so nobody really got to hear the conversation. I was able to answer the questions that needed to be answered, and just be able to take those next four steps." (ID 33, age 26) #12 "They gave me the option of going to the clinic or having the appointment over the phone and I felt really comfortable doing it over the phone." (ID 3, age 28)
Autonomy and control	Telemedicine options afforded participants greater autonomy and control over their space, emotions, and overall experience. They felt more comfortable taking care of their needs in the comfort of their homes.	#13 "I was actually really sick during that pregnancy. I was vomiting the whole time up until the end of the abortion. So that was definitely a plus of not having to leave the house and be able to be in the comfort of my home and have the visits there" (ID 10, age unknown). #14 "You could just be transparent and bare and not have to worry about being stripped in front of someone…Having done both, I would go virtual again a billion times over… I was able to be more free with [my clinician]… And I could light a cigarette or if I needed to pace around or move or get ice water or anything, it was all at my disposal right there… They gave me control of a situation that was uncontrollable to me and was freaking me out … I felt very in the driver's seat." (ID 9, age 32)
Primary care normalizes abortion care		
Continuity of care	Participants felt more comfortable having abortion care in the primary care setting because their provider knew them and their needs and could take care of them in the full context of their health and social histories.	#15 "Yes, I like [abortion services provided at a primary care center]. It's a great clinic, where you can get treatment for everything. It's nice. It's because when you see an abortion clinic, it feels like a strange place. A place dedicated to abortions. It sounds strange. However, when it's a hospital where they treat all kinds of diseases and offer many treatments, it sounds better." (ID 15, age 31)
Primary care as a protective force	Participants felt their primary care providers helped reduce feelings of isolation, affirm their decisions, and mitigate difficult situations.	#16 "I'm a very traumatized person. I had a lot of childhood trauma and they just put ease in my life for the first time. I was just so appreciative. Because kindness isn't owed to you, it's something given as a gift… [the clinician] didn't have judgment on me." (ID 9, age 32) #17 "I didn't know that it was going to go so bad… but I kept my cries in and I was able to talk to [the primary care doctor] about it. I just told him that I totally appreciate him being there for me because, besides the boyfriend, I had nobody else that I could speak to about everything that I went through." (ID 54, age 33) #18 "I was being pressured (by the CPC) to make a different decision than what I came here for, but they want to try to tell me that they understand me and that they feel my emotion. You don't feel my emotion or understand my decision, if you're trying to force me to do something that I've even planned to come here to do." (ID 33, age 26)

CPC = crisis pregnancy center; PCP = primary care physician; teleMAB = telemedicine medication abortion.

Note: Fourteen Massachusetts women of reproductive age were interviewed in 2022. Excerpts have been edited for clarity.

medications] came at the time and date that it was supposed to come" (ID 10, age unknown). When asked what one participant liked about the delivery service, they responded, "All I had to do was just sit back at home and wait. It was great. It was the best part" (ID 15, age 31).

Existing relationships within the participants' primary care network made them feel comfortable navigating their care. While some participants were cared for by their own primary care physicians (PCPs), many participants received care by providers who were not necessarily their primary care doctor. Their trust extended from their provider to the health system. Participants felt more comfortable reaching out to their primary care network than to unfamiliar abortion clinics (Table 1, #6). While some felt comfortable asking their provider about pregnancy options because of existing relationships (Table 1, 7), others knew the health system provided abortion from prior pregnancy experiences (Table 1, #8 & #9). Despite being cared for by multiple

individuals—administrative staff, nurses, and physicians—participants described smooth transitions of care.

Advantages of Telemedicine

Participants discussed how TeleMAB supported their ability to exercise control, autonomy, and flexibility (Table 1). In particular, patients described decreased interruptions to their daily lives, increased agency over their chosen surroundings and access to preferred coping mechanisms. For example, one participant shared that they completed their appointment while at work. Another participant noted a sense of agency by having their appointment at their desired location. One participant felt too sick from pregnancy symptoms to travel and valued staying home during the appointment. One shared, "It just made it an overall easy experience, and I didn't even have to go to my doctor for this. I'm doing this in my own time, my own energy, in my own home" (ID 33, age 26). Being in their own space gave participants greater access to coping strategies that helped decrease their anxiety and helped them feel safer expressing emotions and private information, "I could be a lot more vulnerable because I was right in my bed. And then you didn't have to worry about crying or wiping your face up and seeing people after that. Or people overhearing you in the office or something. You were just at home so you could just be like… this is worrying me" (ID 9, age 32).

Primary Care Normalizes Abortion Care

Many participants perceived their primary care system as the place to go for pregnancy-related needs, including abortion. Their first instinct when they missed their period was "to call [their] PCP" (ID 54, age 33). Participants felt abortion should be part of routine primary care, whereas an independent abortion clinic seemed more isolating and "strange." Participants felt comfortable knowing that their abortion providers had access to their medical histories: "It was just comforting knowing I know the person [doing the abortion care] and we've seen each other multiple times before and she knows a little bit of my history and what I was going through at the time, so we had a good relationship as far as communication" (ID 10, age unknown). Another participant shared how their physician considered their history of gastrointestinal issues and the potential interaction of their chronic medications, noting, "she actually probably saved me from an overdose, too" (ID 9, age 32). They appreciated that their provider delivered care in the full context of their health and social needs.

Although complications from MABs are extremely rare, when medical or social challenges did arise participants reported their PCPs helped assuage difficult situations (Table 1). One participant had excessive bleeding after taking the medications and visited the emergency department, but felt relieved to talk to their PCP throughout the complication. Another participant inadvertently initially visited a crisis pregnancy center where they felt pressured to continue the pregnancy despite being certain about wanting an abortion. They subsequently had an overall affirming abortion experience with their PCP, however, as "I feel like my doctor did a really good job of giving me my options, but also giving me the opportunity to choose what I want to do, regardless of what they believe or regardless of what they feel is right," highlighting the importance of a trusted PCP relationship as a protective force in difficult situations (ID 33, age 26).

DISCUSSION

Overall, participants who received TeleMABs within their primary care health system appreciated the ease of process, clear communication, non-judgmental interactions, continuity of care, and familiarity and trust with the system. Participants' TeleMAB experience contributed to increased feelings of autonomy, flexibility, and comfort. Participants noted a positive experience regardless of whether their PCP or another primary care clinician within the health system provided abortion care, but when difficult situations arose, established relationships with one's PCP helped mitigate the impact. Our findings highlight the ability of a primary care system to provide safe and positive abortion experiences in a high-quality, patient-centered way.

The more abortion is integrated into routine health care, the more normalized it becomes.[39] In our study, participants highlighted how familiarity with the system, ongoing patient-provider relationships, and being cared for in the context of their overall health made the abortion process more normal. Prior studies have found that providing emotional support and having a supportive patient-provider relationship reduces individual-level abortion stigma.[40] Though further research is needed on the link between normalizing care and decreasing stigma, we hypothesize that the factors found in our study which are unique to primary care may also destigmatize abortion care.

Although first trimester abortion care falls within the skill set of PCPs, significant barriers to providing abortion services remain. Barriers include limited abortion education within clinical training, policy restrictions limiting its provision in Federally Qualified Health Centers, onerous regulations around mifepristone prescribing, and state-level abortion bans.[41-43] There are limitations of implementing new abortion care models in states with complete bans. In states where access is protected or with limited restrictions, however, primary care systems can increase abortion access by implementing TeleMAB services, restructuring pay scale and reimbursement models, and partnering with abortion funds. In states where abortion bans exist, primary care providers can advocate with their state legislatures to remove state-level abortion restrictions.

Our study has several limitations. Because we interviewed participants 4 to 22 months after receiving TeleMAB (average of 7.7), our findings may be susceptible to limited recall. Our findings may reflect more positive patient experiences as people with negative experiences may have been less

willing to participate. Our patient population resided in Massachusetts, a state with better abortion access compared with other states, decreasing its generalizability.[44] Additionally, the majority of patients were English speaking, which may have biased our findings toward the English-speaking subgroup. We did not track if the participants received TeleMAB from their regular PCPs or whether appointments were via telephone or video. Future research could explore primary care patients' experiences prospectively, in more languages, telehealth modality, and with a larger sample size to address these limitations. While we hypothesize that integrating TeleMAB into primary care would increase abortion equity particularly for historically marginalized populations who have experienced racism and discrimination within medicine, this should be investigated further in future research.[45]

Findings from our study support primary care clinicians in advocating for TeleMAB implementation in ways that best address patients' needs. Since primary care clinicians vastly outnumber obstetrician-gynecologists in the United States and are more likely to practice in underserved and rural communities, barriers must be addressed to increase access and improve patient experience. Ultimately, a collaborative effort across state Departments of Health, primary care practices, and reproductive rights and justice organizations is needed to begin dismantling barriers to primary care provision of MAB, increasing access to care for millions.[46]

FDA U.S. FOOD & DRUG ADMINISTRATION

ANDA 091178

ANDA APPROVAL

(b) (6), (b) (4)
GenBioPro, Inc.
(b) (6), (b) (4)
Attention: (b) (6), (b) (4)

Dear Sir:

This letter is in reference to your abbreviated new drug application (ANDA) received for review on February 3, 2009, submitted pursuant to section 505(j) of the Federal Food, Drug, and Cosmetic Act (FD&C Act) for Mifepristone Tablets, 200 mg.

Reference is also made to the complete response letter issued by this office on February 23, 2018, and to any amendments thereafter.

We have completed the review of this ANDA and have concluded that adequate information has been presented to demonstrate that the drug is safe and effective for use as recommended in the submitted labeling. Accordingly, the ANDA is **approved**, effective on the date of this letter. The (b) (6) has determined your Mifepristone Tablets, 200 mg, to be bioequivalent and, therefore, therapeutically equivalent to the reference listed drug (RLD), Mifeprex Tablets, 200 mg, of Danco Laboratories, LLC.

Under section 506A of the FD&C Act, certain changes in the conditions described in this ANDA require an approved supplemental application before the change may be made.

RISK EVALUATION AND MITIGATION STRATEGY (REMS) REQUIREMENTS

Section 505-1 of the FD&C Act authorizes FDA to require the submission of a risk evaluation and mitigation strategy (REMS), if FDA determines that such a strategy is necessary to ensure that the benefits of the drug outweigh the risks [section 505-1(a)]. In accordance with section 505-1(i) of the FD&C Act, a drug that is the subject of an ANDA under section 505(j) is subject to certain elements of the REMS required for the applicable listed drug.

The details of the REMS requirements were outlined in our letter dated June 15, 2011. In that letter, you were also notified that pursuant to section 505-1(i) of the FD&C Act, a drug that is the subject of an ANDA and the listed drug it references must use a single, shared system for elements to assure safe use (ETASU), unless FDA waives that requirement.

Your REMS, known as the Mifepristone REMS Program, submitted on May 30, 2017; is approved, and will be posted on the FDA REMS website: http://www.fda.gov/rems

The REMS consists of ETASU and an implementation system.

U.S. Food & Drug Administration
10903 New Hampshire Avenue
Silver Spring, MD 20993
www.fda.gov

Your REMS must be fully operational before you introduce Mifepristone Tablets, 200 mg, into interstate commerce.

The Mifepristone REMS uses a single, shared system for the ETASU. This single, shared system REMS Program currently includes the products listed on the FDA REMS website, available at http://www.fda.gov/rems. Other products may be added in the future if additional NDAs or ANDAs are approved.

Under section 505-1(g)(2)(C) of the FD&C Act, FDA can require the submission of a REMS assessment if FDA determines an assessment is needed to evaluate whether the REMS should be modified to ensure the benefits of the drug outweigh the risks or to minimize the burden on the healthcare delivery system of complying with the REMS.

We remind you that you must include an adequate rationale to support a proposed REMS modification for the addition, modification, or removal of any goal or element of the REMS, as described in section 505-1(g)(4) of the FD&C Act.

We also remind you that section 505-1(f)(8) of the FD&C Act prohibits holders of an approved covered application from using any element to assure safe use to block or delay approval of an application under section 505(b)(2) or (j). A violation of this provision in 505-1(f) could result in enforcement action.

Prominently identify any submission containing a REMS assessment or proposed modifications of the REMS with the following wording in bold capital letters at the top of the first page of the submission as appropriate:

ANDA 091178 REMS ASSESSMENT

NEW SUPPLEMENT FOR ANDA 091178/S-000
CHANGES BEING EFFECTED IN 30 DAYS
PROPOSED MINOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR ANDA 091178/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED MAJOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR ANDA 091178/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED REMS MODIFICATIONS DUE TO SAFETY LABELING CHANGES
SUBMITTED IN SUPPLEMENT XXX

Should you choose to submit a REMS revision, prominently identify the submission containing the REMS revisions with the following wording in bold capital letters at the top of the first page of the submission:

REMS REVISION FOR ANDA 091178

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, are only in PDF format, they may be submitted as such, but the preference is to include as many as possible in Word format.

SUBMISSION OF REMS DOCUMENT IN SPL FORMAT

In addition to submitting the proposed REMS as described above, you can also submit the REMS document in Structured Product Labeling (SPL) format. If you intend to submit the REMS document in SPL format, include the SPL file with your proposed REMS submission.

For more information on submitting REMS in SPL format, please email REMSWebsite@fda.hhs.gov

REPORTING REQUIREMENTS

Postmarketing reporting requirements for this ANDA are set forth in 21 CFR 314.80-81 and 314.98 and at section 506I of the FD&C Act. The Agency should be advised of any change in the marketing status of this drug or if this drug will not be available for sale after approval. In particular, under section 506I(b) of the FD&C Act, you are required to notify the Agency in writing within 180 days from the date of this letter if this drug will not be available for sale within 180 days from the date of approval. As part of such written notification, you must include (1) the identity of the drug by established name and proprietary name (if any); (2) the ANDA number; (3) the strength of the drug; (4) the date on which the drug will be available for sale, if known; and (5) the reason for not marketing the drug after approval.

PROMOTIONAL MATERIALS

You may request advisory comments on proposed introductory advertising and promotional labeling materials prior to publication or dissemination. Please note that these submissions are voluntary. To do so, submit, in triplicate, a cover letter requesting advisory comments, the proposed materials in draft or mock-up form with annotated references, and the package insert (PI), Medication Guide, and patient PI (as applicable) to:

OPDP Regulatory Project Manager
Food and Drug Administration
Center for Drug Evaluation and Research
Office of Prescription Drug Promotion
5901-B Ammendale Road
Beltsville, MD 20705

Alternatively, you may submit a request for advisory comments electronically in eCTD format. For more information about submitting promotional materials in eCTD format, see the draft Guidance for Industry (available at: http://www.fda.gov/downloads/Drugs/GuidanceComplianceRegulatoryInformation/Guidances/UCM443702.pdf).

You must also submit final promotional materials and package insert(s), accompanied by a Form FDA 2253, at the time of initial dissemination or publication [21 CFR 314.81(b)(3)(i)]. Form FDA 2253 is available at http://www.fda.gov/downloads/AboutFDA/ReportsManualsForms/Forms/UCM083570.pdf. Information and Instructions for completing the form can be found at http://www.fda.gov/downloads/AboutFDA/ReportsManualsForms/Forms/UCM375154.pdf. For more information about submission of promotional materials to the Office of Prescription Drug Promotion (OPDP), see http://www.fda.gov/AboutFDA/CentersOffices/CDER/ucm090142.htm.

ANNUAL FACILITY FEES

The Generic Drug User Fee Amendments of 2012 (GDUFA) (Public Law 112-144, Title III) established certain provisions[1] with respect to self-identification of facilities and payment of annual facility fees. Your ANDA identifies at least one facility that is subject to the self-identification requirement and payment of an annual facility fee. Self-identification must occur by June 1st of each year for the next fiscal year. Facility fees must be paid each year by the date specified in the *Federal Register* notice announcing facility fee amounts.

All finished dosage forms (FDFs) or active pharmaceutical ingredients (APIs) manufactured in a facility that has not met its obligations to self-identify or to pay fees when they are due will be deemed misbranded. This means that it will be a violation of federal law to ship these products in interstate commerce or to import them into the United States. Such violations can result in prosecution of those responsible, injunctions, or seizures of misbranded products. Products misbranded because of failure to self-identify or pay facility fees are subject to being denied entry into the United States.

CONTENT OF LABELING

As soon as possible, but no later than 14 days from the date of this letter, submit, using the FDA automated drug registration and listing system (eLIST), the content of labeling [21 CFR 314.50(l)] in structured product labeling (SPL) format, as described at http://www.fda.gov/ForIndustry/DataStandards/StructuredProductLabeling/default.htm, that is identical in content to the approved labeling (including the package insert, and any patient package insert and/or Medication Guide that may be required). Information on submitting SPL files using eLIST may be found in the guidance for industry titled "SPL Standard for Content of Labeling Technical Qs and As" at http://www.fda.gov/downloads/DrugsGuidanceComplianceRegulatoryInformation/Guidances/UCM072392.pdf. The SPL will be accessible via publicly available labeling repositories.

Sincerely yours,

{See appended electronic signature page}

APPROVAL LETTER

U.S. FOOD & DRUG ADMINISTRATION

NDA 020687/S-025

SUPPLEMENT APPROVAL

Danco Laboratories, LLC
(b) (4), (b) (6)
P.O. Box 4816
New York, NY 10185

Dear (b) (4), (b) (6):

Please refer to your supplemental new drug application (sNDA) dated and received June 22, 2022, and your amendments, submitted under section 505(b) of the Federal Food, Drug, and Cosmetic Act (FDCA) for Mifeprex (mifepristone) Tablets, 200 mg.

This Prior Approval sNDA provides for modification to the approved single, shared system (SSS) risk evaluation and mitigation strategy (REMS) for mifepristone 200 mg tablets, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation, as well as corresponding labeling revisions to the prescribing information and the Medication Guide to align with the modification to the Mifepristone REMS Program. This SSS REMS is known as the Mifepristone REMS Program.

APPROVAL & LABELING

We have completed our review of the supplemental application, as amended. It is approved effective the date of this letter.

CONTENT OF LABELING

As soon as possible, but no later than 14 days from the date of this letter, submit the content of labeling [21 CFR 314.50(l)] in structured product labeling (SPL) format using the FDA automated drug registration and listing system (eLIST), as described at FDA.gov.[1] Content of labeling must be identical to the enclosed labeling (text for the Prescribing Information and Medication Guide), with the addition of any labeling changes in pending "Changes Being Effected" (CBE) supplements, as well as annual reportable changes not included in the enclosed labeling.

[1] http://www.fda.gov/ForIndustry/DataStandards/StructuredProductLabeling/default.htm

Information on submitting SPL files using eList may be found in the guidance for industry *SPL Standard for Content of Labeling Technical Qs and As*.[2]

The SPL will be accessible from publicly available labeling repositories.

Also within 14 days, amend all pending supplemental applications that include labeling changes for this NDA, including CBE supplements for which FDA has not yet issued an action letter, with the content of labeling [21 CFR 314.50(l)(1)(i)] in Microsoft Word format, that includes the changes approved in this supplemental application, as well as annual reportable changes. To facilitate review of your submission(s), provide a highlighted or marked-up copy that shows all changes, as well as a clean Microsoft Word version. The marked-up copy should provide appropriate annotations, including supplement number(s) and annual report date(s).

We request that the labeling approved today be available on your website within 10 days of receipt of this letter.

REQUIRED PEDIATRIC ASSESSMENTS

Under the Pediatric Research Equity Act (PREA) (21 U.S.C. 355c), all applications for new active ingredients (which includes new salts and new fixed combinations), new indications, new dosage forms, new dosing regimens, or new routes of administration are required to contain an assessment of the safety and effectiveness of the product for the claimed indication in pediatric patients unless this requirement is waived, deferred, or inapplicable.

Because none of these criteria apply to your application, you are exempt from this requirement.

RISK EVALUATION AND MITIGATION STRATEGY (REMS) REQUIREMENTS

The Mifepristone REMS Program, of which Mifeprex is a member, was originally approved on April 11, 2019, and the most recent REMS modification was approved on May 14, 2021. The Mifepristone REMS Program consists of elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS.

In order to ensure the benefits of Mifeprex outweigh its risks and to minimize burden on the healthcare delivery system of complying with the REMS, we determined that you were required to make the REMS modifications outlined in our REMS Modification

[2] We update guidances periodically. For the most recent version of a guidance, check the FDA Guidance Documents Database https://www.fda.gov/RegulatoryInformation/Guidances/default.htm.

Notification letter dated December 16, 2021. In addition the following modifications were communicated during the course of the review:

- Revisions to the REMS goal to align with the updated REMS requirements.
- Replacing serial number with recording of NDC and lot number of mifepristone dispensed.
- Additional edits for clarification and consistency in the REMS Document and REMS materials (*Prescriber Agreement Forms, Patient Agreement Form,* and *Pharmacy Agreement Forms*).

Your proposed modified REMS, received on June 22, 2022, amended and appended to this letter, is approved. The modified REMS consists of the elements to assure safe use, implementation system, and a timetable for submission of assessments of the REMS.

The modification of the approved REMS must be fully implemented within 120 calendar days of this letter.

This shared system REMS, known as the Mifepristone REMS Program, currently includes those products listed on the FDA REMS website[3].

Other products may be added in the future if additional NDAs or ANDAs are approved.

The timetable for submission of assessments of the REMS must be revised to one year from the date of the approval of the modified SSS REMS (1/3/2023) and annually thereafter.

The revised REMS assessment plan must include, but is not limited to, the following:

Program Implementation and Operations

1. REMS Certification Statistics
   a. Prescribers
      i. Number of certified prescribers who have certified with the Sponsor's distributor(s) and number who have submitted *Prescriber Agreement Forms* to Certified Pharmacies
      ii. Number and percentage of newly certified prescribers
      iii. Number and percentage of active certified prescribers (i.e., who ordered mifepristone or submitted a prescription during the reporting period)

   b. Pharmacies

[3] https://www.accessdata.fda.gov/scripts/cder/rems/index.cfm

i. Number of certified pharmacies
ii. Number and percentage of newly certified pharmacies
iii. Number and percentage of active certified pharmacies (i.e., that dispensed mifepristone during the reporting period)

c. Wholesalers/Distributors
i. Number of authorized wholesalers/distributors
ii. Number and percentage of newly authorized wholesalers/distributors
iii. Number and percentage of active authorized wholesalers/distributors (i.e. that shipped mifepristone during the reporting period)

2. Utilization Data
a. Total number of tablets shipped by wholesalers/distributors, stratified by Certified Prescriber or Certified Pharmacy location
b. Number of prescriptions dispensed from pharmacies

3. REMS Compliance Data
a. Audits: Summary of audit activities for each stakeholder (i.e., certified pharmacies and wholesalers/distributors) including but not limited to:
i. A copy of the final audit plan for each stakeholder type (provide for the current reporting period)
ii. The number of audits expected, and the number of audits performed
iii. The number and type of deficiencies noted
iv. For those with deficiencies noted, report the corrective and preventive actions (CAPAs) required, if any, to address the deficiencies, including the status (e.g., completed, not completed, in progress) (provide for the current reporting period)
v. For any stakeholders that did not complete the CAPA within the timeframe specified in the audit plan, describe actions taken (provide for the current reporting period)
vi. A summary report of all resulting changes to processes and procedures necessary to ensure compliance with the REMS requirements (provide for the current reporting period)

b. A summary report of non-compliance, associated corrective action plans (CAPAs), and the status of CAPAs including but not limited to:
i. A copy of the final non-compliance plans for Pharmacies and Distributors (provide for the current reporting period)
ii. For each instance of noncompliance below (iii-v), report the following information (provide for the current reporting period):
1. A unique, anonymized ID for the stakeholder(s) associated with the non-compliance event to enable tracking over time
2. The source of the non-compliance data (e.g., self-reported, audit, other)
3. A root cause analysis of the non-compliance

4. Actions to prevent future occurrences and outcomes of such actions

iii. Prescriber compliance

1. Number and percentage of certified prescribers who became decertified as a result of non- compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
2. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

iv. Pharmacy compliance

1. Number and percentage of prescriptions dispensed that were written by prescriber(s) who did not submit a Prescriber Agreement to the dispensing Certified Pharmacy
2. Number and percentage of mifepristone tablets dispensed by non-certified pharmacies
3. Number and percentage of pharmacies that became decertified as a result of non- compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
4. An assessment of prescription delivery timelines, including percentage delivered more than four days after receipt of the prescription, duration and causes for delay. A proposal for this assessment will be submitted within 60 days of the approval of the REMS Modification.
5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

v. Wholesaler/distributor compliance

1. Number of healthcare providers who successfully ordered mifepristone who were not certified
2. Number of non-certified pharmacies that successfully ordered mifepristone
3. Number of shipments sent to non-certified prescriber receiving locations
4. Number of shipments sent to non-certified pharmacy receiving locations
5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

Overall Assessment of REMS Effectiveness

The requirements for assessments of an approved REMS under section 505-1(g)(3) include with respect to each goal included in the strategy, an assessment of the extent to which the approved strategy, including each element of the strategy, is meeting the goal or whether one or more such goals or such elements should be modified.

We remind you that in addition to the REMS assessments submitted according to the timetable in the approved REMS, you must include an adequate rationale to support a

proposed REMS modification for the addition, modification, or removal of any goal or element of the REMS, as described in section 505-1(g)(4) of the FDCA.

We also remind you that you must submit a REMS assessment when you submit a supplemental application for a new indication for use, as described in section 505-1(g)(2)(A) of the FDCA. This assessment should include:

a) An evaluation of how the benefit-risk profile will or will not change with the new indication;

b) A determination of the implications of a change in the benefit-risk profile for the current REMS;

c) *If the new indication for use introduces unexpected risks*: A description of those risks and an evaluation of whether those risks can be appropriately managed with the currently approved REMS.

d) *If a REMS assessment was submitted in the 18 months prior to submission of the supplemental application for a new indication for use*: A statement about whether the REMS was meeting its goals at the time of that last assessment and if any modifications of the REMS have been proposed since that assessment.

e) *If a REMS assessment has not been submitted in the 18 months prior to submission of the supplemental application for a new indication for use:* Provision of as many of the currently listed assessment plan items as is feasible.

f) *If you propose a REMS modification based on a change in the benefit-risk profile or because of the new indication of use, submit an adequate rationale to support the modification, including*: Provision of the reason(s) why the proposed REMS modification is necessary, the potential effect on the serious risk(s) for which the REMS was required, on patient access to the drug, and/or on the burden on the health care delivery system; and other appropriate evidence or data to support the proposed change. Additionally, include any changes to the assessment plan necessary to assess the proposed modified REMS. *If you are not proposing REMS modifications*, provide a rationale for why the REMS does not need to be modified.

If the assessment instruments and methodology for your REMS assessments are not included in the REMS supporting document, or if you propose changes to the submitted assessment instruments or methodology, you should update the REMS supporting document to include specific assessment instrument and methodology information at least 90 days before the assessments will be conducted. Updates to the REMS supporting document may be included in a new document that references previous REMS supporting document submission(s) for unchanged portions. Alternatively,

updates may be made by modifying the complete previous REMS supporting document, with all changes marked and highlighted.

Prominently identify the submission containing the assessment instruments and methodology with the following wording in bold capital letters at the top of the first page of the submission:

NDA 020687 REMS ASSESSMENT METHODOLOGY
(insert concise description of content in bold capital letters, e.g.,
ASSESSMENT METHODOLOGY, PROTOCOL, SURVEY METHODOLOGIES, AUDIT PLAN, DRUG USE STUDY)

An authorized generic drug under this NDA must have an approved REMS prior to marketing. Should you decide to market, sell, or distribute an authorized generic drug under this NDA, contact us to discuss what will be required in the authorized generic drug REMS submission.

We remind you that section 505-1(f)(8) of FDCA prohibits holders of an approved covered application with elements to assure safe use from using any element to block or delay approval of an application under section 505(b)(2) or (j). A violation of this provision in 505-1(f) could result in enforcement action.

Prominently identify any submission containing the REMS assessments or proposed modifications of the REMS with the following wording in bold capital letters at the top of the first page of the submission as appropriate:

NDA 020687 REMS ASSESSMENT

or

NEW SUPPLEMENT FOR NDA 020687/S-000
CHANGES BEING EFFECTED IN 30 DAYS
PROPOSED MINOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR NDA 020687/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED MAJOR REMS MODIFICATION

or

NEW SUPPLEMENT FOR NDA 020687/S-000/
PRIOR APPROVAL SUPPLEMENT

PROPOSED REMS MODIFICATIONS DUE TO SAFETY LABELING CHANGES SUBMITTED IN SUPPLEMENT XXX

or

NEW SUPPLEMENT (NEW INDICATION FOR USE)
FOR NDA 020687/S-000
REMS ASSESSMENT
PROPOSED REMS MODIFICATION (if included)

Should you choose to submit a REMS revision, prominently identify the submission containing the REMS revisions with the following wording in bold capital letters at the top of the first page of the submission:

REMS REVISIONS FOR NDA 020687

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, or website screenshots are only in PDF format, they may be submitted as such, but Word format is preferred.

SUBMISSION OF REMS DOCUMENT IN SPL FORMAT

FDA can accept the REMS document in Structured Product Labeling (SPL) format. If you intend to submit the REMS document in SPL format, as soon as possible, but no later than 14 days from the date of this letter, submit the REMS document in SPL format using the FDA automated drug registration and listing system (eLIST).

For more information on submitting REMS in SPL format, please email FDAREMSwebsite@fda.hhs.gov
.

PATENT LISTING REQUIREMENTS

Pursuant to 21 CFR 314.53(d)(2) and 314.70(f), certain changes to an approved NDA submitted in a supplement require you to submit patent information for listing in the Orange Book upon approval of the supplement. You must submit the patent information required by 21 CFR 314.53(d)(2)(i)(A) through (C) and 314.53(d)(2)(ii)(A) and (C), as applicable, to FDA on Form FDA 3542 within 30 days after the date of approval of the supplement for the patent information to be timely filed (see 21 CFR 314.53(c)(2)(ii)). You also must ensure that any changes to your approved NDA that require the submission of a request to remove patent information from the Orange Book are submitted to FDA at the time of approval of the supplement pursuant to 21 CFR 314.53(d)(2)(ii)(B) and 314.53(f)(2)(iv).

REPORTING REQUIREMENTS

We remind you that you must comply with reporting requirements for an approved NDA (21 CFR 314.80 and 314.81).

If you have any questions, call (b) (6)

Sincerely,

LABELING

HIGHLIGHTS OF PRESCRIBING INFORMATION
These highlights do not include all the information needed to use MIFEPREX safely and effectively. See full prescribing information for MIFEPREX.

MIFEPREX® (mifepristone) tablets, for oral use
Initial U.S. Approval: 2000

WARNING: SERIOUS AND SOMETIMES FATAL INFECTIONS OR BLEEDING

See full prescribing information for complete boxed warning.

Serious and sometimes fatal infections and bleeding occur very rarely following spontaneous, surgical, and medical abortions, including following MIFEPREX use.

- **Atypical Presentation of Infection. Patients with serious bacterial infections and sepsis can present without fever, bacteremia or significant findings on pelvic examination. A high index of suspicion is needed to rule out serious infection and sepsis. (5.1)**
- **Bleeding. Prolonged heavy bleeding may be a sign of incomplete abortion or other complications and prompt medical or surgical intervention may be needed. (5.2)**

MIFEPREX is only available through a restricted program called the mifepristone REMS Program (5.3).
Before prescribing MIFEPREX, inform the patient about these risks. Ensure the patient knows whom to call and what to do if they experience sustained fever, severe abdominal pain, prolonged heavy bleeding, or syncope, or if they experience abdominal pain or discomfort or general malaise for more than 24 hours after taking misoprostol.

----------INDICATIONS AND USAGE----------
MIFEPREX is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. (1)

----------DOSAGE AND ADMINISTRATION----------
- 200 mg MIFEPREX on Day 1, followed 24-48 hours after MIFEPREX dosing by 800 mcg buccal misoprostol. (2.1)
- Instruct the patient what to do if significant adverse reactions occur. (2.2)
- Follow-up is needed to confirm complete termination of pregnancy. (2.3)

----------DOSAGE FORMS AND STRENGTHS----------
Tablets containing 200 mg of mifepristone each, supplied as 1 tablet on one blister card (3)

----------CONTRAINDICATIONS----------
- Confirmed/suspected ectopic pregnancy or undiagnosed adnexal mass (4)
- Chronic adrenal failure (4)
- Concurrent long-term corticosteroid therapy (4)
- History of allergy to mifepristone, misoprostol, or other prostaglandins (4)
- Hemorrhagic disorders or concurrent anticoagulant therapy (4)
- Inherited porphyria (4)
- Intrauterine device (IUD) in place (4)

----------WARNINGS AND PRECAUTIONS----------
- Ectopic pregnancy: Exclude before treatment. (5.4)
- Rhesus immunization: Prevention needed as for surgical abortion. (5.5)

----------ADVERSE REACTIONS----------
Most common adverse reactions (>15%) are nausea, weakness, fever/chills, vomiting, headache, diarrhea, and dizziness. (6)

To report SUSPECTED ADVERSE REACTIONS, contact Danco Laboratories, LLC at 1-877-432-7596 or medicaldirector@earlyoptionpill.com or FDA at 1-800-FDA-1088 or *www.fda.gov/medwatch*.

----------DRUG INTERACTIONS----------
- CYP3A4 inducers can lower mifepristone concentrations. (7.1)
- CYP3A4 inhibitors can increase mifepristone concentrations. Use with caution. (7.2)
- CYP3A4 substrate concentrations can be increased. Caution with coadministration of substrates with narrow therapeutic margin. (7.3)

----------USE IN SPECIFIC POPULATIONS----------
- Pregnancy: Risk of fetal malformations in ongoing pregnancy if not terminated is unknown. (8.1)

See 17 for PATIENT COUNSELING INFORMATION, Medication Guide.

FULL PRESCRIBING INFORMATION

WARNING: SERIOUS AND SOMETIMES FATAL INFECTIONS OR BLEEDING

Serious and sometimes fatal infections and bleeding occur very rarely following spontaneous, surgical, and medical abortions, including following MIFEPREX use. No causal relationship between the use of MIFEPREX and misoprostol and these events has been established.

- **Atypical Presentation of Infection. Patients with serious bacterial infections (e.g., *Clostridium sordellii*) and sepsis can present without fever, bacteremia, or significant findings on pelvic examination following an abortion. Very rarely, deaths have been reported in patients who presented without fever, with or without abdominal pain, but with leukocytosis with a marked left shift, tachycardia, hemoconcentration, and general malaise. A high index of suspicion is needed to rule out serious infection and sepsis *[see Warnings and Precautions (5.1)]*.**
- **Bleeding. Prolonged heavy bleeding may be a sign of incomplete abortion or other complications and prompt medical or surgical intervention may be needed. Advise patients to seek immediate medical attention if they experience prolonged heavy vaginal bleeding *[see Warnings and Precautions (5.2)]*.**

Because of the risks of serious complications described above, MIFEPREX is available only through a restricted program under a Risk Evaluation and Mitigation Strategy (REMS) called the mifepristone REMS Program *[see Warnings and Precautions (5.3)]*.

Before prescribing MIFEPREX, inform the patient about the risk of these serious events. Ensure that the patient knows whom to call and what to do, including going to an Emergency Room if none of the provided contacts are reachable, if they experience sustained fever, severe abdominal pain, prolonged heavy bleeding, or syncope, or if they experience abdominal pain or discomfort, or general malaise (including weakness, nausea, vomiting, or diarrhea) for more than 24 hours after taking misoprostol.

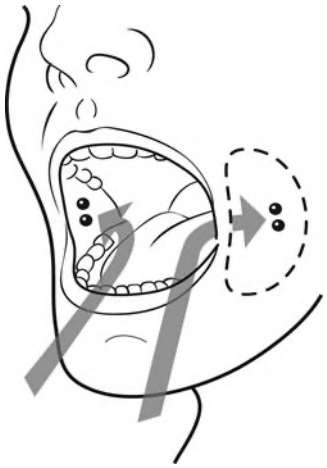
1 INDICATIONS AND USAGE

MIFEPREX is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation.

2 DOSAGE AND ADMINISTRATION

2.1 Dosing Regimen

For purposes of this treatment, pregnancy is dated from the first day of the last menstrual period. The duration of pregnancy may be determined from menstrual history and clinical examination. Assess the pregnancy by ultrasonographic scan if the duration of pregnancy is uncertain or if ectopic pregnancy is suspected.



Remove any intrauterine device (“IUD”) before treatment with MIFEPREX begins [*see Contraindications (4)*].

The dosing regimen for MIFEPREX and misoprostol is:

- MIFEPREX 200 mg orally + misoprostol 800 mcg buccally
  - *Day One:* MIFEPREX Administration
    One 200 mg tablet of MIFEPREX is taken in a single oral dose.
  - *Day Two or Three:* Misoprostol Administration (minimum 24-hour interval between MIFEPREX and misoprostol)
    Four 200 mcg tablets (total dose 800 mcg) of misoprostol are taken by the buccal route.

    Tell the patient to place two 200 mcg misoprostol tablets in each cheek pouch (the area between the cheek and gums) for 30 minutes and then swallow any remnants with water or another liquid (see Figure 1).

    Figure 1

    2 pills between cheek and gum on left side + 2 pills between cheek and gum on right side

Patients taking MIFEPREX must take misoprostol within 24 to 48 hours after taking MIFEPREX. The effectiveness of the regimen may be lower if misoprostol is administered less than 24 hours or more than 48 hours after mifepristone administration.

Because most women will expel the pregnancy within 2 to 24 hours of taking misoprostol *[see Clinical Studies (14)]*, discuss with the patient an appropriate location for them to be when taking the misoprostol, taking into account that expulsion could begin within 2 hours of administration.

2.2 Patient Management Following Misoprostol Administration

During the period immediately following the administration of misoprostol, the patient may need medication for cramps or gastrointestinal symptoms *[see Adverse Reactions (6)].*

Give the patient:

- Instructions on what to do if significant discomfort, excessive vaginal bleeding or other adverse reactions occur
- A phone number to call if the patient has questions following the administration of the misoprostol
- The name and phone number of the healthcare provider who will be handling emergencies.

2.3 Post-treatment Assessment: Day 7 to 14

Patients should follow-up with their healthcare provider approximately 7 to 14 days after the administration of MIFEPREX. This assessment is very important to confirm that complete termination of pregnancy has occurred and to evaluate the degree of bleeding. Termination can be confirmed by medical history, clinical examination, human Chorionic Gonadotropin (hCG) testing, or ultrasonographic scan. Lack of bleeding following treatment usually indicates failure; however, prolonged or heavy bleeding is not proof of a complete abortion.

The existence of debris in the uterus (e.g., if seen on ultrasonography) following the treatment procedure will not necessarily require surgery for its removal.

Patients should expect to experience vaginal bleeding or spotting for an average of 9 to 16 days. Women report experiencing heavy bleeding for a median duration of 2 days. Up to 8% of women may experience some type of bleeding for more than 30 days. Persistence of heavy or moderate vaginal bleeding at the time of follow-up, however, could indicate an incomplete abortion.

If complete expulsion has not occurred, but the pregnancy is not ongoing, patients may be treated with another dose of misoprostol 800 mcg buccally. There have been rare reports of uterine rupture in women who took MIFEPREX and misoprostol, including women with prior uterine rupture or uterine scar and women who received multiple doses of misoprostol within 24 hours. Patients who choose to use a repeat dose of misoprostol should have a follow-up visit with their healthcare provider in approximately 7 days to assess for complete termination.

Surgical evacuation is recommended to manage ongoing pregnancies after medical abortion *[see Use in Specific Populations (8.1)]*. Advise the patient whether you will provide such care or will refer them to another provider as part of counseling prior to prescribing MIFEPREX.

2.4 Contact for Consultation

For consultation 24 hours a day, 7 days a week with an expert in mifepristone, call Danco Laboratories at 1-877-4 Early Option (1-877-432-7596).

3 DOSAGE FORMS AND STRENGTHS

Tablets containing 200 mg of mifepristone each, supplied as 1 tablet on one blister card. MIFEPREX tablets are light yellow, cylindrical, and bi-convex tablets, approximately 11 mm in diameter and imprinted on one side with “MF.”

4 CONTRAINDICATIONS

- Administration of MIFEPREX and misoprostol for the termination of pregnancy (the “treatment procedure”) is contraindicated in patients with any of the following conditions:
  - Confirmed or suspected ectopic pregnancy or undiagnosed adnexal mass (the treatment procedure will not be effective to terminate an ectopic pregnancy) *[see Warnings and Precautions (5.4)]*
  - Chronic adrenal failure (risk of acute adrenal insufficiency)
  - Concurrent long-term corticosteroid therapy (risk of acute adrenal insufficiency)
  - History of allergy to mifepristone, misoprostol, or other prostaglandins (allergic reactions including anaphylaxis, angioedema, rash, hives, and itching have been reported *[see Adverse Reactions (6.2)]*)
  - Hemorrhagic disorders or concurrent anticoagulant therapy (risk of heavy bleeding)

- Inherited porphyrias (risk of worsening or of precipitation of attacks)

- Use of MIFEPREX and misoprostol for termination of intrauterine pregnancy is contraindicated in patients with an intrauterine device ("IUD") in place (the IUD might interfere with pregnancy termination). If the IUD is removed, MIFEPREX may be used.

5 WARNINGS AND PRECAUTIONS

5.1 Infection and Sepsis

As with other types of abortion, cases of serious bacterial infection, including very rare cases of fatal septic shock, have been reported following the use of MIFEPREX *[see Boxed Warning]*. Healthcare providers evaluating a patient who is undergoing a medical abortion should be alert to the possibility of this rare event. A sustained (> 4 hours) fever of 100.4°F or higher, severe abdominal pain, or pelvic tenderness in the days after a medical abortion may be an indication of infection.

A high index of suspicion is needed to rule out sepsis (e.g., from *Clostridium sordellii*) if a patient reports abdominal pain or discomfort or general malaise (including weakness, nausea, vomiting, or diarrhea) more than 24 hours after taking misoprostol. Very rarely, deaths have been reported in patients who presented without fever, with or without abdominal pain, but with leukocytosis with a marked left shift, tachycardia, hemoconcentration, and general malaise. No causal relationship between MIFEPREX and misoprostol use and an increased risk of infection or death has been established. *Clostridium sordellii* infections have also been reported very rarely following childbirth (vaginal delivery and caesarian section), and in other gynecologic and non-gynecologic conditions.

5.2 Uterine Bleeding

Uterine bleeding occurs in almost all patients during a medical abortion. Prolonged heavy bleeding (soaking through two thick full-size sanitary pads per hour for two consecutive hours) may be a sign of incomplete abortion or other complications, and prompt medical or surgical intervention may be needed to prevent the development of hypovolemic shock. Counsel patients to seek immediate medical attention if they experience prolonged heavy vaginal bleeding following a medical abortion *[see Boxed Warning]*.

Women should expect to experience vaginal bleeding or spotting for an average of 9 to 16 days. Women report experiencing heavy bleeding for a median duration of 2 days. Up to 8% of all subjects may experience some type of bleeding for 30 days or more. In general, the duration of bleeding and spotting increased as the duration of the pregnancy increased.

Decreases in hemoglobin concentration, hematocrit, and red blood cell count may occur in patients who bleed heavily.

Excessive uterine bleeding usually requires treatment by uterotonics, vasoconstrictor drugs, surgical uterine evacuation, administration of saline infusions, and/or blood transfusions. Based on data from several large clinical trials, vasoconstrictor drugs were used in 4.3% of all subjects, there was a decrease in hemoglobin of more than 2 g/dL in 5.5% of subjects, and blood transfusions were administered to ≤ 0.1% of subjects. Because heavy bleeding requiring surgical uterine evacuation occurs in about 1% of patients, special care should be given to patients with hemostatic disorders, hypocoagulability, or severe anemia.

5.3 Mifepristone REMS Program

MIFEPREX is available only through a restricted program under a REMS called the mifepristone REMS Program, because of the risks of serious complications *[see Warnings and Precautions (5.1, 5.2)]*.

Notable requirements of the mifepristone REMS Program include the following:

- Prescribers must be certified with the program by completing the Prescriber Agreement Form.
- Patients must sign a Patient Agreement Form.
- MIFEPREX must only be dispensed to patients by or under the supervision of a certified prescriber, or by certified pharmacies on prescriptions issued by certified prescribers.

Further information is available at 1-877-4 Early Option (1-877-432-7596).

5.4 Ectopic Pregnancy

MIFEPREX is contraindicated in patients with a confirmed or suspected ectopic pregnancy because MIFEPREX is not effective for terminating ectopic pregnancies *[see Contraindications (4)].* Healthcare providers should remain alert to the possibility that a patient who is undergoing a medical abortion could have an undiagnosed ectopic pregnancy because some of the expected symptoms experienced with a medical abortion (abdominal pain, uterine bleeding) may be similar to those of a ruptured ectopic pregnancy. The presence of an ectopic pregnancy may have been missed even if the patient underwent ultrasonography prior to being prescribed MIFEPREX.

Patients who became pregnant with an IUD in place should be assessed for ectopic pregnancy.

5.5 Rhesus Immunization

The use of MIFEPREX is assumed to require the same preventive measures as those taken prior to and during surgical abortion to prevent rhesus immunization.

6 ADVERSE REACTIONS

The following adverse reactions are described in greater detail in other sections:

- Infection and sepsis *[see Warnings and Precautions (5.1)]*
- Uterine bleeding *[see Warnings and Precautions (5.2)]*

6.1 Clinical Trials Experience

Because clinical studies are conducted under widely varying conditions, adverse reaction rates observed in the clinical studies of a drug cannot be directly compared to rates in the clinical studies of another drug and may not reflect the rates observed in practice.

Information presented on common adverse reactions relies solely on data from U.S. studies, because rates reported in non-U.S. studies were markedly lower and are not likely generalizable to the U.S. population. In three U.S. clinical studies totaling 1,248 women through 70 days gestation who used mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally, women reported adverse reactions in diaries and in interviews at the follow-up visit. These studies enrolled generally healthy women of reproductive age without contraindications to mifepristone or misoprostol use according to the MIFEPREX product label. Gestational age was assessed prior to study enrollment using the date of the woman's last menstrual period, clinical evaluation, and/or ultrasound examination.

About 85% of patients report at least one adverse reaction following administration of MIFEPREX and misoprostol, and many can be expected to report more than one such reaction. The most commonly reported adverse reactions (>15%) were nausea, weakness, fever/chills, vomiting, headache, diarrhea, and dizziness (see Table 1). The frequency of adverse reactions varies between studies and may be dependent on many factors, including the patient population and gestational age.

Abdominal pain/cramping is expected in all medical abortion patients and its incidence is not reported in clinical studies. Treatment with MIFEPREX and misoprostol is designed to induce uterine bleeding and cramping to cause termination of an intrauterine pregnancy. Uterine bleeding and cramping are expected consequences of the action of MIFEPREX and misoprostol as used in the treatment procedure. Most patients can expect bleeding more heavily than they do during a heavy menstrual period *[see Warnings and Precautions (5.2)]*.

Table 1 lists the adverse reactions reported in U.S. clinical studies with incidence >15% of women.

Table 1
Adverse Reactions Reported in Women Following Administration of Mifepristone (oral) and Misoprostol (buccal) in U.S. Clinical Studies

Adverse Reaction	# U.S. studies	Number of Evaluable Women	Range of frequency (%)	Upper Gestational Age of Studies Reporting Outcome
Nausea	3	1,248	51-75%	70 days
Weakness	2	630	55-58%	63 days
Fever/chills	1	414	48%	63 days
Vomiting	3	1,248	37-48%	70 days
Headache	2	630	41-44%	63 days
Diarrhea	3	1,248	18-43%	70 days
Dizziness	2	630	39-41%	63 days

One study provided gestational-age stratified adverse reaction rates for women who were 57-63 and 64-70 days; there was little difference in frequency of the reported common adverse reactions by gestational age.

Information on serious adverse reactions was reported in six U.S. and four non-U.S. clinical studies, totaling 30,966 women through 70 days gestation who used mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally. Serious adverse reaction rates were similar between U.S. and non-U.S. studies, so rates from both U.S. and non-U.S. studies are presented. In the U.S. studies, one studied women through 56 days gestation, four through 63 days gestation, and one through 70 days gestation, while in the non-U.S. studies, two studied women through 63 days gestation, and two through 70 days gestation. Serious adverse reactions were reported in <0.5% of women. Information from the U.S. and non-U.S. studies is presented in Table 2.

Table 2
Serious Adverse Reactions Reported in Women Following Administration of Mifepristone (oral) and Misoprostol (buccal) in U.S. and Non-U.S. Clinical Studies

Adverse Reaction	U.S.			Non-U.S.		
	# of studies	Number of Evaluable Women	Range of frequency (%)	# of studies	Number of Evaluable Women	Range of frequency (%)
Transfusion	4	17,774	0.03-0.5%	3	12,134	0-0.1%
Sepsis	1	629	0.2%	1	11,155	<0.01%*
ER visit	2	1,043	2.9-4.6%	1	95	0
Hospitalization Related to Medical Abortion	3	14,339	0.04-0.6%	3	1,286	0-0.7%
Infection without sepsis	1	216	0	1	11,155	0.2%
Hemorrhage	NR	NR	NR	1	11,155	0.1%

NR= Not reported
* This outcome represents a single patient who experienced death related to sepsis.

6.2 Postmarketing Experience

The following adverse reactions have been identified during postapproval use of MIFEPREX and misoprostol. Because these reactions are reported voluntarily from a population of uncertain size, it is not always possible to reliably estimate their frequency or establish a causal relationship to drug exposure.

Infections and infestations: post-abortal infection (including endometritis, endomyometritis, parametritis, pelvic infection, pelvic inflammatory disease, salpingitis)
Blood and the lymphatic system disorders: anemia
Immune system disorders: allergic reaction (including anaphylaxis, angioedema, hives, rash, itching)
Psychiatric disorders: anxiety
Cardiac disorders: tachycardia (including racing pulse, heart palpitations, heart pounding)
Vascular disorders: syncope, fainting, loss of consciousness, hypotension (including orthostatic), light-headedness
Respiratory, thoracic and mediastinal disorders: shortness of breath
Gastrointestinal disorders: dyspepsia
Musculoskeletal, connective tissue and bone disorders: back pain, leg pain
Reproductive system and breast disorders: uterine rupture, ruptured ectopic pregnancy, hematometra, leukorrhea
General disorders and administration site conditions: pain

7 DRUG INTERACTIONS

7.1 Drugs that May Reduce MIFEPREX Exposure (Effect of CYP 3A4 Inducers on MIFEPREX)

CYP450 3A4 is primarily responsible for the metabolism of mifepristone. CYP3A4 inducers such as rifampin, dexamethasone, St. John's Wort, and certain anticonvulsants (such as phenytoin, phenobarbital, carbamazepine) may induce mifepristone metabolism (lowering serum concentrations of mifepristone). Whether this action has an impact on the efficacy of the dose

regimen is unknown. Refer to the follow-up assessment *[see Dosage and Administration (2.3)]* to verify that treatment has been successful.

7.2 Drugs that May Increase MIFEPREX Exposure (Effect of CYP 3A4 Inhibitors on MIFEPREX)

Although specific drug or food interactions with mifepristone have not been studied, on the basis of this drug's metabolism by CYP 3A4, it is possible that ketoconazole, itraconazole, erythromycin, and grapefruit juice may inhibit its metabolism (increasing serum concentrations of mifepristone). MIFEPREX should be used with caution in patients currently or recently treated with CYP 3A4 inhibitors.

7.3 Effects of MIFEPREX on Other Drugs (Effect of MIFEPREX on CYP 3A4 Substrates)

Based on *in vitro* inhibition information, coadministration of mifepristone may lead to an increase in serum concentrations of drugs that are CYP 3A4 substrates. Due to the slow elimination of mifepristone from the body, such interaction may be observed for a prolonged period after its administration. Therefore, caution should be exercised when mifepristone is administered with drugs that are CYP 3A4 substrates and have narrow therapeutic range.

8 USE IN SPECIFIC POPULATIONS

8.1 Pregnancy

Risk Summary

MIFEPREX is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. Risks to pregnant patients are discussed throughout the labeling.

Refer to misoprostol labeling for risks to pregnant patients with the use of misoprostol.

The risk of adverse developmental outcomes with a continued pregnancy after a failed pregnancy termination with MIFEPREX in a regimen with misoprostol is unknown; however, the process of a failed pregnancy termination could disrupt normal embryo-fetal development and result in adverse developmental effects. Birth defects have been reported with a continued pregnancy after a failed pregnancy termination with MIFEPREX in a regimen with misoprostol. In animal reproduction studies, increased fetal losses were observed in mice, rats, and rabbits and skull deformities were observed in rabbits with administration of mifepristone at doses lower than the human exposure level based on body surface area.

Data

Animal Data

In teratology studies in mice, rats and rabbits at doses of 0.25 to 4.0 mg/kg (less than 1/100 to approximately 1/3 the human exposure based on body surface area), because of the antiprogestational activity of mifepristone,fetal losses were much higher than in control animals. Skull deformities were detected in rabbit studies at approximately 1/6 the human exposure, although no teratogenic effects of mifepristone have been observed to date in rats or mice. These deformities were most likely due to the mechanical effects of uterine contractions resulting from inhibition of progesterone action.

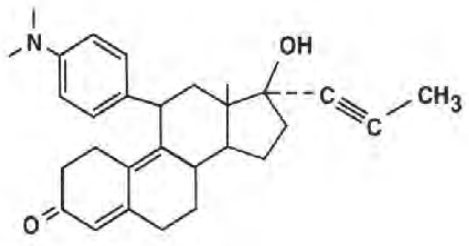
8.2 Lactation

MIFEPREX is present in human milk. Limited data demonstrate undetectable to low levels of the drug in human milk with the relative (weight-adjusted) infant dose 0.5% or less as compared to maternal dosing. There is no information on the effects of MIFEPREX in a regimen with

misoprostol in a breastfed infant or on milk production. Refer to misoprostol labeling for lactation information with the use of misoprostol. The developmental and health benefits of breast-feeding should be considered along with any potential adverse effects on the breast-fed child from MIFEPREX in a regimen with misoprostol.

8.4 Pediatric Use

Safety and efficacy of MIFEPREX have been established in pregnant females. Data from a clinical study of MIFEPREX that included a subset of 322 females under age 17 demonstrated a safety and efficacy profile similar to that observed in adults.



10 OVERDOSAGE

No serious adverse reactions were reported in tolerance studies in healthy non-pregnant female and healthy male subjects where mifepristone was administered in single doses greater than 1800 mg (ninefold the recommended dose for medical abortion). If a patient ingests a massive overdose, the patient should be observed closely for signs of adrenal failure.

11 DESCRIPTION

MIFEPREX tablets each contain 200 mg of mifepristone, a synthetic steroid with antiprogestational effects. The tablets are light yellow in color, cylindrical, and bi-convex, and are intended for oral administration only. The tablets include the inactive ingredients colloidal silica anhydrous, corn starch, povidone, microcrystalline cellulose, and magnesium stearate.

Mifepristone is a substituted 19-nor steroid compound chemically designated as 11ß-[*p*-(Dimethylamino)phenyl]-17ß-hydroxy-17-(1-propynyl)estra-4,9-dien-3-one. Its empirical formula is $C_{29}H_{35}NO_2$. Its structural formula is:

The compound is a yellow powder with a molecular weight of 429.6 and a melting point of 192-196°C. It is very soluble in methanol, chloroform and acetone and poorly soluble in water, hexane and isopropyl ether.

12 CLINICAL PHARMACOLOGY

12.1 Mechanism of Action

The anti-progestational activity of mifepristone results from competitive interaction with progesterone at progesterone-receptor sites. Based on studies with various oral doses in several animal species (mouse, rat, rabbit, and monkey), the compound inhibits the activity of endogenous or exogenous progesterone, resulting in effects on the uterus and cervix that, when combined with misoprostol, result in termination of an intrauterine pregnancy.

During pregnancy, the compound sensitizes the myometrium to the contraction-inducing activity

of prostaglandins.

12.2 Pharmacodynamics

Use of MIFEPREX in a regimen with misoprostol disrupts pregnancy by causing decidual necrosis, myometrial contractions, and cervical softening, leading to the expulsion of the products of conception.

Doses of 1 mg/kg or greater of mifepristone have been shown to antagonize the endometrial and myometrial effects of progesterone in women.

Antiglucocorticoid and antiandrogenic activity: Mifepristone also exhibits antiglucocorticoid and weak antiandrogenic activity. The activity of the glucocorticoid dexamethasone in rats was inhibited following doses of 10 to 25 mg/kg of mifepristone. Doses of 4.5 mg/kg or greater in human beings resulted in a compensatory elevation of adrenocorticotropic hormone (ACTH) and cortisol. Antiandrogenic activity was observed in rats following repeated administration of doses from 10 to 100 mg/kg.

12.3 Pharmacokinetics

Mifepristone is rapidly absorbed after oral ingestion with non-linear pharmacokinetics for Cmax after single oral doses of 200 mg and 600 mg in healthy subjects.

Absorption

The absolute bioavailability of a 20 mg mifepristone oral dose in females of childbearing age is 69%. Following oral administration of a single dose of 600 mg, mifepristone is rapidly absorbed, with a peak plasma concentration of 1.98 ± 1.0 mg/L occurring approximately 90 minutes after ingestion.

Following oral administration of a single dose of 200 mg in healthy men (n=8), mean Cmax was 1.77 ± 0.7 mg/L occurring approximately 45 minutes after ingestion. Mean $AUC_{0-\infty}$ was 25.8 ± 6.2 mg*hr/L.

Distribution

Mifepristone is 98% bound to plasma proteins, albumin, and α_1-acid glycoprotein. Binding to the latter protein is saturable, and the drug displays nonlinear kinetics with respect to plasma concentration and clearance.

Elimination

Following a distribution phase, elimination of mifepristone is slow at first (50% eliminated between 12 and 72 hours) and then becomes more rapid with a terminal elimination half-life of 18 hours.

Metabolism

Metabolism of mifepristone is primarily via pathways involving N-demethylation and terminal hydroxylation of the 17-propynyl chain. *In vitro* studies have shown that CYP450 3A4 is primarily responsible for the metabolism. The three major metabolites identified in humans are: (1) RU 42 633, the most widely found in plasma, is the N-monodemethylated metabolite; (2) RU 42 848, which results from the loss of two methyl groups from the 4-dimethylaminophenyl in position 11ß; and (3) RU 42 698, which results from terminal hydroxylation of the 17-propynyl chain.

Excretion

By 11 days after a 600 mg dose of tritiated compound, 83% of the drug has been accounted for by the feces and 9% by the urine. Serum concentrations are undetectable by 11 days.

Specific Populations

The effects of age, hepatic disease and renal disease on the safety, efficacy and pharmacokinetics of mifepristone have not been investigated.

13 NONCLINICAL TOXICOLOGY

13.1 Carcinogenesis, Mutagenesis, Impairment of Fertility

Carcinogenesis

No long-term studies to evaluate the carcinogenic potential of mifepristone have been performed.

Mutagenesis

Results from studies conducted *in vitro* and in animals have revealed no genotoxic potential for mifepristone. Among the tests carried out were: Ames test with and without metabolic activation; gene conversion test in *Saccharomyces cerevisiae* D4 cells; forward mutation in *Schizosaccharomyces pompe* P1 cells; induction of unscheduled DNA synthesis in cultured HeLa cells; induction of chromosome aberrations in CHO cells; *in vitro* test for gene mutation in V79 Chinese hamster lung cells; and micronucleus test in mice.

Impairment of Fertility

In rats, administration of 0.3 mg/kg mifepristone per day caused severe disruption of the estrus cycles for the three weeks of the treatment period. Following resumption of the estrus cycle, animals were mated and no effects on reproductive performance were observed.

14 CLINICAL STUDIES

Safety and efficacy data from clinical studies of mifepristone 200 mg orally followed 24-48 hours later by misoprostol 800 mcg buccally through 70 days gestation are reported below. Success was defined as the complete expulsion of the products of conception without the need for surgical intervention. The overall rates of success and failure, shown by reason for failure based on 22 worldwide clinical studies (including 7 U.S. studies) appear in Table 3.

The demographics of women who participated in the U.S. clinical studies varied depending on study location and represent the racial and ethnic variety of American females. Females of all reproductive ages were represented, including females less than 18 and more than 40 years of age; most were 27 years or younger.

Table 3
Outcome Following Treatment with Mifepristone (oral) and Misoprostol (buccal) Through 70 Days Gestation

	U.S. Trials	Non-U.S. Trials
N	16,794	18,425
Complete Medical Abortion	97.4%	96.2%
Surgical Intervention*	2.6%	3.8%
Ongoing Pregnancy**	0.7%	0.9%

* Reasons for surgical intervention include ongoing pregnancy, medical necessity, persistent or heavy bleeding after treatment, patient request, or incomplete expulsion.
** Ongoing pregnancy is a subcategory of surgical intervention, indicating the percent of women who have surgical intervention due to an ongoing pregnancy.

The results for clinical studies that reported outcomes, including failure rates for ongoing pregnancy, by gestational age are presented in Table 4.

Table 4
Outcome by Gestational Age Following Treatment with Mifepristone and Misoprostol (buccal) for U.S. and Non-U.S. Clinical Studies

	≤49 days			50-56 days			57-63 days			64-70 days		
	N	%	Number of Evaluable Studies	N	%	Number of Evaluable Studies	N	%	Number of Evaluable Studies	N	%	Number of Evaluable Studies
Complete medical abortion	12,046	98.1	10	3,941	96.8	7	2,294	94.7	9	479	92.7	4
Surgical intervention for ongoing pregnancy	10,272	0.3	6	3,788	0.8	6	2,211	2	8	453	3.1	3

One clinical study asked subjects through 70 days gestation to estimate when they expelled the pregnancy, with 70% providing data. Of these, 23-38% reported expulsion within 3 hours and over 90% within 24 hours of using misoprostol.

16 HOW SUPPLIED/STORAGE AND HANDLING

is only available through a restricted program called the Mifepristone REMS Program *[see Warnings and Precautions (5.3)].*

MIFEPREX is supplied as light yellow, cylindrical, and bi-convex tablets imprinted on one side with “MF.” Each tablet contains 200 mg of mifepristone. One tablet is individually blistered on one blister card that is packaged in an individual package (National Drug Code 64875-001-01).

Store at 25°C (77°F); excursions permitted to 15 to 30°C (59 to 86°F) [see USP Controlled Room Temperature].

17 PATIENT COUNSELING INFORMATION

Advise the patient to read the FDA-approved patient labeling (Medication Guide), included with each package of MIFEPREX. Additional copies of the Medication Guide are available by contacting Danco Laboratories at 1-877-4 Early Option (1-877-432-7596) or from www.earlyoptionpill.com.

Serious Infections and Bleeding

- Inform the patient that uterine bleeding and uterine cramping will occur [*see Warnings and Precautions (5.2)*].
- Advise the patient that serious and sometimes fatal infections and bleeding can occur very rarely [*see Warnings and Precautions (5.1, 5.2)*].
- MIFEPREX is only available through a restricted program called the Mifepristone REMS Program [*see Warnings and Precautions (5.3)*]. Under the mifepristone REMS Program:
    - Patients must sign a Patient Agreement Form.
    - MIFEPREX is only dispensed by or under the supervision of certified prescribers or by certified pharmacies on prescriptions issued by certified prescribers.

Provider Contacts and Actions in Case of Complications

- Ensure that the patient knows whom to call and what to do, including going to an Emergency Room if none of the provided contacts are reachable, or if the patient experiences complications including prolonged heavy bleeding, severe abdominal pain, or sustained fever *[see Boxed Warning]*.
-

Compliance with Treatment Schedule and Follow-up Assessment

- Advise the patient that it is necessary to complete the treatment schedule, including a follow-up assessment approximately 7 to14 days after taking MIFEPREX *[see Dosage and Administration (2.3)]*.
- Explain that
    - prolonged heavy vaginal bleeding is not proof of a complete abortion,
    - if the treatment fails and the pregnancy continues, the risk of fetal malformation is unknown,
    - it is recommended that ongoing pregnancy be managed by surgical termination *[see Dosage and Administration (2.3)]*. Advise the patient whether you will provide such care or will refer them to another provider.

Subsequent Fertility

- Inform the patient that another pregnancy can occur following medical abortion and before resumption of normal menses.
- Inform the patient that contraception can be initiated as soon as pregnancy expulsion has been confirmed, or before resuming sexual intercourse.

MIFEPREX is a registered trademark of Danco Laboratories, LLC.

MEDICATION GUIDE

Mifeprex (MIF-eh-prex) (mifepristone tablets, for oral use

Read this information carefully before taking Mifeprex and misoprostol. It will help you understand how the treatment works. This Medication Guide does not take the place of talking with your healthcare provider.

What is the most important information I should know about Mifeprex?

What symptoms should I be concerned with? Although cramping and bleeding are an expected part of ending a pregnancy, rarely, serious and potentially life-threatening bleeding, infections, or other problems can occur following a miscarriage, surgical abortion, medical abortion, or childbirth. Seeking medical attention as soon as possible is needed in these circumstances. Serious infection has resulted in death in a very small number of cases. There is no information that use of Mifeprex and misoprostol caused these deaths. If you have any questions, concerns, or problems, or if you are worried about any side effects or symptoms, you should contact your healthcare provider. You can write down your healthcare provider's telephone number here _____.

Be sure to contact your healthcare provider promptly if you have any of the following:

- **Heavy Bleeding.** Contact your healthcare provider right away if you bleed enough to soak through two thick full-size sanitary pads per hour for two consecutive hours or if you are concerned about heavy bleeding. In about 1 out of 100 women, bleeding can be so heavy that it requires a surgical procedure (surgical aspiration or D&C).
- **Abdominal Pain or "Feeling Sick."** If you have abdominal pain or discomfort, or you are "feeling sick," including weakness, nausea, vomiting, or diarrhea, with or without fever, more than 24 hours after taking misoprostol, you should contact your healthcare provider without delay. These symptoms may be a sign of a serious infection or another problem (including an ectopic pregnancy, a pregnancy outside the womb).
- **Fever.** In the days after treatment, if you have a fever of 100.4°F or higher that lasts for more than 4 hours, you should contact your healthcare provider right away. Fever may be a symptom of a serious infection or another problem.

If you cannot reach your healthcare provider, go to the nearest hospital emergency room.

What to do if you are still pregnant after Mifeprex with misoprostol treatment. If you are still pregnant, your healthcare provider will talk with you about a surgical procedure to end your pregnancy. In many cases, this surgical procedure can be done in the office/clinic. The chance of birth defects if the pregnancy is not ended is unknown.

Talk with your healthcare provider. Before you take Mifeprex, you should read this Medication Guide and you and your healthcare provider should discuss the benefits and risks of your using Mifeprex.

What is Mifeprex?

Mifeprex is used in a regimen with another prescription medicine called misoprostol, to end an early pregnancy. Early pregnancy means it is 70 days (10 weeks) or less since your last menstrual period began. Mifeprex is not approved for ending pregnancies that are further along. Mifeprex blocks a hormone needed for your pregnancy to continue. When you use Mifeprex on Day 1, you also need to take another medicine called misoprostol 24 to 48 hours after you take Mifeprex, to cause the pregnancy to be passed from your uterus.

The pregnancy is likely to be passed from your uterus within 2 to 24 hours after taking Mifeprex and misoprostol. When the pregnancy is passed from the uterus, you will have bleeding and cramping that will likely be heavier than your usual period. About 2 to 7 out of 100 women taking Mifeprex will need a surgical procedure because the pregnancy did not completely pass from the uterus or to stop bleeding.

Who should not take Mifeprex?

Some patients should not take Mifeprex. Do not take Mifeprex if you:

- Have a pregnancy that is more than 70 days (10 weeks). Your healthcare provider may do a clinical examination, an ultrasound examination, or other testing to determine how far along you are in pregnancy.
- Are using an IUD (intrauterine device or system). It must be taken out before you take Mifeprex.
- Have been told by your healthcare provider that you have a pregnancy outside the uterus (ectopic pregnancy).
- Have problems with your adrenal glands (chronic adrenal failure).
- Take a medicine to thin your blood.
- Have a bleeding problem.
- Have porphyria.
- Take certain steroid medicines.
- Are allergic to mifepristone, misoprostol, or medicines that contain misoprostol, such as Cytotec or Arthrotec.

Ask your healthcare provider if you are not sure about all your medical conditions before taking this medicine to find out if you can take Mifeprex.

What should I tell my healthcare provider before taking Mifeprex?

Before you take Mifeprex, tell your healthcare provider if you:

- cannot follow-up within approximately 7 to 14 days of your first visit
- are breastfeeding. Mifeprex can pass into your breast milk. The effect of the Mifeprex and misoprostol regimen on the breastfed infant or on milk production is unknown.
- are taking medicines, including prescription and over-the-counter medicines, vitamins, and herbal supplements.
  Mifeprex and certain other medicines may affect each other if they are used together. This can cause side effects.

How should I take Mifeprex?

- Mifeprex will be given to you by a healthcare provider or pharmacy.
- You and your healthcare provider will plan the most appropriate location for you to take the misoprostol, because it may cause bleeding, cramps, nausea, diarrhea, and other symptoms that usually begin within 2 to 24 hours after taking it.
- Most women will pass the pregnancy within 2 to 24 hours after taking the misoprostol tablets.

Follow the instruction below on how to take Mifeprex and misoprostol:

<u>Mifeprex (1 tablet) orally + misoprostol (4 tablets) buccally</u>

Day 1:

- Take 1 Mifeprex tablet by mouth.

24 to 48 hours after taking Mifeprex:

- Take 4 misoprostol tablets by placing 2 tablets in each cheek pouch (the area between your teeth and cheek - see Figure A) for 30 minutes and then swallow anything left over with a drink of water or another liquid.
- The medicines may not work as well if you take misoprostol sooner than 24 hours after Mifeprex or later than 48 hours after Mifeprex.
- Misoprostol often causes cramps, nausea, diarrhea, and other symptoms. Your healthcare provider may send you home with medicines for these symptoms.

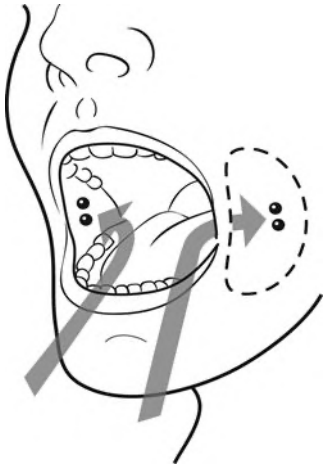

Figure A (2 tablets between your left cheek and gum and 2 tablets between your right cheek and gum).

Follow-up Assessment at Day 7 to 14:

- This follow-up assessment is very important. You must follow-up with your healthcare provider about 7 to 14 days after you have taken Mifeprex to be sure you are well and that you have had bleeding and the pregnancy has passed from your uterus.
- Your healthcare provider will assess whether your pregnancy has passed from your uterus. If your pregnancy continues, the chance that there may be birth defects is unknown. If you are still pregnant, your healthcare provider will talk with you about a surgical procedure to end your pregnancy.
- If your pregnancy has ended, but has not yet completely passed from your uterus, your provider will talk with you about other choices you have, including waiting, taking another dose of misoprostol, or having a surgical procedure to empty your uterus.

When should I begin birth control?

You can become pregnant again right after your pregnancy ends. If you do not want to become pregnant again, start using birth control as soon as your pregnancy ends or before you start having sexual intercourse again.

What should I avoid while taking Mifeprex and misoprostol?

Do not take any other prescription or over-the-counter medicines (including herbal medicines or supplements) at any time during the treatment period without first asking your healthcare provider about them because they may interfere with the treatment. Ask your healthcare provider about what medicines you can take for pain and other side effects.

What are the possible side effects of Mifeprex and misoprostol?

Mifeprex may cause serious side effects. See "What is the most important information I should know about Mifeprex?"

Cramping and bleeding. Cramping and vaginal bleeding are expected with this treatment. Usually, these symptoms mean that the treatment is working. But sometimes you can get cramping and bleeding and still be pregnant. This is why you must follow-up with your healthcare provider approximately 7 to 14 days after taking Mifeprex. See "How should I take Mifeprex?" for more information on your follow-up assessment. If you are not already bleeding after taking Mifeprex, you probably will begin to bleed once you take misoprostol, the medicine you take 24 to 48 hours after Mifeprex. Bleeding or spotting can be expected for an average of 9 to16 days and may last for up to 30 days. Your bleeding may be similar to, or greater than, a normal heavy period. You may see blood clots and tissue. This is an expected part of passing the pregnancy.

The most common side effects of Mifeprex treatment include: nausea, weakness, fever/chills, vomiting, headache, diarrhea and dizziness. Your provider will tell you how to manage any pain or other side effects. These are not all the possible side effects of Mifeprex.

Call your healthcare provider for medical advice about any side effects that bother you or do not go away. You may report side effects to FDA at 1-800-FDA-1088.

General information about the safe and effective use of Mifeprex.

Medicines are sometimes prescribed for purposes other than those listed in a Medication Guide. This Medication Guide summarizes the most important information about Mifeprex. If you would like more information, talk with your healthcare provider. You may ask your healthcare provider for information about Mifeprex that is written for healthcare professionals.

For more information about Mifeprex, go to www.earlyoptionpill.com or call 1-877-4 Early Option (1-877-432-7596).

REMS

Initial Shared System REMS approval: 04/2019
Most Recent Modification: 01/2023

Mifepristone Tablets, 200 mg
Progestin Antagonist

RISK EVALUATION AND MITIGATION STRATEGY (REMS)
SINGLE SHARED SYSTEM FOR MIFEPRISTONE 200 MG

I. GOAL

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.

c) Informing patients about the risk of serious complications associated with mifepristone.

II. REMS ELEMENTS

A. Elements to Assure Safe Use

1. Healthcare providers who prescribe mifepristone must be specially certified.
   a. To become specially certified to prescribe mifepristone, healthcare providers must:
      i. Review the Prescribing Information for mifepristone.
      ii. Complete a *Prescriber Agreement Form*. By signing[1] a *Prescriber Agreement Form*, prescribers agree that:
         1) They have the following qualifications:
            a) Ability to assess the duration of pregnancy accurately
            b) Ability to diagnose ectopic pregnancies
            c) Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or to have made plans to provide such care through others, and ability to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary
         2) They will follow the guidelines for use of mifepristone (see b.i-vii below).
   b. As a condition of certification, prescribers must follow the guidelines for use of mifepristone described below:
      i. Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
      ii. Ensure that the healthcare provider and patient sign the *Patient Agreement Form.*

[1] In this REMS, the terms "sign" and "signature" include electronic signatures.

Reference ID: 5103833

iii. Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.

iv. Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.

v. Ensure that any deaths are reported to the Mifepristone Sponsor that provided the mifepristone, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of mifepristone that was dispensed to the patient.

vi. If mifepristone will be dispensed by a certified pharmacy:

1) Provide the certified pharmacy a signed *Prescriber Agreement Form*.

2) Assess appropriateness of dispensing mifepristone when contacted by a certified pharmacy about patients who will receive mifepristone more than 4 calendar days after the prescription was received by the certified pharmacy.

3) Obtain the NDC and lot number of the package of mifepristone the patient received in the event the prescriber becomes aware of the death of the patient.

vii. The certified prescriber who dispenses mifepristone or who supervises the dispensing of mifepristone must:

1) Provide an authorized distributor with a signed *Prescriber Agreement Form*.

2) Ensure that the NDC and lot number from each package of mifepristone dispensed are recorded in the patient's record.

3) Ensure that healthcare providers under their supervision follow guidelines i.-v.

c. Mifepristone Sponsors must:

i. Ensure that healthcare providers who prescribe their mifepristone are specially certified in accordance with the requirements described above and de-certify healthcare providers who do not maintain compliance with certification requirements.

ii. Ensure prescribers previously certified in the Mifepristone REMS Program complete the new *Prescriber Agreement Form*:

1) Within 120 days after approval of this modification, for those previously certified prescribers submitting prescriptions to certified pharmacies.

2) Within one year after approval of this modification, if previously certified and ordering from an authorized distributor.

iii. Ensure that healthcare providers can complete the certification process by email or fax to an authorized distributor and/or certified pharmacy.

iv. Provide the Prescribing Information and their *Prescriber Agreement Form* to healthcare providers who inquire about how to become certified.

v. Ensure annually with each certified prescriber that their locations for receiving mifepristone are up to date.

The following materials are part of the Mifepristone REMS Program:

- *Prescriber Agreement Form for Danco Laboratories, LLC*
- *Prescriber Agreement Form for GenBioPro, Inc.*
- *Patient Agreement Form*

2. Pharmacies that dispense mifepristone must be specially certified
    a. To become specially certified to dispense mifepristone, pharmacies must:
        i. Be able to receive *Prescriber Agreement Forms* by email and fax.
        ii. Be able to ship mifepristone using a shipping service that provides tracking information.
        iii. Designate an authorized representative to carry out the certification process on behalf of the pharmacy.
        iv. Ensure the authorized representative oversees implementation and compliance with the Mifepristone REMS Program by doing the following:
            1) Review the Prescribing Information for mifepristone.
            2) Complete a *Pharmacy Agreement Form*. By signing a *Pharmacy Agreement Form*, the authorized representative agrees that the pharmacy will put processes and procedures in place to ensure the following requirements are completed:
                a) Verify that the prescriber is certified by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with the pharmacy.
                b) Dispense mifepristone such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in c) below.
                c) Confirm with the prescriber the appropriateness of dispensing mifepristone for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
                d) Record in the patient's record the NDC and lot number from each package of mifepristone dispensed.
                e) Track and verify receipt of each shipment of mifepristone.
                f) Dispense mifepristone in its package as supplied by the Mifepristone Sponsor.
                g) Report any patient deaths to the prescriber, including the NDC and lot number from the package of mifepristone dispensed to the patient, and remind the prescriber of their obligation to report the deaths to the Mifepristone Sponsor that provided the mifepristone. Notify the Mifepristone Sponsor that provided the dispensed mifepristone that the pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
                h) Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
                i) Maintain records of *Prescriber Agreement Forms*.
                j) Maintain records of dispensing and shipping.
                k) Maintain records of all processes and procedures including compliance with those processes and procedures.
                l) Maintain the identity of the patient and prescriber as confidential, including limiting access to patient and prescriber identity only to those personnel necessary to dispense mifepristone in accordance with the Mifepristone REMS Program requirements, or as necessary for payment and/or insurance purposes.
                m) Train all relevant staff on the Mifepristone REMS Program requirements.

n) Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

b. Mifepristone Sponsors must:

i. Ensure that pharmacies are specially certified in accordance with the requirements described above and de-certify pharmacies that do not maintain compliance with certification requirements.

ii. Ensure that pharmacies can complete the certification process by email and fax to an authorized distributor.

i. Verify annually that the name and contact information for the pharmacy's authorized representative corresponds to that of the current designated authorized representative for the certified pharmacy, and if different, require the pharmacy to recertify with the new authorized representative.

The following materials are part of the Mifepristone REMS Program:

- *Pharmacy Agreement Form for Danco Laboratories, LLC*
- *Pharmacy Agreement Form for GenBioPro, Inc.*

3. Mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions as ensured by the certified prescriber in signing the *Prescriber Agreement Form*.

a. The patient must sign a *Patient Agreement Form* indicating that the patient has:

i. Received, read and been provided a copy of the *Patient Agreement Form*.

ii. Received counseling from the healthcare provider regarding the risk of serious complications associated with mifepristone.

B. Implementation System

1. Mifepristone Sponsors must ensure that their mifepristone is only distributed to certified prescribers and certified pharmacies by:

a. Ensuring that distributors who distribute their mifepristone comply with the program requirements for distributors.

i. The distributors must put processes and procedures in place to:

1) Complete the certification process upon receipt of a *Prescriber Agreement Form* or *Pharmacy Agreement Form*.

2) Notify healthcare providers and pharmacies when they have been certified by the Mifepristone REMS Program.

3) Ship mifepristone only to certified pharmacies or locations identified by certified prescribers.

4) Not ship mifepristone to pharmacies or prescribers who become de-certified from the Mifepristone REMS Program.

5) Provide the Prescribing Information and their Prescriber Agreement Form to healthcare providers who (1) attempt to order mifepristone and are not yet certified, or (2) inquire about how to become certified.

ii. Put processes and procedures in place to maintain a distribution system that is secure,

confidential and follows all processes and procedures, including those for storage, handling, shipping, tracking package serial numbers, NDC and lot numbers, proof of delivery and controlled returns of mifepristone.

iii. Train all relevant staff on the Mifepristone REMS Program requirements.

iv. Comply with audits by Mifepristone Sponsors or a third party acting on behalf of Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed for the Mifepristone REMS Program. In addition, distributors must maintain appropriate documentation and make it available for audits.

b. Ensuring that distributors maintain secure and confidential distribution records of all shipments of mifepristone.

2. Mifepristone Sponsors must monitor their distribution data to ensure compliance with the Mifepristone REMS Program.

3. Mifepristone Sponsors must ensure that adequate records are maintained to demonstrate that the Mifepristone REMS Program requirements have been met, including, but not limited to records of mifepristone distribution; certification of prescribers and pharmacies; and audits of pharmacies and distributors. These records must be readily available for FDA inspections.

4. Mifepristone Sponsors must audit their new distributors within 90 calendar days and annually thereafter after the distributor is authorized to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their distributor compliance if noncompliance is identified.

5. Mifepristone Sponsors must audit their certified pharmacies within 180 calendar days after the pharmacy places its first order of mifepristone, and annually thereafter audit certified pharmacies that have ordered mifepristone in the previous 12 months, to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their pharmacy compliance if noncompliance is identified.

6. Mifepristone Sponsors must take reasonable steps to improve implementation of and compliance with the requirements of the Mifepristone REMS Program based on monitoring and assessment of the Mifepristone REMS Program.

7. Mifepristone Sponsors must report to FDA any death associated with mifepristone whether or not considered drug-related, as soon as possible but no later than 15 calendar days from the initial receipt of the information by the Mifepristone Sponsor. This requirement does not affect the sponsors' other reporting and follow-up requirements under FDA regulations.

C. Timetable for Submission of Assessments

The NDA Sponsor must submit REMS assessments to FDA one year from the date of the approval of the modified REMS (1/3/2023) and annually thereafter. To facilitate inclusion of as much information as possible while allowing reasonable time to prepare the submission, the reporting interval covered by each assessment should conclude no earlier than 90 calendar days before the submission date for that assessment. The NDA Sponsor must submit each assessment so that it will be received by the FDA on or before the due date.

MIFEPREX® (Mifepristone) Tablets, 200 mg

PRESCRIBER AGREEMENT FORM

Mifeprex* (Mifepristone) Tablets, 200 mg, is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. Please see Prescribing Information and Medication Guide for complete safety information.

To ***become a certified prescriber***, you must:

- **If you submit Mifeprex prescriptions for dispensing from certified pharmacies**:
  - Submit this form to each certified pharmacy to which you intend to submit Mifeprex prescriptions. The form must be received by the certified pharmacy before any prescriptions are dispensed by that pharmacy.
- **If you order Mifeprex for dispensing by you or healthcare providers under your supervision:**
  - Submit this form to the distributor. This form must be received by the distributor before the first order will be shipped to the healthcare setting.
  - Healthcare settings, such as medical offices, clinics, and hospitals, where Mifeprex will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

Prescriber Agreement: By signing this form, you agree that you meet the qualifications below and will follow the guidelines for use. You are responsible for overseeing implementation and compliance with the Mifepristone REMS Program. You also understand that if the guidelines below are not followed, the distributor may stop shipping mifepristone to the locations that you identify and certified pharmacies may stop accepting your mifepristone prescriptions.

Mifepristone must be provided by or under the supervision of a certified prescriber who meets the following qualifications:

- Ability to assess the duration of pregnancy accurately.
- Ability to diagnose ectopic pregnancies.
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the Prescribing Information for mifepristone. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free), or by visiting www.earlyoptionpill.com.

In addition to meeting these qualifications, you also agree to follow these guidelines for use:

- Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
- Ensure the healthcare provider and patient sign the *Patient Agreement Form*.
- Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.
- Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.
- Ensure that any deaths of patients who received Mifeprex are reported to Danco Laboratories, LLC, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of Mifeprex that was dispensed to the patient.

*MIFEPREX is a registered trademark of Danco Laboratories, LLC
P.O. Box 4816-New York, NY 10185
1-877-4-EARLY-OPTION (1-877-432-7596) www.earlyoptionpill.com

Ensure that healthcare providers under your supervision follow the guidelines listed above.

- If Mifeprex will be dispensed through a certified pharmacy:
  - Assess appropriateness of dispensing Mifeprex when contacted by a certified pharmacy about patients who will receive Mifeprex more than 4 calendar days after the prescription was received by the certified pharmacy.
  - Obtain the NDC and lot number of the package of Mifeprex the patient received in the event the prescriber becomes aware of the death of a patient.
- If Mifeprex will be dispensed by you or by healthcare providers under your supervision:
  - Ensure the NDC and lot number from each package of Mifeprex are recorded in the patient's record.

I understand that a certified pharmacy may dispense mifepristone made by a different manufacturer than that stated on this Prescriber Agreement Form.

PATIENT AGREEMENT FORM Mifepristone Tablets, 200 mg

Healthcare Providers: *Counsel the patient on the risks of mifepristone. Both you and the patient must provide a written or electronic signature on this form.*

Patient Agreement:

1. I have decided to take mifepristone and misoprostol to end my pregnancy and will follow my healthcare provider's advice about when to take each drug and what to do in an emergency.
2. I understand:
   a. I will take mifepristone on Day 1.
   b. I will take the misoprostol tablets 24 to 48 hours after I take mifepristone.
3. My healthcare provider has talked with me about the risks, including:
   - heavy bleeding
   - infection
4. I will contact the clinic/office/provider right away if in the days after treatment I have:
   - a fever of 100.4°F or higher that lasts for more than four hours
   - heavy bleeding (soaking through two thick full-size sanitary pads per hour for two hours in a row)
   - severe stomach area (abdominal) pain or discomfort, or I am “feeling sick,” including weakness, nausea, vomiting, or diarrhea, more than 24 hours after taking misoprostol
     — these symptoms may be a sign of a serious infection or another problem (including an ectopic pregnancy, a pregnancy outside the womb).

   My healthcare provider has told me that these symptoms listed above could require emergency care. If I cannot reach the clinic/office/provider right away, my healthcare provider has told me who to call and what to do.
5. I should follow up with my healthcare provider about 7 to 14 days after I take mifepristone to be sure that my pregnancy has ended and that I am well.
6. I know that, in some cases, the treatment will not work. This happens in about 2 to 7 out of 100 women who use this treatment. If my pregnancy continues after treatment with mifepristone and misoprostol, I will talk with my provider about a surgical procedure to end my pregnancy.
7. If I need a surgical procedure because the medicines did not end my pregnancy or to stop heavy bleeding, my healthcare provider has told me whether they will do the procedure or refer me to another healthcare provider who will.
8. I have the MEDICATION GUIDE for mifepristone.
9. My healthcare provider has answered all my questions.

MIFEPREX®(Mifepristone) Tablets, 200mg

PHARMACY AGREEMENT FORM

Pharmacies must designate an authorized representative to carry out the certification process and oversee implementation and compliance with the Mifepristone REMS Program on behalf of the pharmacy.

Healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

By signing this form, as the Authorized Representative I certify that:

- Each location of my pharmacy that will dispense Mifeprex is able to receive *Prescriber Agreement Forms* by email and fax.
- Each location of my pharmacy that will dispense Mifeprex is able to ship Mifeprex using a shipping service that provides tracking information.
- I have read and understood the Prescribing Information for Mifeprex. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free) or online at www.earlyoptionpill.com; and
- Each location of my pharmacy that will dispense Mifeprex will put processes and procedures in place to ensure the following requirements are completed. I also understand that if my pharmacy does not complete these requirements, the distributor may stop accepting Mifeprex orders.
  - Verify that the prescriber is certified in the Mifepristone REMS Program by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with your pharmacy.
  - Dispense Mifeprex such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in the following bullet.
  - Confirm with the prescriber the appropriateness of dispensing Mifeprex for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
  - Record in the patient's record the NDC and lot number from each package of Mifeprex dispensed.
  - Track and verify receipt of each shipment of Mifeprex.
  - Dispense mifepristone in its package as supplied by Danco Laboratories, LLC.
  - Report any patient deaths to the prescriber, including the NDC and lot number from the package of Mifeprex dispensed to the patient, and remind the prescriber of their obligation to report the deaths to Danco Laboratories, LLC. Notify Danco that your pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
  - Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
  - Maintain records of *Prescriber Agreement Forms*, dispensing and shipping, and all processes and procedures including compliance with those processes and procedures.
  - Maintain the identity of Mifeprex patients and prescribers as confidential and protected from disclosure except to the extent necessary for dispensing under this REMS or as necessary for payment and/or insurance.
  - Train all relevant staff on the Mifepristone REMS Program requirements.
  - Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

Any new authorized representative must complete and submit the *Pharmacy Agreement Form*.

PHARMACY AGREEMENT FORM **Mifepristone Tablets, 200 mg**

Pharmacies must designate an authorized representative to carry out the certification process and oversee implementation and compliance with the Mifepristone REMS Program on behalf of the pharmacy.

Healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

By signing this form, as the Authorized Representative I certify that:

- Each location of my pharmacy that will dispense mifepristone is able to receive *Prescriber Agreement Forms* by email and fax.
- Each location of my pharmacy that will dispense mifepristone is able to ship mifepristone using a shipping service that provides tracking information.
- I have read and understood the Prescribing Information for mifepristone. The Prescribing Information is available by calling 1-855-MIFE-INFO (1-855-643-3463 toll-free) or online at www.MifeInfo.com; and
- Each location of my pharmacy that will dispense mifepristone will put processes and procedures in place to ensure the following requirements are completed. I also understand that if my pharmacy does not complete these requirements, the distributor may stop accepting mifepristone orders.
  - Verify that the prescriber is certified in the Mifepristone REMS Program by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with your pharmacy.
  - Dispense mifepristone such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in the following bullet.
  - Confirm with the prescriber the appropriateness of dispensing mifepristone for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
  - Record in the patient's record the NDC and lot number from each package of mifepristone dispensed.
  - Track and verify receipt of each shipment of mifepristone.
  - Dispense mifepristone in its package as supplied by GenBioPro, Inc.
  - Report any patient deaths to the prescriber, including the NDC and lot number from the package of mifepristone dispensed to the patient, and remind the prescriber of their obligation to report the deaths to GenBioPro, Inc. Notify GenBioPro that your pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
  - Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
  - Maintain records of *Prescriber Agreement Forms*, dispensing and shipping, all processes and procedures including compliance with those processes and procedures.
  - Maintain the identity of mifepristone patients and prescribers as confidential and protected from disclosure except to the extent necessary for dispensing under this REMS or as necessary for payment and/or insurance purposes.
  - Train all relevant staff on the Mifepristone REMS Program requirements.
  - Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

Any new authorized representative must complete and submit the *Pharmacy Agreement Form*.

EXECUTIVE SUMMARY

This is a review of the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and by GenBioPro, Inc. (GBP) for abbreviated new drug application (ANDA) 091178. The Sponsors submitted proposed modification to the Mifepristone REMS Program on June 22, 2022, and amended their submissions on October 19, 2022 (Danco), October 20, 2022 (GBP), November 30, 2022 (both), December 9, 2022 (both) and December 16, 2022 (both).

The Mifepristone REMS Program was originally approved on April 11, 2019, to mitigate the risk of serious complications associated with mifepristone 200 mg. The most recent REMS modification was approved on May 14, 2021.[a] The Mifepristone REMS Program consists of elements to assure safe use (ETASU) A, C and D, an implementation system, and a timetable for submission of assessments of the REMS.

The Sponsors submitted the proposed modification to the REMS in response to the Agency's REMS Modification Notification letters dated December 16, 2021, which required removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement") and the addition of certification of pharmacies that dispense the drug.

In addition, the following were addressed during the course of the review:

- revisions to the REMS goal to align with the updated REMS requirements.
- replacing serial number with recording of NDC and lot number of mifepristone dispensed.
- additional edits for clarification and consistency in the REMS Document and REMS materials (*Prescriber Agreement Forms*, *Patient Agreement Form*, and *Pharmacy Agreement Forms*).

The review team finds the proposed modification to the Mifepristone REMS Program last submitted on December 16, 2022, to be acceptable and recommends approval of the REMS modification. The proposed REMS modification includes changes to the REMS goal, additional REMS requirements for prescribers to incorporate dispensing from certified pharmacies and new REMS requirements for pharmacy certification.

The proposed goal of the modified REMS for mifepristone 200 mg is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.

c) Informing patients about the risk of serious complications associated with mifepristone.

[a] The May 14, 2021 REMS modification approved the inclusion of gender neutral language in the Patient Agreement Form as well as corresponding minor changes to the REMS document to be consistent with the changes made to the Patient Agreement Form.

The timetable for submission of assessments of the REMS was modified to one year from the date of the approval of the modified REMS and annually thereafter. The assessment plan was revised to align with the changes to the REMS and capture additional metrics for drug utilization and REMS operations.

The modified REMS includes ETASU A, B and D, an implementation system, and a timetable for submission of assessments of the REMS. Mifepristone will no longer be required to be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (referred to as the "in-person dispensing requirement" for brevity) and will be able to be dispensed from certified pharmacies.

1. Introduction

This review evaluates the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and by GenBioPro, Inc. (GBP) for abbreviated new drug application (ANDA) 091178.

The Sponsors initially submitted proposed modification to the Mifepristone REMS Program on June 22, 2022, in response to the Agency's REMS Modification Notification letters issued on December 16, 2021, to Danco and GBP, requiring the following modification to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks:

- removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement")
- addition of certification of pharmacies that dispense the drug

Per the Agency's December 16, 2021, REMS Modification Notification letters, the proposed REMS was required to include the following ETASU to mitigate the risk of serious complications associated with mifepristone, including at least the following:

- healthcare providers have particular experience or training, or are specially certified
- pharmacies, practitioners, or health care settings that dispense the drug are specially certified
- the drug is dispensed to patients with evidence or other documentation of safe use conditions

The REMS was also required to include an implementation system and timetable for submission of assessments.

2. Background

2.1. Product Information and REMS Information

Mifepristone is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy (IUP) through 70 days gestation. Mifepristone is available as 200 mg tablets for oral use.

Mifeprex (mifepristone) was approved on September 28, 2000, with a restricted distribution program under 21 CFR 314.520 (subpart H)[b] to ensure that the benefits of the drug outweighed

[b] NDA approval letter Mifeprex (NDA 020687) dated September 28, 2000.

the risk of serious complications associated with mifepristone when used for medical abortion.[c] Mifeprex was deemed to have in effect an approved REMS under section 505-1 of the Federal Food, Drug, and Cosmetic Act with the passage of the Food and Drug Administration Amendments Act of 2007 (FDAAA), and the Mifeprex REMS was approved on June 8, 2011.

On March 29, 2016, FDA approved an efficacy supplement for Mifeprex, which included changes in the dose of Mifeprex and the dosing regimen for taking Mifeprex and misoprostol, as well as a modification of the gestational age up to which Mifeprex has been shown to be safe and effective and a modification to the process for follow-up after administration of the drug. FDA also approved modification to the Mifeprex REMS that reflected the changes approved in the efficacy supplement.[1-5] On April 11, 2019, FDA approved ANDA 091178 and the Mifepristone REMS Program.[6-7] The Mifepristone REMS Program is a single, shared system REMS that includes NDA 020687 and ANDA 091178. The goal of the approved Mifepristone REMS Program is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program (under ETASU A).
b) Ensuring that mifepristone is only dispensed in certain healthcare settings by or under the supervision of a certified prescriber (under ETASU C).
c) Informing patients about the risk of serious complications associated with mifepristone (under ETASU D).

The Mifepristone REMS Program was last modified and approved in 2021 to revise the *Patient Agreement Form* to include gender-neutral language; however, the goal of the Mifepristone REMS Program has not changed since the initial approval in 2019.

Under ETASU A, to become specially certified to prescribe mifepristone, a healthcare provider must review the prescribing information, complete and sign the *Prescriber Agreement Form,* and agree to follow the guidelines for use of mifepristone. Under ETASU C, in the Mifepristone REMS Program as approved prior to today's action, mifepristone was required to be dispensed to patients only in certain healthcare settings, specifically clinics, medical offices, and hospitals, by or under the supervision of a certified prescriber. Under ETASU D, mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions (i.e., the patient must sign a *Patient Agreement Form*). The approved Mifepristone REMS Program includes an implementation system, and a timetable for assessments (one year from the date of the initial approval of the REMS on April 11, 2019, and every three years thereafter).

In April 2021, FDA communicated its intent to exercise enforcement discretion during the COVID-19 public health emergency (PHE) regarding the in-person dispensing requirement in the Mifepristone REMS Program. Specifically, FDA communicated that provided all other requirements of the Mifepristone REMS Program are met, the Agency intended to exercise enforcement discretion with respect to the in-person dispensing requirement of the Mifepristone REMS Program, including any in-person requirements that may be related to the *Patient Agreement Form*, during the COVID-19 PHE. This determination, which FDA made on April 12, 2021, was effective immediately. We also note that from July 13, 2020, to January 12, 2021, per a court order, FDA was enjoined from enforcing the in-person dispensing requirement of the Mifepristone REMS Program.[8]

[c] Mifepristone is also approved in approximately 80 other countries. https://gynuity.org/assets/resources/biblio_ref_lst_mife_en.pdf

Further, and as we also communicated on April 12, 2021, to the extent all of the other requirements of the Mifepristone REMS Program are met, the Agency intended to exercise enforcement discretion during the COVID-19 PHE with respect to the dispensing of Mifeprex or the approved generic version of Mifeprex, Mifepristone Tablets, 200 mg, through the mail, either by or under the supervision of a certified prescriber, or through a mail-order pharmacy when such dispensing is done under the supervision of a certified prescriber.

2.2. Regulatory History

The following is a summary of the regulatory history relevant to this review:

- 04/11/2019: Approval of the Mifepristone REMS Program, a single, shared system REMS that includes NDA 020687 and ANDA 091178.
- 04/12/2021: The Agency issued a General Advice letter to both the NDA and ANDA Applicants, explaining that FDA intended to exercise enforcement discretion during the COVID-19 PHE with respect to the in-person dispensing requirement in the Mifepristone REMS Program, including any in-person requirements that may be related to the Patient Agreement Form.
- 05/07/2021: The Agency stated that it would be reviewing the elements of the Mifepristone REMS Program in accordance with section 505-1 of the FD&C Act.
- 12/16/2021: The Agency completed its review of the Mifepristone REMS Program and determined, among other things, that the REMS must be modified to remove the in-person dispensing requirement and add pharmacy certification.[9]
- 12/16/2021: REMS Modification Notification letters were sent to both Sponsors stating that the approved Mifepristone REMS Program must be modified to minimize the burden on the healthcare system of complying with the REMS and ensure that the benefits of the drug outweigh the risks.
- 04/08/2022: Final written responses to a Type A meeting request were provided to Danco, the point of contact for the Mifepristone REMS Program. The questions pertained to the 12/16/2021 REMS Modification Notification letter requirements.
- 04/13/2022: The Sponsors requested an extension to 6/30/2022, to submit a proposed REMS modification in response to the Agency's 12/16/2021 REMS Modification Notification letters.
- 04/15/2022: The Agency granted the Sponsors' request for an extension to submit a proposed REMS modification and conveyed that the modification must be submitted no later than 06/30/2022.[10]
- 06/22/2022: Danco and GBP submitted a proposed REMS modification to their respective applications in response to the 12/16/2021 REMS Modification Notification letters.
- 07/22/2022: An Information Request was sent to the Sponsors requesting clarification of the proposed prescriber and dispenser requirements and additional rationale to support their proposal.
- 08/26/2022: Sponsors submitted responses to 07/22/2022 Information Request.
- 09/19/2022: Teleconference was held between Agency and Sponsors where the Agency communicated the REMS requirements that are necessary to support the addition of pharmacy

certification. The Agency proposed focusing on the pharmacy settings where a closed system[d] REMS could be implemented using the existing email and facsimile based system, (b) (4) , as the best strategy for an approvable modification by the goal date.

- 09/22/2022: An Information Request was sent to Sponsors requesting confirmation that the Sponsors agree with the pharmacy distribution approach outlined in the 09/19/2022 teleconference so that the Agency's feedback could be appropriately tailored.
- 09/23/2022: The Sponsors confirmed via email that they were willing to pursue (b) (4) , as discussed in the 09/19/2022 teleconference. The Sponsors also requested a teleconference to discuss the current modification (b) (4) .
- 09/27/2022: Comments from the 09/19/2022 teleconference sent to Sponsors with additional comments and requests regarding what will be necessary for pharmacy certification.
- 09/29/2022: An Information request was sent to the Sponsors asking for agenda items, questions, and a request to walk through their proposed system for pharmacy certification, including dispensing through mail-order or specialty pharmacies, at the 10/06/2022 scheduled teleconference.
- 10/04/2022: Sponsors emailed that they will focus the 10/06/2022 teleconference on the 09/27/2022 Agency comments and their mail order and specialty pharmacy distribution model.
- 10/06/2022: Teleconference was held between Agency and Sponsors where Sponsors outlined their proposal for pharmacy certification, including dispensing through mail order and specialty pharmacies, as well as their concerns with certain requirements and general timelines.
- 10/19/2022: Danco submitted a REMS amendment to their pending sNDA, which included a REMS document and REMS materials. They did not submit a REMS Supporting Document.
- 10/20/2022: GBP submitted a REMS amendment to their pending sANDA, which included a REMS document and REMS materials. They did not submit a REMS Supporting Document.
- 10/25/2022: Teleconference was held between Agency and Sponsors to discuss the *Patient Agreement Form* and timing related to shipping a mifepristone prescription from a certified pharmacy to the patient.
- 11/23/2022: An Information Request was sent to Sponsors with comments on their proposed REMS Document, submitted on 10/19/2022 (Danco) and 10/20/2022 (GBP).
- 11/30/2022: Danco and GBP submitted REMS amendments, which included the REMS Document, to their respective pending supplemental applications.
- 12/01/2022: Teleconference was held between Agency and Sponsors to discuss the REMS Document.
- 12/05/2022: An Information Request was sent to Sponsors with comments on their proposed REMS Document submitted on 11/30/2022 and discussed at the teleconference on 12/01/2022, and REMS materials submitted to their applications on 10/19/2022 and 10/20/2022.

[d] "Closed system" in this case refers to a system where prescribers, pharmacies, and distributors are certified or authorized in the REMS and the certification of the stakeholder must be verified prior to distribution or dispensing, as per the REMS.

- 12/07/2022: Teleconference was held between Agency and Sponsors to discuss the REMS Document and REMS materials the Agency sent to the Sponsors on 12/05/22.
- 12/08/2022: Danco and GBP submitted REMS amendments, including the REMS Document, *Prescriber Agreement Form, Pharmacy Agreement Form, Patient Agreement Form* and REMS Supporting Document, to their respective pending applications.
- 12/09/2022: An Information Request was sent to Sponsors with the Agency's comments on the REMS assessment plan.
- 12/14/2022: An Information Request was sent to Sponsors with the Agency's comments on the REMS Document, *Prescriber Agreement Form, Pharmacy Agreement Form*, and REMS Supporting Document.
- 12/15/2022: Two teleconferences were held between Agency and Sponsors to discuss the proposed REMS Document and REMS materials the Agency sent to the Sponsors on 12/14/22.
- 12/16/2022: Sponsors submitted a REMS amendment to their respective applications.

3. Review of Proposed REMS Modification

(b) (6) has discussed the Sponsors' proposed modification with the review team, which includes members of the (b) (6) and the (b) (6) ; hereafter referred to as the review team. This review includes their input and concurrence with the analysis and proposed changes to the Mifepristone REMS Program.

3.1. REMS Goal

The Sponsors proposed modification to the goal for the Mifepristone REMS Program to add that mifepristone can also be dispensed from certified pharmacies on prescriptions issued by certified prescribers. The proposed REMS goal is:

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.

c) Informing patients about the risk of serious complications associated with mifepristone.

Reviewer Comment: *We agree with the Sponsors' proposal.*

3.2. REMS Document

The proposed REMS Document is not in the format as outlined in the 2017 Draft Guidance for Industry, Format and Content of a REMS Document.[11]

Reviewer Comment: *To avoid the misperception that this REMS modification is making major changes to the REMS document that go beyond our December 16, 2021, determination that the REMS must be modified to remove the in-person dispensing requirement and add pharmacy certification, CDER staff and management discussed whether to change the format of the REMS document to that described in the 2017 draft guidance.*[11] *After internal discussion, CDER staff and management aligned not to transition the REMS document at this time to the format described in the 2017 draft guidance.*

3.3. REMS Requirements

3.3.1. Addition and Removal of ETASU

The December 16, 2021, REMS Modification Notification letters specified that the ETASU must be modified to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure the benefits of the drug outweigh the risks by:

- Removing the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices and hospitals (i.e., the "in-person dispensing requirement"), and;
- Adding a requirement that pharmacies that dispense the drug be specially certified.

The Sponsors proposed changes to the REMS as reflected in the subsections below.

3.3.2. REMS Participant Requirements and Materials

3.3.2.1. Prescriber Requirements

Consistent with the approved Mifepristone REMS Program prescribers must be specially certified. To become specially certified to prescribe mifepristone, healthcare providers who prescribe must review the Prescribing Information for mifepristone and complete the *Prescriber Agreement Form*. In signing the *Prescriber Agreement Form*, prescribers agree they meet certain qualifications and will follow the guidelines for use of mifepristone. The guidelines for use include ensuring i) that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained; ii) that the healthcare provider (HCP) and the patient sign the *Patient Agreement Form*, iii) the patient receives a copy of the *Patient Agreement Form* and Medication Guide, iv) the *Patient Agreement Form* is placed in the patient's medical record; v) that any patient deaths are reported to the Mifepristone Sponsor that provided the mifepristone, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of mifepristone that was dispensed to the patient. The language on the guidelines for use was revised from the Mifepristone REMS Program approved in 2021 to clarify that, if the certified prescriber supervises the dispensing of mifepristone, they must ensure the guidelines for use of mifepristone are followed by those under their supervision. This clarification reflects the ongoing implementation of the approved Mifepristone REMS Program. For example, consistent with the approved REMS, the *Patient Agreement Form* does not require the certified prescriber's signature, but rather the signature of the healthcare provider counseling the patient on the risks of mifepristone. Additional changes were made globally to provide consistency and clarity of the requirements for certified prescribers and healthcare providers who complete tasks under the supervision of certified prescribers.

A certified prescriber may submit the *Prescriber Agreement Form* to an authorized distributor if the certified prescriber wishes to dispense or supervise the dispensing of mifepristone; this is consistent with the current requirements of the Mifepristone REMS Program. Additional requirements were

added to incorporate mifepristone dispensing by a certified pharmacy. If a healthcare provider wishes to prescribe mifepristone by sending a prescription to a certified pharmacy for dispensing, the healthcare provider must become certified by providing the pharmacy a *Prescriber Agreement Form* signed by the provider. A certified prescriber must also assess the appropriateness of dispensing mifepristone when contacted by a certified pharmacy about patients who will receive mifepristone more than four calendar days after the prescription was received by the certified pharmacy.

The NDC and lot number of the dispensed drug will be recorded in the patient's record when mifepristone is dispensed by or under the supervision of a certified prescriber, replacing the requirement that serial numbers from each package of mifepristone be recorded in the patient's record. If prescribers become aware of the death of a patient for whom the mifepristone was dispensed from a certified pharmacy, the prescribers will be required to obtain the NDC and lot number of the package of mifepristone the patient received from the pharmacy.

The following materials support prescriber requirements:

- *Prescriber Agreement Form* for Danco Laboratories, LLC
- *Prescriber Agreement Form* for GenBioPro, Inc.
- *Patient Agreement Form*

Reviewer Comment: *We agree with the Sponsors' proposal.*

Although certain activities (review of the Patient Agreement Form with patients and answering any questions about treatment, signing, providing a copy to the patient and retaining the Patient Agreement Form, providing a copy of the Medication Guide, and ensuring any deaths are reported to the Mifepristone Sponsor, recording the NDC and lot number from drug dispensed from the certified prescriber or those under their supervision) may be conducted by healthcare providers under the supervision of a certified prescriber, the certified prescriber remains responsible for ensuring compliance with the requirements of the Mifepristone REMS Program. We agree with the additional language to further clarify that the certified prescriber must ensure the guidelines for use of mifepristone are followed.

As proposed, certified prescribers may either, 1) continue to submit the Prescriber Agreement Form to an authorized distributor if the certified prescriber is dispensing or supervising the dispensing of the drug (as already required in the REMS), or 2) if the drug will be dispensed from a certified pharmacy, submit the Prescriber Agreement Form to the certified pharmacy that will dispense the drug (as proposed in the modification). Regarding #2, the pharmacy can only fill prescriptions written by a certified prescriber.

Based on our review of the proposed changes, the review team finds it acceptable for prescribers to submit their Prescriber Agreement Form directly to the certified pharmacy. Although certified prescribers still have the option of in-person dispensing of the drug, not all prescribers may want to stock mifepristone. Typically due to the number of drugs that are available and the expense associated with stocking prescription medications intended for outpatient use, most prescribers do not stock many medications, if they stock medications at all.

The proposal to submit a Prescriber Agreement Form to a certified pharmacy provides another option for dispensing mifepristone. The burden of providing the Prescriber Agreement Form prior to or when the prescription is provided to a certified pharmacy does not create unreasonable burden for prescribers. The burden of prescriber certification has been minimized to the extent possible. The Prescriber Agreement Form is designed to require minimal time to complete and requires that the prescriber submit it to the authorized distributor once, and if the prescriber chooses to use a certified pharmacy to dispense mifepristone, they will need to submit the form to the certified pharmacy.

There is an additional requirement added for certified pharmacies and certified prescribers in the event that a patient will not receive their medication from the certified pharmacy within four calendar days of the pharmacy's receipt of the prescription (for example, if the medication is not in stock). In this circumstance, the pharmacy will be required to contact the certified prescriber to make them aware of the delay and will be required to obtain from the prescriber confirmation that it is appropriate to dispense mifepristone to the patient even though they will receive mifepristone more than four calendar days after the prescription was received by the certified pharmacy. This confirmation is intended to ensure timeliness of delivery in light of the labeled indication and gestational age. Additional details and rationale on the pharmacy requirements to dispense and ship drug in a timely manner are described in section 3.3.2.3.

If a certified prescriber becomes aware of a patient death that occurs subsequent to the use of mifepristone dispensed from a pharmacy, the certified prescriber must obtain the NDC and lot number of the package of mifepristone the patient received from the pharmacy. This information will be reported to the appropriate Mifepristone Sponsor in the same manner prescribers have done previously. This additional requirement to obtain the NDC and lot number from the pharmacy is needed to ensure consistent adverse event reporting when mifepristone is dispensed from a certified pharmacy.

Prescriber Agreement Form

The Sponsors' proposed changes to the *Prescriber Agreement Form* aligned with those described above. The proposed *Prescriber Agreement Form* explains the two methods of certification which are: 1) submitting the form to the authorized distributor and 2) submitting the form to the dispensing certified pharmacy. Further clarification was added that healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification. The statement that certified prescribers are responsible for overseeing implementation and compliance with the REMS Program was also added. The following statement was added to the form: "I understand that the pharmacy may dispense mifepristone made by a different manufacturer than that stated on the Prescriber Agreement Form." The account set up information was removed and replaced with prescriber information response fields.

***Reviewer Comment**: We agree with the Sponsors' proposal. Changes in the above prescriber requirements were incorporated in the Prescriber Agreement Form.*

3.3.2.2. Patient Requirements

The *Patient Agreement Form* was updated to clarify that the signatures may be written or electronic, to reorganize the risk information about ectopic pregnancy, and to remove the statement that the Medication Guide will be taken to an emergency room or provided to a healthcare provider who did not prescribe mifepristone so that it is known that the patient had a medical abortion with mifepristone.

The following materials support patient requirements:

- *Patient Agreement Form*

***Reviewer Comment:** We agree with the Sponsors' proposal.*

The Patient Agreement Form continues to be an important part of standardizing the medication information on the use of mifepristone that prescribers communicate to their patients, and also provides the information in a brief and understandable format for patients. The requirement to counsel the

patient, to provide the patient with the Patient Agreement Form, and to have the healthcare provider and patient sign the Patient Agreement Form, ensures that each provider, including new providers, informs each patient of the appropriate use of mifepristone, risks associated with treatment, and what to do if the patient experiences symptoms that may require emergency care. The form is signed by the patient and the provider and placed in the patient's medical record, and a copy is provided to the patient, to document the patient's acknowledgment of receiving the information from the prescriber. The Agency agrees that the further clarification that signatures can be written or electronic is appropriate for the continued use of the form.

The reference to ectopic pregnancy has been reorganized in the document since it is not a risk of the drug. The signs and symptoms of an untreated ectopic pregnancy that may persist after mifepristone use have been clarified in the section of the form that explains the signs and symptoms of potential problems that may occur after mifepristone use.

The review team agrees with removing the patient's agreement to take the Medication Guide with them if they visit an emergency room or HCP who did not give them mifepristone so the emergency room or HCP will understand that the patient is having a medical abortion. Although this statement has been in the Medication Guide for a number of years, upon further consideration, the Agency has concluded that patients seeking emergency medical care are not likely to carry a Medication Guide with them, the Medication Guide is readily available online, and information about medical conditions and previous treatments can be obtained at the point of care.

3.3.2.3. Pharmacy Requirements

The Sponsors proposed that certified pharmacies, in addition to certified prescribers and HCPs under the supervision of certified prescribers, can dispense mifepristone. In order for a pharmacy to become certified, the pharmacy must designate an authorized representative to carry out the certification process and oversee implementation and compliance with the Mifepristone REMS Program on behalf of the pharmacy. The Authorized Representative must certify that they have read and understood the Prescribing Information for mifepristone. Each location of the pharmacy must be able to receive *Prescriber Agreement Forms* by email and fax and be able to ship mifepristone using a shipping service that provides tracking information.

Additionally, each dispensing pharmacy location must put processes and procedures in place to fulfill the REMS requirements. Certified pharmacies must verify prescriber certification by confirming they have obtained a copy of the prescriber's signed *Prescriber Agreement Form* before dispensing. Certified pharmacies must dispense mifepristone such that it is received by the patient within four days from the day of prescription receipt by the pharmacy. If the pharmacy will not be able to deliver mifepristone to the patient within four days of receipt of the prescription, the pharmacy must contact the prescriber to confirm the appropriateness of dispensing mifepristone and document the certified prescriber's decision. The pharmacy must also record the NDC and lot number from each package of mifepristone dispensed in the patient's record, track and verify receipt of each shipment of mifepristone, dispense mifepristone in its original package, and only distribute, transfer, loan, or sell mifepristone to certified prescribers or between locations of the certified pharmacy. The pharmacy must also report any patient deaths to the prescriber, including the NDC and lot number from the package dispensed to the patient, and remind the prescriber of their obligation under the REMS to report patient deaths to the Sponsor that supplied the mifepristone; the certified pharmacy also must notify the Sponsor that supplied the mifepristone that the pharmacy submitted a report of a patient death to the prescriber and include the name and contact information for the prescriber as well as the NDC and lot number of the dispensed

product. Record-keeping requirements of the pharmacy include records of *Prescriber Agreement Forms*, mifepristone dispensing and shipping, and all processes and procedures and compliance with those processes and procedures. Pharmacies must train all relevant staff and participate in compliance audits. Pharmacies must also maintain the identity of patients and providers as confidential, including limiting access to patient and provider identity only to those personnel necessary to dispense mifepristone in accordance with the Mifepristone REMS Program requirements, or as necessary for payment and/or insurance purposes. The requirement that mifepristone not be dispensed from retail pharmacies was removed.

The following materials support pharmacy requirements:

- *Pharmacy Agreement Form* for Danco Laboratories, LLC
- *Pharmacy Agreement Form* for GenBioPro, Inc.

Reviewer Comment: *We agree with the Sponsors' proposal. The Mifepristone REMS Program continues to require that mifepristone be prescribed only by certified prescribers. With the removal of the in-person dispensing requirement, however, mifepristone can be dispensed from a pharmacy, provided the product is prescribed by a certified prescriber and all other requirements of the REMS are met. Given this modification to the dispensing requirements in the REMS, it is necessary to add a requirement for certification of pharmacies. Adding the pharmacy certification requirement incorporates pharmacies into the REMS, ensures that pharmacies are aware of and agree to follow applicable REMS requirements, and ensures that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers. Without pharmacy certification, a pharmacy might dispense product that was not prescribed by a certified prescriber. Adding pharmacy certification ensures that the prescriber is certified prior to dispensing the product to a patient; certified prescribers, in turn, have agreed to meet all the conditions of the REMS, including ensuring that the Patient Agreement Form is completed. In addition, wholesalers and distributors can only ship to certified pharmacies. Based on our review and our consideration of the distribution model implemented by the Sponsors during the periods when the in-person dispensing requirement was not being enforced, as well as REMS assessment data and published literature, we conclude that provided all other requirements of the REMS are met, the REMS program, with the removal of the in-person dispensing requirement and the addition of a requirement for pharmacy certification, will continue to ensure the benefits of mifepristone for medical abortion outweigh the risks while minimizing the burden imposed by the REMS on healthcare providers and patients.*

The requirement to maintain confidentiality, including limiting access to patient and provider identity only to those personnel necessary for dispensing under the Mifepristone REMS Program or as necessary for payment and/or insurance purposes, is included to avoid unduly burdening patient access.

The Sponsors proposed inclusion of this requirement because of concerns that patients may be reluctant or unwilling to seek to obtain mifepristone from pharmacies if they are concerned that confidentiality of their medical information could be compromised, potentially exposing them to intimidation, threats, or acts of violence by individuals opposed to the use of mifepristone for medical abortion.[e] *Further, unwillingness on the part of prescribers to participate in the Mifepristone REMS Program on the basis of*

[e] See e.g., *2020 Violence and Disruption Statistics,* National Abortion Federation (Dec. 16, 2021), https://prochoice.org/national-abortion-federation-releases-2020-violence-disruption-statistics/; Amanda Musa, CNN, *Wyoming Authorities Search for a Suspect Believed to Have Set an Abortion Clinic on Fire*, CNN WIRE (June 10, 2022), https://abc17news.com/news/2022/06/10/wyoming-authorities-search-for-a-suspect-believed-to-have-set-an-abortion-clinic-on-fire/.

Reference ID: 5103819

similar confidentiality concerns may unduly burden patient access by limiting the number of prescribers who are willing to send prescriptions to certified pharmacies. Addition of this requirement protects patient access by requiring the pharmacy to put processes and procedures in place to limit access to confidential information to only those individuals who are essential for dispensing mifepristone under the Mifepristone REMS Program or as necessary for payment or insurance purposes. Inclusion of this requirement for certified pharmacies is consistent with the requirement in the current Mifepristone REMS Program, that distributors maintain secure and confidential records.

Reference to mifepristone not being available in retail pharmacies was removed from the REMS. There is no single definition of the term "retail pharmacy" and therefore the scope of the exclusion in the REMS was not well defined. Including a restriction in the Mifepristone REMS Program that retail pharmacies cannot participate in the REMS may unintentionally prohibit the participation of mail order and specialty pharmacies that could, under one or more definitions, also be considered a "retail pharmacy."

After reconsideration of the term, "retail," the Agency concluded that a more appropriate approach was to articulate the specific requirements that would be necessary for pharmacy certification. As modified, the REMS will not preclude the participation of any pharmacy that meets the certification requirements. However, we acknowledge that the provision in the REMS related to pharmacies' verification of prescriber enrollment will likely limit the types of pharmacies that will choose to certify in the REMS. The REMS requires that pharmacies dispense mifepristone only after verifying that the prescriber is certified. The REMS further requires that pharmacies be able to receive the Prescriber Agreement Forms by email and fax. (b) (4)

The pharmacy certification requirements include that the drug reach patients within four days of the certified pharmacy receiving the prescription. During the course of the review, the review team concluded that requiring medication delivery to the patient within four days of the pharmacy's receipt of a prescription is acceptable based on the labeled indication and literature,[13] while taking into account practical shipping considerations (e.g., shipping over weekends and holidays). For patients who will not receive the drug within four calendar days of the date the pharmacy receives the prescription, the pharmacy must notify the certified prescriber and the certified prescriber must determine if it is still appropriate for the certified pharmacy to dispense the drug. The pharmacy must document the certified prescriber's decision. A prescriber's confirmation that it is appropriate to dispense mifepristone when it will not be delivered to the patient within the allotted four days is intended to ensure timeliness of delivery in light of the labeled indication and gestational age.

Pharmacy Agreement Form

The proposed *Pharmacy Agreement Form* is a new form and is the means by which a pharmacy becomes certified to dispense mifepristone. The form, which is submitted by an authorized representative on behalf of a pharmacy seeking certification, outlines all requirements proposed above. Clarification is included in the form that healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program, do not require pharmacy certification. Any new authorized representative must complete and submit the *Pharmacy Agreement Form*. Spaces for specific authorized representative information and pharmacy name and address are included. The completed form can be submitted by email or fax to the authorized distributor.

Reviewer Comment: *We agree with the Sponsors' proposal. The Pharmacy Agreement Form aligns with the pharmacy requirements discussed above.*

3.3.2.4. Distributor Requirements

The Sponsors proposed that the distributors' processes and procedures in the approved Mifepristone REMS Program be updated to ensure that mifepristone is only shipped to clinics, medical offices and hospitals identified by certified prescribers and to certified pharmacies. Distributors will continue to complete the certification process for any *Prescriber Agreement Forms* they receive and also will complete the certification process for pharmacies upon receipt of a *Pharmacy Agreement Form*, including notifying pharmacies when they become certified. FDA was removed as a potential auditor for distributors.

Reviewer Comment: *We agree with the Sponsors' proposal. At this time, FDA does not audit distributors directly, it carries out inspections of Sponsors to monitor industry compliance with REMS requirements.*

3.3.3. REMS Sponsor Requirements

3.3.3.1. Sponsor Requirements to Support Prescriber Certification

The Sponsors proposed additions to this section of the REMS document, including that Sponsors will ensure prescribers can complete the certification process by email or fax to an authorized distributor and/or certified pharmacy, and that Sponsors will ensure annually with each certified prescriber that their locations for receiving mifepristone are up to date. Sponsors will also ensure prescribers previously certified in the Mifepristone REMS Program complete the new *Prescriber Agreement Form*: (1) within 120 days after approval of this modification, for those previously certified prescribers submitting prescriptions to certified pharmacies, or (2) within one year after approval of this modification, if previously certified and ordering from an authorized distributor.

Reviewer Comment: *We agree with the Sponsors' proposal. The requirement to confirm that the locations associated with the certified prescriber are current is parallel to the pharmacy requirement that the authorized representative's contact information is up to date. In determining the pharmacy requirement, which is necessary to ensure program compliance and is consistent with other approved REMS that include pharmacy certification, the Agency also concluded that a parallel requirement for certified prescribers should be added.*

With respect to recertification, it is important that active certified prescribers are informed of and agree to new REMS requirements to ensure the continued safe use of mifepristone. There is minimal burden to recertification and the timelines allow sufficient time to accomplish recertification.

3.3.3.2. Sponsor Requirements to Support Pharmacy Certification

The Sponsors proposed the addition of Sponsor requirements to support pharmacy certification and compliance, including ensuring that pharmacies are certified in accordance with the requirements in the Mifepristone REMS Program, de-certifying pharmacies that do not maintain compliance with the certification requirements, and ensuring that pharmacy certification can be completed by email and fax to an authorized distributor. Annually, the authorized representative's name and contact information will be verified to ensure it corresponds to that of the current designated authorized representative for the certified pharmacy, and if different, a new authorized representative must certify for the pharmacy. All reference to the requirement in the 2021 Mifepristone REMS Program that mifepristone to be dispensed to patients only in clinics, medical offices and hospitals by or under the supervision of a certified prescriber, and not from retail pharmacies, was removed.

Reviewer Comment: *We agree with the Sponsors' proposal. Changes are in line with the REMS Modification Notification letters sent December 16, 2021. Refer to section 3.3.2.3 Reviewer Comments on Pharmacy Certification for rationale for removing the statement that mifepristone is not distributed to or dispensed from retail pharmacies. Ensuring that the authorized representative's contact information is up to date is necessary to ensure that there is always a point person who is responsible for implementing the Mifepristone REMS Program in their pharmacy and can address any changes that are needed if pharmacy audits identify a need for improvement.*

3.3.3.3. Sponsor Implementation Requirements

The Sponsors proposed that they will ensure that adequate records are maintained to demonstrate that REMS requirements have been met (including but not limited to records of mifepristone distribution, certification of prescribers and pharmacies, and audits of pharmacies and distributors), and that the records must be readily available for FDA inspections. The distributor audit requirement was updated to audit new distributors within 90 calendar days of becoming authorized and annually thereafter (a one-time audit requirement was previously required). The Sponsors also proposed a pharmacy audit requirement whereby certified pharmacies that order mifepristone are audited within 180 calendar days after the pharmacy places its first order of mifepristone, and annually thereafter for pharmacies that ordered in the previous 12 months.

Reviewer's Comment: *We agree with the Sponsors' proposal.*

The number of pharmacies that will certify in the REMS is uncertain; therefore, to obtain a reliable sample size for the audits, the Sponsors will need to audit all certified pharmacies within 180 calendar days after the pharmacy places its first order and annually thereafter for pharmacies that have ordered mifepristone in the previous 12 months. Audits performed at 180 days should allow time for establishment and implementation of audit protocols and for the Sponsors to perform the audits. With the addition of more stakeholders (i.e., certified pharmacies), it is also necessary to audit distributors annually to ensure the REMS requirements are followed. The requirement to conduct audits annually may be revisited if assessment data shows that the REMS is meeting its goal.

3.4. REMS Assessment Timetable

The Sponsors proposed that assessments must be submitted one year from the approval of the modified REMS and annually thereafter, instead of every three years as per the previous requirement.

Reviewer's Comment*: We agree with the Sponsors' proposal. With the addition of new pharmacy stakeholders and removal of the in-person dispensing requirement, more frequent assessment after this REMS modification is needed to ensure REMS processes are being followed and that the REMS is meeting its goal. The requirement can be revisited at a later date if assessment data shows that the modified REMS is meeting its goal. The NDA applicant is required to submit assessment reports as outlined in the timetable for submission of assessments. These reports address requirements for the Mifepristone REMS Program. The Sponsors have indicated that some data will be submitted as separate reports when Sponsor-specific information is needed to address the assessment metrics.*

4. Supporting Document

The Sponsors' REMS Supporting Document was substantially updated to include information regarding the proposed modification under review. Background and rationale from the 12/16/21 REMS Modification Notification letters was included. An updated description of the REMS goal and the ETASU was also included to align with the changes in the REMS Document and provide further clarification. Further explanation of prescriber requirements and rationale for various pharmacy requirements was also included.

Regarding implementation of the modified REMS, the Sponsors additionally proposed that pharmacies that received and shipped mifepristone during the Agency's exercise of enforcement discretion during the COVID-19 PHE, that wish to continue to dispense mifepristone, will be required to comply with the pharmacy certification requirements within 120 days of approval of the modified REMS.

The communication strategy to alert current and future prescriber and pharmacy stakeholders was outlined. Distributors, certified prescribers that purchased mifepristone in the last twelve months, and various professional organizations will receive information about REMS changes within 120 days of modification approval. The Sponsors proposed to list pharmacies that agree to be publicly disclosed on their respective product websites but disclosure of this nature is not a requirement of the REMS. The Sponsors indicated that they anticipate certified pharmacies that do not agree to public disclosure will communicate with the certified prescribers they wish to work with.

The REMS Assessment Plan is discussed in the following section.

Reviewer's Comment*: We agree with the Sponsors' proposal. The Supporting Document addresses all REMS requirements and provides sufficient clarification of implementation and maintenance of the REMS. The implementation requirements for pharmacies currently dispensing mifepristone under FDA's exercise of enforcement discretion during the COVID-19 PHE provide for continued use of these pharmacies without breaks in service. The communication strategy is also adequate given the efforts to reach both established certified prescribers and potentially new prescribers through professional organizations.*

The Sponsors' plan to communicate which pharmacies are certified to certified prescribers is adequate. For the reasons listed in section 3.3.2.3, confidentiality is a concern for REMS stakeholders. Disclosure of pharmacy certification status should be a choice made by individual certified pharmacies. The Sponsors have indicated that there will be some certified pharmacies that have agreed to publicly disclose their status, making this information available to certified prescribers who wish to use a pharmacy to dispense mifepristone.

5. REMS Assessment Plan

The REMS Assessment Plan is summarized in the REMS Supporting Document and will be included in the REMS Modification Approval letter.

The REMS Assessment Plan was revised to align with the modified REMS goal and objectives.

The goal of the Mifepristone REMS Program is to mitigate the risk of serious complications associated with mifepristone by:

a. Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.
    - This objective will be assessed using REMS Certification Statistics and REMS Compliance metrics.

b. Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.
    - This objective will be assessed using REMS Certification Statistics and REMS Compliance metrics.

c. Informing patients about the risk of serious complications associated with mifepristone.
    - This objective will be indirectly assessed using REMS Certification Statistics to avoid compromising patient and prescriber confidentiality. As part of the certification process, healthcare providers agree to:
        - Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained
        - Ensure that the *Patient Agreement Form* is signed by the healthcare provider and the patient
        - Ensure that the patient is provided with a copy of the *Patient Agreement Form* and the Medication Guide
        - Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record

The following revisions were made from the Mifepristone REMS Assessment Plan in the April 11, 2019, Supplement Approval letter:

The Assessment Plan Categories of 1) Program Implementation and Operations and 2) Overall Assessment of REMS Effectiveness were added.

REMS Certification Statistics metrics were added to capture certification numbers for program stakeholders to assess the first objective of requiring healthcare providers who prescribe mifepristone to be certified and the second objective of ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers. The total number of certified prescribers who certified with the wholesaler/distributor and the total number of certified prescribers who submitted a *Prescriber Agreement Form* to certified pharmacies were added to capture the additional method of prescriber certification. The number of newly certified prescribers and the number of active certified prescribers (i.e., those who ordered mifepristone or submitted a prescription during the reporting period) were added. Metrics were also added to capture the total number of certified, newly certified, and active certified pharmacies as well as the total number of authorized, newly authorized, and active authorized wholesaler/distributors.

Drug Utilization Data metrics were added to obtain information on shipment and dispensing of mifepristone. Metrics were added to capture the total number of tablets shipped by the wholesaler/distributor and the number of prescriptions dispensed.

REMS Compliance Data metrics were added to assess the first objective of requiring healthcare providers who prescribe mifepristone to be certified and the second objective of ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers. These metrics capture program deviations and evaluate overall if the REMS is operating as intended. Metrics include certified pharmacies and wholesaler/distributor audit results and a summary of instances of non-compliance and actions taken to address non-compliance. Prescriber compliance metrics were added to assess if prescribers are decertified along with reasons why. Pharmacy compliance metrics were added to assess if prescriptions were dispensed that were written by non-certified prescribers or if mifepristone tablets were dispensed by non-certified pharmacies as well as the number of pharmacies that were decertified along with reasons why. Wholesaler/distributor metrics were added to assess if shipments were sent to non-certified prescribers and non-certified pharmacies and corrective actions taken. The audit plan and non-compliance plans will be submitted for FDA review within 60 days after the REMS modification approval.

The Sponsors were asked to develop an assessment of prescription delivery timelines to determine what percentage of prescriptions were delivered on time (within four calendar days) and what percentage were delivered late (more than four calendar days) along with the length of the delay and reasons for the delay (e.g., mifepristone is out of stock shipment issues, other). The protocol for this assessment will be submitted for FDA review within 60 days after the REMS modification approval.

The revised REMS Assessment Plan is in the Appendix.

Reviewer's Comment*: We agree with the Sponsors' proposed REMS Assessment Plan.*

6. Discussion

The Sponsors submitted changes to the REMS to remove the requirement that mifepristone be dispensed only in certain healthcare settings (i.e., the "in-person dispensing requirement") and to add that certified pharmacies can dispense the drug in order to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks. The REMS goal was updated to this effect. Changes were required for prescriber requirements and Sponsors to support the change in ETASU, and new pharmacy requirements were introduced.

The qualifications to become a certified prescriber have not changed as a result of the modification to the Mifepristone REMS Program; however, clarification has been provided for certain prescriber requirements and new prescriber requirements have been added to support pharmacy dispensing. Although certain responsibilities may be conducted by staff under the supervision of a certified prescriber, the certified prescriber remains responsible for ensuring compliance with the requirements of the Mifepristone REMS Program. In order to clarify this, revisions were made throughout the prescriber requirements and REMS materials to reflect that the certified prescriber is responsible for ensuring that the prescriber requirements are met. Additionally, the review team finds it acceptable that certified prescribers who wish to use a certified pharmacy to dispense mifepristone submit their *Prescriber Agreement Form* to the dispensing certified pharmacy (b) (4) . The burden to prescriber and

pharmacy stakeholders of having certified prescribers submit the form directly to the certified pharmacy that will be dispensing the mifepristone is not unreasonable and has been minimized to the extent possible; it does not impact the safe use of the product. Prescriber requirements necessitated by the addition of some pharmacy requirements were added as well and include prescriber responsibilities in deciding whether or not mifepristone should be dispensed if the patient will receive the drug from the certified pharmacy more than four days after the pharmacy receives the prescription, and prescriber adverse event reporting requirements if a prescriber becomes aware of a patient death and the mifepristone was dispensed from a certified pharmacy. The addition of the latter requirements will ensure consistent adverse event data is relayed to the relevant Mifepristone Sponsor.

Changes were made to the *Patient Agreement Form.* Changes to the form were added to improve clarity of the safety messages. After further consideration, the patient's agreement to take the Medication Guide with them if they visit an emergency room or HCP who did not give them mifepristone so the emergency room or HCP will understand that the patient is having a medical abortion has been removed from the *Patient Agreement Form*. The Medication Guide is not typically carried by patients and this information can be obtained at the point of care. Changes align with updates to labeling submitted with this modification.[13, 14]

The Agency and Sponsors agreed during this modification to focus on certification of pharmacies that can receive *Prescriber Agreement Forms* via email or fax to complete the prescriber certification process. The proposed pharmacy certification requirements also support timely dispensing of mifepristone. If the mifepristone is shipped to the patient, the REMS requires that it must be delivered within four calendar days from the receipt of the prescription by the pharmacy; if the patient will receive the mifepristone more than four calendar days from pharmacy receipt of prescription, the REMS requires the pharmacist to confirm with the certified prescriber that it is still appropriate to dispense the drug to the patient. This allows prescribers to make treatment decisions based on individual patient situations. A requirement to maintain confidentiality was also added to avoid unduly burdening patient access since patients and prescribers may not utilize pharmacy dispensing if they believe their personal information is at risk. Ultimately, the addition of pharmacy distribution with the proposed requirements will offer another option for dispensing mifepristone, alleviating burden associated with the REMS.

(b) (4)

.

The Agency reviewed the REMS in 2021, and per the review team's conclusions, a REMS modification was necessary to remove the in-person dispensing requirement and add a requirement that pharmacies that dispense the drug be specially certified; the review team concluded that these changes could occur without compromising patient safety. There have been no new safety concerns identified relevant to the REMS ETASUs that the applicants proposed modifying in their June 22, 2022 submissions since the REMS Modification Notification letters dated 12/16/2021. It is still the position of the review team that the proposed modification is acceptable.

Because the modification proposed include changes to the ETASU of the Mifepristone REMS Program, the assessment plan and timetable of assessments were changed. The assessment plan will capture information on pharmacy dispensing and provide valuable insight as to whether the program is operating as intended Annual assessments are consistent with other approved REMS modifications for major modifications necessitating extensive assessment plan changes.

As part of the REMS Assessment Plan, the REMS goal and objectives are assessed using Program Implementation and Operations Metrics, including REMS Certification Statistics and REMS Compliance Data. The metrics will provide information on the number of certified prescribers, certified pharmacies, and authorized wholesalers/distributors as well as if mifepristone is dispensed by non-certified prescribers or pharmacies. The Sponsors will use the indirect measure of healthcare provider certification to address the objective of informing patients of the risk of serious complications of mifepristone, due to concerns with prescriber and patient confidentiality. Although we typically assess whether patients are informed of the risks identified in a REMS through patient surveys and/or focus groups, we agree that the Sponsors' continued use of the indirect measure of healthcare provider certification adequately addresses the Mifepristone REMS Program objective of informing patients. In addition, because of these prescriber and patient confidentiality concerns, we believe it is unlikely that the Agency would be able to use the typical methods of assessment of patient knowledge and understanding of the risks and safe use of mifepristone.

7. Conclusions and Recommendations

The review team finds the proposed REMS modification for the Mifepristone REMS Program, as submitted on June 22, 2022, and amended on October 19, 2022 (Danco) and October 20, 2022 (GBP), November 30, 2022 (both), December 9 (both), and December 16 (both) acceptable. The REMS materials were amended to be consistent with the revised REMS document. The review team recommends approval of the Mifepristone REMS Program, received on June 22, 2022, and last amended on December 16, 2022, and appended to this review.

RISK EVALUATION AND MITIGATION STRATEGY (REMS)
SINGLE SHARED SYSTEM FOR MIFEPRISTONE 200 MG

I. GOAL

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.

c) Informing patients about the risk of serious complications associated with mifepristone.

II. REMS ELEMENTS

A. Elements to Assure Safe Use

1. Healthcare providers who prescribe mifepristone must be specially certified.
   a. To become specially certified to prescribe mifepristone, healthcare providers must:
      i. Review the Prescribing Information for mifepristone.
      ii. Complete a *Prescriber Agreement Form*. By signing[1] a *Prescriber Agreement Form*, prescribers agree that:
         1) They have the following qualifications:
            a) Ability to assess the duration of pregnancy accurately
            b) Ability to diagnose ectopic pregnancies
            c) Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or to have made plans to provide such care through others, and ability to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary
         2) They will follow the guidelines for use of mifepristone (see b.i-vii below).
   b. As a condition of certification, prescribers must follow the guidelines for use of mifepristone described below:
      i. Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
      ii. Ensure that the healthcare provider and patient sign the *Patient Agreement Form.*

[1] In this REMS, the terms "sign" and "signature" include electronic signatures.

Reference ID: 5103819

iii. Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.

iv. Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.

v. Ensure that any deaths are reported to the Mifepristone Sponsor that provided the mifepristone, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of mifepristone that was dispensed to the patient.

vi. If mifepristone will be dispensed by a certified pharmacy:

1) Provide the certified pharmacy a signed *Prescriber Agreement Form*.

2) Assess appropriateness of dispensing mifepristone when contacted by a certified pharmacy about patients who will receive mifepristone more than 4 calendar days after the prescription was received by the certified pharmacy.

3) Obtain the NDC and lot number of the package of mifepristone the patient received in the event the prescriber becomes aware of the death of the patient.

vii. The certified prescriber who dispenses mifepristone or who supervises the dispensing of mifepristone must:

1) Provide an authorized distributor with a signed *Prescriber Agreement Form*.

2) Ensure that the NDC and lot number from each package of mifepristone dispensed are recorded in the patient's record.

3) Ensure that healthcare providers under their supervision follow guidelines i.-v.

c. Mifepristone Sponsors must:

i. Ensure that healthcare providers who prescribe their mifepristone are specially certified in accordance with the requirements described above and de-certify healthcare providers who do not maintain compliance with certification requirements.

ii. Ensure prescribers previously certified in the Mifepristone REMS Program complete the new *Prescriber Agreement Form*:

1) Within 120 days after approval of this modification, for those previously certified prescribers submitting prescriptions to certified pharmacies.

2) Within one year after approval of this modification, if previously certified and ordering from an authorized distributor.

iii. Ensure that healthcare providers can complete the certification process by email or fax to an authorized distributor and/or certified pharmacy.

iv. Provide the Prescribing Information and their *Prescriber Agreement Form* to healthcare providers who inquire about how to become certified.

v. Ensure annually with each certified prescriber that their locations for receiving mifepristone are up to date.

The following materials are part of the Mifepristone REMS Program:

- *Prescriber Agreement Form for Danco Laboratories, LLC*
- *Prescriber Agreement Form for GenBioPro, Inc.*
- *Patient Agreement Form*

2. Pharmacies that dispense mifepristone must be specially certified
   a. To become specially certified to dispense mifepristone, pharmacies must:
      i. Be able to receive *Prescriber Agreement Forms* by email and fax.
      ii. Be able to ship mifepristone using a shipping service that provides tracking information.
      iii. Designate an authorized representative to carry out the certification process on behalf of the pharmacy.
      iv. Ensure the authorized representative oversees implementation and compliance with the Mifepristone REMS Program by doing the following:
         1) Review the Prescribing Information for mifepristone.
         2) Complete a *Pharmacy Agreement Form*. By signing a *Pharmacy Agreement Form*, the authorized representative agrees that the pharmacy will put processes and procedures in place to ensure the following requirements are completed:
            a) Verify that the prescriber is certified by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with the pharmacy.
            b) Dispense mifepristone such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in c) below.
            c) Confirm with the prescriber the appropriateness of dispensing mifepristone for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
            d) Record in the patient's record the NDC and lot number from each package of mifepristone dispensed.
            e) Track and verify receipt of each shipment of mifepristone.
            f) Dispense mifepristone in its package as supplied by the Mifepristone Sponsor.
            g) Report any patient deaths to the prescriber, including the NDC and lot number from the package of mifepristone dispensed to the patient, and remind the prescriber of their obligation to report the deaths to the Mifepristone Sponsor that provided the mifepristone. Notify the Mifepristone Sponsor that provided the dispensed mifepristone that the pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
            h) Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
            i) Maintain records of *Prescriber Agreement Forms*.
            j) Maintain records of dispensing and shipping.
            k) Maintain records of all processes and procedures including compliance with those processes and procedures.
            l) Maintain the identity of the patient and prescriber as confidential, including limiting access to patient and prescriber identity only to those personnel necessary to dispense mifepristone in accordance with the Mifepristone REMS Program requirements, or as necessary for payment and/or insurance purposes.
            m) Train all relevant staff on the Mifepristone REMS Program requirements.

n) Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

b. Mifepristone Sponsors must:

i. Ensure that pharmacies are specially certified in accordance with the requirements described above and de-certify pharmacies that do not maintain compliance with certification requirements.

ii. Ensure that pharmacies can complete the certification process by email and fax to an authorized distributor.

i. Verify annually that the name and contact information for the pharmacy's authorized representative corresponds to that of the current designated authorized representative for the certified pharmacy, and if different, require the pharmacy to recertify with the new authorized representative.

The following materials are part of the Mifepristone REMS Program:

- *Pharmacy Agreement Form for Danco Laboratories, LLC*
- *Pharmacy Agreement Form for GenBioPro, Inc.*

3. Mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions as ensured by the certified prescriber in signing the *Prescriber Agreement Form*.

a. The patient must sign a *Patient Agreement Form* indicating that the patient has:

i. Received, read and been provided a copy of the *Patient Agreement Form*.

ii. Received counseling from the healthcare provider regarding the risk of serious complications associated with mifepristone.

B. Implementation System

1. Mifepristone Sponsors must ensure that their mifepristone is only distributed to certified prescribers and certified pharmacies by:

a. Ensuring that distributors who distribute their mifepristone comply with the program requirements for distributors.

i. The distributors must put processes and procedures in place to:

1) Complete the certification process upon receipt of a *Prescriber Agreement Form* or *Pharmacy Agreement Form*.

2) Notify healthcare providers and pharmacies when they have been certified by the Mifepristone REMS Program.

3) Ship mifepristone only to certified pharmacies or locations identified by certified prescribers.

4) Not ship mifepristone to pharmacies or prescribers who become de-certified from the Mifepristone REMS Program.

5) Provide the Prescribing Information and their Prescriber Agreement Form to healthcare providers who (1) attempt to order mifepristone and are not yet certified, or (2) inquire about how to become certified.

ii. Put processes and procedures in place to maintain a distribution system that is secure,

confidential and follows all processes and procedures, including those for storage, handling, shipping, tracking package serial numbers, NDC and lot numbers, proof of delivery and controlled returns of mifepristone.

iii. Train all relevant staff on the Mifepristone REMS Program requirements.

iv. Comply with audits by Mifepristone Sponsors or a third party acting on behalf of Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed for the Mifepristone REMS Program. In addition, distributors must maintain appropriate documentation and make it available for audits.

b. Ensuring that distributors maintain secure and confidential distribution records of all shipments of mifepristone.

2. Mifepristone Sponsors must monitor their distribution data to ensure compliance with the Mifepristone REMS Program.

3. Mifepristone Sponsors must ensure that adequate records are maintained to demonstrate that the Mifepristone REMS Program requirements have been met, including, but not limited to records of mifepristone distribution; certification of prescribers and pharmacies; and audits of pharmacies and distributors. These records must be readily available for FDA inspections.

4. Mifepristone Sponsors must audit their new distributors within 90 calendar days and annually thereafter after the distributor is authorized to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their distributor compliance if noncompliance is identified.

5. Mifepristone Sponsors must audit their certified pharmacies within 180 calendar days after the pharmacy places its first order of mifepristone, and annually thereafter audit certified pharmacies that have ordered mifepristone in the previous 12 months, to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their pharmacy compliance if noncompliance is identified.

6. Mifepristone Sponsors must take reasonable steps to improve implementation of and compliance with the requirements of the Mifepristone REMS Program based on monitoring and assessment of the Mifepristone REMS Program.

7. Mifepristone Sponsors must report to FDA any death associated with mifepristone whether or not considered drug-related, as soon as possible but no later than 15 calendar days from the initial receipt of the information by the Mifepristone Sponsor. This requirement does not affect the sponsors' other reporting and follow-up requirements under FDA regulations.

C. Timetable for Submission of Assessments

The NDA Sponsor must submit REMS assessments to FDA one year from the date of the approval of the modified REMS (1/3/2023) and annually thereafter. To facilitate inclusion of as much information as possible while allowing reasonable time to prepare the submission, the reporting interval covered by each assessment should conclude no earlier than 90 calendar days before the submission date for that assessment. The NDA Sponsor must submit each assessment so that it will be received by the FDA on or before the due date.

MIFEPREX® (Mifepristone) Tablets, 200 mg

PRESCRIBER AGREEMENT FORM

Mifeprex* (Mifepristone) Tablets, 200 mg, is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. Please see Prescribing Information and Medication Guide for complete safety information.

To ***become a certified prescriber***, you must:

- **If you submit Mifeprex prescriptions for dispensing from certified pharmacies**:
  - Submit this form to each certified pharmacy to which you intend to submit Mifeprex prescriptions. The form must be received by the certified pharmacy before any prescriptions are dispensed by that pharmacy.
- **If you order Mifeprex for dispensing by you or healthcare providers under your supervision:**
  - Submit this form to the distributor. This form must be received by the distributor before the first order will be shipped to the healthcare setting.
  - Healthcare settings, such as medical offices, clinics, and hospitals, where Mifeprex will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

Prescriber Agreement: By signing this form, you agree that you meet the qualifications below and will follow the guidelines for use. You are responsible for overseeing implementation and compliance with the Mifepristone REMS Program. You also understand that if the guidelines below are not followed, the distributor may stop shipping mifepristone to the locations that you identify and certified pharmacies may stop accepting your mifepristone prescriptions.

Mifepristone must be provided by or under the supervision of a certified prescriber who meets the following qualifications:

- Ability to assess the duration of pregnancy accurately.
- Ability to diagnose ectopic pregnancies.
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the Prescribing Information for mifepristone. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free), or by visiting www.earlyoptionpill.com.

In addition to meeting these qualifications, you also agree to follow these guidelines for use:

- Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
- Ensure the healthcare provider and patient sign the *Patient Agreement Form*.
- Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.
- Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.
- Ensure that any deaths of patients who received Mifeprex are reported to Danco Laboratories, LLC, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of Mifeprex that was dispensed to the patient.

*MIFEPREX is a registered trademark of Danco Laboratories, LLC
P.O. Box 4816-New York, NY 10185
1-877-4-EARLY-OPTION (1-877-432-7596) www.earlyoptionpill.com

Ensure that healthcare providers under your supervision follow the guidelines listed above.

- If Mifeprex will be dispensed through a certified pharmacy:
  - Assess appropriateness of dispensing Mifeprex when contacted by a certified pharmacy about patients who will receive Mifeprex more than 4 calendar days after the prescription was received by the certified pharmacy.
  - Obtain the NDC and lot number of the package of Mifeprex the patient received in the event the prescriber becomes aware of the death of a patient.
- If Mifeprex will be dispensed by you or by healthcare providers under your supervision:
  - Ensure the NDC and lot number from each package of Mifeprex are recorded in the patient's record.

I understand that a certified pharmacy may dispense mifepristone made by a different manufacturer than that stated on this Prescriber Agreement Form.

PATIENT AGREEMENT FORM Mifepristone Tablets, 200 mg

Healthcare Providers: *Counsel the patient on the risks of mifepristone. Both you and the patient must provide a written or electronic signature on this form.*

Patient Agreement:

1. I have decided to take mifepristone and misoprostol to end my pregnancy and will follow my healthcare provider's advice about when to take each drug and what to do in an emergency.
2. I understand:
   a. I will take mifepristone on Day 1.
   b. I will take the misoprostol tablets 24 to 48 hours after I take mifepristone.
3. My healthcare provider has talked with me about the risks, including:
   - heavy bleeding
   - infection
4. I will contact the clinic/office/provider right away if in the days after treatment I have:
   - a fever of 100.4°F or higher that lasts for more than four hours
   - heavy bleeding (soaking through two thick full-size sanitary pads per hour for two hours in a row)
   - severe stomach area (abdominal) pain or discomfort, or I am “feeling sick,” including weakness, nausea, vomiting, or diarrhea, more than 24 hours after taking misoprostol
     — these symptoms may be a sign of a serious infection or another problem (including an ectopic pregnancy, a pregnancy outside the womb).

   My healthcare provider has told me that these symptoms listed above could require emergency care. If I cannot reach the clinic/office/provider right away, my healthcare provider has told me who to call and what to do.
5. I should follow up with my healthcare provider about 7 to 14 days after I take mifepristone to be sure that my pregnancy has ended and that I am well.
6. I know that, in some cases, the treatment will not work. This happens in about 2 to 7 out of 100 women who use this treatment. If my pregnancy continues after treatment with mifepristone and misoprostol, I will talk with my provider about a surgical procedure to end my pregnancy.
7. If I need a surgical procedure because the medicines did not end my pregnancy or to stop heavy bleeding, my healthcare provider has told me whether they will do the procedure or refer me to another healthcare provider who will.
8. I have the MEDICATION GUIDE for mifepristone.
9. My healthcare provider has answered all my questions.

MIFEPREX®(Mifepristone) Tablets, 200mg

PHARMACY AGREEMENT FORM

Pharmacies must designate an authorized representative to carry out the certification process and oversee implementation and compliance with the Mifepristone REMS Program on behalf of the pharmacy.

Healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

By signing this form, as the Authorized Representative I certify that:

- Each location of my pharmacy that will dispense Mifeprex is able to receive *Prescriber Agreement Forms* by email and fax.
- Each location of my pharmacy that will dispense Mifeprex is able to ship Mifeprex using a shipping service that provides tracking information.
- I have read and understood the Prescribing Information for Mifeprex. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free) or online at www.earlyoptionpill.com; and
- Each location of my pharmacy that will dispense Mifeprex will put processes and procedures in place to ensure the following requirements are completed. I also understand that if my pharmacy does not complete these requirements, the distributor may stop accepting Mifeprex orders.
  - Verify that the prescriber is certified in the Mifepristone REMS Program by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with your pharmacy.
  - Dispense Mifeprex such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in the following bullet.
  - Confirm with the prescriber the appropriateness of dispensing Mifeprex for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
  - Record in the patient's record the NDC and lot number from each package of Mifeprex dispensed.
  - Track and verify receipt of each shipment of Mifeprex.
  - Dispense mifepristone in its package as supplied by Danco Laboratories, LLC.
  - Report any patient deaths to the prescriber, including the NDC and lot number from the package of Mifeprex dispensed to the patient, and remind the prescriber of their obligation to report the deaths to Danco Laboratories, LLC. Notify Danco that your pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
  - Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
  - Maintain records of *Prescriber Agreement Forms*, dispensing and shipping, and all processes and procedures including compliance with those processes and procedures.
  - Maintain the identity of Mifeprex patients and prescribers as confidential and protected from disclosure except to the extent necessary for dispensing under this REMS or as necessary for payment and/or insurance.
  - Train all relevant staff on the Mifepristone REMS Program requirements.
  - Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

Any new authorized representative must complete and submit the *Pharmacy Agreement Form*.

  - Record in the patient's record the NDC and lot number from each package of mifepristone dispensed.
  - Track and verify receipt of each shipment of mifepristone.
  - Dispense mifepristone in its package as supplied by GenBioPro, Inc.
  - Report any patient deaths to the prescriber, including the NDC and lot number from the package of mifepristone dispensed to the patient, and remind the prescriber of their obligation to report the deaths to GenBioPro, Inc. Notify GenBioPro that your pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
  - Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
  - Maintain records of *Prescriber Agreement Forms*, dispensing and shipping, all processes and procedures including compliance with those processes and procedures.
  - Maintain the identity of mifepristone patients and prescribers as confidential and protected from disclosure except to the extent necessary for dispensing under this REMS or as necessary for payment and/or insurance purposes.
  - Train all relevant staff on the Mifepristone REMS Program requirements.
  - Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

Any new authorized representative must complete and submit the *Pharmacy Agreement Form*.

Authorized Representative Name: _____ Title: _____

Signature: _____ Date: _____

Email: _____ Phone: _____ Preferred __ email __ phone

Pharmacy Name: _____

Pharmacy Address: _____

Return completed form to **RxAgreements@GenBioPro.com** or fax to **1-877-239-8036.**

The REMS Assessment Plan must include but is not limited to the following items.

Program Implementation and Operations

1. REMS Certification Statistics
   a. Prescribers
      i. Number of certified prescribers who have certified with the Sponsor's distributor(s) and number who have submitted *Prescriber Agreement Forms* to Certified Pharmacies
      ii. Number and percentage of newly certified prescribers
      iii. Number and percentage of active certified prescribers (i.e., who ordered mifepristone or submitted a prescription during the reporting period)

   b. Pharmacies
      i. Number of certified pharmacies
      ii. Number and percentage of newly certified pharmacies
      iii. Number and percentage of active certified pharmacies (i.e., that dispensed mifepristone during the reporting period)
   c. Wholesalers/Distributors
      i. Number of authorized wholesalers/distributors
      ii. Number and percentage of newly authorized wholesalers/distributors
      iii. Number and percentage of active authorized wholesalers/distributors (i.e. that shipped mifepristone during the reporting period)

2. Utilization Data
   a. Total number of tablets shipped by wholesalers/distributors, stratified by Certified Prescriber or Certified Pharmacy location
   b. Number of prescriptions dispensed from pharmacies

3. REMS Compliance Data
   a. Audits: Summary of audit activities for each stakeholder (i.e., certified pharmacies and wholesalers/distributors) including but not limited to:
      i. A copy of the final audit plan for each stakeholder type (provide for the current reporting period)
      ii. The number of audits expected, and the number of audits performed
      iii. The number and type of deficiencies noted
      iv. For those with deficiencies noted, report the corrective and preventive actions (CAPAs) required, if any, to address the deficiencies, including the status (e.g., completed, not completed, in progress) (provide for the current reporting period)
      v. For any stakeholders that did not complete the CAPA within the timeframe specified in the audit plan, describe actions taken (provide for the current reporting period)

vi. A summary report of all resulting changes to processes and procedures necessary to ensure compliance with the REMS requirements (provide for the current reporting period)

b. A summary report of non-compliance, associated corrective action plans (CAPAs), and the status of CAPAs including but not limited to:

i. A copy of the final non-compliance plans for Pharmacies and Distributors (provide for the current reporting period)

ii. For each instance of noncompliance below (iii-v), report the following information (provide for the current reporting period):

1. A unique, anonymized ID for the stakeholder(s) associated with the non-compliance event to enable tracking over time
2. The source of the non-compliance data (e.g., self-reported, audit, other)
3. A root cause analysis of the non-compliance
4. Actions to prevent future occurrences and outcomes of such actions

iii. Prescriber compliance

1. Number and percentage of certified prescribers who became decertified as a result of non- compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
2. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

iv. Pharmacy compliance

1. Number and percentage of prescriptions dispensed that were written by prescriber(s) who did not submit a Prescriber Agreement to the dispensing Certified Pharmacy
2. Number and percentage of mifepristone tablets dispensed by non-certified pharmacies
3. Number and percentage of pharmacies that became decertified as a result of non-compliance
   - Provide a summary of reasons for decertification (provide for the current reporting period)
4. An assessment of prescription delivery timelines, including percentage delivered more than four days after receipt of the prescription, duration and causes for delay. A proposal for this assessment will be submitted within 60 days of the approval of the REMS Modification.
5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

v. Wholesaler/distributor compliance

1. Number of healthcare providers who successfully ordered mifepristone who were not certified
2. Number of non-certified pharmacies that successfully ordered mifepristone
3. Number of shipments sent to non-certified prescriber receiving locations
4. Number of shipments sent to non-certified pharmacy receiving locations

5. Summary and analysis of any program deviations and corrective actions taken (provide for the current reporting period)

The requirements for assessments of an approved REMS under section 505-1(g)(3) include with respect to each goal included in the strategy, an assessment of the extent to which the approved strategy, including each element of the strategy, is meeting the goal or whether one or more such goals or such elements should be modified.

EXECUTIVE SUMMARY

This review provides the [redacted] rationale and conclusions regarding modifications to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (Mifepristone REMS Program) for new drug application (NDA) 20687 and abbreviated new drug application (ANDA) 91178.

ANDA 91178 was approved with the approval of the Mifepristone REMS Program on April 11, 2019 to mitigate the risk of serious complications associated with mifepristone 200 mg. The most recent REMS modification was approved on May 14, 2021. The REMS consists of elements to assure safe use (ETASU) under ETASU A, C and D, an implementation system, and a timetable for submission of assessments. To determine whether a modification to the REMS was warranted, FDA undertook a comprehensive review of the published literature; safety information collected during the COVID-19 public health emergency (PHE); the one-year REMS assessment report of the Mifepristone REMS Program; adverse event data; and information provided by advocacy groups, individuals and the Applicants. Our review also included an examination of literature references provided by plaintiffs in the *Chelius v. Becerra* litigation discussed below.

The modifications to the REMS will consist of:

- Removing the requirement under ETASU C that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (referred to here as the "in-person dispensing requirement" for brevity)
- Adding a requirement under ETASU B that pharmacies that dispense the drug be specially certified

A REMS Modification Notification letter will be sent to both Applicants in the Single Shared System.

1. Introduction

In connection with the *Chelius v. Becerra* litigation, FDA agreed to undertake a full review of the Mifepristone REMS Program, in accordance with the REMS assessment provisions of the Federal Food, Drug, and Cosmetic Act (FD&C Act).[a] This review provides the analysis of the (b) (6) ((b) (6) and the (b) (6) ((b) (6) regarding whether any changes are warranted to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone (hereafter referred to as the Mifepristone REMS Program) for new drug application (NDA) 20687 and abbreviated new drug application (ANDA) 91178. The Mifeprex REMS was initially approved in 2011; the single, shared system REMS for mifepristone 200 mg, known as the Mifepristone REMS Program, was approved in 2019.

The last time the existing REMS elements to assure safe use (under ETASU A, C and D) were reviewed was in the context of our review of supplement S-020 to NDA 20687; these ETASU were updated following review and approval of supplement S-020 on March 29, 2016. The key changes approved in 2016 are summarized below.

Changes to labeling included:

- Changing the dosing of Mifeprex to 200 mg orally x 1
- Extension of maximum gestational age through 70 days
- Inclusion of misoprostol in the indication statement
- Replacing the term “physician” with “licensed healthcare provider”
- Removal of the phrase “Under Federal Law”

The Mifeprex REMS and REMS materials were updated to reflect the changes above, and additional changes were made including:

- Removing the Medication Guide as part of the REMS but retaining it as part of labeling.

2. Background

2.1. PRODUCT AND REMS INFORMATION

[a] Section 505-1(g)(2) of the FD&C Act (21 U.S.C. § 355-1(g)(2)).

Mifepristone is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy (IUP) through 70 days gestation. Mifepristone is available as 200 mg tablets for oral use.

Mifeprex (mifepristone) was approved on September 28, 2000 with a restricted distribution program under 21 CFR 314.520 (subpart H)[b] to ensure that the benefits of the drug outweighed the risk of serious complications associated with mifepristone when used for medical abortion. Mifeprex was deemed to have a REMS under section 505-1 of the Federal Food, Drug, and Cosmetic Act with the passage of the Food and Drug Administration Amendments Act (FDAAA) of 2007, and the Mifeprex REMS was approved on June 8, 2011. On March 29, 2016, as noted above, a supplemental application and REMS modification was approved for Mifeprex. On April 11, 2019, ANDA 091178 was approved, and the Mifepristone REMS Program was approved. The Mifepristone REMS Program is a single, shared system REMS that includes NDA 020687 and ANDA 91178.

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a. Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program (under ETASU A).
b. Ensuring that mifepristone is only dispensed in certain healthcare settings, by or under the supervision of a certified prescriber (under ETASU C).
c. Informing patients about the risk of serious complications associated with mifepristone (under ETASU D).

Under ETASU A, to become specially certified to prescribe mifepristone, a healthcare provider must review the prescribing information, complete and sign the *Prescriber Agreement Form,* and follow the guidelines for use of mifepristone. Under ETASU C, mifepristone must be dispensed to patients only in certain healthcare settings, specifically clinics, medical offices, and hospitals, by or under the supervision of a certified prescriber. Under ETASU D, mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions (i.e., the patient must sign a *Patient Agreement Form*). The Mifepristone REMS Program also includes an implementation system, and a timetable for assessments (one year from the date of the initial approval of the REMS on April 11, 2019, and every three years thereafter).

[b] NDA approval letter Mifeprex (NDA 020687) dated September 28, 2000.

2.2. REGULATORY HISTORY AND EVENTS RELEVANT TO THIS REMS MODIFICATION RATIONALE REVIEW

The following is a summary of significant regulatory history since approval of the REMS modification on March 29, 2016:

- 03/29/2016: FDA approved an efficacy supplement (S-020) that, among other things, provided a new dosing regimen (200 mg mifepristone, followed in 24 to 48 hours by 800 mcg buccal misoprostol), increased the gestational age (GA) to which mifepristone may be used (through 70 days gestation), and modified the REMS.

- 03/29/2019: A Citizen Petition was received requesting that FDA revise the product labeling to reflect pre-2016 provisions (including limiting GA to 49 days and requiring patients to make 3 office visits) and that FDA maintain the REMS.

- 04/11/2019: ANDA 91178 was approved along with the Single Shared System REMS for Mifepristone 200 mg (Mifepristone REMS Program) for NDA 20687 and ANDA 91178.

- 01/31/2020: the COVID-19 public health emergency (PHE) was declared by the Secretary of Health and Human Services (HHS) as having existed since January 27, 2020.[c]

- 7/13/2020: The United States (US) District Court of Maryland granted a preliminary injunction in the *ACOG v. FDA* litigation to temporarily bar enforcement of the Mifepristone REMS Program in-person dispensing requirement during the COVID-19 PHE.

- 1/12/2021: US Supreme Court granted a stay of that injunction.

- 04/12/2021: FDA issued a General Advice Letter to both the NDA and ANDA Applicants, stating that provided that all other requirements of the Mifepristone REMS Program are met, and given that in-person dispensing of mifepristone for medical termination of early pregnancy may present additional COVID-related risks to patients and healthcare

[c] *See* Secretary of Health and Human Services, Determination that a Public Health Emergency Exists (originally issued January 31, 2020, and subsequently renewed), available at https://www.phe.gov/emergency/news/healthactions/phe/Pages/default.aspx

personnel because it may involve a clinical visit solely for this purpose, FDA intends to exercise enforcement discretion during the COVID-19 PHE with respect to the in-person dispensing requirement in the Mifepristone REMS Program, including any in-person requirements that may be related to the *Patient Agreement Form.* FDA further stated that to the extent all of the other requirements of the Mifepristone REMS Program are met, FDA intends to exercise enforcement discretion during the COVID-19 PHE with respect to the dispensing of mifepristone through the mail, either by or under the supervision of a certified prescriber, or through a mail-order pharmacy when such dispensing is done under the supervision of a certified prescriber.

- 05/07/2021: FDA stated that it would be reviewing the elements of the Mifepristone REMS Program in accordance with the REMS assessment provisions of section 505-1 of the FD&C Act.

- 05/14/2021: A modification was approved for the Mifepristone REMS Program. This modification was to revise the *Patient Agreement Form* to include gender-neutral language.

- 06/30/2021: An Information Request (IR) was sent to the Applicants for additional information on shipments and any program deviations, adverse events, or noncompliance with the REMS that occurred during the period from April 1, 2021 through September 30, 2021.

- 7/15/2021: An IR was sent to the Applicants to provide the total number of shipments during the period from April 1, 2021 to September 30, 2021 and details on whether any of those shipments were involved in any program deviation or non-compliance.

- 8/5/2021: An IR was sent to the Applicants for additional clinical and other information (e.g., adverse events and units of mifepristone shipped) for the period of March 29, 2016 through June 30, 2021, to be provided by August 31, 2021. This IR also requested information covering the period of July 1, 2021 through September 30, 2021 and an

aggregate summary (for the period of March 29, 2016 through September 30, 2021), to be provided by October 12, 2021.[d]

- 8/26/2021: The ANDA Applicant submitted a response to the IR issued on 8/5/2021.
- 08/27/2021: The NDA Applicant submitted a response to the IR issued on 8/5/2021.
- 10/08/2021: The NDA Applicant submitted a response to the June 30 and July 15, 2021 IRs as well as an aggregate summary for the period March 29, 2016 through September 30, 2021 in response to the August 5, 2021 IR. The NDA Applicant also included a follow-up to their initial response provided on August 27, 2021 to the August 5, 2021 IR.
- 10/12/2021: The ANDA Applicant submitted a response to the June 30 and July 15, 2021 IRs as well as an aggregate summary for the period March 29, 2016 through September 30, 2021 in response to the August 5, 2021 IR.
- 10/16/2021: The ANDA Applicant revised their Oct 12, 2012 response to provide a correction to the number of mifepristone tablets.
- (b) (4)
- 11/02/2021: A (b) (6) ((b) (6) meeting was convened to obtain CDER concurrence on the removal of the in-person dispensing requirement and the addition of a certification requirement for pharmacies. The (b) (6) (b) (6) and senior CDER leadership concurred with removing the in-person dispensing and adding pharmacy certification.

3. Rationale for Proposed REMS Modification

[d] Multiple Information Requests were issued to obtain additional information on drug shipments, any program deviations or noncompliance, and use of alternative methods for drug distribution during the COVID-19 PHE. These IRs are referenced as appropriate in this document and the one-year REMS Assessment Review of the Mifepristone REMS Program, December 16, 2021.

3.1. CURRENT REQUIREMENTS FOR THE APPROVED REMS

The Mifepristone REMS Program includes elements to assure safe use (ETASU), an implementation system, and a timetable for submission of assessments. Elements to assure safe use in the current REMS include a prescriber certification requirement (ETASU A), a requirement that mifepristone be dispensed only in certain healthcare settings by or under the supervision of a certified prescriber (ETASU C), and a requirement that mifepristone be dispensed only with documentation of safe use conditions (ETASU D). Documentation of safe use conditions under ETASU D consists of a *Patient Agreement Form* between the prescriber and the patient indicating that the patient has received counseling from the prescriber regarding the risk of serious complications associated with mifepristone 200 mg for medical termination of early pregnancy.

3.2. EVALUATION OF THE EVIDENCE

We reviewed multiple different sources of information, including published literature, safety information submitted to the Agency during the COVID-19 PHE, FDA Adverse Event Reporting System (FAERS) reports, the first REMS assessment report for the Mifepristone REMS Program, and information provided by advocacy groups, individuals, and the Applicants. Our review also included an examination of literature references provided by plaintiffs in the *Chelius v. Becerra* litigation. Below is an overview of how information relevant to the current Mifepristone REMS Program was retrieved, analyzed, and applied to each of the individual ETASUs to determine if further changes should be considered.

Methods for the literature search

(b) (6) conducted a literature search in PubMed and Embase to retrieve publications relevant to this review. The time period used for this literature search was between March 29, 2016 (when the Mifeprex labeling and REMS were last substantially revised) through July 26, 2021. The search terms used were “medical abortion” and “mifepristone” and “pregnancy termination and mifepristone.”

The search retrieved 306 publications from PubMed and 613 from Embase, respectively; the search yielded 646 unique publications after eliminating duplications between the two databases. The result of our literature search was also supplemented by an examination of literature references provided by advocacy groups, individuals, plaintiffs in the *Chelius* litigation, and the Applicants, as well as letters from healthcare providers and researchers.

References included in these letters were considered for inclusion in this review using identical selection criteria to the (b) (6) literature search (outlined below).

For this review of the REMS, (b) (6) focused on publications containing safety data related to outcomes of medical abortion (objective safety data) obtained from our literature search and from the references provided to us relevant to the REMS ETASUs. We excluded systematic reviews and meta-analyses because these publications did not include original safety data related to the outcomes of medical abortion. The following are examples of materials that were excluded from our literature search:

- Information from survey studies or qualitative studies that evaluated perspectives on and/or satisfaction with medical abortion procedures from patients, pharmacists, clinic staff, or providers, even if the study assessed REMS ETASUs. These surveys or qualitative studies did not include objective safety data related to outcomes of medical abortion.

- Opinions, commentaries, or policy/advocacy statements. These publications did not include objective safety data related to outcomes of medical abortion.

- Safety data related to mifepristone use for second trimester medical abortion. These publications reported data not applicable to the approved indication for medical abortion up to 70 days gestation.

- Safety data related to mifepristone use for spontaneous first trimester abortion (i.e., miscarriages). These publications reported data not applicable to the approved indication for medical abortion up to 70 days gestation.

- Safety data that pertained only to surgical abortion or did not separate out medical abortion from surgical abortion.

- Other safety information unrelated to the REMS elements (e.g., articles limited to case reports or those discussing unrelated gynecologic or medical issues)

- Publications for which it was not possible to conduct a full review of the methods or results, i.e., the references were limited to an abstract of the study methods and results.

- Publications that provided only general statistics on abortion care in the United States.

- Information pertinent to molecular or other basic science aspects of mifepristone.

- Data on the logistics of accessing abortion care in general, such as time to appointment or the distance traveled to obtain care.

- Publications that provided data not related specifically to abortion care or the REMS (e.g., references focused on federal poverty guidelines, poverty data, or the financial impact of the COVID-19 pandemic).

One exception to the above literature search criteria was the inclusion in Section 3.2.2 of this review, which discusses the *Patient Agreement Form*, of publications that discussed changes in provider volume. The data discussed in relation to provider volume was obtained from surveys. This data was included because changes in provider volume could only be obtained from well-conducted survey studies.

Regarding medical/scientific references submitted with letters from the plaintiffs in the *Chelius* litigation, we applied the same criteria as for the literature search, as described above.

Letters from the plaintiffs in the *Chelius* litigation included several references that preceded our 2016 review of the REMS. Two of those pre-2016 studies were not captured in our 2016 literature search. These two studies were assessed as part of our current review; their results are consistent with the existing safety profile of the approved medical abortion regimen, and therefore, support our current conclusions regarding the REMS. See Appendix A.

3.2.1. Evaluation of the requirement for healthcare providers who prescribe the drug to be specially certified (ETASU A)

In order to become specially certified, prescribers must: 1) review the prescribing information for mifepristone and 2) complete the *Prescriber Agreement Form*. In signing the *Prescriber Agreement Form*, prescribers agree they meet the qualifications listed below:

- Ability to assess the duration of pregnancy accurately
- Ability to diagnose ectopic pregnancies
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or to have made plans to provide such care through others, and ability to

ensure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the Prescribing Information of mifepristone (which the provider can access by phone or online).

In addition to meeting these qualifications, as a condition of certification the healthcare provider also agrees to follow the guidelines for use below:

- Review the *Patient Agreement Form* with the patient and fully explain the risks of the mifepristone treatment regimen. Answer any questions the patient may have prior to receiving mifepristone.
- Sign and obtain the patient's signature on the *Patient Agreement Form*.
- Provide the patient with a copy of the *Patient Agreement Form* and the Medication Guide.
- Place the signed *Patient Agreement Form* in the patient's medical record.
- Record the serial number from each package of mifepristone in each patient's record.
- Report deaths to the Applicant, identifying the patient by a non-identifiable patient reference and the serial number from each package of mifepristone.

The literature review was the primary source of information that contributed to our reassessment of ETASU A.

We continue to be concerned that absent these provider qualifications, serious and potentially fatal complications associated with medical abortion, including missed ectopic pregnancy and heavy bleeding from incomplete abortion, would not be detected or appropriately managed. Our review of the literature did not identify any studies comparing providers who met these qualifications with providers who did not. In the absence of such studies, there is no evidence to contradict our previous finding that prescribers' ability to accurately date pregnancies, diagnose ectopic pregnancies, and provide surgical intervention or arrange for such care through others if needed, is necessary to mitigate the serious risks associated with the use of mifepristone in a regimen with misoprostol. Therefore, our review continues to support the conclusion that a healthcare provider who prescribes mifepristone should meet the above qualifications. We conclude it is reasonable to maintain the requirement for a one-time prescriber certification where prescribers attest to having the ability to diagnose an intrauterine

pregnancy, to diagnose an ectopic pregnancy,[e] and to either manage serious complications themselves or arrange for other providers to provide the needed care in a timely manner.

In addition, in signing the *Prescriber Agreement Form* and placing it in the patient's medical record, the prescribers acknowledge the requirement to report patient deaths associated with mifepristone to the manufacturer. Such a requirement ensures that the manufacturer receives all reports of patient deaths and, in turn, fulfills its regulatory obligations to report those deaths to the FDA.

As discussed in Section 3.2.2 below, there is a potential for doubling of the number of prescribers of mifepristone if the in-person dispensing requirement in ETASU C is removed from the Mifepristone REMS Program. Given the potential addition of new prescribers, in addition to the considerations described above, we conclude that we should maintain the requirement for prescriber certification, to ensure that providers meet the necessary qualifications and adhere to the guidelines for use. Our literature review supports that these requirements are still necessary, and the potential increase in new prescribers under the REMS is a further reason to maintain prescriber certification. Healthcare provider certification continues to be a necessary component of the REMS to ensure the benefits of mifepristone for medical abortion outweigh the risks. The burden of prescriber certification has been minimized to the extent possible by requiring prescribers to certify only one time for each applicant.

3.2.2. Evaluation of the requirement for the drug to be dispensed with evidence or other documentation of safe-use conditions (ETASU D)

In order to receive mifepristone for medical termination of pregnancy through 70 days gestation, the patient must sign a *Patient Agreement Form* indicating that the patient has received, read, and been provided a copy of the *Patient Agreement Form* and received counseling from the prescriber regarding the risk of serious complications associated with mifepristone for this indication. The *Patient Agreement Form* ensures that patients are informed of the risks of serious complications associated with mifepristone for this indication.

[e] American College of Obstetricians and Gynecologists (ACOG) Practice Bulleting Number 191, February 2018. Tubal Ectopic Pregnancy. https://www.acog.org/clinical/clinical-guidance/practice-bulletin/articles/2018/03/tubal-ectopic-pregnancy. Mifepristone is not effective for terminating ectopic pregnancy. Some of the expected symptoms experienced with a medical abortion (abdominal pain, uterine bleeding) may be similar to those of a ruptured ectopic pregnancy. A missed ectopic pregnancy that ruptures is a medical emergency that requires immediate surgical intervention.

In a number of approved REMS, *Patient Agreement Forms* or *Patient Enrollment Forms* ensure that patients are counseled about the risks of the product and/or informed of appropriate safe use conditions.[f]

As a condition of certification under the Mifepristone REMS Program, healthcare providers must follow the guidelines for use of mifepristone, including reviewing the *Patient Agreement Form* with the patient, fully explaining the risks of the treatment regimen, and answering any questions the patient may have before receiving the medication. With this form, the patient acknowledges that they have received and read the form, and that they have received the counseling regarding when to take mifepristone, the risk of serious complications associated with mifepristone and what to do if they experience adverse events (e.g., fever, heavy bleeding). Both the healthcare provider and patient must sign the document and the patient must receive a copy of the signed form. In addition to the counseling described in the *Patient Agreement Form*, patients also receive a copy of the Medication Guide for mifepristone. Ultimately, the *Patient Agreement Form* serves as an important counseling component, and documentation that the safe use conditions of the Mifepristone REMS Program have been satisfied, as the prescriber is required to place the signed *Patient Agreement Form* in the patient's medical record.

Prior to the March 29, 2016 approval of the S-020 efficacy supplement for Mifeprex, FDA undertook a review of all elements of the REMS. At that time, the (b) (6) ((b) (6)), along with the (b) (6) ((b) (6)), recommended removal of the *Patient Agreement Form* (ETASU D). This recommendation received concurrence from the (b) (6) on February 23, 2016. The rationale for this recommendation in the 2016 review[g] is summarized here as follows:

- The safety profile of Mifeprex is well-characterized over 15 years of experience, with known risks occurring rarely; the safety profile has not changed over the period of surveillance.
- Established clinical practice includes patient counseling and documentation of informed consent and evidence shows that practitioners are providing appropriate patient

[f] REMS@FDA, https://www.accessdata fda.gov/scripts/cder/rems/index.cfm, Accessed November 15, 2021.
[g] (b) (6) Clinical Review, NDA 020687/S20, dated March 29, 2016. https://darrts fda.gov/darrts/faces/ViewDocument?documentId=090140af803dc7bd&_afrRedirect=386175573203745

counseling and education; the *Patient Agreement Form* is duplicative of these established practices.

- Medical abortion with Mifeprex is provided by a small group of organizations and their associated providers. Their documents and guidelines are duplicated in the *Patient Agreement Form*.
- ETASUs A and C remain in place: The *Prescriber Agreement Form* and the requirement that Mifeprex be dispensed to patients only in certain healthcare settings, specifically, clinics, medical offices, and hospitals under the supervision of a certified prescriber, remain in place.

In light of a memorandum from the Director of the Center for Drug Evaluation and Research, an addendum to the (b) (6) March 29, 2016 review and a memorandum from the signatory authority in (b) (6) indicated that the *Patient Agreement Form* would be retained in the REMS.[h,i]

The current review of literature from March 29, 2016 to July 26, 2021, is relevant to our assessment of the necessity of the *Patient Agreement Form* as part of the REMS. While our literature search yielded no publications which directly addressed this element of the REMS, we identified the following literature that focused on the informed consent process. These studies were reviewed for their potential relevance on this topic, though the articles do not directly assess the need for the *Patient Agreement Form* as a condition necessary to assure safe use of Mifepristone under ETASU D.

- Two studies[1,2] (both authored by Dr. Grossman in 2021) used the *Patient Agreement Form* and additional clinic-specific written informed consent forms as part of the study methodology. One study evaluated medical abortion with pharmacist dispensing of mifepristone and another evaluated mail-order pharmacy dispensing. Safety and efficacy outcomes were not assessed regarding the element of consent in isolation or the *Patient Agreement Form*.
- Several studies included use of electronic or verbal consent. Two studies were conducted using signed electronic consent (Chong[3], Kerestes[4]). Aiken[5] reported that patients had the option of providing consent verbally and the discussion had to be recorded in the notes. Rocca[6] described obtaining verbal informed consent from patients seeking medical abortion provided in pharmacies or government-certified

h (b) (6) Review of proposed REMS modifications to Mifeprex. March 29, 2106.
i (b) (6) Summary of Regulatory Action for Mifeprex. March 29, 2016.

public health facilities by auxiliary nurse midwives (ANMs) in Nepal. Outcomes were not assessed regarding the single element of consent and its role in the efficacy of medical abortion.

- A retrospective chart review (Wiebe[7]) was conducted in Canada. This study included telemedicine abortions between January 31, 2017 and January 31, 2019 and a similar group of controls seen in the clinic during the same time frame, matched by date of initial appointment. As part of the telemedicine process, patients read a consent form (not specified whether they could view an electronic version) and gave verbal consent "witnessed by the counselor". Again, outcomes were not assessed regarding the single element of consent and its role in the efficacy of medical abortion.

After review, we conclude that there are no outcome data from these studies that address the need for the *Patient Agreement Form* as a condition necessary to assure safe use of mifepristone. Nor do any of these studies provide evidence of whether the patient's informed consent has been adequately documented under the process set out in the study protocol. Therefore, these studies do not provide evidence that would support removing ETASU D.

Although (b) (6) agrees that informed consent in medicine is an established practice, the National Abortion Federation's 2020 Clinical Policy Guidelines for Abortion Care[8] continue to include a detailed section on patient education, counseling, and informed consent. The guidelines state that these steps are essential parts of the abortion process; that they should be conducted by appropriate personnel, with accurate information, including about alternatives and potential risks and benefits; and that the patients must have an opportunity to have any questions answered to their satisfaction prior to any intervention. Under these guidelines, documentation must show that the patient affirms that they understand all the information provided and that the decision to undergo an abortion is voluntary. The guidelines specifically list the risks that must be addressed at a minimum, including those pertinent to medical abortion: hemorrhage, infection, continuing pregnancy, and death. Additionally, Practice Bulletins from ACOG[9] and the Society of Family Planning also support detailed patient counseling.

In addition, trends in US clinical practice are developing which could negatively impact adequate patient counseling about the risks of medical abortion. One survey by Jones 2017[10] of abortion providers in the United States and Canada prior to the COVID-19 pandemic did reveal strong adherence to evidence-based guidelines. However, this same survey noted continued increasing uptake of medical abortion by US providers. Grossman[11] conducted a US survey in

2019 which suggested that the number of obstetrician/gynecologists providing medical abortion care may be increasing and that uptake might increase if mifepristone were dispensed by pharmacies instead of being dispensed in-person. A subsequent survey of US obstetricians/ gynecologists by Daniel in 2021[12] evaluated a subsample (n = 868) from a prior national survey of providers and found that 164 (19%) reported providing medical abortion in the previous year. Of those obstetrician/gynecologists not providing medical abortion, 171 (24%) said they would offer the method to their patients if the in-person dispensing requirement for mifepristone were removed. This indicates a potential doubling of providers (+ 104%, 95% confidence interval (CI): 97% −112%). There were geographical variations, with the largest potential increases being in the Midwest (+ 189%, 95% CI: 172% −207%) and the South (+ 118%, 95% CI: 103% −134%).

Based on the articles discussed above, removal of the in-person dispensing requirement from the Mifepristone REMS Program (as discussed below in section 3.2.3) could significantly increase the number of providers to a larger group of practitioners. The *Patient Agreement Form* is an important part of standardizing the medication information on the use of mifepristone that prescribers communicate to their patients, and also provides the information in a brief and understandable format for patients. The requirement to counsel the patient, to provide the patient with the *Patient Agreement Form*, and to have the healthcare provider and patient sign the *Patient Agreement Form*, ensures that each provider, including new providers, informs each patient of the appropriate use of mifepristone, risks associated with treatment, and what to do if the patient experiences symptoms that may require emergency care. The single-page *Patient Agreement Form* is in line with other elements of this REMS, in that it supports the requirement that certified prescribers be able to accurately assess a patient, counsel a patient appropriately and recognize and manage potential complications. The form is placed in the patient's medical record to document the patient's acknowledgment of receiving the information from the prescriber and a copy is provided to the patient. We determined, consistent with section 505-1(f)(2) of the FD&C Act, that this does not impose an unreasonable burden on providers or patients, and that the *Patient Agreement Form* remains necessary to assure the safe use of Mifepristone.

After considering potential burden on healthcare providers and patients and considering the available data discussed above, including the potential for increased prescribing of mifepristone if in-patient dispensing is removed from the REMS, we conclude that the *Patient Agreement Form* should remain a safe use condition in the REMS.

3.2.3. Evaluation of the requirement for drug to be dispensed only in certain healthcare settings (ETASU C)

Mifepristone applicants must ensure that mifepristone is available to be dispensed to patients only in clinics, medical offices, and hospitals by or under the supervision of a certified prescriber. This creates what we refer to in this document as an in-person dispensing requirement under the REMS; i.e., the patient must be present in person in the clinic, medical office or hospital when the drug is dispensed. The mifepristone REMS document states that mifepristone may not be distributed to or dispensed through retail pharmacies or settings other than these.

The following information contributed to our analysis of this requirement: Mifepristone REMS Program year-one assessment data, postmarketing safety information and literature review.

REMS Assessment Data

Reporting period for the Mifepristone REMS Program - April 11, 2019 through February 29, 2020

We evaluated information included in the one-year (1st)[j] REMS assessment reports for the Mifepristone REMS Program, which included healthcare provider certification data, program utilization data, compliance data, audit results and patient exposure data.[13] The assessment reports were submitted on April 10, 2020 by the NDA Applicant and April 15, 2020 by the ANDA Applicant and cover a reporting period from April 11, 2019 through February 29, 2020. During this reporting period, the NDA Applicant reported (b) (4) newly certified healthcare providers, and the ANDA Applicant reported (b) (4) newly certified healthcare providers in the Mifepristone REMS Program. The NDA Applicant reported a total of (b) (4) certified healthcare providers (includes new and previously certified) ordered mifepristone during the assessment reporting period, and the ANDA Applicant reported a total of (b) (4) certified healthcare providers ordered mifepristone during the assessment reporting period. The NDA Applicant estimated that a total of (b) (4) patients were exposed to mifepristone during the assessment reporting period. The ANDA Applicant reported an estimated total of (b) (4) patients were exposed to mifepristone during the reporting period.

During the reporting period, a small number of non-compliance events were reported. The authorized distributor for the NDA applicant reported to the NDA Applicant that they experienced deviations with scanning of the product serial numbers which were confirmed during the February 2020 audit. The authorized distributor conducted a root cause analysis and developed a corrective and preventive action (CAPA) on February 12, 2020. The CAPA was

[j] This REMS assessment report was the first to be submitted following the approval of the single, shared system REMS for mifepristone.

validated and deployed with monitoring of the system through April 10, 2020. The corrective action will prevent similar events from occurring in the future.

January 27, 2020 through September 30, 2021

During the timeframe from January 27, 2020 through September 30, 2021, there were periods when the in-person dispensing requirement was not being enforced.

- On July 13, 2020, the United States District Court for the District of Maryland granted a preliminary injunction in the *ACOG* case to temporarily bar enforcement of the in-person dispensing requirement during the COVID-19 PHE.
- On January 12, 2021, the United States Supreme Court issued a stay of the injunction.
- On April 12, 2021, the FDA issued a General Advice Letter informing the applicants of the Agency's intent to exercise enforcement discretion during the COVID-19 public health emergency regarding the in-person dispensing requirement in the Mifepristone REMS Program.[k,l]

To better understand whether there was any impact on safety or noncompliance during the periods when the in-person dispensing requirement was not being enforced, we requested additional information from the Applicants to provide for more comprehensive assessment of the REMS for the time period from January 27, 2020 (the effective date of the COVID-19 PHE) to September 30, 2021. We requested the Applicants provide a summary and analysis of any program deviation or noncompliance events from the REMS requirements and any adverse events that occurred during this time period that had not already been submitted to FDA. As part of an additional request for information for the REMS assessment report, the Applicants were also asked to submit the adverse events to FAERS and to notify FDA that the reports were submitted.

Between January 27, 2020 and September 30, 2021, the NDA Applicant distributed (b) (4) shipments representing (b) (4) tablets. The NDA Applicant reported that there were (b) (4) shipments representing a total of (b) (4) tablets sent to (b) (4) non-certified healthcare providers.[m,n] (b) (4) of these healthcare providers subsequently became certified while (b) (4) did not. Of the (b) (4) healthcare providers who were not subsequently certified, (b) (4) returned a total of 12 of the 13

[k] FDA General Advice Letter for NDA 20687, April 12, 2021.
[l] FDA General Advice Letter for ANDA 091178, April 12, 2021.

[m] NDA 020687 September 9, 2021 response to the FDA's September 2, 2021 Information Request.
[n] NDA 020687 October 8, 2021 response to the FDA's June 30, 2021 Information Request.

Mifeprex tablets to the distributor. (b) (4) non-certified healthcare provider dispensed one tablet to a patient; no adverse events were reported. The NDA Applicant attributed the non-compliance observed to the authorized distributor's transition to a new platform. The NDA Applicant implemented a corrective and preventative action to address this issue, which we found to be acceptable.

The ANDA Applicant distributed (b) (4) shipments representing (b) (4) tablets of mifepristone from January 27, 2020 to September 30, 2021 and reported no instances of shipments to non-certified healthcare providers during this timeframe.

The NDA and the ANDA applicants reported a total of eight cases reporting adverse events between January 27, 2020 and September 30, 2021. These eight cases were also identified in the FAERS database and are described in the section below.

The number of adverse events reported to FDA during the COVID-19 PHE with mifepristone use for medical termination of pregnancy is small, and the data provide no indication that any program deviation or noncompliance with the Mifepristone REMS Program contributed to these reported adverse events. Further analysis of the adverse events is included below in the section on Pharmacovigilance Data.

Pharmacovigilance Data

The (b) (6) ((b) (6) conducted a search of the FAERS database and the published medical literature to identify U.S. postmarketing adverse events that reportedly occurred from January 27, 2020 through September 30, 2021 with mifepristone use for medical termination of pregnancy.[o,p]

The data for this time period were then further divided into date ranges when the in-person dispensing requirement was being enforced per the REMS (January 27, 2020 - July 12, 2020 & January 13, 2021 - April 12, 2021) versus when the in-person dispensing requirement was not being enforced (July 13, 2020 - January 12, 2021 (in-person dispensing requirement was temporarily enjoined) & April 13, 2021 - September 30, 2021 (in-person dispensing requirement was not being enforced because of the COVID-19 PHE)).

---

[o] (b) (6). Pharmacovigilance Memorandum: Mifepristone and All Adverse Events. NDA 020687 and ANDA 091178. (b) (6) # 2007-525. Finalized April 12, 2021.

[p] (b) (6) Pharmacovigilance Memorandum: Mifepristone and All Adverse Events. NDA 020687 and ANDA 091178. (b) (6) # 2007-525. Finalized December 16, 2021.

A total of eight cases that met the search criteria were identified in FAERS and no additional case reports were identified in the medical literature. Two of the eight cases reported adverse events that occurred when the in-person dispensing requirement in the REMS was being enforced (i.e., January 27, 2020 - July 12, 2020 & January 13, 2021 - April 12, 2021). These two cases reported the occurrence of uterine/vaginal bleeding (case 1) and uterine/vaginal bleeding and sepsis (case 2). Of note, uterine/vaginal bleeding and sepsis are labeled adverse events. Five of the eight cases reported adverse events that occurred when the in-person dispensing requirement was not being enforced (i.e., July 13, 2020 - January 12, 2021 & April 13, 2021 - September 30, 2021). These five cases reported the occurrence of ongoing pregnancy (case 3), drug intoxication and death approximately 5 months after ingestion of mifepristone (case 4), death [cause of death is currently unknown] (case 5), sepsis and death (case 6), and pulmonary embolism (case 7). Although these adverse events occurred during the period when the in-person dispensing requirement was not being enforced, the narratives provided in the FAERS reports for cases 5, 6, and 7 explicitly stated that mifepristone was dispensed in-person. Of note, ongoing pregnancy, and sepsis, including the possibility of fatal septic shock, are labeled adverse events. The remaining case from July 2021 reported the occurrence of oral pain/soreness (case 8) but did not provide sufficient information to determine the exact date of the adverse event. Based upon the U.S. postmarketing data reviewed, no new safety concerns were identified by (b) (6)

In addition to the FAERS data provided above, (b) (6) routinely monitors adverse events reported to FAERS and published in the medical literature for mifepristone for medical termination of pregnancy. (b) (6) has not identified any new safety concerns with the use of mifepristone for medical termination of pregnancy.

To enable additional review of adverse events, the Applicants were requested[q] to provide a summary and analysis of adverse events reported with incomplete medical abortion requiring surgical intervention to complete abortion, blood transfusion following heavy bleeding or hemorrhage, ectopic pregnancies, sepsis, infection without sepsis, hospitalization related to medical abortion, and emergency department (ED)/urgent care encounter related to medical abortion. The Applicant for Mifeprex provided a summary of postmarketing safety information from March 29, 2016, when S-020 was approved, through September 30, 2021, on August 27 and October 8, 2021. During the time period in question, (b) (4) tablets were shipped, and

[q] On August 5, 2021, an IR was sent to the Applicants requesting a summary and analysis of adverse events from March 29, 2016 through June 30, 2021 and from July 1, 2021 through September 30, 2021.

48 adverse events were received. The 48 adverse events included 4 deaths (one of which occurred in 2010 but was reported in 2017), 25 incomplete abortions requiring surgical intervention, 17 blood transfusions following heavy vaginal bleeding, 2 ectopic pregnancies, 7 infections (1 sepsis and 6 infection without sepsis), 13 hospitalizations, and 43 ED or urgent care visits related to medical abortion. For the period between January 27, 2020 and September 30, 2021, a time frame that includes the entire period when the COVID-19 public health emergency (PHE) has been in effect, there were three adverse events reported corresponding to the above cases from FAERS identified by (b) (6) case 1 (uterine/vaginal bleeding), case 2 (uterine/vaginal bleeding and sepsis), and case 4 (drug intoxication and death).

The ANDA Applicant provided a summary of postmarketing safety information from April 11, 2019 (date of ANDA approval) through September 30, 2021. On August 26, 2021, the Applicant provided distribution and adverse event information from April 11, 2019 through June 30, 2021. During this time period, a total of (b) (4) tablets were shipped. There were 7 adverse events including 3 deaths (1 from sepsis, 1 from bilateral pulmonary artery thromboemboli, 1 in a patient who complained of not being able to breathe), 1 ongoing pregnancy treated with uterine aspiration, 2 blood transfusions, 1 sepsis (with death), 1 hospitalization, and 3 ED or urgent care visits related to medical abortion. On October 12, 2021 the Applicant provided information from July 1, 2021 to September 30, 2021; there were no additional adverse events. For the period between January 27, 2020 and September 30, 2021, there were four adverse events reported corresponding to the above cases from FAERS identified by (b) (6) case 3 (ongoing pregnancy), case 5 (death unknown cause), case 6 (sepsis and death), and case 7 (pulmonary embolism).[r]

The postmarketing data from FAERS were analyzed by (b) (6) to determine if there was a difference in adverse events between periods when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced. Based on this review, we conclude that there does not appear to be a difference in adverse events between periods when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced. This suggests that mifepristone may be safely used without an in-person dispensing requirement.

[r] The eighth FAERS case, oral pain/soreness, was not within the scope of the August 5, 2021 IR and was not considered for this review of postmarketing safety information submitted by the Applicants in response to the IRs.

(b) (6) review of the Applicants' IR responses, which included the same cases identified by (b) (6) from FAERS, did not change our conclusion.[s]

Literature Review

Published studies have described alternatives in location and method for dispensing mifepristone by a certified prescriber (or an equivalent healthcare provider in countries other than the US). Some studies have examined replacing in-person dispensing in certain health care settings with dispensing at retail pharmacies (Grossman[2], Wiebe[7], Rocca[6]) and dispensing mifepristone from pharmacies by mail (Grossman[1], Upadhyay[14], Hyland[15]). Other studies have evaluated two modes of dispensing by prescribers: (1) prescribers mailing the medications to women (Gynuity study [Raymond[16], Chong[3], Anger[17]], Kerestes[4], Aiken[5] (2021)) and (2) prescribers using couriered delivery of medications (Reynolds-Wright[18]). Other studies have evaluated dispensing mifepristone by mail by an entity described as "a partner organization" (Aiken[19] (2017), Norton[20], Endler[21]). For ease of review, in the sections below that describe these studies, we have separated relevant references by the methodology used to dispense mifepristone.

Retail pharmacy dispensing

Three studies report medical abortion outcomes for retail pharmacy dispensing of mifepristone after clinical evaluation. Grossman[2] conducted a US-based study in which mifepristone and misoprostol were dispensed from a pharmacy partnered with the clinic where the participant had an evaluation by ultrasound and counseling. Of the 266 participants enrolled, 260 had known abortion outcomes. Complete abortion without additional procedure occurred in 243 participants (93.5% of those with known outcomes). Seventeen participants (6.5% of those with known outcomes) were diagnosed with incomplete abortion and underwent uterine aspiration. The reported proportion of complete abortion is within the range described in the approved mifepristone labeling. However, the finding represents a lower-than-expected efficacy based on the cohort's GA (84% of participants were at ≤ 56 days GA, a cohort for which the labeled success rate is 96.8%). No participants experienced a serious adverse event, were hospitalized, or required transfusion. Three participants had ED visits with treatment (intravenous hydration, pain medication, pelvic infection after uterine aspiration for incomplete abortion). The study's

[s] The reporting period of (b) (6) assessment of the adverse events in FAERS is not identical to the time period for summaries of adverse events in the IRs to the Applicants. Therefore, the numbers of cases and adverse events summarized in (b) (6) assessment may differ from the numbers of cases and adverse events summarized by the Applicants in their responses to IRs (note that each case report may include more than one adverse event).

safety and efficacy outcomes are consistent with labeled frequencies. The majority of participants (65%) were very satisfied with the experience. There were some complaints from participants about not receiving all prescribed medications at the initial pharmacy visit, privacy not being adequately maintained, and perceived negative pharmacist attitude.

Overall, we conclude that this study has limited generalizability because it was conducted in two US states and involved partnered pharmacies, some of which were in the same building as the clinic. Additionally, all participating pharmacies in this study were required to have a pharmacist on duty during clinic hours who had been trained in the study protocol and was willing to dispense mifepristone. The study conditions may not be generalizable to US retail pharmacies; there is insufficient information to assess this. Rocca[6] conducted an observational study evaluating 605 participants at ≤63 days GA who obtained medical abortions in Nepal by comparing the provision of medical abortion service by newly trained nurse midwives in pharmacies to medical abortion provided in government-certified clinics. Participants who presented to pharmacy study sites underwent clinical screening including a pelvic exam by trained nurse midwives at the pharmacy (which was equipped with an examination room) and if eligible for medical abortion, were dispensed mifepristone and misoprostol in the pharmacy at the time of their visit. Participants who presented to public health facilities underwent clinical screening including pelvic examination by abortion providers including trained nurse midwives and if eligible for medical abortion were dispensed mifepristone and misoprostol in the clinic at the time of their visit. The authors reported that, with respect to complete abortion (>97%) and complications (no hospitalizations or transfusions), evaluation and dispensing in pharmacy was non-inferior to in-clinic evaluation and dispensing.

Wiebe,[7] in a retrospective, chart review study conducted in Canada, compared abortion outcomes of 182 women at ≤ 70 days GA who underwent medical abortion with telemedicine consult, and either received medications by courier or picked them up at a local pharmacy, with outcomes of a matched control cohort of 199 women who received the medications at a pharmacy after an in-clinic visit. The groups had similar documented complete medical abortion outcomes (90%, calculated maintaining subjects with unknown outcomes in the denominator; ≥ 95% calculated with known outcomes only). The telemedicine group had one case of hemorrhage (0.5%) and one case of infection requiring antibiotics (0.5%) compared with no cases of hemorrhage or infection requiring antibiotics in the in-clinic cohort. The telemedicine group had more ED visits (3.3% compared to 1.5% in-clinic cohort). Both models of dispensing mifepristone resulted in efficacy and safety outcomes within labeled frequency.

None of the three studies described above allow a determination regarding differences in safety between in-person dispensing by a certified prescriber in a health care setting and dispensing through a retail pharmacy, due to limitations on the generalizability of the studies to the current retail pharmacy environment in the US. The outcome findings from the one US study (Grossman[2]), in which the pharmacies were partnered with prescribers, may not be generalizable to much of the US as they do not reflect typical prescription medication availability with use of retail pharmacy dispensing. Although retail pharmacy dispensing of mifepristone and misoprostol in Canada has been described in the literature, there are important differences in healthcare systems between Canada and the US that render the findings from studies in Canada (Wiebe[7]) not generalizable to the US. In the Wiebe study, timely provision of medication from the retail pharmacy was accomplished by either courier to the woman or faxed prescription to the woman's pharmacy. It is unknown whether conditions that allow timely access to medications for medical abortion would occur in retail pharmacies throughout the US. Canada's federal government has reaffirmed that abortion is an essential health service[t] which may have implications affecting access to medical abortion from retail pharmacies in Canada. The Rocca[6] study evaluated medical abortion provided in Nepali pharmacies and essentially moved the abortion provider and clinical examination into the pharmacy, a scenario that is not, at this time, applicable to the US retail setting.

Mail order pharmacy

Grossman[1] published an interim analysis of an ongoing prospective cohort study evaluating medical abortion with mifepristone and misoprostol dispensed by mail-order pharmacy after in-person clinical assessment. All participants were evaluated for eligibility during a clinic visit with GA up to 63 days confirmed with either an ultrasound or examination; instead of receiving medication at the clinic visit, participants received medications from a mail-order pharmacy. A total of 240 participants have been enrolled; three participants did not take either medication. A total of 227 (94.6%) provided some outcome information, of whom 224 provided abortion outcome information. Complete abortion without additional procedures occurred in 217 participants (96.9% of those with known outcomes). Two (0.9%) participants experienced serious adverse events (SAE); one received a blood transfusion, and one was hospitalized overnight. Nine (4%) participants attended 10 ED visits. In this interim analysis, the outcomes are consistent with labeled frequencies. With respect to the time interval between a

[t] As noted in Mark[23] and Martin[24], most provincial and federal health insurance programs in Canada cover medical abortion, and covered services are free at the point of care.

participant's clinic visit and receipt of medications, of the 224 participants with known abortion outcomes, 184 (82.1%) received medication within 3 days. However, 17% received between 4-7 days and one participant waited over 7 days for receipt. Seven of 216 (3.2%) participants who completed the day-3 survey reported compromised confidentiality (e.g., someone found their medication, privacy concerns).

Upadhyay[14] reports findings from a retrospective cohort study of 141 women undergoing medical abortion in the US without a consultation or visit. Eligibility was assessed based on a participant-completed online form collecting pregnancy and medical history. Participants who were considered eligible received medication delivered by a mail-order pharmacy. Three interactions via text, messaging or telephone occurred to confirm medication administration, assessment of expulsion and pregnancy symptoms, and results of a 4-week home pregnancy test. Abortion outcome was determined by either the day 3 assessment or the 4-week pregnancy test. The investigators reported a complete abortion rate without additional procedures of 95% (105 participants out of 110 for whom outcomes were known) and stated that no participants had any major adverse events. The proportion of abortion outcomes assessed at 3 days versus 4 weeks is not reported. Regardless, determining outcomes at 3 days is insufficient to determine outcome rates or safety findings because a 3-day follow-up period is too short. Additionally, a substantial number of participants (31) provided no outcomes information. Among the 141 participants enrolled, 128 had any follow-up contact with the study staff, and 110 provided outcomes information. Excluding outcomes of 22% of the cohort is a limitation of this study. This study used a model with numerous deviations from standard provision of medical abortion in the US, such as no synchronous interaction with the prescriber during informed consent or prior to prescribing medication, no confirmation of self-reported medical, surgical, and menstrual history. Further, follow-up information based on a 3-day period is insufficient to determine outcome rates or safety findings. These deviations, limited follow-up information, and small sample size limit the usefulness of this study.

Hyland[15] describes findings from a cohort study in Australia evaluating medical abortion outcomes utilizing telemedicine and a central mail order pharmacy. All participants obtained screening tests including ultrasound confirmation of GA. A total of 1010 participants completed the screening process and were provided mifepristone and misoprostol. Abortion outcomes were determined for 754 (75%) of the 1010. Outcomes for the remaining 256 participants (25%) were not included because 31 provided no relevant information after shipment, 14 reported not taking misoprostol, and 211 did not have "full follow up" (i.e., known outcome of either complete medical abortion, uterine evacuation, or ongoing pregnancy with plan to continue).

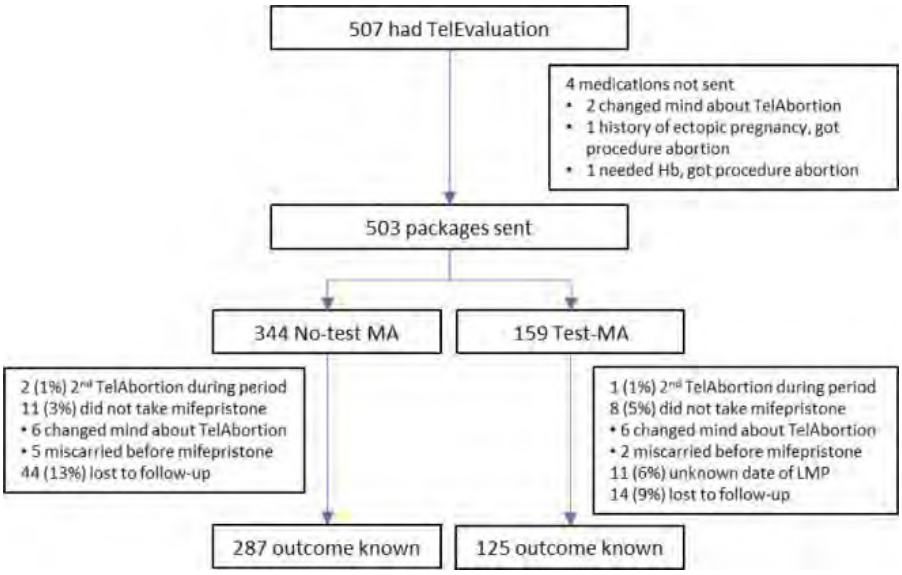
Complete abortions without additional procedures occurred in 727 participants (96% of those with definitively documented outcomes) and is consistent with labeled efficacy. Of the 754 participants included in the analysis 717 (95%) had no face-to-face clinical encounters after medications were mailed while 21 (3%) were admitted to the hospital and 16 (2%) had an outpatient encounter. One participant who was hospitalized and underwent a surgical uterine evacuation received a transfusion. Not included in the findings are 7 hospitalizations occurring in 7 participants who did not have "full follow up". The authors do not report any other adverse events and conclude use of the telemedicine medical abortion service is safe. The reasons for hospitalization are not discussed by the authors; therefore, it is unknown why the patients were hospitalized. Although the reported number of hospitalizations (3%) is higher than the less than 1% in the FDA-approved mifepristone labeling, conclusions regarding the safety findings in this study cannot be made in the absence of information about the reasons for hospitalization. Other limitations of this study include incomplete information about outcomes with face-to-face encounters, and not reporting outcomes of 25% of the enrolled cohort.

Overall, the three studies evaluating mail order pharmacy dispensing suggest that the efficacy of medical abortion is maintained with mail order pharmacy dispensing. In the Grossman[1] study, the interim analysis, although small, does not raise serious safety concerns. We note that 18% of participants did not receive medications within 3 days; the potential for delay in receiving medication by mail could limit the GA eligible for medical abortion through mail order pharmacy dispensing, because women at GA closer to 70 days might not receive medication in time. A small proportion (3%) of participants raised concerns regarding the issues of confidentiality and privacy. Safety findings from the Hyland[15] study are difficult to interpret. Although only one transfusion is reported, and the authors state the findings demonstrate safety, the higher hospitalization rates, and lack of information on the reasons for hospitalization do not allow any conclusions about safety findings. Lastly, the Upadhyay[14] study had no reported adverse events, but the findings are less useful because of the limited follow-up, and because medical abortions were provided using a model with numerous deviations from standard provision of medical abortion in the US.

Clinic dispensing by mail

A total of five studies evaluated clinic dispensing by mail.[3,4,5,16,17] Gynuity Health Projects conducted a prospective cohort study (the "TelAbortion" study) evaluating use of telemedicine for remote visits and mifepristone being dispensed from clinics via overnight or regular tracked mail. Three publications reviewed have reported outcomes for the Gynuity population

exclusively: Raymond[16] from May 2016 to December 2018, Chong[3] from May 2016 to September 2020 and Anger[17] from March 2020 to September 2020. Due to the pandemic, the Gynuity study deviated from the protocol requirement of confirmation of GA by examination or ultrasound for many participants treated from March 2020 onward (although none of the three publications reported on the single element of dispensing mifepristone from the healthcare setting by mail). A fourth study, Kerestes,[4] reports outcomes of medical abortion at the University of Hawai'i from April 2020 to November 2020: seventy-five (of whom 71 were enrolled in the Gynuity study) of the 334 participants in Kerestes were dispensed mifepristone by mail after a telemedicine consult. The section below discusses these four studies from the US as well as a large UK study by Aiken[5] (2021).



Raymond [16] (2019) reported outcomes from the Gynuity study prior to the pandemic. In the TelAbortion study, participants were not required to have an in-person clinic visit; rather, they obtained screening tests at laboratories and radiology offices and then communicated with the abortion provider by videoconference. If the participant was eligible for treatment, the provider dispensed the medications by mail. Of 433 women screened, 165 (38%) either declined to schedule the videoconference or did not keep the videoconference appointment. Among the 268 participants evaluated via videoconference, medication packages were sent to 248. Abortion outcomes were determined for 190 (77%) of the 248; outcomes for 58 (23%) participants were unknown. Complete abortion without additional procedures occurred in 177 participants (93% of those with known outcomes). The investigators obtained follow-up information from 217 participants after package shipment; there were two hospitalizations (one received a transfusion for severe anemia despite having had a complete abortion), and 16 other participants (7%) had clinical encounters in ED and urgent care centers. The reported outcomes in Raymond[16] (2019) are similar to outcomes described in approved labeling except the combined ED/urgent care center encounters (7%) exceeded the ED visits in approved labeling (2.9-4.6%). The authors note that half of the ED/urgent care visits did not entail any medical treatment and opine that the increased number of visits may have been due to the study participants living farther from the abortion providers.[16] All participants received medications within 8 days.

Chong[3] updated the findings from the Gynuity study described in Raymond[16] and reported on 1157 medical abortion outcomes, of which approximately 50% occurred during the period of the COVID-19 PHE. Although a screening ultrasound was required per the protocol, sites determined in 52% (346/669) of abortions that occurred during the period of the COVID-19 PHE that, in order to avoid potential exposure to COVID-19 at a health care facility, those

participants were not required to obtain a screening ultrasound. Use of urine pregnancy test to confirm abortion completion also increased from 67% (144/214) in the 6 months prior to the pandemic to 90% (602/669) in the 6 months during the pandemic. Of the 1390 participants to whom medicine packages (containing both mifepristone and misoprostol) were mailed, 1157 (83.2%) had known abortion outcomes. Complete abortion without a procedure occurred in 1103 participants (95% of the those with a known outcome). Ten women experienced an SAE (5 transfusions (0.4%) and 7 hospitalizations (0.7%)) and 70 (6%) participants had unplanned clinical encounters in ED/urgent care. Surgical interventions were required in 47 participants (4.1% of 1390) to complete abortion. The reported outcomes in this study are similar to outcomes described in approved labeling, except that the combined ED/urgent care center encounters (6%) exceeded the ED visits in approved labeling (2.9-4.6%).

Anger[17] compared outcomes among participants enrolled in the Gynuity study who did versus did not have confirmation of GA/intrauterine location with an examination or ultrasound from 10 jurisdictions across the US. These participants were screened for enrollment from March 25 through September 15, 2020. All participants had a telemedicine consultation and received mifepristone and misoprostol by mail from the healthcare facility. Determination of which participants did not require confirmation of GA by examination or ultrasound to be eligible depended on the study clinician's assessment of eligibility for "no-test medication abortion"[u] based on a sample protocol published by Raymond[22] (2020). There were two key differences between the two groups. Participants for whom the study clinician determined a pre-abortion ultrasound was required were more likely than the participants who had no ultrasound or examination to live further than 150 miles from the clinic (51.2% vs. 31.7%) and were more likely to have a GA above 63 days (12.0% vs. 1.7%). The study sites shipped 503 medication packages during the analysis period; 344 packages went to the "no test" group while 159 went to the "test" medical abortion cohort (see figure below). However, because the two cohorts were not randomized in this study, they had different baseline characteristics. Consequently, findings based on the comparisons between the two cohorts should be interpreted carefully.

[u] "No-test medication abortion" refers to medical abortion provided without a pretreatment ultrasound, pelvic examination, or laboratory tests when, in the judgment of the provider, doing so is medically appropriate (appropriateness based on history and symptoms); "no-test medication abortion" does include post-abortion follow up. A sample protocol is described by Raymond et al.[22]

Source: Figure 1 in this publication. MA= medical abortion.

The investigators' analyses excluded 91 (18% of 503; 57 in the no-test group and 34 in the test group) participants because they did not provide a date of the last menstrual period (LMP), did not take mifepristone, or did not have a recorded abortion outcome. Overall, 410 participants (81.5% of 503) provided outcomes data. There were no reported ectopic pregnancies in either group. The number of ED/urgent care visits and the proportion of unplanned clinical encounters that led to medical treatment were not reported. In the no-test group, complete medical abortion was confirmed in 271 participants who took medications (94% among those with known outcome). In the no-test cohort, two participants were "hospitalized and/or blood transfusion," and 36 (12.5%) had an unplanned clinical encounter (participant sought in-person medical care related to abortion and the visit was not planned prior to abortion).

In the test medical abortion group, complete abortion was confirmed in 123 participants (of 125 with known outcomes); the completion rate was 98% among those with known outcomes. In the test medical abortion group, one participant was "hospitalized and/or blood transfusion," and 10 (8.0%) had an unplanned clinical encounter. The authors concluded that, compared to participants who had an ultrasound prior to medical abortion, those without an examination prior to medical abortion were more likely to require procedural interventions and had more unplanned clinical encounters.

Kerestes[4] was the only publication that linked outcomes of medical abortion with different delivery models. Participants included in the report had GA up to 77 days and received

medications in Hawaii between April 2020 and January 2020. A total of 334 medication packages (to 330 unique participants) were dispensed containing mifepristone and misoprostol; three different delivery models were used concurrently: 110 (32.9%) had traditional in-person visits, 149 (44.6%) had telemedicine consultation with in-person pick-up of medications, and 75 (22.5%) were sent medications by mail (71 of these were enrolled through Gynuity's TelAbortion study). Seven participants of the 330 participants who received 334 medication packages reported that they did not take them and were excluded from analysis of the outcomes. Among participants with follow-up data, the rates of successful medical abortion without surgery were 93.6%, 96.8%, and 97.1% in the in-clinic group, telemedicine + in-person pickup group, and telemedicine + mail group, respectively; these were consistent with outcomes in approved labeling. Blood transfusion was given to two participants (both in the telemedicine + in-person pickup group). Eleven participants went to an ED. Although ED visits occurred the most frequently in the telemedicine + mail group (four participants or 5.8%) and the least in the in-person group (two participants or 2.1%), the study reported no increases in other serious adverse events.

Taken together, the three Gynuity study reports[3,16,17] and Kerestes[4] support dispensing mifepristone and misoprostol by mail after a telemedicine visit. Efficacy was maintained in all four studies. All of the studies reported SAEs frequencies comparable to labeled rates, except two of the Gynuity study reports (Raymond[16], Chong[3]) and Kerestes[4] report a higher frequency of ED/urgent care visits than the labeled frequency of ED visits. We do not know whether the reporting of combined ED and urgent care visits represents an increased rate of ED visits compared to the labeled rate of ED visits (2.9-4.6%). Other labeled SAEs (e.g., transfusion) occur infrequently (< 1%).

Aiken[5] (2021) reports outcomes of medical abortion up to 70 days GA in the UK before and during the pandemic in a retrospective cohort study. In the UK, prior to the COVID-19 pandemic, all patients attended an in-clinic visit where they received an ultrasound, were administered mifepristone in the clinic, and given misoprostol in-clinic for use at home (traditional model). During the pandemic, medical abortion consultations were performed remotely by telephone or video. Based on the consultation and questionnaire (including date of last menstrual period; menstrual, contraceptive and medical history; symptoms; risk for ectopic pregnancy), an assessment of eligibility for treatment via telemedicine was made. If eligible, medications were delivered to participants via mail or were made available for collection from the clinic for use at home. If the participant was assessed to be ineligible for treatment via

telemedicine, an in-person assessment with ultrasound was performed and medications were provided from the clinic for home use (hybrid model).

The study compared the two cohorts: 22,158 obtained medical abortion before the pandemic and had in-person visits and dispensing (traditional model) and 29,984 obtained medical abortion during the pandemic with either in-person visit and in-person dispensing, or a telemedicine visit and dispensing by mail or picked up from the clinic (hybrid model). Outcomes were obtained from electronic records and incident databases. Outcomes of all hospitalizations related to abortion, ED visits, infection without sepsis, and hemorrhage without transfusion were not reported. The investigators' analysis for non-inferiority determined the efficacy and safety were comparable between both cohorts. Complete abortion occurred in > 98% in both cohorts. Hemorrhage requiring transfusion was reported in 0.04% and 0.02% of the traditional and hybrid cohorts, respectively; this is lower than the labeled 0.5% transfusion rate. There were no severe infections requiring hospitalization, major surgery or deaths reported.

A secondary analysis of the hybrid cohort was reported. Within the 29,984-person hybrid model cohort, 11,549 (39%) abortions were conducted in-person (in-person assessment with ultrasound was performed and medications provided from the clinic for home use) and 18,435 (61%) abortions were provided by telemedicine visit, without tests or confirmation of GA/intrauterine position by ultrasound, and medications either mailed or picked up from the clinic. Outcomes stratified by type of mifepristone dispensing were not reported. The rate of complete abortion was slightly higher in the telemedicine group (99.2%) than that in the in-person group (98.1%). There were no significant differences in the rates of reported SAEs. Adjustments for clinical and demographic characteristics were made because the two groups differed in baseline characteristics, including a higher proportion of pregnancies with GA over 6 weeks in the in-person group (68.2% compared with 55.1%). The authors conclude a hybrid model for medical abortion that includes no-test medical abortion[u] (no ultrasound, no pelvic exam, no pregnancy test) is effective and safe.

We conclude that although the Aiken[5] (2021) study has a large sample size and includes 85% of all medical abortions performed in England and Wales during the study period, the study has limitations. The authors acknowledge the main limitation of their study was that analysis was based on deidentified information in the NHS database and the investigators were unable to verify the outcomes extracted. Other limitations included that their search only captured

outcomes in electronic records and incident databases that met the authors' defined threshold for SAE reporting, and that the labeled abortion outcomes considered serious, such as hospitalizations related to abortion, infection without sepsis, hemorrhage without transfusion, or ED/urgent care visits, were not all included in the authors' definition of serious adverse event.

Data from the mail order dispensing studies with telemedicine visits from Gynuity (Raymond, Chong and Anger),[3,16,17] Kerestes[4], and Aiken[5] (2021) support that efficacy of medical abortion was maintained. The Aiken[5] study appears to be of sufficient sample size to determine whether safety outcomes with mail dispensing differ from in-person dispensing; however, the study's design did not capture all serious safety outcomes, thus limiting the certainty of the findings. Study reports of Raymond[16] Chong[3], and Kerestes[4] all suggest there may be an increase in ED/urgent care visits with telemedicine visits and dispensing by mail without increases in other adverse events. Anger's[17] comparative analysis suggests a pre-abortion examination may decrease the occurrence of procedural intervention and decrease the number of unplanned visits for postabortion care. Overall, despite the limitations noted, these studies support that dispensing by mail is safe and effective. Although the literature suggests there may be more frequent ED/urgent care visits related to the use of mifepristone when dispensed by mail from the clinic, there are no apparent increases in other SAEs related to mifepristone use. One reason for the increase in frequent ED/urgent care visits in the Raymond[16] publication, according to its authors, may have been that a substantial proportion of participants lived significant distances from their providers and increased distances have been associated with higher use of ED following treatment. Raymond[16] reported that half of the participants who had an ED/urgent care visit did not require medical treatment.

Clinic dispensing by courier

Reynolds-Wright[18] reported findings from a prospective cohort study of 663 women at less than 12 weeks' GA in Scotland undergoing medical abortion at home with use of telemedicine during the pandemic (from April 1 to July 9, 2020). The majority of medical abortions (78.7%) used telemedicine visits, eliminated pre-abortion ultrasound, and provided mifepristone for pick up at the service or by couriered delivery to woman's home. The number of couriered deliveries was not reported; thus, this study does not provide abortion outcomes separately for couriered delivery of mifepristone and misoprostol. With access to NHS regional hospital databases, the investigators were able to verify pregnancy outcomes and complications. Of the 663 participants, 642 (98.2%) were under 10 weeks GA, 21 (1.8%) were between 10 and 12 weeks

GA, and one participant was never pregnant. A total of 650 participants had complete abortion without requiring surgical intervention (98%), 5 (0.8%) an ongoing pregnancy and 4 (0.6%) an incomplete abortion. The outcomes from this study in Scotland are consistent with labeled mifepristone outcomes. The study shares the same limitations as the Aiken[5] (2021) study.

Partner organization dispensing by mail

Women on Web (WoW), an internet group, connects patients and providers outside of the US and provides medical abortion globally, dispensing mifepristone through "a partner organization" by mail.[v] Medical abortion eligibility is determined using an online questionnaire with asynchronous physician review. If eligible, medications are mailed to the women. WoW provides help and support by email or instant messaging.

Aiken[19] (2017) conducted a population-based study analyzing findings from 1,636 women in the Republic of Ireland and Northern Ireland who were sent medications between 2010 and 2012. Receipt of medications was confirmed for 1,181 women, among whom 1,023 confirmed use of mifepristone and misoprostol; outcome information was available for 1,000 (61% of women sent medications). Of the 1,000 women, the majority (781, 78%) were less than 7 weeks GA and 219 (22%) were at 7-9 weeks. Complete abortion without surgical intervention occurred in 947 (94.7% of 1,000 with known outcome); 7 (0.7%) women received a blood transfusion, 26 (2.6%) received antibiotics (route of administration undetermined) and 87 (8.7%) sought medical care at a hospital or clinic for symptoms related to medical abortion. Hospitalizations related to abortion were not reported. The reported proportion of complete abortion is within the range labeled for medical abortion up to 70 days (92.7-98.1%). However, the finding of 94.7% complete abortion represents a lower-than-expected efficacy based on the cohort's GA (almost 80% less than 7 weeks, labeled success for medical abortion ≤ 49 days is 98.1%). This study has limitations, including outcomes based on self-report without validation of completed abortion by examination or laboratory testing, and no known outcomes for 39% of study cohort. Additionally, the authors noted medical abortion was provided in a legally-restrictive setting, where the law provided a maximum penalty of life imprisonment for the woman undergoing the abortion, which may affect participants' self-reporting.

[v] In March 2019, FDA sent a WL to Aidaccess.org, a group affiliated with WoW. Aidaccess.org received this WL because it was introducing misbranded and unapproved new drugs into the U.S. In the context of this REMS review, studies involving WoW are included solely for purposes of evaluating of data regarding the methods of dispensing mifepristone.

Endler[21] and Norten[20] have reported outcomes from WoW cohorts but do not provide relevant information on mifepristone dispensing by mail, because neither provide meaningful outcomes data for consideration. Endler[21] compared the outcomes of self-reported heavy bleeding and clinical visits occurring during the "first or second day of abortion" that occurred in women undergoing medical abortion at 9 weeks GA or less, with outcomes from women at more than 9 weeks GA. Outcome data from day 1 or 2 is of limited usefulness. Norten[20] describes findings from a survey of women who were sent medical abortion medication through WoW and provided self-reported outcomes. Results were based on surveys returned from only 37% of participants, a return rate that is too low for the study to be considered valid.

WoW uses a model with numerous deviations from the standard provision of medical abortion in the US. For example, this model has no synchronous interaction with the prescriber during informed consent or prior to prescribing medication and no confirmation of self-reported medical, surgical, and menstrual history or confirmed pregnancy testing. Further, although Aiken[19] (2017) is a large cohort study, the outcomes are self-reported with no verification of complete abortion by laboratory or clinical evaluation and 39% of outcomes are unaccounted for. These limitations in the Aiken study result in the data being insufficient to determine the safety of dispensing mifepristone by mail through a partner organization.

4. Discussion

After review of the published literature, safety information collected during the COVID-19 PHE, postmarketing data, information from the first Mifepristone REMS Program assessment report, responses to information requests to the Applicants, and information provided by advocacy groups, individuals and the plaintiffs in the *Chelius v. Becerra* litigation, we conclude that the REMS can be modified to reduce burden without compromising patient safety.

Prescriber Certification

None of the publications we reviewed would support a conclusion that a healthcare provider who prescribes mifepristone does not need to meet the qualifications included in the Mifepristone REMS Program as described above in section 3.2.1. Absent these provider qualifications, serious complications associated with medical abortion, including missed ectopic pregnancy and heavy bleeding from incomplete abortion, would not be detected or appropriately managed.

We conclude that prescriber certification (ETASU A) should be maintained. The current process requires the prescriber to agree to the requirements of the Mifepristone REMS Program and to attest that they meet the qualifications described in section 3.2.1 above. The REMS has been structured to minimize burden to prescribers by requiring only a one-time certification by the prescriber for each Applicant. We have determined that healthcare provider certification continues to be necessary to ensure the benefits outweigh the risks, especially considering that, if the in-person dispensing requirement is removed from the Mifepristone REMS Program, the number of new providers may increase (see discussion in section 3.2.2 above).

Drug to be dispensed with evidence or other documentation of safe use conditions

The requirement to counsel the patient and provide them with the *Patient Agreement Form* ensures that each patient is informed of the appropriate use of mifepristone, the risks associated with treatment, and what to do if they experience symptoms that may require emergency care.

In 2016, we initially recommended eliminating the *Patient Agreement Form* (see section 3.2.2), though the form was ultimately maintained as part of the REMS. As discussed above, our current literature review has indicated that there is no basis to remove the *Patient Agreement Form* from the REMS. In addition, surveys we reviewed suggest that if the in-person dispensing requirement for mifepristone is removed, there could be a potential doubling of medical abortion providers. This potential doubling of medical abortion providers supports the continued need to ensure that patients are consistently provided patient education under the Mifepristone REMS Program regarding the use and risks of mifepristone. The *Patient Agreement Form* is an important part of standardizing the medication information that prescribers communicate to their patients, including new prescribers, and also provides the information in a brief and understandable format to patients. We determined, in accordance with section 505-1(f)(2) of the FD&C Act, that this does not impose an unreasonable burden on providers or patients.[w]

Given the likelihood of a potential increase in new prescribers if the in-person dispensing requirement is removed from the Mifepristone REMS Program, we conclude that maintaining the *Patient Agreement Form* remains necessary to assure safe use at this time.

[w] *The Patient Agreement Form* can be signed in person or through other means.

Drug to be dispensed only in certain healthcare settings

As discussed above in section 3.2.3, our evaluation of information submitted by the applicants in the one-year (1st) REMS assessment report for the Mifepristone REMS Program and in response to follow-up requests from the Agency indicates that the number of adverse events reported to FDA during the COVID-19 PHE with mifepristone use is small, and the data provide no indication that any program deviation or noncompliance with the Mifepristone REMS Program contributed to these adverse events. We further conclude, based our review of the postmarketing safety data from FAERS during the COVID-19 PHE and information submitted by the applicants for the timeframe of January 27, 2020 through September 30, 2021, that there does not appear to be a difference in adverse events between periods during the COVID-19 PHE when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced; nor have we identified any new safety concerns with the use of mifepristone for medical termination of early pregnancy.

Alternatives to in-person dispensing of mifepristone have been investigated in several studies and countries. The literature review identified 15 publications[x] that assessed safety outcomes from various medication delivery models (US, UK, Canada, Ireland, Australia, Nepal), including dispensing by retail and mail order pharmacies, prescribers mailing medications or using couriered service to deliver medications, and dispensing by "partner organizations". The ability to generalize the results of these studies to the US population is hampered by differences in pre-abortion care (e.g., telemedicine versus in-person, testing), and the usefulness of the studies is limited in some instances by small sample sizes and lack of follow-up information on outcomes with regard to both safety and efficacy.

In addition, there are factors which complicate the analysis of the dispensing element alone. Some of these factors are: (1) only a few studies have evaluated alternatives for in-person dispensing of mifepristone in isolation; for example, most studies on mail dispensing of mifepristone also include telemedicine consultation, and (2) because most SAEs with medical abortion are infrequent, though they can be life threatening, further evaluation of changes in dispensing would require studies with larger numbers of participants. We did not find any large clinical studies that were designed to collect safety outcomes in healthcare systems similar to the US.

[x] The 15 publications correspond to endnote numbers: 1-7, 14-21.

Based on the literature identified by our review, dispensing mifepristone by mail from the clinic or from a mail order pharmacy does not appear to jeopardize the efficacy of medical abortion. The studies we reviewed are not adequate on their own to establish the safety of the model of dispensing mifepristone by mail, although the safety and efficacy outcomes reported in these studies remain within the ranges described in mifepristone labeling except for increased numbers of ED/urgent care visits and hospitalizations.

Four publications (Raymond[16], Chong[3], Anger[17] and Kerestes[4]), describe a relevant US cohort where dispensing mifepristone from the clinic by mail was paired with telemedicine visits. These studies showed that efficacy was maintained and there was no increased frequency of SAEs except for higher ED/urgent care visits. The increased ED/urgent care visits were not associated with increases of other SAEs, and in the view of one study's authors (Raymond[16]), may be associated with participants being located significant distances from their providers. The Aiken[5] (2021) study of a large UK cohort where the clinics mailed mifepristone report small (lower than labeled) occurrences of transfusion and no significant infections requiring hospitalization. In Grossman[1] and Hyland[15], where the pharmacies mailed mifepristone after prescribers confirmed GA, efficacy is maintained. Grossman's[1] interim analysis found no increases in SAEs. Hyland[15] reported higher numbers of hospitalizations but did not report increases of other SAEs. Overall, while the studies assessing mifepristone dispensing by mail suggest more frequent encounters with healthcare providers, they generally support a conclusion that dispensing by mail is safe. Despite the limitations of the studies we reviewed, we conclude that overall, the outcomes of these studies are not inconsistent with our conclusion that, based on the 1st year REMS assessment report and postmarketing safety data, mifepristone will remain safe, and efficacy will be maintained if the in-person dispensing requirement is removed from the Mifepristone REMS Program.

Based on the REMS assessment data, FAERS data from the time period when the in-person dispensing requirement was not being enforced, our review of the literature, and information provided by advocacy groups, individuals, the Applicants, and the plaintiffs in the *Chelius v. Becerra* litigation, we conclude that mifepristone will remain safe and effective for medical abortion if the in-person dispensing requirement is removed, provided all the other requirements of the REMS are met, and pharmacy certification is added as described below.

Removing the in-person dispensing requirement will render the REMS less burdensome to healthcare providers and patients and provided all other requirements of the REMS are met, including the additional requirement for pharmacy certification, the REMS will continue to

ensure that the benefits of mifepristone for medical abortion outweigh the risks. Therefore, to reduce the burden imposed by the REMS, the Mifepristone REMS Program should be modified to remove the in-person dispensing requirement, which would allow, for example, dispensing of mifepristone by mail via certified prescribers or pharmacies, in addition to in-person dispensing in clinics, medical offices and hospitals as currently outlined in ETASU C.

New requirement to be added for pharmacy certification

The current distribution model requires the certified prescriber to dispense mifepristone directly to the patient in a clinic, medical office, or hospital. During the periods when the in-person dispensing requirement was not being enforced, both applicants used mail order pharmacies to receive and hold mifepristone on behalf of the certified healthcare providers who had purchased the product.[j,y,z] Pursuant to a prescription for mifepristone, the mail order pharmacy would ship the product to a named patient.

The Mifepristone REMS Program continues to require that mifepristone be prescribed only by certified prescribers. With the removal of the in-person dispensing requirement, however, the drug is no longer required to be dispensed only in a clinic, medical office or hospital. Under the REMS as modified, mifepristone can be dispensed through a pharmacy, provided the product is prescribed by a certified prescriber and all other requirements of the REMS are met. Given this modification to the dispensing requirements in the REMS, it is necessary to add a requirement for certification of pharmacies under ETASU B. Adding the pharmacy certification requirement incorporates pharmacies into the REMS, ensures that pharmacies are aware of and agree to follow applicable REMS requirements, and ensures that mifepristone is only dispensed pursuant to prescriptions that are written by certified prescribers. Without pharmacy certification, a pharmacy might dispense product that was not prescribed by a certified prescriber. Adding pharmacy certification ensures that ETASU A is met prior to dispensing the product to a patient; certified prescribers, in turn, have agreed to meet all the conditions of the REMS, including ensuring that the *Patient Agreement Form* (ETASU D) is completed. In addition, wholesalers and distributors can only ship to certified pharmacies. Based on our review of the safety data and our consideration of the distribution model implemented by the Applicants during the periods

y ANDA 091178: September 23, 2021 response to the September 15, 2021 information request; October 11 and 16, 2021 responses to the June 30, 2021 and July 15, 2021 information requests; October 26, 2021 response to the October 22, 2021 information request; October 29, 2021 response to the October 27 information request.
z NDA 020687: September 20, 2021 response to the September 15, 2021 information request; October 26, 2021 response to the October 22 information request.

when the in-person dispensing requirement was not being enforced, as well as REMS assessment data and published literature, we conclude that provided all other requirements of the REMS are met, the REMS program, with the removal of the in-person dispensing requirement and the addition of a requirement for pharmacy certification, will continue to ensure the benefits of mifepristone for medical abortion outweigh the risks while minimizing the burden imposed by the REMS on healthcare providers and patients. As modified, the REMS would allow, for example, dispensing by mail order or specialty pharmacies, similar to the distribution model used by applicants during the periods when the in-person dispensing requirement was not being enforced.[aa]

The above recommendations were discussed with the (b) (6) ((b) (6) and senior leadership from CDER on November 2, 2021. The (b) (6) (b) (6) along with senior CDER leadership, concurred with removing the in-person dispensing requirement provided that all of the remaining REMS requirements are met, including but not limited to prescriber certification where prescribers need to attest to having certain qualifications, and maintaining the *Patient Agreement Form*. The (b) (6) (b) (6) and senior leadership from CDER were also in favor of adding pharmacy certification to assure the safe use of mifepristone.

5. Conclusions and Recommendations

Based on the results of REMS assessments; our review of safety data collected during the PHE as well as data from FAERS; our literature search; and information provided by advocacy groups, individuals, the Applicants, and the plaintiffs in the *Chelius v. Becerra* litigation, (b) (6) and (b) (6) have concluded that a REMS modification is necessary and should include the following changes:

- Removing the requirement under ETASU C that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals.
- Adding a requirement under ETASU B that pharmacies that dispense the drug be specially certified.

[aa] Our current conclusion that the REMS would allow dispensing by mail order or specialty pharmacies is based on data received from Applicants relating to the periods when the in-person dispensing requirement was not enforced and mail-order pharmacies were used to dispense the product, as well as our analysis of postmarketing safety data and available literature. At this time we do not have data (from the Applicants or from other sources) to assess the certification of retail pharmacies under the REMS. We have not yet determined the details of pharmacy certification requirements, including whether any limitations on the types of pharmacies that may dispense the product are necessary.

(b) (6) and (b) (6) recommend the Applicants be issued a REMS Modification Notification Letter that requests submission within 120 days from the date of the letter.

OTHER REVIEW(S)

Review of Labeling

(b) (6)

NDA Number/Supplement	**020687/025**
Applicant	**Danco Laboratories, LLC**
Product Name	**Mifeprex (mifepristone) tablets**
Therapeutic Class	**Progestin antagonist**
Indication	**For the medical termination of intrauterine pregnancy through 70 days gestation, in a regimen with misoprostol**
Material Reviewed	**Prescribing Information and Medication Guide received December 16, 2022**
Date of Review	**January 3, 2023**
Reviewer	(b) (6)

This memorandum is the (b) (6) (Division's) review of the proposed revisions to the labeling and Medication Guide for Mifeprex submitted by Danco Laboratories (Applicant) on December 16, 2022. These revisions are to align the language in the Prescribing Information and the Medication Guide with the proposed modification to the Mifepristone single, shared system Risk Evaluation and Mitigation Strategy (REMS) (referred to as the Mifepristone REMS Program) submitted under NDA 020687/Supplement-025, as amended.

1. Background

Mifeprex (mifepristone), in a regimen with misoprostol, is indicated for the medical termination of intrauterine pregnancy through 70 days gestation. Mifeprex and its approved generic are subject to the Mifepristone REMS Program to mitigate the risk of serious complications associated with mifepristone. The Mifepristone REMS Program consists of elements to assure safe use (ETASU), an implementation system, and a timetable for submission of assessments of the REMS.

The goal of the Mifepristone REMS Program is to mitigate the risk of serious complications associated with mifepristone by:

- Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program (ETASU A).
- Ensuring that mifepristone is only dispensed in certain healthcare settings by or under the supervision of certified prescribers (ETASU C).
- Informing patients about the risk of serious complications associated with mifepristone (ETASU D).

On December 16, 2021, FDA sent REMS Modification Notification letters to the Applicants for Mifeprex and the approved generic version of Mifeprex, Mifepristone Tablets, 200 mg (Danco

Laboratories and GenBioPro, respectively). The letters informed the Applicants of the FDA's determination that the approved Mifepristone REMS Program must be modified to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks by: (1) removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement") (ETASU C) and (2) to add the requirement for certification of pharmacies that dispense the drug (ETASU B).[1] For a detailed discussion of the modification recommendations refer to the REMS Modification Rationale Review, jointly completed by the (b) (6) and the (b) (6) on December 16, 2021.[2]

As proposed by the Applicants in their December 16, 2022, amendments to their pending supplements, the modified goal of the Mifepristone REMS Program would read as follows:

> The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:
>
> a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.
>
> b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.
>
> c) Informing patients about the risk of serious complications associated with mifepristone.

The Division reviewed the Applicant's proposed revisions to the approved Mifeprex labeling under NDA 020687 Supplement 025, as amended, which provides REMS document and materials to align with the changes described in the REMS Modification Notification letters. Specifically, the requirement that mifepristone must be dispensed to patients in certain healthcare settings (ETASU C) was removed and the dispensing of mifepristone through specially certified pharmacies (ETASU B) was added. This REMS modification ensures that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers. There were no changes to ETASU A and ETASU D (prescribers must be specially certified and mifepristone must be dispensed to patients with evidence of safe use conditions, respectively).

On December 16, 2022, final labeling for the Mifeprex Prescribing Information (PI) and Medication Guide (MG) were received to align with the Mifepristone REMS Program modification. This submission is reviewed below. Review of the labeling changes made in the PI

[1] REMS Modification Notification letter dated December 16, 2021.
https://darrts.fda.gov/darrts/faces/ViewDocument?documentId=090140af80633e9f
[2] REMS memorandum dated December 16, 2021.
https://darrts.fda.gov/darrts/faces/ViewDocument?documentId=090140af80633d74

and in the MG for the approved generic (ANDA 091178) will be completed by the (b) (6) .

2. **Review of Labeling Changes**

Prescribing Information and Medication Guide

The following two changes were made in both the PI and MG for Mifeprex:

1. Gender neutral edits were made throughout the PI and MG.

   Reviewer comment: The Division agrees to the use of gender-neutral language to align with such changes previously approved for documents associated with this REMS.

2. Removal of instructions for patients to take the MG when they visit an emergency room or another healthcare provider who did not prescribe Mifeprex, so the provider knows that the patient is undergoing a medical abortion.

   Reviewer comment: The Applicant requested this change. Removal of the instructions in the PI and MG aligns with the updated Patient Agreement Form submitted in Supplement S-025, which removes instructions for patients to take the MG to healthcare visits with providers who did not provide Mifeprex. Although these instructions were added to the MG a number of years ago, upon further consideration the Division agrees with removing them because patients seeking emergency medical care are not likely to carry a MG with them, the MG is readily available online, and information about medical conditions and previous treatments can be obtained at the point of care.

Prescribing Information

Additional changes were made in the PI to include pharmacy dispensing in Section 5.3 Mifepristone REMS Program and Section 17 Patient Counseling Information. Typographical errors were corrected in Sections 16 and 17.

1. Section 5.3 Mifepristone REMS Program

   The Applicant proposed changes to one of the three bulleted ETASU requirements, to state “MIFEPREX must only be dispensed to patients by or under the supervision of a certified prescriber, or by certified pharmacies on prescriptions issued by certified prescribers.”

   Reviewer comment: The revised language is consistent with the REMS modification to include certified pharmacy dispensing. The Division agrees with the proposed language.

2. Section 17 Patient Counseling Information

The Applicant proposed changes to one of the two bulleted ETASU requirements, to state "MIFEPREX is only dispensed by or under the supervision of certified prescribers or by certified pharmacies on prescriptions issued by certified prescribers."

Reviewer comment: As above, the revised language for the PI for the approved MIFEPREX product is consistent with the REMS modification to include certified pharmacies and the Division agrees with the proposed language.

3. Section 16 How Supplied/Storage and Handling and Section 17 Patient Counseling Information
    a. Both Sections 16 and 17 refer to the "mifepristone REMS Program" which was edited to "Mifepristone REMS Program".
    b. In Section 17, reinstatement was made of "a" before Patient Agreement Form in the bullet "Patients must sign a Patient Agreement Form".

Reviewer comment: The Applicant will be informed of these minor edits.

Medication Guide

Additional changes were made in the MG within the section titled "How should I take Mifeprex?", as follows:

1. Addition of obtaining Mifeprex at a pharmacy: "Mifeprex will be given to you by a healthcare provider or pharmacy."
2. Removal of statement "Your healthcare provider will either give you or prescribe for you 4 misoprostol tablets to take 24 to 48 hours later."

Reviewer comment: The proposed MG changes for Mifeprex are acceptable to (b) (6). The addition of Mifeprex to be dispensed at a pharmacy reflects the REMS modification change. The statement on misoprostol dispensing is removed because it is not necessary to specify in the Mifeprex labeling how misoprostol is dispensed. The directions to take misoprostol tablets 24 to 48 hours after taking mifepristone are maintained in the Mifeprex patient instructions.

3. Conclusion

We received the final proposed labeling revisions to the Prescribing Information and Medication Guide from the Applicant on December 16, 2022. The Prescribing Information and Medication Guide for Mifeprex were revised to align with the Mifepristone REMS Program modification, which include removing the requirement that Mifeprex be dispensed only in certain healthcare settings and adding the requirement for pharmacy certification. The proposed labeling revisions were reviewed and found to be acceptable with minor edits.

All labeling changes outlined above will be applied to the approved generic mifepristone (ANDA 091178). The (b) (6) will review labeling for the approved generic and ensure it mirrors the updated approved labeling for the Mifeprex product.

MEMORANDUM

DEPARTMENT OF HEALTH AND HUMAN SERVICES
PUBLIC HEALTH SERVICE
FOOD AND DRUG ADMINISTRATION
CENTER FOR DRUG EVALUATION AND RESEARCH

TO: FILE

FROM: [redacted] (b) (6) [redacted] (b) (6) Digitally signed by [redacted] (b) (6) Date: 2022.12.23 13:11:43 -05'00'

DATE: December 23, 2022

SUBJECT: Review of Supplemental Drug Applications Proposing Modifications to the Mifepristone REMS Program

FDA is currently reviewing a supplemental new drug application from Danco Laboratories, LLC (Danco) and a supplemental abbreviated new drug application from GenBioPro, Inc. (GBP) that propose to modify the Mifepristone Risk Evaluation and Mitigation Strategy (REMS) Program as approved under Danco's new drug application for Mifeprex (mifepristone) (NDA 020867) and GBP's abbreviated new drug application for Mifepristone Tablets 200 mg (ANDA 091178). Citing the Comstock Act, 18 U.S.C. §§ 1461, 1462, Plaintiffs in *Alliance for Hippocratic Medicine v. U.S. Food and Drug Administration*, No. 2:22-cv-00223-Z (N.D. Tex.), have alleged that FDA's actions regarding mifepristone do not comply with "federal laws that expressly prohibit the mailing or delivery by any letter carrier, express company, or other common carrier of any substance or drug intended for producing abortion" and also that FDA "failed to acknowledge and address" those laws. Complaint ¶¶ 22, 392 (Nov. 18, 2022). This memorandum notes that the Office of Legal Counsel of the United States Department of Justice, which provides controlling advice to Executive Branch officials on questions of law, has concluded that the Comstock Act provisions cited by Plaintiffs "[do] not prohibit the mailing of mifepristone or misoprostol where the sender lacks the intent that the recipient will use them unlawfully. And in light of the many lawful uses of mifepristone and misoprostol, the fact that these drugs are being mailed to a jurisdiction that significantly restricts abortion is not a sufficient basis for concluding that the mailing violates [these provisions]." Memorandum for Thomas J. Marshall, General Counsel, United States Postal Service, from Christopher H. Schroeder, Assistant Attorney General, Office of Legal Counsel, *Re: Application of the Comstock Act to the Mailing of Prescription Drugs That Can Be Used for Abortions*, at 15 (December 23, 2022).[1] Thus, even if the Comstock Act provisions bear on FDA's analysis of the pending supplemental drug applications, in light of the conclusions set forth by the Office of Legal Counsel, they pose no issue for FDA's approval of the applications.

---

[1] The Office of Legal Counsel's analysis applies to 18 U.S.C. § 1461 and § 1462. *See id.* at 1 n.3.

(b) (6)

NDA/ANDA #s:	NDA 20687, ANDA 91178
Products:	Mifeprex, mifepristone, 200 mg tablets
APPLICANTS:	Danco, GenBioPro
FROM:	(b) (6) (b) (6)
DATE:	December 16, 2021

Mifepristone is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy (IUP) through 70 days gestation. Mifeprex was approved on September 28, 2000, with a restricted distribution program under 21 CFR 314.520 (subpart H) and subsequently was deemed to have a REMS under section 505-1 of the Federal Food, Drug, and Cosmetic Act with the passage of the Food and Drug Administration Amendments Act (FDAAA) of 2007. The Mifeprex REMS with elements to assure safe use (ETASU) was approved on June 8, 2011 and a supplemental efficacy application and REMS modification was approved on March 29, 2016. The Mifepristone REMS Program (a single, shared system REMS that currently includes NDA 020687 and ANDA 91178) was approved on April 11, 2019.

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone. The current Mifepristone REMS Program includes elements to assure safe use (ETASU), an implementation system, and a timetable for submission of assessments. Elements to assure safe use include requirements for prescriber certification (ETASU A), that mifepristone be dispensed only in certain healthcare settings by or under the supervision of a certified prescriber (ETASU C), and that mifepristone be dispensed only with documentation of safe use conditions (ETASU D). Documentation of safe use conditions consists of a Patient Agreement Form between the prescriber and the patient, indicating that the patient has received counseling from the prescriber regarding the risk of serious complications associated with mifepristone.

The requirement under ETASU C that mifepristone be dispensed only in certain health care settings, specifically clinics, medical offices, and hospitals, is referred to as the "in-person dispensing requirement."

On January 31, 2020 the Secretary of Health and Human Services (HHS) declared COVID-19 a public health emergency (PHE) as of January 27, 2020. During the COVID-19 pandemic, there have been periods when the in-person dispensing requirement has not been enforced. From July

13, 2020 until January 12, 2021, enforcement was barred by an injunction issued in the *ACOG v. FDA* litigation. More recently, on April 12, 2021, the Agency stated its intent to exercise enforcement discretion with respect to the in-person dispensing requirement during the COVID-19 PHE, which is still ongoing as of the date of this review. These circumstances have provided additional information regarding the in-person dispensing requirement as there have been periods when the in-person dispensing requirement was not enforced.

As part of the May 7, 2021, joint motion to stay the *Chelius v. Becerra* litigation, the Agency agreed to undertake a full review the Mifepristone REMS Program, in accordance with the REMS assessment provisions of the Federal Food, Drug, and Cosmetic Act (FD&C Act).[1]

After consultations between the (b) (6) , analyzing several different sources of information, including published literature, safety information collected during the COVID-19 PHE, FDA Adverse Event Reporting System (FAERS) reports, REMS assessment reports, and information provided by advocacy groups, individuals, the Applicants, and the plaintiffs in the *Chelius* litigation, we determined that the approved REMS for mifepristone could be modified without adversely impacting patient safety. Importantly, our review did not identify any differences in adverse events between periods when the in-person dispensing requirement was being enforced and periods when that requirement was not being enforced. The data suggested that the requirements for prescriber certification (ETASU A) and the Patient Agreement Form (ETASU D) should be maintained, while the in-person dispensing requirement (under ETASU C) could be removed, to reduce the burden imposed by the REMS. In determining that the in-person dispensing requirement could be removed, we concluded that a new requirement for pharmacy certification (ETASU B) is necessary to ensure the benefits of the product outweigh the risks.

(b) (6) and (b) (6) assessment and recommendations were (b) (6) (b) (6) on November 2, 2021. The (b) (6) unanimously agreed with our recommendations.

For more detailed information on the review and assessments of the information, refer to the REMS Modification Rationale Review, jointly completed by (b) (6) and (b) (6) on December 16, 2021.

In conclusion, provided all other conditions of the Mifepristone REMS Program are met and that the other elements of the REMS are maintained (ETASU A and D), the following are required:

1. Modification of the Mifepristone REMS Program to remove the requirement under ETASU C that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals. This would allow, for example, dispensing of mifepristone by mail, via certified prescribers or pharmacies, in addition to in-person

[1] Section 505-1(g)(2) of the FD&C Act (21 U.S.C. § 355-1(g)(2)).

dispensing in clinics, medical offices and hospitals as currently outlined in ETASU C . We find that this provision is no longer necessary to ensure that the benefits of the drug outweigh the risks and that removing it will help minimize the burden of complying with the REMS on the healthcare delivery system.

2. Modification of the Mifepristone REMS Program to add a requirement under ETASU B that pharmacies that dispense the drug be specially certified.

Based on the (b) (6) and (b) (6) determination that a modified REMS with the components described above is necessary to reduce the burden imposed by the REMS and ensure the benefits of mifepristone outweigh the risks, FDA is requiring submission of the proposed REMS modification within 120 days of the date of the notification letter.

This is a representation of an electronic record that was signed electronically. Following this are manifestations of any and all electronic signatures for this electronic record.

Name of Applicant	Danco Laboratories, LLC and GenBioPro, Inc.
Therapeutic Class	Progestin antagonist
Formulation	Oral tablet

1. Introduction

Refer to the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and by GenBioPro, Inc. (GBP) for abbreviated new drug application (ANDA) 091178.

The Applicants submitted proposed modifications to the Mifepristone REMS Program on June 22, 2022 in response to REMS Modification Notification letters issued on December 16, 2021 to Danco and GBP, requiring the following modifications to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks:

- removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement")
- addition of certification of pharmacies that dispense the drug

The comments in this review focus on the Applicants' amendments that were received on December 9, 2022, which included updates to the REMS Document and materials that were discussed and edited during a teleconference between the Agency and Applicants on December 8, 2022.

2. Comments to the Sponsor

General Comments

The documents have been revised for you per the comments below.

REMS Document

We have revisions in the REMS document in the following sections:

II. A.2.a.iv.2) l, the language must be updated to replace "provider" with "prescriber," and to remove the phrase that (b) (4) .

II.A.2.c.ii A requirement was added to ensure prescribers previously certified in the Mifepristone REMS Program complete the new *Prescriber Agreement Form* (b) (4) .

II. A.3, we have the following edits to align with the statue. Mifepristone must be (b) (4) dispensed (b) (4) to patients with evidence or other documentation of safe use conditions as ensured by the certified prescriber in signing the *Prescriber Agreement Form*.

II.B.5 must be updated to include: Mifepristone Sponsors must audit their certified pharmacies within 180 calendar days after the pharmacy places its first order of mifepristone, and annually thereafter audit certified pharmacies that have ordered mifepristone in the previous 12 months to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their pharmacy compliance if noncompliance is identified.

REMS Supporting Document

We require clarification and revisions in several sections. A red-lined Supporting Document has been attached for reference.

The wording in the Supporting Document was not consistent with the REMS document and REMS materials. Throughout the Supporting Document, the document was revised to align with the wording in the REMS Document, *Prescriber Agreement Form, Patient Agreement Form*, and *Pharmacy Agreement Form*.

The Supporting Document is inconsistent with respect to grammar and punctuation, as well as with respect to capitalization, italicization, and terminology. Review and revise the Supporting Document for grammar and punctuation, and for consistency in capitalization, italicization, and terminology.

The term "(b) (4)" was replaced with "supervised healthcare providers" where applicable.

There was minimal information about account set up processes for the certified prescribers and pharmacies. Include explanation of how accounts will be set up and maintained and what information from the account set up process will be used for REMS assessments.

There was also minimal information about how Sponsors will communicate with each other when stakeholders report information that the other needs to know such as when stakeholders report patient deaths to the wrong Sponsor or when decertifications of pharmacies or prescribers take place. Clarify what actions require timely communication between Sponsors and the timeline in which these actions should be reported to the other Sponsor.

Prescriber Agreement Forms for Danco Laboratories, LLC and GenBioPro, Inc.

(b) (4). This data will be available through the account set up process.

Pharmacy Agreement Forms for Danco Laboratories, LLC and GenBioPro, Inc.

(b) (4) must be removed as it is redundant to the language later in the form. The confidentiality requirement later in the form, under the requirements that certified pharmacies must put processes and procedures in place to accomplish, must be further aligned with the confidentiality requirement added to the REMS Document (discussed above).

Patient Agreement Form

The Patient Agreement Form is acceptable.

Resubmission Instructions

Accept all track changes and submit the following revised REMS materials by 12/16/22. The next submission to the Gateway should include Clean Word, Tracked Word, and pdf formatted versions of the following documents and one clean compiled PDF file that includes the REMS Document and all REMS materials in their final format:

Name of Applicant	Danco Laboratories, LLC and GenBioPro, Inc.
Therapeutic Class	Progestin antagonist
Formulation	Oral tablet

1. Introduction

Refer to the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and from GenBioPro Inc. (GBP) for abbreviated new drug application (ANDA) 091178.

The Applicants submitted proposed modifications to the Mifepristone REMS Program on June 22, 2022 in response to a REMS Modification Notification letter issued on December 16, 2021 to Danco and GBP, requiring the following modifications to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks:

- removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement")
- addition of certification of pharmacies that dispense the drug

The comments in this review focus on revisions to the REMS Assessment Plan.

2. Comments to the Applicant

We have provided a draft REMS Assessment Plan as discussed on the December 7, 2022 teleconference. The proposed Agency edits have been marked in tracked changes from the Mifepristone REMS Assessment Plan in the April 11, 2019, Supplement Approval Letter. Refer to the attached Draft REMS Assessment Plan with tracked changes. Review of the REMS proposal is ongoing; these comments should not be considered final.

We have the following comments:

1. Provide each assessment plan metric for the two previous, current, and cumulative reporting periods (if applicable) for both the NDA and ANDA unless otherwise noted.
2. The Assessment Plan Categories of 1) Program Implementation and Operations and 2) Overall Assessment of REMS Effectiveness were added.
3. A REMS Certification Statistics metric was added to capture the following:
    a. Total number of certified, newly certified, and active prescribers along with a summary of the practice setting of the certified prescribers and the method in which they became certified.
    b. Total number of certified, newly certified, and active certified pharmacies.
    c. Total number of authorized, newly authorized, and active wholesaler/distributors.
4. A Utilization Data metric was added to capture wholesaler/distributor shipment and pharmacy data.
5. A REMS Compliance Data metric was added to capture stakeholder audit results and a summary of instances of non-compliance and actions taken to address non-compliance.

Resubmission Instructions

Submit the revised REMS Assessment Plan in the REMS Supporting Document with your 12/9/22 submission. Accept the tracked changes in the draft REMS Assessment Plan with which you agree and only indicate any new changes you propose as tracked changes in your next submission. The submission should include clean Word, tracked changes Word, and pdf formatted versions of the following document.

Formulation	Oral tablet

1. Introduction

Refer to the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and by GenBioPro, Inc. (GBP) for abbreviated new drug application (ANDA) 091178.

The Applicants submitted proposed modifications to the Mifepristone REMS Program on June 22, 2022 in response to REMS Modification Notification letters issued on December 16, 2021 to Danco and GBP, requiring the following modifications to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks:

- removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement")
- addition of certification of pharmacies that dispense the drug

The comments in this review focus on the Applicants' amendments that were received on October 19 and 20, 2022 and November 30, 2022 (REMS Document). The comments also reflect the REMS Document that was further discussed and edited during a teleconference between the Agency and Applicants on December 1, 2022.

2. Comments to the Sponsor

General Comments

We have updated the REMS Document as discussed during the December 1, 2022 teleconference and aligned the REMS materials. Your edits, where the Agency agrees, have been accepted and Agency edits have been marked in tracked changes. Refer to the attached, red-lined REMS Document and REMS Materials. Review of the REMS proposal is ongoing; these comments should not be considered final.

- The Agency has determined that further clarification that certified prescribers are responsible for overseeing implementation and compliance with the REMS Program is appropriate in the *Prescriber Agreement Form* and has been added. This clarification provides flexibility for certified prescribers in overseeing REMS implementation and compliance. The certified prescriber may do so in a manner that may include the use of a larger healthcare team and delegation of tasks. We have determined that to make additional changes to the prescriber certification requirements would constitute a substantive modification to the REMS that would go beyond the required REMS modifications set forth in the December 16, 2021 REMS Modification Notification letters. Adequate rationale is required to support a proposed REMS modification for the addition, modification, or removal of any goal or element of the REMS, as described in section 505-1(g)(4) of the FD&C Act. Your application does not include such adequate rationale.
- We agree that healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone is dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification and have added this clarification to the *Prescriber Agreement Forms* and *Pharmacy Agreement Forms*. These clarifications negate the need for further clarification in the REMS Document as you proposed in the footnote to section II.A.2.
- Moving forward, italicize all proper names of forms e.g. *Prescriber Agreement Form* in the REMS.

Prescriber Agreement Forms for Danco Laboratories, LLC and GenBioPro, Inc.

The instructions on the *Prescriber Agreement Forms* were revised for clarity. Prescriber information collected on the forms was updated to capture practice setting (b) (4) address, and an additional line for medical license state was added. Duplicative or unnecessary instructions have been removed.

Pharmacy Agreement Forms for Danco Laboratories, LLC and GenBioPro, Inc.

The titles of the *Pharmacy Agreement Forms* were edited to remove "(b) (4)." The REMS pharmacy requirements will dictate whether a pharmacy can participate in the Mifepristone REMS Program and therefore (b) (4). Additional information fields regarding authorized representatives and pharmacies were added and the term "(b) (4)" was replaced with "pharmacy." Duplicative or unnecessary instructions have been removed.

Patient Agreement Form

The first paragraph of the form has been aligned with the currently approved Mifepristone REMS Program and clarification that signatures on the document can be written or electronic was added. Risk information regarding ectopic pregnancy has been reorganized. (b) (4) .

Resubmission Instructions

Accept all track changes and submit the following revised REMS materials by 12/08/22. The next submission to the Gateway should include Clean Word, Tracked Word, and pdf formatted versions of the following documents and one clean compiled PDF file that includes the REMS Document and all REMS materials in their final format:

REMS Document
Prescriber Agreement Form for Danco Laboratories, LLC
Prescriber Agreement Form for GenBioPro, Inc.
Pharmacy Agreement Form for Danco Laboratories, LLC
Pharmacy Agreement Form for GenBioPro, Inc
Patient Agreement Form
REMS Supporting Document with the Assessment Plan
Updated prescription label and Medication Guide

Appendix

1. Introduction

Refer to the proposed modification to the single, shared system Risk Evaluation and Mitigation Strategy (REMS) for mifepristone 200 mg (hereafter referred to as the Mifepristone REMS Program) submitted by Danco Laboratories, LLC (Danco) for new drug application (NDA) 020687 and from GenBioPro Inc. (GBP) for abbreviated new drug application (ANDA) 091178.

The Applicants submitted proposed modifications to the Mifepristone REMS Program on June 22, 2022 in response to a REMS Modification Notification letter issued on December 16, 2021 to Danco and GBP, requiring the following modifications to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks:

- removal of the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement")
- addition of certification of pharmacies that dispense the drug

Danco amended their submission on October 19, 2022 and GBP amended their submission on October 20, 2022.

2. Comments to the Sponsor

General Comments

For clarity, we have used the approved REMS Document to provide edits. Your proposed edits and Agency edits have been marked in tracked changes. Refer to the attached, red-lined REMS Document. Review of the REMS proposal is ongoing; these comments should not be considered final.

We have additional questions that must be addressed. Refer to the red-lined REMS Document attached. You must address the following question with your next submission:

1. Refer to the distributor requirement on page five (in all markup), "Put processes and procedures in place to maintain a distribution system that is secure, confidential and follows all processes and procedures, including those for storage, handling, shipping, tracking package serial numbers, proof of delivery and controlled returns of mifepristone" (underline added for emphasis)

Clarify whether the packages that are tracked by the distributors will still be done by serial numbers or if tracking will only use the NDC and lot numbers.

REMS Goal

(b) (4)

We have revised the goal to the following:

"The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers or by certified pharmacies.

c) Informing patients about the risk of serious complications associated with mifepristone."

REMS Document

We have provided edits to the REMS Document to reflect the requirements communicated in the December 16, 2021 letter and to incorporate additional requirements. We have determined that for this modification we will not be using the format for the REMS that is in the 2017 draft Guidance for Industry - Format and Content of a REMS Document, as not all requirements are easily transferred to the newer format and may result in creating unnecessary confusion to stakeholders. Note that all REMS Materials and the REMS Supporting Document must align with the REMS Document.

Prescriber requirements were edited for clarity, brevity and to align with certified prescriber qualifications in the currently approved REMS. Additional requirements were needed to address situations that may arise if a certified prescriber opts to dispense through a certified pharmacy.

Pharmacy requirements were revised: to ensure pharmacies are able to ship mifepristone using a shipping service that provides tracking information, to include the use of an authorized representative to coordinate REMS implementation on behalf of the pharmacy, to dispense mifepristone such that it is delivered to the patient within four calendar days of the date the pharmacy receives the prescription, and to confirm with the prescriber and document the appropriateness of dispensing mifepristone for patients who will not receive the drug within four calendar days of the date the pharmacy receives the prescription. Additional record-keeping and reporting requirements were also added.

Additional Sponsor requirements were added to support prescriber, pharmacy, and distributor REMS stakeholder requirements, and to ensure the REMS operates as intended.

REMS Supporting Document

The REMS Supporting Document must be included in your next submission and is necessary to help us understand how these changes will be implemented before we can take an action.

Resubmission Instructions

Submit the following revised REMS materials by 11/30/22. Accept the track changes in the REMS Document with which you agree in the Word newly redlined documents and only indicate any new changes you propose as redlined changes in your next submission. The next submission to the Gateway should include Clean Word, Tracked Word, and pdf formatted versions of the following documents:

NDA 020687

REMS MODIFICATION NOTIFICATION

Danco Laboratories, LLC
(b) (4), (b) (6)
P.O. Box 4816
New York, NY 10185

Dear (b) (4), (b) (6):

We refer to your new drug application (NDA) submitted under section 505(b) of the Federal Food, Drug, and Cosmetic Act (FDCA) for Mifeprex (mifepristone) Tablets.

RISK EVALUATION AND MITIGATION STRATEGY (REMS) REQUIREMENTS

The REMS for mifepristone was originally approved on June 8, 2011, and your single shared system REMS (SSS REMS) was approved on April 11, 2019. Your last SSS REMS modification was approved May 14, 2021. The SSS REMS consists of elements to assure safe use, an implementation system, and a timetable for submission of assessments of the REMS.

In accordance with section 505-1(g)(4)(B) of the Federal Food, Drug, and Cosmetic Act (FDCA), we have determined that your approved REMS for mifepristone must be modified to minimize the burden on the healthcare delivery system of complying with the REMS and to ensure that the benefits of the drug outweigh the risks.

This determination is based on a review of published literature, safety information collected during the COVID-19 PHE, FDA Adverse Event Reporting System (FAERS) reports, REMS assessment reports, and information provided by advocacy groups, individuals, the Applicants, and plaintiffs in ongoing litigation.

Your approved REMS must be modified as follows:

Elements to Assure Safe Use: We have determined that the requirement that mifepristone be dispensed only in certain healthcare settings, specifically clinics, medical offices, and hospitals (i.e., the "in-person dispensing requirement") is no longer necessary to ensure the benefits of mifepristone outweigh the risks of serious complications associated with mifepristone that are listed in the labeling of the drug. Removal of the requirement for in-person dispensing will also minimize the burden on the healthcare delivery system of complying with the REMS.

Elements to Assure Safe Use: Pursuant to 505-1(f)(1), we have also determined that an additional element to assure safe use is necessary to mitigate the risk of serious

complications associated with mifepristone listed in the labeling of the drug. Modification of the Mifepristone REMS to allow dispensing of mifepristone by pharmacies requires the addition of certification of pharmacies that dispense the drug.

Your REMS must include elements to mitigate this risk, including at least the following:

- Healthcare providers have particular experience or training, or are specially certified

- Pharmacies, practitioners, or health care settings that dispense the drug are specially certified

- The drug is dispensed to patients with evidence or other documentation of safe use conditions.

  The REMS must include an implementation system to monitor, evaluate, and work to improve the implementation of the elements to assure safe use (outlined above). Include an intervention plan to address any findings of non-compliance with the ETASU.

The proposed REMS must include a timetable for submission of assessments.
The proposed REMS modification submission should include a new proposed REMS document and appended REMS materials, as appropriate, that show the complete previously approved REMS with all proposed modifications highlighted and revised REMS materials.

In addition, the submission should also include an update to the REMS supporting document that includes a description of all proposed modifications and their potential impact on other REMS elements. Revisions to the REMS supporting document should be submitted with all changes marked and highlighted.

Because we have determined that a REMS modification as described above is necessary to minimize the burden on the health care delivery system of complying with the REMS, and to ensure that the benefits of the drug outweigh the risks, you must submit a proposed REMS modification within 120 days of the date of this letter.

Submit the proposed modified REMS as a Prior Approval supplement (PAS) to your NDA.

Because FDA is requiring the REMS modifications in accordance with section 505-1(g)(4)(B), you are not required to submit an adequate rationale to support the proposed modifications, as long as the proposals are consistent with the modifications described in this letter. If the proposed REMS modification supplement includes changes that differ from the modifications described in this letter, an adequate rationale is required for those additional proposed changes in accordance with section 505-1(g)(4)(A).

Prominently identify the submission with the following wording in bold capital letters at the top of the first page of the submission:

NEW SUPPLEMENT FOR NDA 020687/S-000
PRIOR APPROVAL SUPPLEMENT
PROPOSED MAJOR REMS MODIFICATION

Prominently identify subsequent submissions related to the proposed REMS modification with the following wording in bold capital letters at the top of the first page of the submission:

NDA 020687/S-000
PROPOSED REMS MODIFICATION-AMENDMENT

To facilitate review of your submission, we request that you submit your proposed modified REMS and other REMS-related materials in Microsoft Word format. If certain documents, such as enrollment forms, are only in PDF format, they may be submitted as such, but the preference is to include as many as possible in Word format.

SUBMISSION OF REMS DOCUMENT IN SPL FORMAT

In addition to submitting the proposed modified REMS as described above, you can also submit the REMS document in Structured Product Labeling (SPL) format. If you intend to submit the REMS document in SPL format, include the SPL file with your proposed REMS modification submission.

For more information on submitting REMS in SPL format, please email FDAREMSwebsite@fda.hhs.gov.

If you have any questions, call (b) (6), at (b) (6).

Sincerely,

{See appended electronic signature page}

FINDING OF NO SIGNIFICANT IMPACT

NDA 20-687

Mifepristone Tablets

The National Environmental Policy Act of 1969 (NEPA) requires all Federal agencies to assess the environmental impact of their actions. FDA is required under NEPA to consider the environmental impact of approving certain drug product applications as an integral part of its regulatory process.

The Food and Drug Administration, Center for Drug Evaluation and Research (CDER) has carefully considered the potential environmental impact of this action and has concluded that this action will not have a significant effect on the quality of the human environment and that an environmental impact statement therefore will not be prepared.

In support of their new drug application for **Mifepristone Tablets, The Population Council** has prepared an environmental assessment in accordance with 21 CFR 25.31a (attached) which evaluates the potential environmental impacts of the manufacture, use and disposal of the product.

Mifepristone is a synthetic drug which will be administered orally to provide a medical approach to the termination of early pregnancy. Mifepristone may enter the environment from excretion by patients, from disposal of pharmaceutical waste or from emissions from manufacturing sites.

The projected environmental introduction concentration from use is less than 1 ppb. CDER has routinely found that concentrations less than 1 ppb have no effect on relevant standard test organism, therefore the applicant has submitted a Tier 0 EA in accordance with CDER guidance.

Disposal may result from production waste such as out of specification lots, returned goods and user disposal of empty or partly used product and packaging. Pharmaceutical waste will be disposed of by the manufacturer and The Population Council at licensed disposal facilities. At U.S. hospitals, pharmacies or clinics, empty or partially empty packages will be disposed of according to standard procedures.

Precautions taken at the sites of manufacture of the bulk product and its final formulation are expected to minimize occupational exposures and environmental release.

The Center for Drug Evaluation and Research has concluded that the product can be manufactured, used and disposed of without any expected adverse environmental effects. Adverse effects are not anticipated upon endangered or threatened species or upon property listed in or eligible for listing in the National Register of Historic Places.

Attachment: Environmental Assessment

APPEARS THIS WAY
ON ORIGINAL

1. DATE

March 1, 1996

2. NAME of APPLICANT

The Population Council

3. ADDRESS

1230 York Avenue
New York, NY 10021

4. DESCRIPTION OF PROPOSED ACTION

a. Requested Approval

Applicant seeks approval for mifepristone tablets, (200 mg/tablet), packaged in a 200 µm white opaque poly (vinyl chloride-aceto chloride) blister with a 20 um aluminum foil with heat sealable varnish.

b. Need for Action

Mifepristone is a synthetic norsteroid which has demonstrated activity as a potent antagonist for progestins and glucocorticoids, due to its high relative binding to the progestorone and glucocorticoid receptor.
Progesterone is a critical hormone in mammalian reproduction and is essential for the maintenance of pregnancy. Withdrawl of the influence of progesterone in the uterus due to its competitive inhibition by mifepristone at the receptor site results in uterine bleeding, disruption of the placental function and disruption of the inhibitory effects of progesterone on the myometrial stimulatory actions of prostaglandins. These antiprogestational activities of the compound serve to provide a medical approach to the termination of early pregnancy.

c. Production Location

To perserve confidentiality of proprietary information, the name and location of the third-party manufacturer of

01

mifepristone drug substance and drug product is contained in confidential Appendix A.

d. Locations of Use

The drug product will be used by women in the United States. It will be administered in hospitals, health clinics and private physicians' offices.

e. Disposal Sites

Rejected, expired, returned or waste drug products are expected to be disposed of in accordance with the Center for Disease Control Guidelines for the handling of hazardous waste in the clinic or healthcare provider's office.

Rejected, expired or waste drug products will be collected and sent to a licensed facility to be processed and incinerated or for grinding and landfill. The facility and the permit/license under which it operates is identified in confidential Appendix B.

5. IDENTIFICATION OF CHEMICAL SUBSTANCES THAT ARE THE SUBJECT OF THE PROPOSED ACTION

a. Nomenclature

i. Established Name

Mifepristone

ii. Brand/Proprietary Names

Tradename in US not established
Mifegyne® (tradename used in European countries)
Xi Bai Lu (tradename used in China)

iii. Chemical Names

Chemical Abstracts:
(11beta,17beta)-11-[(4-dimethylamino)phenyl]-17-hydroxy-17-(1-propynyl)-estra-4,9-dien-3-one

IUPAC:
11beta-(4-Dimethylaminophenyl)-17beta-hydroxy-17α-(1-propynyl)-estra-4,9-dien-3-one

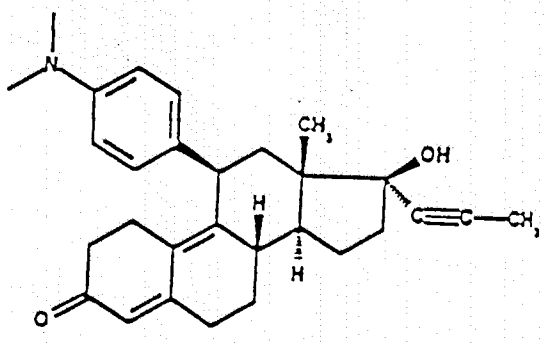
02

iv. Laboratory Code Designations

RU 38 486
RU 486

b. Chemical Abstracts Service (CAS) Registration Number

84371-65-3



c. Molecular Formula

$C_{29}H_{35}NO_2$

d. Molecular Weight

429.58

e. Structural Formula

f. Physical Description

Mifepristone is a light yellow to yellow crystalline powder. The melting point is 191 - 196° C.

g. Additives

The dosage form is a pale yellow, cylindrical biconvex tablet, 11 ml in diameter. Each 350 mg tablet contains:

mifepristone: 200 mg
colloidal silica anhydrous: 3 mg
maize starch: 102 mg
povidone: 12 mg
cellulose microcrystalline: 30 mg
magnesium stearate: 3 mg

h. Impurities

The drug substance specifications, including impurities is included in confidential Appendix C.
No impurities are greater than 1%.

6. INTRODUCTION OF SUBSTANCES INTO THE ENVIRONMENT

Items a - d are covered in the information included in confidential Appendix A.

The Material Safety Data Sheet (MSDS) is included in nonconfidential Appendix D.

e. Expected Introduction Concentrations

i. Expected Introduction Concentration from Use

The expected environmental concentration was calculated using the following equation:

EIC-Aquatic (ppm) = A x B x C x D

where A = kg/year production
B = 1/liters per day entering POTW's*
C = year/365 days
D = 10^6 mg/kg (conversion factor)

* 1.115×10^{11} liters per day entering publicly owned treatment works (POTW's), Source: 1992 Needs Survey, Report to Congress, September 1993, EPA 832-R-93-002

The actual calculations are considered confidential business information and are provided in confidential Appendix E.

The expected concentration is less than 1 ppb, which normally relieves the applicant from providing information in format items 7 - 11 and 15 in accordance with the Tier 0 approach described in the FDA's *Guidance for Industry for the Submission of an Environmental Assessment in Human Drug Appliations and Supplements* (November 1995).

7 - 11. Not provided, based on the Tier 0 approach described in FDA's *Guidance for Industry for the Submission of an Environmental Assessment in Human Drug Appliations and Supplements* (November 1995).

12. LIST OF PREPARERS

Ann Robbins, Ph.D
Scientist

The names of prepares from the third party manufacturer are contained in confidential Appendix A.

13. CERTIFICATION

The undersigned official certifies that the information presented is true, accurate and complete to the best of the knowledge of the Population Council.

The undersigned official certifies that the EA summary document and Appendix E contain non-confidential information and acknowledges that this information will be made available to the public in accordance with 40 CRF 1506.6

Date Mar 1 1996

Signature Ann Robbins

Ann Robbins, Ph.D
Scientist
The Population Council
Center for Biomedical Research

The certification from the third-party manufacturer is included in confidential Appendix A.

Guidance for Industry for the Submission of an Environmental Assessment in Human Drug Appliations and Supplements, Center for Drug Evaluation and Research (CDER), FDA, November 1995.

APPENDICES

Appendix A: (CONFIDENTIAL) Information on third party manufacturer
Appendix B: (CONFIDENTIAL) Name and location of licensed disposal site
Appendix C: (CONFIDENTIAL) Drug substance specifications
Appendix D: Material Safety Data Sheet (MSDS)
Appendix E: (CONFIDENTIAL) Expected introduction concentration calculations

APPENDIX D

APPEARS THIS WAY
ON ORIGINAL

MATERIAL SAFETY DATA SHEET

1. IDENTIFICATION OF THE SUBSTANCE/PREPARATION

IDENTIFICATION OF THE SUBSTANCE OR PREPARATION

TRADE NAME	: MIFEPRISTONE
CHEMICAL FAMILY	: Hormone
FORMULA	: C29H35NO2
MOLECULAR MASS	: 429
KIND OF USE	: Medical use

2. COMPOSITION/INFORMATION ON INGREDIENTS

SUBSTANCE

CAS NUMBER	: 84371-65-3
CHEMICAL NAME	: 17beta-hydroxy-11beta-(4-dimethylaminophenyl)17-alpha-(pro 1-ynyl)estra 4,9-dien 3-one.

3. HAZARDS IDENTIFICATION

MAIN HAZARDS : TOXIC BY INHALATION, IN CONTACT WITH SKIN AND IF SWALLOWED.

4. FIRST-AID MEASURES IN CASE OF EXPOSURE

INHALATION	: Make the victim blow his nose Make victim breathe fresh air
SKIN CONTACT	: Rinse with plenty of water
EYES CONTACT	: Rinse immediately with plenty of water for at least 15 minutes
INGESTION	: Alert a physician

5. FIRE-FIGHTING MEASURES

SUITABLE EXTINGUISHING MEDIA	: Usual means .
UNSUITABLE EXTINGUISHING MEDIA	: None.

FIRE AND EXPLOSION HAZARDS	: In case of fire, the product emits toxic and irritating fumes .
SPECIAL PROTECTIVE EQUIPMENT	: Wear a self-contained respiratory apparatus.
OTHER RECOMMENDATIONS	: None.

6. ACCIDENTAL RELEASE MEASURES

MEASURES AFTER LEAKING OR SPIL	: Collect thouroughly into plastic bag. Avoid dust emissions. Rinse the polluted area with plenty of water.

7. HANDLING AND STORAGE

HANDLING

TECHNICAL MEASURES	: Mechanical sucking ventilation at source of formation of dust.
SPECIAL PROTECTION MEASURES	: Have a shower after handling.

STORAGE

SENSITIVITY TO DAMP	: Not observed.
SENSITIVITY TO LIGHT	: Not observed.
SENSITIVITY TO OXIDATION	: Sensitive to air
SPECIAL STORAGE REQUIREMENTS	: Room temperature (<86 F)
STORAGE CONDITIONS	: Usual conditions (T <= 86 F, away from light)
SHELF LIFE	: 5 years.
STORAGE FACILITIES	: Toxic products.
INCOMPATIBLE SUBSTANCES	: None.
RECOMMENDED PACKAGING MATERIAL	: Glass, polythene.
SUPPLIER PACKAGING	: polythene bag.
PACKAGING MATERIAL TO BE AVOIDED	: Unknown.

8. EXPOSURE CONTROLS/PERSONAL PROTECTION

CONTROL OF EXPOSURE

TWA	: ND
STEL	: ND
IDLH	: ND
OLFACTORY THRESHOLD	: ND

PERSONAL PROTECTION/WORKSHOP

RESPIRATORY TRACT PROTECTION	: Wear a dust respirator.
PROTECTIVE GLOVES	: Wear suitable gloves
EYES PROTECTION	: Wear glasses
OTHER EQUIPMENT PROTECTION	: Complete overall, skullcap

PERSONAL PROTECTION/LABORATORY

RESPIRATORY TRACT PROTECTION	: Wear a dust respirator.
PROTECTIVE GLOVES	: Wear suitable gloves
EYES PROTECTION	: Wear glasses

9. PHYSICAL AND CHEMICAL PROPERTIES

APPEARANCE	: Crystallized solid,(yellow)

pH	: Not applicable.
CHARACTERISTIC TEMPERATURES	: Melting point : 192-196°C
FLASH POINT	: Not applicable.
AUTOINFLAMMABILITY	: Not determined.
EXPLOSIVITY CHARACTERISTICS	: NA
COMMENTS ON FLAMMABILITY	: Not concerned.
VAPOUR PRESSURE	: Not determined.
VOLUMIC MASS	: Not determined.
SOLUBILITY	: Insoluble in water Soluble in : alcohol,ether,chloroform.
OTHER DATA	: alpha D : + 143° (1%,chloroform). alpha D : + 125°(0.5%, methylene chloride)

10. STABILITY AND REACTIVITY

HAZARDOUS REACTIONS	: Unknown.
HAZARDOUS DECOMPOSITION PRODUCTS	: Unknown.

11. TOXICOLOGICAL INFORMATION

ACUTE TOXICITY	: LD 50 oral route/rat : > 5000 mg/kg. LD50 oral/route in dogs : > 5000 mg/kg.
PHYSIOLOGICAL ACTIVITY	: Substance physiologically very active., : anti-progestative, abortive.
SPECIFIC EFFECTS	: Teratogenicity : embryolethal in rat, mice, rabbit per oral route. Not teratogenic in surviving rat and mice foetuses. Teratogenic effects have been seen in rabbit foetuse (undirect action, at low frequency). Mutagenicity : not mutagenic.
COMMENTS/SYMPTOMS	: TOXIC BY INHALATION, IN CONTACT WITH SKIN AND IF SWALLOWED.
OTHER RECOMMENDATIONS	: Handling inadvisable for pregnant women Possibly, seek medical advice

12. ECOLOGICAL INFORMATION

ENVIRONMENT	: Biodegradable in natural media
