UNITED STATES DISTRICT COURT
FOR THE WESTERN DISTRICT OF LOUISIANA
LAFAYETTE DIVISION

THE STATE OF LOUISIANA, by and through its Attorney General, LIZ MURRILL, and ROSALIE MARKEZICH, *Plaintiffs*, *v.* U.S. FOOD AND DRUG ADMINISTRATION, *et al*., *Defendants*.	Civil Action No. 6:25-cv-01491 Judge: David C. Joseph Mag. Judge: David J. Ayo

GENBIOPRO, INC.'S MOTION TO INTERVENE

Pursuant to Federal Rule of Civil Procedure 24, GenBioPro, Inc. ("GenBioPro") hereby moves to intervene as a defendant in this action. As detailed in the accompanying Memorandum of Law, GenBioPro has protectable interests in this action that may be impaired by the disposition of the case, and which are not adequately represented by Defendants. GenBioPro therefore is entitled to intervene as of right under Rule 24(a). Alternatively, at a minimum, the Court should grant GenBioPro intervention on a permissive basis under Rule 24(b) because GenBioPro's prospective defenses share common questions of law and fact with the existing action and no party would suffer prejudice from GenBioPro's intervention.

Pursuant to Federal Rule of Civil Procedure 24(c) and Local Rule 7.6, GenBioPro also attaches hereto two proposed pleadings: (1) a Conditional Memorandum in Opposition to Plaintiffs' Motion for Preliminary Relief, and (2) a Conditional Motion to Dismiss. GenBioPro respectfully requests that these documents be deemed filed if this Motion for Leave to Intervene is granted.

GenBioPro has conferred with the existing parties regarding their positions on this motion. Plaintiffs oppose intervention and Defendants take no position on intervention.

For the foregoing reasons, and those set forth in the accompanying Memorandum of Law, GenBioPro respectfully requests that the Court grant its motion to intervene as a defendant in this action.

Dated: February 3, 2026

Respectfully submitted,

/s/ *Robert J. Katerberg*

GenBioPro, Inc. ("GenBioPro") respectfully submits this Memorandum of Law in Support of its Motion for Leave to Intervene pursuant to Rule 24 of the Federal Rules of Civil Procedure.

INTRODUCTION

This case challenges the regulatory terms on which GenBioPro is permitted to distribute its primary product nationwide, and GenBioPro has a right to intervene to defend its interests. Since 2019, GenBioPro has manufactured generic mifepristone in the United States, and sales of mifepristone represent the majority of its revenue. A significant portion of GenBioPro's revenue derives from the sale of mifepristone prescribed via telehealth services and dispensed via pharmacies in non-party states to non-party patients nationwide. Because this lawsuit seeks to reimpose an obsolete condition, last in effect in early 2021—that mifepristone can be dispensed only in-person in clinics, medical offices, and hospitals ("in-person dispensing requirement," ECF 1-50 at 8)—it directly and concretely threatens GenBioPro's interests.

The drug manufacturers' stake in these issues is self-evident. Indeed, in the predecessor case to this one in Texas, in which various organizations and individuals (and later three intervenor-plaintiff States), sued the U.S. Food and Drug Administration ("FDA") and others challenging regulatory actions relating to mifepristone, the court granted motions to intervene by both GenBioPro and mifepristone's branded manufacturer, Danco Laboratories, LLC ("Danco"). *See All. for Hippocratic Med. v. FDA*, 2023 WL 11840559 (N.D. Tex. Feb. 6, 2023); *Missouri v. FDA*, 2025 WL 1223581, at *1 (N.D. Tex. Apr. 28, 2025). Danco's motion to intervene was not even contested by the plaintiffs, who were represented by the same counsel that represent Plaintiffs here. And the only objection that the State intervenor-plaintiffs raised to permissive intervention by GenBioPro was timeliness, an argument that the court overruled there, and which is plainly inapplicable in this case, which was just filed and remains at the pleadings stage.

Here, GenBioPro meets all of the requirements for intervention as of right under Rule 24(a). This motion is timely; GenBioPro has a paradigmatic and obvious interest in defending the regulatory regime governing its own product; GenBioPro's interest would be impaired by Plaintiffs' requested relief; and the existing parties will suffer no prejudice from intervention.

Defendants do not adequately protect GenBioPro's interests, as their recent combined motion to stay and response to Plaintiffs' motion for preliminary relief (ECF 51, "Defs.' Br.") amply illustrates. Defendants do not defend the merits of the challenged FDA action, even though it was based on a robust body of scientific evidence that the agency detailed at length in its decision. *See generally* ECF 1-50 (FDA 2023 Summary Review). Instead, Defendants rest largely on a recently announced administrative review of what they call the "safety risks of mifepristone." Defs.' Br. 3. Defendants thus echo Plaintiffs' Complaint, which alleges that, in connection with launching this new review, Defendants "admitted that there was a 'lack of adequate consideration' of the safety risks 'underlying the prior REMS approvals,' including the decision to 'remov[e] the in-person dispensing requirement.'" Compl. ¶ 13. GenBioPro emphatically disagrees.

Indeed, comparing Defendants' Brief, on the one hand, with GenBioPro's Conditional Opposition and Conditional Motion to Dismiss (both submitted with this motion), on the other, makes clear that their positions are far from aligned. Defendants' Brief ignores the merits, opposing Plaintiffs' request for preliminary relief solely on standing grounds and because Defendants prefer a stay. *See* Defs.' Br. 9-20. Most glaringly, Defendants stay silent on the reasoned basis for FDA's 2023 modifications to the Risk Evaluation and Mitigation Strategy ("REMS") for mifepristone. In contrast, GenBioPro, if permitted to intervene, would oppose preliminary relief on the grounds that the 2023 REMS was supported by overwhelming scientific

and medical evidence that was the basis of FDA's action, has been bolstered by subsequent studies, and is still lawful and scientifically sound today.

GenBioPro would also argue that Plaintiffs' arguments under the Comstock Act are incorrect, that Plaintiffs failed to exhaust administrative remedies, and that their claims are not ripe, all of which render Plaintiffs unlikely to succeed on the merits. Moreover, unlike Defendants, who seek a stay that would permit this litigation to resume later, GenBioPro would seek dismissal now. Those differences in positions are stark, fundamentally distinguishing this case from others where an intervenor-movant was unable to overcome the presumption of adequate representation because its proposed pleading sought the same objective without adding new evidence, claims, or defenses. GenBioPro thus more than satisfies the requirements for intervention under Rule 24(a) and is entitled to intervene in this action.

At a minimum, permissive intervention under Rule 24(b) is appropriate. In the predecessor case in Texas, the court correctly found that "GenBioPro's claim [had] a question of law or fact in common with the main action," as "GenBioPro seeks to protect its product's FDA approval" whereas "Plaintiffs challenge GenBioPro's product's FDA approval." *Missouri*, 2025 WL 1223581, at *6. Moreover, "intervention [would] not 'unduly delay or prejudice' [the State Plaintiffs'] rights" because it would "change nothing in the existing case schedule." *Id.* Each of those propositions is equally true in this case, and the Court should grant GenBioPro's motion.

BACKGROUND

In April 2019, FDA approved GenBioPro's Abbreviated New Drug Application ("ANDA") for Mifepristone Tablets, 200mg, a generic version of mifepristone. Approved by FDA as safe and effective for performing medical abortions at up to ten weeks of gestation, mifepristone has been marketed and prescribed under the brand name Mifeprex for more than a quarter of a century, since 2000. Mifepristone's approval is subject to a set of distribution and administration

conditions known as a "Risk Evaluation and Mitigation Strategy" or "REMS," which FDA has periodically revised. *See, e.g.*, ECF 1-50 at 6-8.

Until 2020, as part of the REMS, FDA required that mifepristone be dispensed only in-person at clinics, medical offices, and hospitals. A court enjoined that requirement during the COVID-19 pandemic. *See Am. Coll. of Obstetricians & Gynecologists v. FDA*, 472 F. Supp. 3d 183 (D. Md. 2020). Although the Supreme Court later stayed that injunction, *see FDA v. Am. Coll. of Obstetricians & Gynecologists*, 141 S. Ct. 578 (2021), FDA suspended enforcement of the in-person dispensing requirement in April 2021, ECF 1-50 at 48-49. Then, in December 2021, based on a "comprehensive review" of the published literature and postmarketing safety data, including real-world evidence from when the in-person dispensing requirement was not being enforced, FDA concluded that this requirement was unnecessary from a safety perspective. *See id.* at 45, 77.

On January 3, 2023, FDA published a new, shared REMS for Mifeprex and generic mifepristone. The 2023 REMS formally withdrew the in-person dispensing requirement for mifepristone. FDA's decision was based on a robust administrative record that included its review of safety data, the distribution model in use while the in-person dispensing requirement was not being enforced, and other REMS assessment data and published literature. *Id.* at 80-83. Having evaluated that evidence, FDA concluded that "the REMS program, with the removal of the in-person dispensing requirement and the addition of a requirement for pharmacy certification, will continue to ensure the benefits of mifepristone for medical abortion outweigh the risks while minimizing the burden imposed by the REMS on healthcare providers and patients." *Id.* at 82. Without the in-person dispensing requirement, prescribers and pharmacies can now dispense mifepristone by mail or in-person, making it available and accessible to many more patients.

In the meantime, in November 2022, several individuals and organizations (represented by counsel who also represent Plaintiffs in this case) sued FDA, the U.S. Department of Health and Human Services, and various federal officials in the Northern District of Texas challenging regulatory actions relating to mifepristone, including the 2021 policy of non-enforcement of the in-person dispensing requirement. *FDA v. All. for Hippocratic Med.*, 602 U.S. 367, 372-77 (2024). Those plaintiffs sought a preliminary injunction or a stay of the effective dates of the challenged FDA actions.

Mifeprex's manufacturer Danco intervened in the case without opposition. *See All. for Hippocratic Med.*, 2023 WL 11840559, at *1. The district court and the Fifth Circuit then granted the plaintiffs different forms of partial relief, but the Supreme Court barred those orders from taking effect. *Danco Lab'ys, LLC v. All. for Hippocratic Med.*, 143 S. Ct. 1075 (2023) (staying case pending resolution of petition for certiorari, and if granted, until judgment of the Court). Ultimately, the Supreme Court unanimously held that the plaintiffs lacked Article III standing. *All. for Hippocratic Med.*, 602 U.S. at 374.

While the appeal in that case was pending, the States of Missouri, Kansas, and Idaho intervened in the district court in an effort to defuse defendants' standing-based challenges to the original plaintiffs' lawsuit. The States also sought to intervene in the Supreme Court, but their motion was denied. On remand following the Supreme Court's ruling, the State plaintiffs amended their complaint; GenBioPro then moved to intervene to defend the challenged FDA actions, which the court permitted under Rule 24(b). *Missouri*, 2025 WL 1223581, at *6. The Texas district court subsequently held that venue was improper and transferred the case to the Eastern District of Missouri. *Missouri v. FDA*, 2025 WL 2825980, at *12-13 (N.D. Tex. Sept. 30, 2025).

On October 6, 2025, after unsuccessfully attempting to intervene in the *Missouri* case, *see id.*, Louisiana and Rosalie Markezich filed this lawsuit against FDA challenging the 2023 REMS. Plaintiffs allege that the 2023 REMS is arbitrary and capricious and contrary to law and ask the Court to stay, set aside, and vacate FDA's approval of the REMS.

More than two months later, on December 17, 2025, Plaintiffs filed a Motion for Preliminary Relief under 5 U.S.C. § 705, seeking to stay the effective date of the 2023 REMS, which has now been in effect for three years. ECF 20. The Court ordered the Government to respond to Plaintiffs' motion by January 27, 2026, and further ordered prospective intervenors Danco and GenBioPro to file their motions and conditional responses to Plaintiffs' motion by January 30, ECF 28, later extended to February 3, ECF 39. The Court also stayed FDA's deadline to respond to the Complaint. ECF 39.

On January 27, Defendants filed a motion to stay the proceedings, ECF 50, and a memorandum in support of the motion to stay and in opposition to Plaintiff's motion for preliminary relief, ECF 50-1, 51. In their submissions, Defendants ask the Court to "stay this litigation pending the outcome of FDA's review of the mifepristone REMS," Defs.' Br. 4, 9-13, and argue that Plaintiffs lack Article III standing, *id.* at 14-20. Defendants offer no other arguments in opposition to Plaintiffs' motion for preliminary relief.

Aside from these recent filings, no motion practice has occurred in this case; Defendants have not responded to the Complaint; and the administrative record has not been produced.

ARGUMENT

I. GenBioPro Is Entitled to Intervene As of Right Under Federal Rule 24(a)(2)

A party must be permitted to intervene in an action if it shows by "timely motion" that (a) "it has a protectable 'interest' in the action," (b) "the 'disposing of the action' could 'impair' its ability to protect that interest," and (c) "existing parties do not 'adequately represent' that interest."

Louisiana v. Burgum, 132 F.4th 918, 922 (5th Cir. 2025) (quoting Fed. R. Civ. P. 24(a)(2)). Courts "should liberally construe the test for mandatory intervention" and should "allow intervention where no one would be hurt and the greater justice could be attained." *Rotstain v. Mendez*, 986 F.3d 931, 937 (5th Cir. 2021) (cleaned up); *see Entergy Gulf States La., L.L.C. v. EPA*, 817 F.3d 198, 203 (5th Cir. 2016) ("doubts resolved in favor of the proposed intervenor"); *Wal-Mart Stores, Inc. v. Tex. Alcoholic Beverage Comm'n*, 834 F.3d 562, 569 (5th Cir. 2016) (emphasizing "broad policy favoring intervention"). GenBioPro easily meets that standard here.

There is no question that GenBioPro's motion is timely. Plaintiffs filed this suit in just October 2025 and moved for preliminary relief in December 2025. The day after Plaintiffs filed their motion, GenBioPro notified the Court of its intent to file a motion to intervene. ECF 26. The Court ordered that all proposed intervenors file intervention motions by January 30, 2026, ECF 28, which was later extended to February 3, 2026. ECF 39. Defendants have not answered the Complaint, the administrative record has not been produced, and no substantive activity has occurred in this case other than the filing of the motion for preliminary relief, which GenBioPro seeks to oppose, and Defendants' motion to stay in response to Plaintiffs' motion. This Court's briefing schedule avoids any prejudice to Plaintiffs by giving them a reasonable time after GenBioPro's Conditional Opposition to file their reply in support of preliminary relief. *See id.*

GenBioPro's filing easily qualifies as timely under the Fifth Circuit's standards. *See Sierra Club v. Espy*, 18 F.3d 1202, 1205-06 (5th Cir. 1994) (intervention was timely even though motion to intervene was filed eight years after suit commenced and two months after preliminary injunction was issued); *see also Edwards v. City of Houston*, 78 F.3d 983, 1001 (5th Cir. 1996) ("[M]ost of our case law rejecting petitions for intervention as untimely concern motions filed after judgment was entered in the litigation."); *cf. Missouri*, 2025 WL 1223581, at *5 (finding

GenBioPro's motion to intervene timely because it was filed less than two months after amended complaint implicating GenBioPro's distinct interests).

Having filed a timely motion, GenBioPro meets each of the Rule 24(a)(2) requirements laid out in *Burgum*, as described below.

A. GenBioPro Has a Protectable Interest in This Action

GenBioPro clearly has "direct, substantial, and legally protectable" interests in this action. *John Doe No. 1 v. Glickman*, 256 F.3d 371, 379 (5th Cir. 2001) (cleaned up). Courts routinely recognize that litigation against FDA affecting a drug approval implicates the interests of the holder or potential holder of the approval for Rule 24 purposes. *See, e.g.*, *Mova Pharm. Corp. v. Shalala*, 140 F.3d 1060, 1075-76 (D.C. Cir. 1998) (reversing denial of a motion to intervene as of right of New Drug Application ("NDA") holder in litigation concerning FDA's approval of an ANDA); *Eagle Pharms., Inc. v. Price*, 322 F.R.D. 48, 49-50 (D.D.C. 2017) (manufacturer with a pending ANDA permitted to intervene as of right because plaintiff's requested relief would prevent intervenor "from marketing its generic product"); *Apotex Inc. v. FDA*, 508 F. Supp. 2d 78, 80 n.2 (D.D.C. 2007) (manufacturer permitted to intervene as of right because plaintiff sought to "set aside the FDA's decision as to its approval status" for its generic version of the intervenor's drug).

Here, GenBioPro has a direct and substantial interest in this litigation as a party directly regulated by the 2023 REMS, *Texas v. United States*, 805 F.3d 653, 660 (5th Cir. 2015), with a concrete and "legally protectable interest in the regulatory scheme" under which its product is distributed, *Wal-Mart*, 834 F.3d at 566. At FDA's request, GenBioPro proposed the REMS modifications at issue here, ECF 1-50 at 5, and those FDA-approved distribution conditions control GenBioPro's ability to lawfully market its product nationwide, *see generally* 21 U.S.C. § 355-1. As GenBioPro's CEO explains in the declaration submitted with this motion, GenBioPro's business model relies directly on the 2023 REMS that Plaintiffs seek to stay or vacate. *See* Decl.

of Evan Masingill ¶¶ 7-10. On these facts, "it is obvious that the economic interests of [GenBioPro] are at stake" in this lawsuit. *See Espy*, 18 F.3d at 1207; *see also Wal-Mart*, 834 F.3d at 567-68 (collecting cases "permitting intervention based on economic interests").

B. Disposition of This Action May Impair GenBioPro's Ability to Protect Its Interests

GenBioPro also easily clears the second Rule 24(a)(2) criterion. If Plaintiffs' claims succeed and the challenged 2023 REMS is vacated, GenBioPro would face severe operational distress. *See* Masingill Decl. ¶¶ 7, 11-15. A "stay" of the 2023 REMS and a return to the in-person dispensing requirement would immediately disrupt GenBioPro's national distribution model and network, causing financial, reputational, and operational harm. *Id.* ¶¶ 11-14. If GenBioPro is not able to present its evidence and arguments explaining those harms in this litigation, there is far more than a mere "possibility that [GenBioPro's] interest could be impaired or impeded" as a practical matter. *See La Union del Pueblo Entero v. Abbott*, 29 F.4th 299, 307 (5th Cir. 2022). That harm is a virtual certainty if Plaintiffs are awarded any relief. *See* Masingill Decl. ¶¶ 7, 10-15.

C. GenBioPro's Interests Are Not Adequately Represented by Defendants

The existing Defendants do not adequately represent GenBioPro's interests. "The inadequate-representation factor typically 'is satisfied if the [movant] shows that the representation of his interest may be inadequate.'" *Missouri*, 2025 WL 1223581, at *2 (quoting *Trbovich v. United Mine Workers of Am.*, 404 U.S. 528, 538 n.10 (1972)). That burden is "minimal" unless "one of two presumptions of adequate representation appl[ies]." *Burgum*, 132 F.4th at 922 (quotation marks omitted); *accord Missouri*, 2025 WL 1223581, at *2. The first presumption "arises when the intervenor has the same ultimate objective as a party to the lawsuit." *Burgum*, 132 F.4th at 922 (quotation marks omitted). "The second presumption arises when the existing

party is a governmental body or officer charged by law with representing the interests of the movant." *Id.* (quotation marks omitted).

Neither presumption applies here. The first is inapplicable because the existing Defendants do not have "the same ultimate objective" as GenBioPro. *See Burgum*, 132 F.4th at 922. GenBioPro's ultimate objective is to defend the 2023 REMS on the merits and ensure that the REMS remains in effect, whereas Defendants are in the midst of what they call "a study of the safety of the current REMS, in order to determine whether modifications are necessary." ECF 1-110 at 1; *see* Defs.' Br. 3 (stating FDA is conducting a "review and study of the safety risks of mifepristone"). On its own, GenBioPro's goal of defending the REMS on the merits—while Defendants fail to do so—is dispositive on this element.

The gap between GenBioPro's and Defendants' objectives is vividly illustrated by comparing Defendants' response to Plaintiffs' motion for preliminary relief to the Conditional Opposition that GenBioPro would file if permitted to intervene. Defendants oppose Plaintiffs' motion for preliminary relief on two grounds: (1) Defendants would prefer a stay pending FDA's review of the safety of the current REMS, Defs.' Br. 9-13; and, (2) Plaintiffs lack standing, *id.* at 14-20. Defendants do not address, much less defend against, the merits of Plaintiffs' claims. They do not defend the 2023 REMS as supported by the medical and scientific evidence before the agency, do not engage on any legal issues relating to the Comstock Act, do not invoke FDA's strict exhaustion requirement or the "ripeness" doctrine, and do not address the concrete harms that a suspension of the 2023 REMS would inflict on GenBioPro and public health across the country. Nor do Defendants actively seek dismissal of this case.

GenBioPro departs from Defendants on all of those issues. GenBioPro's Conditional Opposition offers overwhelming scientific and medical evidence—relied on by FDA—that

supports the 2023 REMS, which independently undercuts Plaintiffs' likelihood of success on the merits of their claims. GenBioPro's Conditional Opp. § III.A. GenBioPro also attaches voluminous exhibits supporting FDA's 2023 actions and rebutting Plaintiffs' incorrect claims that subsequent events refute the reasonableness of lifting the in-person dispensing requirement. *See id.*; Ex. B (GenBioPro's Citizen Petition to FDA); Exs. B-1–B-9 (appendix in support of GenBioPro's Citizen Petition). GenBioPro's Conditional Opposition also opposes Plaintiffs' novel Comstock Act argument, which Defendants do not address. GenBioPro's Conditional Opp. § III.B.[1] And GenBioPro seeks outright dismissal of this case due to its jurisdictional flaws, whereas Defendants seek a stay. *See* GenBioPro's Conditional Mot. to Dismiss.

Defendants further illustrate that they do not share GenBioPro's objective of defending and preserving the 2023 REMS when they repeat Plaintiffs' claim that Defendants "admitted that there was a 'lack of adequate consideration' of the safety risks 'underlying the prior REMS approvals,' including the decision to 'remov[e] the in-person dispensing requirement.'" Compl. ¶ 13 (quoting ECF 1-110 at 1); *see* Defs.' Br. 1 (quoting same). Similarly, Defendant Kennedy has pledged to "review all the evidence … on the safety of [mifepristone]," claiming that "[r]ecent studies already point to serious risks when mifepristone is used without proper medical oversight." ECF 1-108. Defendants have explained that their review of the mifepristone REMS was prompted by the same publication by the Ethics and Public Policy Center (EPPC)—an anti-abortion advocacy group—

[1] The government's change in position from the *Alliance for Hippocratic Medicine* litigation further demonstrates that Defendants do not adequately represent GenBioPro's interest. For instance, in their opposition to the plaintiffs' motion for a preliminary injunction in the *Alliance* case, Defendants rebutted plaintiffs' Comstock Act arguments as untimely, unexhausted, and legally incorrect and explained why in-person dispensing is unnecessary based on the scientific and medical evidence. Defs.' Opp. to Mot. for Prelim. Inj. at 23, 28-30, *All. for Hippocratic Med. v. FDA*, No. 2:22-cv-00223 (N.D. Tex. Jan. 13, 2023), ECF 28. In Defendants' response in this case, they make none of those arguments.

that features prominently in Plaintiffs' Complaint. *See* ECF 1-110 at 2 (Defendants Kennedy and Makary citing to the EPPC report, "The Abortion Pill Harms Women," when announcing their "study of the safety of the current REMS"); ECF 1-13 (copy of "The Abortion Pill Harms Women"); Compl. ¶ 38 & nn.18-19 (referencing same). While Defendants' Brief does not address the EPPC study, as GenBioPro's conditional opposition explains, the EPPC report is a self-published (non-peer reviewed) report posted by an advocacy organization and not grounded in any reliable scientific methodology. *See* GenBioPro's Conditional Opp. § III.A; *see* Ex. B at 16-20 (discussing critical methodological problems with EPPC report).

The sharp contrast between GenBioPro's and Defendants' objectives makes this case far different from *Burgum*, where the first presumption of adequate representation applied because would-be intervenor American Petroleum Institute (API) "ha[d] the same ultimate objective as [defendant] BOEM [(the Bureau of Ocean Energy Management)]: to uphold the Rule." *Burgum*, 132 F.4th at 922; *see id.* at 921 (noting API's "proposed answer was materially identical to BOEM's, stating no new claims or defenses"). The same conclusion simply does not apply here.

The divergence in objectives also distinguishes this case from *Missouri*, in which the Texas court determined that GenBioPro's interests were adequately protected by FDA for purposes of mandatory intervention.[2] At that point in the *Missouri* case, no motion for injunctive relief was pending; the only issue presented was whether the States' amended complaint should be dismissed for lack of standing, exhaustion, and venue. On those issues, GenBioPro presented the same arguments as FDA (and Danco, which had already been allowed to intervene). *See Missouri*, 2025

[2] Although the *Missouri* court found that the representation presumption precluded *mandatory* intervention under Rule 24(a)(2), the court ultimately granted GenBioPro *permissive* intervention under Rule 24(b), *see Missouri*, 2025 WL 1223581, at *4-6, which is also warranted in the alternative here, *see* Section II, *infra*.

WL 1223581, at *4. The court held in those circumstances that GenBioPro did "not overcome the same-ultimate-objective presumption" because it showed no "distinct evidence it wished to introduce, remedies it sought, [or] legal arguments it intended to make." *Id.* (quotation marks omitted). The present situation—where GenBioPro seeks to mount a much more expansive opposition to Plaintiffs' motion for preliminary relief than the standing and stay arguments offered by Defendants, and seeks dismissal of the case—is dramatically different. GenBioPro's conditional opposition leaves no doubt that it would introduce distinct evidence, seek additional remedies (*i.e.*, dismissal), and make different legal arguments than FDA.

Even if the "ultimate objective" presumption of adequate representation somehow applied (it does not), Defendants' failure to defend the 2023 REMS on the merits or to seek dismissal, as well as their repetition of statements cited in the Complaint, would be sufficient to overcome it. *See Burgum*, 132 F.4th at 922 (first presumption can be overcome "by showing adversity of interest, collusion, or nonfeasance on the part of the existing party") (quotation marks omitted). Defendants' litigation position and public statements are textbook examples of "specific conduct showing that the party at issue inadequately represent[s] [the proposed intervenor's] interests, notwithstanding that it share[s] an ultimate objective." *Id.* at 923; *see La Union del Pueblo Entero*, 29 F.4th at 308-09 (finding inadequate representation prong satisfied because, even assuming presumptions applied, state officials "prefer[red] to not resolve th[e] case on the merits at all" and moved for dismissal only on standing and sovereign immunity grounds).

The second presumption of adequate representation—arising when "the existing party is a governmental body or officer charged by law with representing the interests of the movant," *Burgum*, 132 F.4th at 922 (quotation marks omitted)—does not apply here either. FDA of course is not charged by law with representing the interests of the drug companies it regulates. *See*

Missouri, 2025 WL 1223581, at *3 ("The second presumption does not apply."). Indeed, Defendants' express statement that they are investigating a change in the REMS, Defs.' Br. 3; ECF 1-110, shows that they are *not* bound to represent GenBioPro's interest in maintaining the status quo.

Since neither presumption applies, GenBioPro's burden of showing inadequate representation is "minimal," and GenBioPro need only show that FDA's representation "may" be inadequate. *Missouri*, 2025 WL 1223581, at *2. GenBioPro easily clears that low threshold. As discussed above, given FDA's and GenBioPro's divergent objectives and positions, there can be no question that FDA's representation *is* inadequate to protect GenBioPro's interests.[3]

II. The Court Should Permit GenBioPro to Intervene Under Rule 24(b)

The Court should, at a minimum, permit GenBioPro to intervene under Rule 24(b). "Permissive intervention may be granted if the movant 'has a claim or defense that shares with the main action a common question of law or fact.'" *Missouri*, 2025 WL 1223581, at *4 (quoting Fed. R. Civ. P. 24(b)(1)(B)). The motion must be timely, and intervention must not "unduly delay or prejudice the adjudication of the original parties' rights." *Id.*; *see also Newby v. Enron Corp.*, 443 F.3d 416, 424 (5th Cir. 2006). Although the *Missouri* court found that the presumption of adequate representation meant GenBioPro could not intervene *as of right* under Rule 24(a)(2), it granted GenBioPro's motion for *permissive* intervention under Rule 24(b) (for which inadequate representation by existing parties is not a requirement). *Missouri*, 2025 WL 1223581, at *4-6.

[3] As explained in GenBioPro's Conditional Opposition to Plaintiffs' motion for preliminary relief, Plaintiffs lack standing, and this Court therefore lacks jurisdiction over this case. GenBioPro's Conditional Opp. § I. Plaintiffs' failure to exhaust administrative remedies and FDA's ongoing review of the mifepristone REMS similarly support dismissal. *Id.* § II. For those reasons, denial of Plaintiffs' request for preliminary relief and dismissal of the Complaint are the appropriate remedies. To the extent the Court declines to dismiss the case at this time, GenBioPro would not oppose Defendants' request for a stay of these proceedings pending the ongoing FDA review.

Here, as in *Missouri*, GenBioPro's defense that the 2023 REMS was reasonable, reasonably explained, and should be upheld clearly shares common questions of law and fact with the main action. *See* GenBioPro's Conditional Opp. § III.A. Louisiana's claims against FDA center on those very same questions. *See Missouri*, 2025 WL 1223581, at *6 (finding common questions for Rule 24(b) purposes where "GenBioPro seeks to protect its product's FDA approval" whereas "Plaintiffs challenge GenBioPro's product's FDA approval").

GenBioPro thus satisfies all requirements for permissive intervention. As discussed above, this motion is plainly timely, *see supra* at 6-8, and there is no conceivable way in which GenBioPro's participation could delay or prejudice adjudication of FDA's or Plaintiffs' rights. As in *Missouri*, GenBioPro's intervention "will change nothing in the case schedule." *Missouri*, 2025 WL 1223581, at *6 (quotation marks omitted). "No deadlines will need to be moved, no additional discovery will be necessary, and no delay will occur, and, therefore, the parties will not be prejudiced." *Id.* (quotation marks omitted). The Court should permit GenBioPro to intervene.

III. GenBioPro's Proposed Response to Plaintiffs' Motion for Preliminary Relief and its Motion to Dismiss Satisfy the Attachment Requirement of Rule 24(c)

Rule 24(c) requires that an intervention motion be "accompanied by a pleading that sets out the claim or defense for which intervention is sought." Fed. R. Civ. P. 24(c); *see* LR7.6 (requiring proposed pleading to be filed with motion to intervene). The Fifth Circuit "takes a 'lenient approach'" to Rule 24(c), *Missouri*, 2025 WL 1223581, at *2 n.1 (quoting *Liberty Surplus Ins. Co. v. Slick Willies of Am., Inc.*, 2007 WL 2330294, at *1 (S.D. Tex. Aug. 15, 2007)); *see Farina v. Mission Inv. Tr.*, 615 F.2d 1068, 1074 (5th Cir. 1980) (rejecting "excessively technical" interpretation of Rule 24(c) as contrary to Rule 8's policy of flexibility in pleadings).

GenBioPro has attached to this motion both its Conditional Memorandum in Opposition to Plaintiffs' Motion for Preliminary Relief and its Conditional Motion to Dismiss. Those

submissions, together with the instant motion, apprise the Court and all parties of the defenses GenBioPro intends to raise if the motion is granted, serving Rule 24(c)'s purpose to "put the parties on notice of [GenBioPro's] grounds for intervention." *Liberty Surplus*, 2007 WL 2330294, at *2; *see United States ex rel. Hernandez v. Team Fin., L.L.C.*, 80 F.4th 571, 575 n.1 (5th Cir. 2023) ("proposed motion to unseal, and supporting declaration" submitted with motion to intervene satisfied attachment requirement).

CONCLUSION

For the foregoing reasons, the Court should grant GenBioPro's Motion for Leave to Intervene and accept GenBioPro's (1) Conditional Memorandum in Opposition to the Motion for Preliminary Relief and (2) Conditional Motion to Dismiss for filing on the docket in this action.

UNITED STATES DISTRICT COURT
FOR THE WESTERN DISTRICT OF LOUISIANA
LAFAYETTE DIVISION

THE STATE OF LOUISIANA, *et al.*, *Plaintiffs*, v. U.S. FOOD AND DRUG ADMINISTRATION, *et al.*, *Defendants*.	Civil Action No. 6:25-cv-01491 Judge: David C. Joseph Mag. Judge: David J. Ayo

DECLARATION OF EVAN MASINGILL

I, Evan Masingill, declare as follows:

1. I am the President and Chief Executive Officer of GenBioPro Inc. I make this declaration in support of GenBioPro's Motion to Intervene and its Opposition to Plaintiffs' Motion for Preliminary Relief under 5 U.S.C. § 705. If called to testify, I would testify competently to all of the statements in this Declaration.

2. GenBioPro is a privately held pharmaceutical company founded in 2011.

3. Between 2011 and 2019, GenBioPro invested several million dollars in working to bring to market a generic version of the drug mifepristone. That investment was necessary to satisfy requirements set by the U.S. Food and Drug Administration (FDA) for approval of an Abbreviated New Drug Application (ANDA) to sell a generic drug.

4. FDA approved GenBioPro's ANDA for generic mifepristone on April 11, 2019, and GenBioPro continues to hold that ANDA.

5. GenBioPro sells only generic mifepristone and misoprostol; it sells no other products. Sales of mifepristone account for the majority of GenBioPro's revenue.

6. GenBioPro currently manufactures and distributes mifepristone according to FDA's Risk Evaluation and Mitigation Strategy ("REMS"), which FDA updated in 2023. The 2023 REMS update, among other things, formally removed a requirement in the prior version of the REMS that mifepristone could be dispensed only in-person in certain healthcare settings, specifically clinics, medical offices, and hospitals. That in-person dispensing requirement, while it was in effect, meant that mifepristone could not be dispensed by pharmacies.

7. I understand that Plaintiffs in this case have asked the Court to suspend, vacate, or otherwise enjoin the 2023 REMS in a way that would reimpose the in-person dispensing requirement, including on a preliminary basis before any final rulings in the litigation. Doing so would have immediate and irreparable consequences for GenBioPro's business. Moreover, if the Court were to suspend the 2023 REMS, but that suspension were later lifted, modified, vacated, or or reversed (causing the 2023 REMS to go back into effect), GenBioPro would have no way to recover the revenue that it lost while the suspension was in effect.

8. In reliance on FDA's 2023 REMS, GenBioPro adapted its distribution model to incorporate a new system of pharmacy-based distribution.

9. GenBioPro's efforts toward adapting the pharmacy distribution model required hundreds (if not thousands) of internal staff hours over an 18-month period to redesign GenBioPro's supply chain and compliance operations. Those efforts included, among many other things, negotiating contracts with distributors, onboarding certified pharmacies, overhauling our information-technology and order-tracking systems, re-training the sales team, re-designing the company website and customer interface, and building new distribution and logistics frameworks.

The endeavor was so significant that we at GenBioPro considered the project to be a product "re-launch."

10. Currently, a significant portion of GenBioPro's total sales are to pharmacies. As such, a suspension of the 2023 REMS and reimposition of the in-person dispensing requirement would have an immediate effect of cutting off sales to pharmacies, and therefore cutting off a substantial portion of GenBioPro's total revenue.

11. Suspending the 2023 REMS would interfere with the entire market for mifepristone. For instance, in-person clinics would see a dramatic influx of patients who must travel to those clinics to obtain the medication in person. Given the inherent limitations on the capacity of the existing clinic network to serve patients in person, there is likely a ceiling on the amount of additional clinic sales that GenBioPro could make in response to a suspension of the 2023 REMS. Any additional sales to clinics could not offset lost pharmacy sales.

12. Any court-ordered suspension of the 2023 REMS would cause significant uncertainty about whether GenBioPro would be permitted to continue selling existing mifepristone stock pending FDA's issuance of new REMS and/or applicable guidance. Accordingly, the immediate impacts of a suspension could be disruptive nationwide.

13. A suspension of the 2023 REMS would also harm GenBioPro because the drop in sales may force GenBioPro to scale back procurement and other internal operations. If the suspension is later lifted and the 2023 REMS go back into effect, GenBioPro would need to incur many of the same costs that it previously expended to adapt to the 2023 REMS (as detailed in paragraph 9 above). In addition, GenBioPro would incur significant delays to ramp back up to the level of operations it was at pre-suspension.

14. A suspension of the 2023 REMS would be particularly disruptive and costly for the pharmacy-specific aspects of GenBioPro's operations. For instance, certain of GenBioPro's distribution contracts are specific to pharmacies, meaning they would need to be either cancelled or paused if pharmacy dispensing were suspended.

15. To the extent a suspension of the 2023 REMS requires changes to the REMS-related documents (such as prescriber and patient agreements), GenBioPro would need to expend time and resources updating those documents. And to the extent a suspension of the 2023 REMS requires changes to the product's labeling, GenBioPro will incur significant expense creating new labels for its product and potentially even re-labeling the inventory that it has already produced. All of these costs would be unnecessary and unrecoverable if the suspension of the 2023 REMS were later lifted, modified, vacated, or reversed (causing the 2023 REMS to go back into effect).

16. I understand that issues have been raised in this litigation about the reporting of adverse events to FDA. As an ANDA holder, GenBioPro is required to and does submit annual reports to FDA detailing all adverse event reports that it receives regarding mifepristone. GenBioPro also submits any serious and unexpected adverse drug experiences within 15 days of receipt. The first page of GenBioPro's mifepristone label also informs prescribers and patients how to report any negative side effects to GenBioPro or to FDA directly, consistent with federal law and regulations.

I declare under penalty of perjury under the laws of the United States of America that the foregoing is true and correct to the best of my knowledge, information, and belief.

INTRODUCTION

The Court should deny the extraordinary relief Plaintiffs seek. The U.S. Food and Drug Administration's ("FDA") decision that mifepristone can be safely dispensed without an in-person clinic visit goes back nearly five years and is grounded in a robust body of scientific evidence. Plaintiffs' request that this Court displace FDA's congressionally assigned role in favor of their own misplaced views of the science defies fundamental precepts of administrative law. It would also have profound nationwide effects sweeping far beyond the purely state-specific interests Louisiana purports to assert. Yet Plaintiffs delayed for years and never brought their request or arguments to FDA itself, and they now seek to press forward despite the fact that FDA is currently conducting its own review and considering similar requests by others.

Plaintiffs' request for relief fails for a host of reasons. For Article III standing, Plaintiffs rely on attenuated theories of sovereign injury and indirect economic injury that falter under directly-on-point Supreme Court precedent. *See FDA v. All. for Hippocratic Med.* ("*AHM*"), 602 U.S. 397 (2024); *United States v. Texas*, 599 U.S. 670, 680 n.3 (2023). Plaintiffs' failure to exhaust administrative remedies independently bars relief and renders their claims unripe.

Nor can Plaintiffs establish any likelihood of success on the merits. The 2023 Risk Evaluation and Mitigation Strategy (or "REMS") (Ex. A) for mifepristone is based on FDA's rigorous, data-based evaluation of the requirements appropriate to promote safe use of the product while fulfilling Congress's direction to appropriately "assur[e] access and minimize[e] [the] burden" on "the health care delivery system." 21 U.S.C. § 355-1(f)(2), (f)(2)(D). After analyzing voluminous data from no fewer than 15 studies evaluating the safety of mifepristone when distributed through pharmacies and by mail, FDA concluded that mifepristone may be safely used without an in-person dispensing requirement. *See, e.g.*, ECF 1-50 at 82-83. Plaintiffs' contention that FDA acted unlawfully in reaching its reasonable, data-backed conclusion fails on its face.

Plaintiffs' suggestion that a 2016 change in FDA's protocol for adverse event reporting by prescribers somehow undermined the integrity of FDA's 2023 findings is also baseless. FDA continues to collect and review adverse event reports relating to mifepristone through multiple

channels, including voluntary physician reports and regular mandatory reporting from manufacturers, just like it does for virtually all other prescription drugs (including many drugs subject to REMS). Plaintiffs' assertion that handling adverse event reporting for mifepristone the same way as it does for other prescription drugs somehow reduced the quality of FDA's adverse event data and hamstrung FDA's later decision-making is meritless.

Nothing in the REMS violates the Comstock Act: FDA neither ships mifepristone itself, nor requires or authorizes anyone else to ship mifepristone in any circumstance that would violate the Comstock Act or any other statute.

Plaintiffs' hyperbolic claims that the REMS was somehow designed to undermine Louisiana's or other states' ability to enforce abortion laws in the wake of *Dobbs* are divorced from reality. It is undisputed that the in-person dispensing requirement was first suspended in 2020, then suspended again by FDA following a review in 2021—all prior to the 2022 *Dobbs* decision. The 2023 REMS simply carried forward that pre-*Dobbs*, evidence-based determination.

In sum, the Court should deny Plaintiffs' baseless request for extraordinary relief that would upend the nearly five-year regulatory status quo.

BACKGROUND

I. Factual and Regulatory Background

A. FDA's Risk Evaluation and Mitigation Strategy (REMS) Program

This case involves FDA's amendment to the conditions for dispensing mifepristone under a "Risk Evaluation and Mitigation Strategy," or REMS. In the Food and Drug Administration Amendments Act of 2007 (FDAAA), Congress charged FDA with determining whether a REMS "is necessary to ensure that the benefits of the drug outweigh the risks of the drug"; if so, FDA must review and approve a plan and conditions to help minimize risks. 21 U.S.C. § 355-1(a)(1). Congress further directed that each REMS must be designed in a manner that "assur[es] access and minimize[s] burden" on "the health care delivery system." *Id.* § 355-1(f)(2), (f)(2)(D). When evaluating whether to impose a REMS on an approved drug, FDA must consider "new safety information," which the statute defines as "information derived from a clinical trial, an adverse

event report, a postapproval study ... , or peer-reviewed biomedical literature; data derived from the postmarket risk identification and analysis system ... ; or other scientific data deemed appropriate by the Secretary." 21 U.S.C. § 355-1(a)(2)(A), (b)(3).

When Congress enacted the FDAAA, mifepristone had been FDA-approved for seven years as a safe and effective medication for terminating pregnancy, subject to certain conditions to assure safe use. ECF 1-11 at 4-5. In the new statute, Congress provided that drugs "approved before the effective date of [the] Act" would be "deemed to have in effect an approved risk evaluation and mitigation strategy" if they were subject to existing "elements to assure safe use" under certain FDA regulations. Pub. L. No. 110-85, § 909(b), 121 Stat. 951 (2007). FDA identified mifepristone as one of those drugs. *See* 73 Fed. Reg. 16,313, 16,314 (Mar. 27, 2008). The "elements" in place at the time included allowing dispensing only in a healthcare setting. ECF 1-24 at 2-3.

In 2016, FDA approved a series of changes to mifepristone's REMS and product label based on a review of over a decade of safety and efficacy data, peer-reviewed studies, and professional medical guidelines. ECF 1-11 at 24-26. Changes in the 2016 REMS included allowing licensed, non-physician healthcare providers to be certified prescribers. ECF 1-11 at 26-28.

FDA also rescinded an unusual provision in the mifepristone prescriber agreement that separately required prescribers to report certain adverse events to manufacturers. ECF 1-11 at 26; *see* ECF 1-30 at 8 (requiring that hospitalizations, transfusions, and other serious events be submitted to the manufacturer). Federal law independently requires drug manufacturers to review reports of adverse drug experiences for their products, including from clinical investigations, studies, scientific literature, and prescribers and patients, and to collect and submit that data to FDA in both periodic and annual reports. *See* 21 U.S.C. § 355(k)(1); 21 C.F.R. §§ 314.98, 314.80(b)-(c), 314.81. FDA collects these reports in the FDA Adverse Event Reporting System, "FAERS."[1] In its 2016 changes to the mifepristone REMS, FDA reasoned that because data on

[1] [1] FAERS "supports the FDA's post-marketing safety surveillance program" for all marketed drug products. *FAERS Public Dashboard - FAQ*, FDA, https://tinyurl.com/39uv9hee (last visited Feb. 3, 2026); *see FAERS Public Dashboard*, FDA (Dec. 7, 2023), https://tinyurl.com/53hbtps5.

"serious adverse events other than deaths" would still be included in the FAERS database via the manufacturer's "periodic safety update reports and annual reports to [FDA]," there was no need for a separate, mifepristone-specific channel for prescribers to report non-fatal events. ECF 1-11 at 28. FDA further explained that such additional reporting was unnecessary because the "safety profile" of mifepristone was "essentially unchanged" after fifteen years of reporting, *id.*, with "known risks occurring rarely," *id.* at 26. FDA thus conformed the adverse event reporting requirements for mifepristone to those applicable to the vast majority of approved drugs, which require no such additional reporting.

Early in the COVID-19 pandemic, FDA suspended the in-person dispensing requirements for most drugs, but maintained it for mifepristone. *See Am. Coll. of Obstetricians & Gynecologists v. FDA*, 472 F. Supp. 3d 183, 191-97 (D. Md. 2020). In July 2020, a court required FDA to temporarily suspend the in-person dispensing requirement in response to a lawsuit filed by mifepristone providers, allowing the drug to be mailed to patients. *Id.* at 233. That suspension was in effect for six months, from July 2020 until January 2021, when the Supreme Court stayed the injunction. *See FDA v. Am. Coll. of Obstetricians & Gynecologists*, 141 S. Ct. 578 (2021). During those six months, FDA observed no impact on patient safety. ECF 1-50 at 45, 61-62.

Based in part on the information gained from the non-enforcement period, in April 2021, FDA exercised its discretion to again suspend enforcement of the in-person dispensing requirement. FDA also initiated a full review of the mifepristone REMS program. ECF 1-50 at 46. In December 2021, FDA announced its determination that the in-person dispensing requirement was not necessary to assure mifepristone's safe use. *Id.* at 45. FDA explained that its decision was based on "a thorough scientific review by [agency] experts," who evaluated data from FDA's assessment report for the mifepristone REMS, postmarketing safety information, and published scientific studies evaluating different methods for dispensing mifepristone. ECF 1-10 at 5, 26-37.

Importantly, an adverse event report does *not* mean the adverse event was *caused* by a drug, but rather that the event occurred "in the course of the use of a drug product." 21 C.F.R. § 314.80(a).

B. Louisiana Law

More than a year after FDA suspended enforcement of the in-person dispensing requirement, the Supreme Court held in *Dobbs v. Jackson Women's Health Organization*, 597 U.S. 215 (2022), that there is no federal constitutional right to abortion. *Dobbs* allowed a Louisiana statute that generally prohibits abortions to go into effect. La. Rev. Stat. Ann. § 40:1061. Louisiana law excludes from its definition of "abortion" procedures necessary to prevent a patient's death (or substantial risk of death), to prevent the serious, permanent impairment of a life-sustaining organ, or to terminate certain "medically futile" pregnancies. La. Rev. Stat. Ann. § 14:87.1(1)(b); *see id.* § 40:1061(F). Mifepristone thus may be used lawfully for abortions that Louisiana law permits and for non-abortion purposes, including miscarriage management. *See id.* § 14:87.1(1)(b)(ii); *id.* § 14:87.1(2)(a) (defining "abortion-inducing drugs" as those used "with the intent to cause an abortion").

C. FDA's Approval of the 2023 REMS

In January 2023, FDA issued a new REMS that formally removed the in-person dispensing requirement for mifepristone, confirming that mifepristone, like most drugs, can be prescribed safely by telemedicine and dispensed by mail or at pharmacies. ECF 1-50 at 3. The 2023 REMS added new requirements for prescribers, *id.*, and also added a pharmacy certification requirement to, among other things, "ensure[] that pharmacies are aware of and agree to follow applicable REMS requirements." ECF 1-50 at 15. Particularly with those additional certification requirements, FDA determined that the REMS will "continue to ensure that the benefits of mifepristone for medical abortion outweigh the risks." *Id.*

The administrative record underlying FDA's 2023 REMS decision, which has been produced in other litigation concerning the mifepristone REMS, shows that the 2023 REMS rested on a robust scientific record. *See* Index to AR, *Washington v. FDA*, No. 23-cv-03026 (E.D. Wash. Sept. 1, 2023), ECF No. 127. FDA's review was grounded in its more than two decades of experience with mifepristone, and its analysis included its 2021 review of published literature, safety information submitted during the COVID-19 pandemic, more than five years of adverse

event data, a separate one-year assessment report for the mifepristone REMS, and information provided by advocacy groups, individuals, and manufacturers. *See, e.g.*, ECF 1-50 at 3, 45. FDA found that all this information supported the safety of the REMS modification. *Id.*

That record included 15 studies evaluating the safety and efficacy of mifepristone when dispensed outside the clinical setting, including by pharmacies and through the mail. ECF 1-50 at 65. These studies, which collectively evaluated outcomes for more than 55,000 individuals, repeatedly showed the safety of the drug was consistent when dispensed across a wide variety of non-clinical settings. *See id.* at 65-77. FDA found there were "no new safety concerns" related to the removal of the in-person dispensing requirement. *Id.* at 63. It therefore concluded that "[r]emoving the in-person dispensing requirement will render the REMS less burdensome to healthcare providers and patients and provided all other requirements of the REMS are met, including the additional requirement for pharmacy certification, the REMS will continue to ensure that the benefits of mifepristone for medical abortion outweigh the risks." *Id.* at 80-81.

D. GenBioPro's Operations Under the 2023 REMS

GenBioPro is a generic mifepristone manufacturers, and the sale of mifepristone represents the majority of its total revenue. Decl. of Evan Masingill ¶ 5. In 2019, FDA approved GenBioPro's amended new drug application to market a generic version of mifepristone. The REMS that was in effect for branded mifepristone (sold by Danco Laboratories, LLC) was re-issued to cover GenBioPro's product. ECF 1-57. Before 2021, GenBioPro shipped its product directly to clinics and hospitals for in-person dispensing. *See id.* ¶ 7. When FDA removed the in-person dispensing requirement in the 2023 REMS, GenBioPro redesigned its supply chain to meet pharmacy demand, *id.* ¶ 8, including through new pharmacy-specific distributor contracts, and by redesigning its logistics framework to incorporate pharmacy distribution, *id.* ¶ 9. Pharmacy sales now represent a substantial portion of GenBioPro's total sales. *Id.* ¶ 10.

E. Ongoing FDA Consideration of Mifepristone

The FDAAA directs FDA to periodically reassess its REMS. *See* 21 U.S.C. § 355-1(d), (g). FDA by regulation has also established a process whereby any interested petition can request

that the agency "take or refrain from taking any other form of administrative action," 21 C.F.R. § 10.25(a), including actions related to a REMS. The filing of such a "citizen petition" is a prerequisite to judicial review of FDA action. *Id.* § 10.45(b).

FDA is currently considering the mifepristone REMS. It has eight mifepristone-related citizen petitions pending before it, including one from GenBioPro that includes comprehensive and up-to-date data demonstrating the safety of mifepristone *See* Ex. B at 13-14 n.50 (citing 13 studies published after 2021 reaffirming the safety of mifepristone). In addition, FDA recently denied a petition seeking reinstatement of the in-person dispensing requirement, explaining that it needed more time to review the "complex scientific and policy issues" implicated and would instead evaluate these issues "as part of FDA's ongoing regulation of [mifepristone] products." Ex. C at 13 (FDA Letter denying citizen Petition submitted by American Association of Pro-Life Obstetricians & Gynecologists ("AAPLOG")). The FDA Commissioner in September 2025 similarly announced that the agency will be conducting further safety studies of the 2023 REMS "in order to determine whether modifications are necessary." ECF 1-110 at 2.

II. Procedural Background

A. *AHM* Litigation

In November 2022, several doctors and associations challenged virtually every FDA action ever taken regarding mifepristone, including FDA's initial 2000 approval of the drug, its 2016 changes to the REMS and label, its 2019 approval of GenBioPro's generic mifepristone, and its 2021 non-enforcement of the in-person dispensing requirement. *All. for Hippocratic Med. v. FDA*, 668 F. Supp. 3d 507, 522-23 (N.D. Tex. 2023). Although the district court and Fifth Circuit issued orders suspending certain FDA actions involving mifepristone, those orders were stayed pending appellate review and never took effect. *Danco Lab'ys, LLC v. All. for Hippocratic Med.*, 143 S. Ct. 1075 (2023) (stay order). Ultimately, the Supreme Court unanimously held that the plaintiffs lacked Article III standing. *AHM*, 602 U.S.at 374.

Three states intervened and, on remand, the case has since been transferred to the Eastern District of Missouri, where it remains pending. Shortly before the transfer, on September 19, 2025,

Plaintiffs here sought to intervene, but the court denied that "belated" request. *Missouri v. FDA*, 2025 WL 2825980, at *11-*12 (N.D. Tex. Sept. 30, 2025).

B. This Lawsuit

Plaintiffs filed suit in October 2025, more than four years after FDA first suspended the in-person dispensing requirement and three years after *AHM* was filed, challenging only the 2023 REMS and focusing on FDA's removal of the in-person dispensing requirement. On December 17, 2025, Plaintiffs filed their motion for preliminary relief. ECF 20; *see* ECF 20-26 ("Mot.").

LEGAL STANDARD

To justify Plaintiffs' request for preliminary relief, they must show "(1) a substantial likelihood of success on the merits, (2) a substantial threat of irreparable injury if the injunction does not issue, (3) that the threatened injury if the injunction is denied outweighs any harm that will result if the injunction is granted, and (4) that granting the injunction is in the public interest.'" *See* Mot. 8-9 (quoting *Clarke v. Commodity Futures Trading Comm'n*, 74 F.4th 627, 640-41 (5th Cir. 2023)); *see Wages & White Lion Invs., L.L.C. v. FDA*, 16 F.4th 1130, 1135-36 (5th Cir. 2021).

ARGUMENT

I. Plaintiffs Lack Article III Standing

Plaintiffs lack Article III standing, and they are not entitled to preliminary relief. *See AHM*, 602 U.S. 367 (reversing award of preliminary injunctive relief because plaintiffs lacked standing).

A. Louisiana Lacks a Cognizable Sovereign Injury Traceable to the 2023 REMS

Louisiana first asserts Article III standing based on a theory of sovereign injury, arguing that the 2023 REMS "enables third parties to violate Louisiana's pro-life laws, preventing Louisiana from effectively enforcing its prohibition on abortion." Compl. ¶ 109; *see* Mot. 19-21.

Louisiana's sovereign injury theory is precluded by precedent. In *United States v. Texas*, 599 U.S. 670 (2023), the Supreme Court held that Louisiana's and Texas's alleged "sovereign" and economic injuries did not give them standing to challenge a federal policy that they claimed violated federal law. *Id.* at 680 n.3. The Court reaffirmed that the underenforcement of federal law does not support a sovereign-harm theory of standing, declining to "start the Federal Judiciary

down th[e] uncharted path" of adjudicating "alleged Executive Branch under-enforcement of any similarly worded laws—whether they be drug laws, gun laws, obstruction of justice laws, or the like." *Id.* at 681. Applying *United States v. Texas*, one circuit court rejected an argument materially identical to the one Plaintiffs assert here regarding the mifepristone REMS, holding that, even if "the availability of retail and mail-order dispensing does make mifepristone more difficult to police, [courts] have never held that a logistical burden on law enforcement constitutes a cognizable Article III injury." *Washington v. FDA*, 108 F.4th 1163, 1177 (9th Cir. 2024).

Louisiana relies on *Louisiana v. EEOC*, 784 F. Supp. 3d 886 (W.D. La. 2025), as supporting its theory of sovereign injury. But in that case, the Court found that the federal action "force[d]" state action "that directly conflict[ed] with the States' own laws and policies" in the State's capacity as an employer. *Id.* at 901. Here, the REMS neither overrides Louisiana laws nor prevents Louisiana from enforcing them. Rather, as in *AHM*, the 2023 REMS does not require Louisiana "to do or refrain from doing anything." *AHM*, 602 U.S. at 374.

Contrary to Plaintiffs' assertion, Louisiana was not the "object" of the 2023 REMS. Mot. 18-19. The REMS does not, in any way, operate to regulate Louisiana. It regulates pharmaceutical manufacturers (and the supply chain) and guides providers' and pharmacies' prescribing and dispensing of mifepristone. *See* 21 U.S.C. § 355-1; Ex. A (2023 REMS). Thus, this case is nothing like *Diamond Alternative Energy, LLC v. EPA*, 606 U.S. 100 (2025), where the Supreme Court noted that private fuel producers "might" be considered the "object" of a state regulation that "explicitly [sought] to restrict the use" of the producers' products. *Id.* at 114-15.

Plaintiffs' contention that "the whole point" of the 2023 REMS was "to override the sovereign prerogatives of pro-life states" after *Dobbs*, Mot. 18 (citation omitted), is pure fiction. The in-person dispensing requirement was first removed by court injunction in 2020 (two years before *Dobbs*) and then voluntarily suspended by FDA in 2021 (more than a year before *Dobbs*). *See supra* § I.A. As FDA's website says expressly, the "Mifepristone REMS Program" was *not* "modified in 2023 in response to" *Dobbs* or any state abortion law. FDA, *Questions and Answers on Mifepristone for Medical Termination of Pregnancy Through Ten Weeks Gestation*, Question

Nos. 33, 34, https://tinyurl.com/38m6ea9f; *see* ECF 1-50 at 46 (FDA's REMS evaluation was initiated "in connection with *Chelius v. Becerra*, [No. 17-cv-00493, (D. Haw.)]"). Since abortion remained legal nationwide in 2021, FDA could not possibly have been motivated by a desire "to override the sovereign prerogatives of pro-life states." *Contra* Mot. 18.

To argue otherwise, Plaintiffs rely on assorted statements by various public officials supporting the goal of maintaining lawful abortion access. Mot. 19-20. In addition to postdating the key 2021 determination, none of these statements is by an FDA official responsible for making REMS determinations. *See id.* at 20. Judicial review of agency action is based on the administrative record generated by the decision-makers, not miscellaneous comments by other government actors, particularly those made after the fact. *See FDA v. Wages & White Lion Invs., L.L.C.*, 604 U.S. 542, 576-77 (2025) (rejecting allegations of "surreptitious[]" agency action).

Even if Louisiana had a cognizable sovereign injury, any such injury would be attributable to independent actors, not the 2023 REMS. Louisiana complains that its enforcement is hindered because individuals and organizations have been mailing mifepristone to Louisiana and other states have refused to cooperate with Louisiana's extradition requests. *See, e.g.*, Mot. 18, 20. However, if a party were already mailing mifepristone illegally, Plaintiffs offer no evidence to suggest that individual would be less likely to do so in the absence of the in-person dispensing requirement. Plaintiffs thus cannot avoid the reality that the "unfettered choices made by independent actors not before the courts" break the chain of causation between the 2023 REMS and any sovereign harm to Louisiana. *AHM*, 602 U.S. at 383 (citation omitted).

Louisiana asserts another "quasi-sovereign" standing theory in its Complaint—albeit not its motion for preliminary relief—based on the notion that the REMS interferes with Louisiana's right to regulate and protect its own citizens. Compl. ¶¶ 120-131. This "quasi-sovereign" theory is equally without merit: "States do not have 'standing as *parens patriae* to bring an action against the Federal Government.'" *Murthy v. Missouri*, 603 U.S. 43, 76 (2024) (quoting *Haaland v. Brackeen*, 599 U.S. 255, 295 n.11 (2023)); *see Washington*, 108 F.4th at 1178 (rejecting "thinly veiled attempt to circumvent the limits on parens patriae standing" based on similar allegations).

Plaintiffs also fail to allege traceability or that the 2023 REMS affects a "substantial segment" of Louisiana's population. *See Arizona v. Garland*, 730 F. Supp. 3d 258, 276 (W.D. La. 2024).

B. Louisiana Lacks a Cognizable Economic Injury Traceable to the 2023 REMS

Louisiana's other theory of standing is that FDA's "deregulatory action" "causes Louisiana textbook pocketbook injuries" of "Medicaid-related expenses" and increased payments to public hospitals for the care of patients who have taken mifepristone. Compl. ¶¶ 109, 148-149; *see* Mot. 21-23. This theory is equally flawed, not the least of which because the Court in *United States v. Texas* rejected the notion that a federal policy's "indirect effects" on "state spending" establishes standing. 599 U.S. at 680 n.3. As the Court noted, "in our system of dual federal and state sovereignty, federal policies frequently generate indirect effects on state revenues or state spending." *Id.* But those "indirect effects" were not adequate to demonstrate standing in *United States v. Texas*, *id.*, and any indirect effect of the 2023 REMS on Louisiana's Medicaid spending is even "far[ther] removed from" the "distant … ripple effects" that the Court found too attenuated in *AHM*, 602 U.S. at 383. For these reasons, one circuit court confronting similar arguments easily rejected other states' standing claims based on allegations of "downstream medical costs …borne by the state" that purportedly result from the "elimination of the in-person dispensing requirement." *Washington*, 108 F.4th at 1175-76.

Plaintiffs rely on *Texas v. United States*, 126 F.4th 392 (5th Cir. 2025). Mot. 21, 24. But in that case, Texas challenged a federal immigration policy, alleging an increase in spending that was directly traceable to the additional *number of non-citizens* who would stay in the state as a result of the challenged policy and who could thus take advantage of state services like Medicaid. *Id.* at 412. Here, in contrast, Louisiana does not contend that the 2023 REMS has any bearing on the number of Medicaid beneficiaries. It instead alleges that, by virtue of the potential for increased mifepristone use in the state, the *amount of money spent* on those individuals will increase. Mot. 22-23. But federal policy on any number of subjects can be "indirect[ly]" traced to increased state spending, from nutrition to pharmaceuticals to tobacco to guns to automobile safety, *see United*

States v. Texas, 599 U.S. at 680-81 & n.3, yet those sorts of indirect contingent economic interests are "too attenuated," and too "far removed" to support standing, *AHM*, 602 U.S. at 383, 390-93.

Louisiana cites specific Medicaid expenditures for emergency care that patients allegedly sought after taking mifepristone. Mot. 23. But Louisiana does not attempt—because it cannot—to tie those expenditures to the challenged FDA action, *i.e.*, FDA's safety determination in the 2023 REMS, as opposed to the mere use of mifepristone, which remains a lawful FDA-approved drug. *Supra* § I.B. Louisiana's economic injury theory is no more availing than its other theories.

C. Ms. Markezich Lacks Standing

Nor does Ms. Markezich have Article III standing. Her alleged past injuries are not redressable through APA claims against FDA seeking prospective relief. *See Lujan v. Defs. Of Wildlife*, 504 U.S. 555, 564 (1992). To the extent she claims to be at risk of suffering similar injury again in the future, such claims are too speculative to support standing. *See City of Los Angeles v. Lyons*, 461 U.S. 95, 105 (1983); *Clapper v. Amnesty Int'l USA*, 568 U.S. 398, 409 (2013) (emphasizing that the "purpose" of Article III's "imminence" requirement is to "ensure that the alleged injury is not too speculative for Article III purposes—that the injury is *certainly* impending" (quoting *Lujan*, 504 U.S. at 565 n.2)). Plaintiffs' argument (Mot. 23 n.5) highlights why neither Plaintiff has standing, confirming that any alleged injury necessarily depends on third-party acts—including coercion, abuse, and identity theft by Ms. Markezich's ex-boyfriend, *see* Compl. ¶¶ 150-54—which cannot be legally traced to FDA, *see AHM*, 602 U.S. at 383.[2]

II. Plaintiffs' Challenge Is Unexhausted and Not Ripe for Judicial Review

Even if Plaintiffs had standing, their case cannot proceed because they failed to exhaust administrative remedies and their claims are unripe.

---

[2] Plaintiffs also have not shown that they "fall[] within the 'zone of interests' sought to be protected by the statutory provision whose violation forms the legal basis for [their] complaint." *Louisiana v. United States*, 948 F.3d 317, 322 (5th Cir. 2020) (quotation marks omitted). Neither the provisions in 21 USC § 355-1 specifying the factors FDA must consider when adopting or amending REMS, nor the Comstock Act's prohibition on shipping materials for the purpose of unlawful abortion, reveals any intent on the part of Congress to protect state interests in enforcing their own laws or in lowering Medicaid costs.

A. Plaintiffs' Challenge Is Unexhausted

When an "agency rule" requires a party to pursue remedies within the agency as a "prerequisite to judicial review," the party's failure to exhaust those remedies generally requires dismissal. *Darby v. Cisneros*, 509 U.S. 137, 153 (1993). This requirement ensures that agencies have an opportunity to bring their expertise to bear on issues before courts intervene, and prevents the circumvention of agency procedures for resolution of those issues. *Gulf Restoration Network v. Salazar*, 683 F.3d 158, 175 (5th Cir. 2012).

Exhaustion is particularly critical in the context of FDA's regulatory decisions, which, as courts recognize, depend on the agency's "background, competence, and expertise to assess public health." *S. Bay United Pentecostal Church v. Newsom*, 140 S. Ct. 1613, 1614 (2020) (Roberts, C.J. concurring). FDA's evaluation of safety and efficacy draws from an array of complex medical evidence—including expert interpretation of clinical-trial data, adverse event reports, and real-world postmarketing studies. And the FDAAA's direction that FDA account for the need to "assur[e] access and minimize[e] burden" on "the health care delivery system," 21 U.S.C. § 355-1(f)(2), further underscores the delicate balancing that informs FDA's REMS decisions.

FDA's exhaustion requirements preclude judicial review here. Under FDA's regulations, a party generally must file a citizen petition with FDA "before any legal action is filed in a court complaining of the action or failure to act." 21 C.F.R. § 10.45(b); *see id.* § 10.25(a) (citizen petition procedures). FDA regulations also include "an issue exhaustion requirement," giving the agency "primary jurisdiction to make the initial determination on issues within its statutory mandate." *Indep. Turtle Farmers of La., Inc., v. United States*, 703 F. Supp. 2d 604, 616 (W.D. La. 2010) (quoting 21 C.F.R. § 10.25(b)). Courts have applied these provisions strictly, requiring the filing of a citizen petition and FDA's resolution of that petition as a precondition to judicial review. *See, e.g.*, *Ass'n of Am. Physicians v. FDA*, 358 F. App'x 179, 180-181 (D.C. Cir. 2009) (affirming

dismissal where plaintiffs failed to file a "citizen petition with FDA contesting the SNDA approval of Plan B and [ ] proffer[ing] no legally viable excuse for this failure").[3]

Under these exhaustion rules, this case cannot proceed. Plaintiffs never filed a citizen petition, and so FDA could not have reached a "final administrative decision based on" that petition, as FDA's regulations require. 21 C.F.R. § 10.45(b). In fact, the "evidence" Plaintiffs invoke *postdates* the challenged FDA decision, *see* Compl. ¶¶ 38 nn.18-19, nn.20-21, meaning the agency *could not* have considered it in the REMS decision that Plaintiffs now seek to enjoin, *cf. Sierra Club v. FERC*, 827 F.3d 59, 69-70 (D.C. Cir. 2016). Meanwhile, other parties (including GenBioPro) have played by the rules, submitting a host of petitions seeking a variety of actions from FDA related to mifepristone. *See, e.g.*, Ex. B (GenBioPro's Citizen Petition); *see also* ECF 50 at 7 n.3 (Defs.' Br.) (listing citizen petitions). Those petitions allow FDA to do its job of collecting data, assessing stakeholders' interests, and evaluating scientific literature. *See Troy Corp. v. Browner*, 120 F.3d 277, 283 (D.C. Cir. 1997).

No exception to exhaustion applies, and Plaintiffs make no attempt to argue otherwise. *See Gardner v. School Bd. Caddo Parish*, 958 F.2d 108, 112 (5th Cir. 1992). FDA plainly is not "powerless to grant the relief requested." *Carr v. Saul*, 593 U.S. 83, 93 (2021). There is no indication that a decision by FDA would "certainly" be adverse. *Tesoro Ref. & Mktg. Co. v. FERC*, 552 F.3d 868, 874 (D.C. Cir. 2009) (futility requires "*certainty* of an adverse decision" (citation omitted)). Rather, as Plaintiffs repeatedly emphasize, FDA is undertaking a review of mifepristone, and current HHS and FDA leadership have signaled uncertainty about the drug's status. *See* ECF 1 ¶ 13; Mot. 2, 8, 10, 11, 12; *see also* Defs.' Br. 3 (noting ongoing review of alleged "safety risks" of mifepristone). Plaintiffs' impatience, Mot. 8, does not grant them a license to bypass a legally required administrative review process.

---

[3] *See also Cody Lab'ys., Inc. v. Sebelius*, 446 F. App'x 964, 969 (10th Cir. 2011) ("Courts have often dismissed suits against the FDA for failure to utilize the citizen petition procedure."); *Indep. Turtle Farmers,* 703 F. Supp. 2d at 616 (noting the "science has progressed since" FDA's action, but declining to consider unexhausted issues because "without presentation of arguments to FDA on these issues, [the court is] foreclosed from evaluating them in any substantive capacity").

B. Plaintiffs' Challenge Is Not Ripe

For similar reasons, Plaintiffs' challenge is not ripe for judicial review. "A claim is not ripe for adjudication if it rests upon 'contingent future events that may not occur as anticipated, or indeed may not occur at all.'" *Texas v. United States*, 523 U.S. 296, 300 (1998). Courts find claims unripe, for example, when "[f]urther factual development" would "enhance th[e] case's fitness for judicial review." *Miss. State Democratic Party v. Barbour*, 529 F.3d 538, 547 (5th Cir. 2008).

Here, there is every reason for FDA's active consideration of the mifepristone REMS, which Plaintiffs acknowledge, Mot. 8, to proceed before court involvement. FDA confirmed as recently as January 16—when it denied without comment a citizen petition requesting that FDA modify the existing REMS—that it needed additional time to review the "complex scientific and policy issues" at the heart of this case, and would do so "as part of FDA's ongoing regulation of [mifepristone] products," Ex. C at 13 (FDA Letter Denying AAPLOG Citizen Petition), a representation it has confirmed in its filings in this Court, *see* Defs. Br. 3, 9-13. There is no basis for short-circuiting that administrative process.

III. Plaintiffs Are Not Likely to Succeed on the Merits for Additional Reasons

A. The 2023 REMS Is Not Arbitrary and Capricious

After ample experience without in-person dispensing during the pandemic, FDA determined that mifepristone—like the vast majority of drugs—could be dispensed without an in-person clinic or office visit. That determination is not arbitrary or capricious by any stretch.

FDA's modification of the REMS in 2023 was "reasonable and reasonably explained," and it easily satisfies the arbitrary-and-capricious standard. *FCC v. Prometheus Radio Project*, 592 U.S. 414, 423 (2021); *see* 5 U.S.C. § 706(2)(A). The FDAAA directs FDA to make the "fact-laden" determination, *see Seven Cnty. Infrastructure Coal. v. Eagle Cnty.*, 605 U.S. 168, 183 (2025), of whether the REMS will "ensure the benefits of the drug outweigh [its] risks"; "minimize the burden on the health care delivery system"; and "accommodate different, comparable aspects of the elements to assure safe use for a drug." 21 U.S.C. § 355-1(g)(4)(B). In addition, REMS

elements must not be "unduly burdensome on patient access to the drug," and, "to the extent practicable," must "minimize the burden on the health care delivery system." *Id.* § 355-1(f)(2).

FDA's application of those factors easily clears the APA's standard for reasoned decision-making. *See Cytori Therapeutics, Inc. v. FDA*, 715 F.3d 922, 923 (D.C. Cir. 2013) (Kavanaugh, J.) ("[C]ourts must be careful not to unduly second-guess [FDA's] scientific judgments."). In approving the 2023 REMS, FDA relied on multiple, independent lines of evidence. It reviewed more than five years of adverse-event data, comparing periods when the in-person dispensing requirement was enforced with periods when it was not. *Supra* § I.C. Based on FAERS data and adverse event data submitted by Danco and GenBioPro, FDA determined there were "no new safety concerns" related to the removal of the in-person dispensing requirement, and concluded "there does not appear to be a difference in adverse events between [those] periods"—which "suggests that mifepristone may be safely used without an in-person dispensing requirement." ECF 1-50 at 63. FDA also analyzed 15 studies that evaluated the safety and efficacy of mifepristone when dispensed to more than 55,000 patients by a variety of means not involving in-person dispensing in a clinic or hospital, finding that their cumulative results corroborated that removing the in-person dispensing requirement did not pose safety risks. *See* ECF 1-50 at 65-66, 69, 73, 74.[4]

Plaintiffs do not identify any evidence—no clinical trials, adverse event reports, post-approval studies, peer-reviewed literature, or other scientific data—that FDA erred in not considering. Instead, Plaintiffs contend that a change FDA made five years earlier, in 2016, to the adverse event reporting requirements for mifepristone made the FAERS data unreliable. That

[4] The studies supporting mifepristone's safety—including the studies upon which FDA relied and the studies published *after* the 2023 REMS—are all included in GenBioPro's citizen petition and the accompanying appendices. Ex. B at 11 n.35 (collecting and attaching studies FDA relied upon demonstrating safety of mifepristone); *see* Ex. B at 14-15 n.50 (collecting and attaching studies published after December 2021 demonstrating safety of mifepristone when dispensed via telehealth); *see also* Ex. E at 1, 6 (Sophie Dilek *et al.*, *The US Food and Drug Administration's Regulation of Mifepristone*, J. Am. Med. Ass'n (Jan. 12, 2026) (noting medical "consensus" that serious complications with mifepristone "are very rare," and commending FDA's "conservative[e]" and "incremental[]" approach to regulating mifepristone)).

argument is incorrect.[5] FDA's 2016 change simply brought the adverse event reporting for mifepristone closer in line with the protocol applicable to virtually all other prescription drugs, including many drugs with a REMS in place, under which prescribers are permitted (but not required) to report other adverse events. ECF 1-11 at 26-28; 21 C.F.R. § 314.80(c) (imposing reporting requirements on manufacturers but not providers). FDA thus maintained a mifepristone-specific reporting requirement for fatalities, while recognizing that, as with other drugs, "serious adverse events other than deaths" continue to reach FDA through manufacturers' "periodic safety update reports and annual reports." ECF 1-11 at 28; *supra* § I.A. Indeed, manufacturers are required to report *all* adverse events that they receive, including from a variety of different sources that are *not* limited to physician reports. *See* 21 C.F.R. § 314.80(b)-(c). Significantly, adverse event reports are overinclusive by nature: they include *all* adverse experiences when taking a drug and do not incorporate any kind of causation analysis. *See id.* § 314.80(a); *supra* § I.A.

The FAERS database that FDA considered in its assessment incorporates all of this data. *Supra* § I.A; *see* Masingill Decl. ¶ 16. Importantly, the relative numbers of non-fatal adverse events in the FAERS database for years after 2016 are comparable to those for years prior to the 2016 change. And FDA had more than ample post-2016 data to make an apples-to-apples comparison of adverse event reports when in-person dispensing was required versus when it was not. Plaintiffs' suggestion that FAERS data is somehow unreliable without a requirement that physicians report non-fatal adverse events also ignores the reality that most drugs have no such reporting requirement, *see* ECF 1-11 at 28; 21 C.F.R. § 314.80(c), yet Congress still directed FDA to rely on "adverse event reports" as one source of data when making its safety determinations, *see* 21 U.S.C. § 355-1(a)(1)(E), (b)(3); *see also Prometheus Radio*, 592 U.S. at 427 (agency decisions do not require "perfect empirical or statistical data").

[5] Plaintiffs emphasize comments about the FAERS database made by the Fifth Circuit in the *AHM* litigation, Mot. 10-12, but the Supreme Court vacated those Fifth Circuit decisions in their entirety, *AHM*, 602 U.S. at 397. They have no legal effect or precedential value. *See O'Connor v. Donaldson*, 422 U.S. 563, 577 n.12 (1975).

Plaintiffs also latch on to a characterization in FDA's analysis that the literature was "not inconsistent with [FDA's] conclusion" to suggest that the literature does not actually support the 2023 REMS. Mot. 12 (quoting ECF 1-10 at 29). That argument ignores the surrounding context of FDA's analysis. FDA reviewed the results of 15 studies that evaluated medication abortion outcomes for over 55,000 patients, and each study reached the conclusion that dispensing by mail, courier, or through pharmacies was safe and effective. *See* ECF 1-50 at 65-81. The 15 studies did not identify any new or increased risks when mifepristone is dispensed outside a clinic or hospital. *Id.* In particular, the largest study—involving patients in the United Kingdom—found "no significant differences in the rates of reported [serious adverse events]" between patients who received mifepristone by mail or picked it up at pharmacies and those who received it via an in-person physical examination. *Id.* at 74. And four studies evaluating post-telemedicine dispensing by mail in the United States showed "no increased frequency of [serious adverse events]," supporting the "conclusion that dispensing by mail is safe." *Id.* at 80.

FDA thus explained that the studies it examined "generally support a conclusion that dispensing by mail is safe" and "there was no increased frequency of" serious adverse events. *Id.* And those studies' conclusions as to safety fully supported FDA's predictive judgment that "mifepristone will remain safe" without requiring in-person dispensing at a clinic or hospital. *Id.* Any limitations in the specific studies that FDA examined were outweighed by the fact that *all* the studies it examined supported the safety of removing the in-person dispensing requirement, *id.*, and by the fact that FDA imposed *additional* requirements on pharmacies and physicians to ensure compliance with the mifepristone REMS, *id.* at 80-81.

Plaintiffs' reliance on FDA's observation in one subset of studies that "there may be more frequent [emergency department]/urgent care visits related to the use of mifepristone when dispensed by mail," Mot. 13 n.2 (quoting ECF 1-10 at 35), ignores FDA's expert *analysis* of those findings, which confirmed that those same studies "support[ed]" the finding "that dispensing by mail is safe and effective," ECF 1-50 at 80. Indeed, in one of those studies, the author noted that "half of the participants who had an "ED/urgent care visit did not require medical treatment," and

the studies did *not* show an increase in other adverse events. *Id.* In other words, FDA reasonably concluded that the fact that a patient visited a healthcare professional after the termination of a pregnancy did not undermine the robust data showing that the drug is safe. *See id.*

Unable to sustain an arbitrary-and-capricious claim based on the actual administrative record before the agency at the time of its decision, Plaintiffs rely most heavily on post-decision, extra-record evidence. Mot. 6; ECF 20-4 (Wallace Study, published 2025); ECF 1-14 (Studnicki Study, published 2024); ECF 1-13 (Hall Study, published 2025). But in APA cases, the administrative record, *i.e.*, "the decision of the agency and the evidence on which it was based," is "[t]he focal point for judicial review," and courts must not consider "some new record made initially in the reviewing court." *Texas v. EPA*, 156 F.4th 523, 537-38 (5th Cir. 2025).

In any event, Plaintiffs' studies do not support their challenge. Not one of the post-decision extra-record studies on which Plaintiffs rely (Wallace (ECF 20-4), Hall (ECF 1-13), or Studnicki (ECF 1-14)) purports to evaluate the safety of mifepristone as dispensed through pharmacies or by mail, and the results are therefore irrelevant to evaluating FDA's decision to remove the in-person dispensing requirement. The Wallace study suggested that *expanded* use of mifepristone with a specific misoprostol regimen past 77 days of pregnancy may "*increase* access to safe, effective abortion," ECF 20-4 (emphasis added), and therefore undermines Plaintiffs' arguments.

The other two studies do not support Plaintiffs' position either. The Hall publication was a self-published (*i.e.*, non-peer reviewed) report authored by two non-physician, non-medical scientists, which was posted on the website of the advocacy organization the Ethics & Public Policy Center (EPPC). Ex. B at 16-20 (explaining critical methodological problems with EPPC report). Among other flaws, the EPPC report does not even disclose certain of the databases upon which it relies, making it impossible for anyone to assess either the "reliability or relevance of that dataset." *Id.* at 19. EPPC's report adopts a medically unsupported, overbroad definition of "adverse events" that is inconsistent with established standards and captures events like ectopic pregnancies, which are not caused by mifepristone. *Id.* at 17-18. And the Studnicki study similarly adopts a flawed methodology that dramatically overstates the acuity of patients' medical treatment, while

basing its findings and recommendations on the assumption that patients and healthcare workers are regularly acting in "bad faith" and lying about the purpose of the visit. Ex. F at 19-23 (letter from UCLA Law Center for Reproductive Health, Law, and Policy and others explaining methodological flaws in Studnicki study). Plaintiffs' post-2023 sources do not resemble anything close to the kind of methodologically sound studies upon which FDA relies.

To the extent Plaintiffs rely on alleged new "evidence" adduced since 2023, they are urging the Court to reach a scientific conclusion on the disputed rates (and types) of hospitalization based on pharmacy versus clinic prescriptions of mifepristone before the agency has even completed its review of that evidence. Even if Plaintiffs' post-decision, extra-record evidence were somehow fit for consideration in this APA case, the Court would also be required to consider the bevy of post-2023 studies *confirming* the safety of mifepristone when dispensed through certified pharmacies. *See* Ex. B at 14-15 n.50 (collecting 13 peer-reviewed studies published since December 2021 supporting safety of dispensing of mifepristone outside the clinic setting). Plaintiffs make no effort to account for that evidence, and the very premise of their request for this Court to assess complex scientific evidence on a cold record in the first instance turns administrative law on its head.

Plaintiffs also rely on extra-record statements by various public officials. None of these statements is part of the administrative record, and none is even by an FDA decision-maker responsible for the decision to remove the in-person dispensing requirement. *See supra* § I.A (noting removal of requirement was made prior to *Dobbs*). As for the recent comments by Defendants Kennedy and Makary, Mot. 10, if anything, those comments support letting FDA's review run its course to consider the post-2023 evidence in the first instance. They do not render FDA's earlier analysis and decisions arbitrary and capricious, and they provide no basis for finding Plaintiffs likely to succeed on the merits of their APA claim challenging the 2023 REMS.

B. The 2023 REMS Is Not Contrary to Law

Plaintiffs are also wrong that the 2023 REMS is somehow contrary to the Comstock Act.

While the Comstock Act restricts shipping of items "intended for producing abortion," 18 U.S.C. §§ 1461, 1462, it has long been construed as applicable only to *knowingly* shipping such

items for the purpose of *illegal* abortions, *see United States v. One Package*, 86 F.2d 737, 739-40 (2d Cir. 1936) (L. Hand, J., concurring); *Youngs Rubber Corp. v. C.I. Lee & Co.*, 45 F.2d 103, 108 (2d Cir. 1930); *Davis v. United States*, 62 F.2d 473, 475 (6th Cir. 1933); *Application of the Comstock Act to the Mailing of Prescription Drugs that Can Be Used for Abortions*, 46 Op. O.L.C. __ (Dec. 23, 2022), https://www.justice.gov/olc/opinion/file/1560596/dl ("OLC Opinion"). By repeatedly amending the statute against that judicial backdrop without changing it to reject that construction, Congress has ratified that interpretation. *See* OLC Opinion, *supra*, at 13; *Texas Dep't of Hous. & Cmty. Affairs v. Inclusive Cmtys. Project*, 576 U.S. 519, 536 (2015).

Under the 2023 REMS, FDA does not ship mifepristone at all, let alone knowingly ship it for the purpose of illegal abortions. In the principal case Plaintiffs rely on, it was the Federal Communication Commission's own action—its revocation of a broadband license—that violated a Bankruptcy Code provision prohibiting such revocations. *FCC v. Next Wave Pers. Commc'ns, Inc.*, 537 U.S. 293, 300 (2003). Here, in contrast, there is no plausible theory that by adopting the 2023 REMS, FDA somehow engaged in illegal shipping under the Comstock Act.[6]

Nor does the 2023 REMS compel or authorize anyone else to violate the Comstock Act. FDA's remit under the FDAAA is narrow and technical: to determine whether various conditions, including the requirement of in-person dispensing, are appropriate in light of the dual criteria of "assur[ing] safe use" while "not be[ing] unduly burdensome on patient access." 21 U.S.C. § 355-1. In the 2023 REMS, FDA determined based on overwhelming data that continuing the in-person dispensing requirement was unnecessary for safe use and would impede patient access. FDA's scientific judgment based on its evaluation of those criteria neither required, nor purported to permit, anyone to knowingly ship mifepristone for the purpose of illegal abortions. Plaintiffs'

[6] Plaintiffs rely on a concurrence to support their novel interpretation of the Comstock Act. Mot. 13-14 (citing *All. for Hippocratic Med. v. FDA*, 78 F.4th 210, 267-69 (5th Cir. 2023) (Ho., J., concurring in part)). Among other issues, that concurrence (which was not joined by any of the other five circuit judges involved in the decisions in the *AHM* litigation) does not cite *Next Wave* or its progeny and fails to explain how *FDA* somehow acted contrary to the Comstock Act.

claim that the 2023 REMS is unlawful under the Comstock Act is therefore wholly lacking in merit, and Plaintiffs have no possibility—much less a likelihood—of succeeding on it.

IV. Plaintiffs Have Not Demonstrated Irreparable Harm

Plaintiffs have not shown the irreparable harm necessary for preliminary relief. Initially, Plaintiffs' extreme delay in seeking relief (nearly three years after the 2023 REMS was adopted, and more than four years from when the in-person dispensing requirement was originally lifted in 2021) belies their assertion of the kind of irreparable harm that would entitle them to the relief they seek. Indeed, the *AHM* district court denied Plaintiffs' "belated" request for intervention in that case, where three other states moved to intervene nearly two years before this case began. *Missouri*, 2025 WL 2825980, at *11-*12. And even after filing this lawsuit, Plaintiffs waited an inexplicable 72 days before moving for preliminary relief. "[A] party requesting a preliminary injunction must generally show reasonable diligence," *Benisek v. Lamone*, 585 U.S. 155, 159 (2018), and courts have denied preliminary relief based on delays measured in just weeks or months, *see Gonannies, Inc. v. Goupair.Com, Inc.*, 464 F. Supp. 2d 603, 609 (N.D. Tex. 2006) (collecting cases).[7]

As Plaintiffs' own delay vividly illustrates, their alleged injuries are not, in fact, irreparable. Even if Louisiana's payment of past Medicaid-related costs might suffice for standing purposes (it does not), it still would fail to satisfy the much heavier "burden of showing that the circumstances justify" the "extraordinary remedy of injunction." *Nken v. Holder*, 556 U.S. 418, 428, 434 (2009). At most, Plaintiffs' argument is that the REMS "could" cause Louisiana to incur expenses for Medicaid patients in the future. Mot. 22. They do not and cannot quantify those expenditures,

[7] Plaintiffs' request for a "stay" under 5 U.S.C. § 705 is improper. That statute authorizes courts to "issue all necessary and appropriate process to postpone the effective date of an agency action or to preserve status or rights pending conclusion of [judicial] review." To "postpone" means to "defer," "put off," or "delay." *See Black's Law Dictionary* 1389 (3d ed. 1933). The 2023 REMS has been in effect for years; it cannot sensibly be "postpone[d]." Nor would relief "preserve" the status quo; it would upend it. *Preserve*, Webster's New International Dictionary 1699 ("[t]o keep or save from injury or destruction," "to guard or defend from evil," "to protect," "to maintain" or "to retain"). As for Plaintiffs' request for traditional injunctive relief, the Fifth Circuit has admonished against allowing "one district court [to] make a binding judgment for the entire country," especially when "many states [ ] have not brought suit" and may have "accepted and even endorsed" the federal policy. *Louisiana v. Becerra*, 20 F.4th 260, 263-64 (5th Cir. 2021).

predict when they will occur, or link them causally to the 2023 REMS itself, as opposed to the independent acts of third parties.

Louisiana also bases irreparable harm on its theory that the REMS prevents it from enforcing its abortion laws. But the REMS neither overrides Louisiana law nor prevents Louisiana from enforcing it. Louisiana continues to prohibit the use of mifepristone for many purposes and retains its existing enforcement tools; any frustration Plaintiffs experience results from the actions of third parties not before this Court (and certainly not FDA). Unlike cases such as *Planned Parenthood of Greater Texas Surgical Health Services v. Abbott*, 734 F.3d 406 (5th Cir. 2013), no Louisiana statute is enjoined by the REMS, *see id.* at 419 (staying injunction of statute pending appeal because "[w]hen a statute is enjoined, the State necessarily suffers the irreparable harm of denying the public interest in the enforcement of its laws").

Regardless, even if Louisiana were correct that the REMS precludes it from enforcing its law (it is not), "the inability to assert" a state interest in enforcement of the law "during the pendency of litigation" is not, without more, an irreparable injury. *Texas v. Ysleta del Sur Pueblo*, 2018 WL 1566866, at *13 (W.D. Tex. Mar. 29, 2018) (denying Texas's motion for preliminary injunction against conduct that allegedly prevented enforcement of gaming laws). The 2023 REMS neither prohibits Louisiana from enforcing its laws nor removes any law-enforcement tools that Louisiana seeks to use for that enforcement. *See id.* Accordingly, as in *Ysleta del Sur Pueblo*, "[t]he Court can make a decision later that would be just as effective as a decision now." *Id.*

V. The Balance of the Equities and Public Interest Militate Against Relief

In considering whether to grant preliminary relief, courts also must account for the harms an injunction (or stay) would impose on parties and non-parties, as well as the public interest. *BST Holdings, LLC v. OSHA*, 17 F.4th 604, 618 (5th Cir. 2021); *SO Apartments, LLC v. City of San Antonio*, 109 F.4th 343, 353 (5th Cir. 2024) (considering interests in public health, safety, and welfare in balancing the harms). Here, those harms are concrete, profound, and irreparable.

There is no doubt that suspending the 2023 REMS would cause immediate and irreparable harm to GenBioPro. Mifepristone accounts for the majority of the company's revenue, and sales

through pharmacy distribution that would be cut off by a stay are a substantial portion of that revenue. Masingill Decl. ¶¶ 5, 10. The preliminary order Plaintiffs seek would undo the months of significant work by GenBioPro to establish a new pharmacy distribution framework in reliance on the 2023 REMS. *Id.* ¶¶ 9, 13-15. It would also create significant confusion, conceivably even compelling GenBioPro to revert to an obsolete regulatory regime, *see id.* ¶¶ 12, 15, and potentially halting distribution of the product entirely, *see* Ex. G ¶ 15 (Decl. of J. Woodcock, Principal Deputy Comm'r of FDA, in Supp. of Stay Application, *FDA v. AHM*, No. 22A902 (U.S. Apr. 14, 2023)). Compliance with any such regulatory regime would fundamentally disrupt the company's compliance and distribution framework, requiring significant time and expense to unwind the very distribution network that GenBioPro created in reliance on the 2023 REMS. Masingill Decl. ¶¶ 9, 12-15. Moreover, all those efforts would be unnecessary and irreparable if the "preliminary" relief is found unwarranted following full adjudication or on appeal. *Id.* ¶¶ 7, 11, 13-15.

The acute disruption to access to mifepristone that would result from suspending the 2023 REMS would also run counter to the public interest. Louisiana seeks relief to address what it alleges are harms to its interests *in Louisiana*—one of 50 states. But the nationwide relief it seeks reaches far beyond Louisiana's borders and would affect countless non-party providers and patients, severely undermining the provision of health care in the states that take less restrictive approaches to abortion than Louisiana. *See* Ex. H at 9-11, 19-20 (Am. College of Obstetricians & Gynecologists' citizen petition detailing benefits of expanding access to abortion, as well as harms from curtailing such access). The very data on which Plaintiffs rely to assert injury to Louisiana shows that in the first half of 2025, 27% of all abortions nationwide were provided via telehealth, constituting a significant portion of the abortion services in states where abortion is more broadly permitted than it is in Louisiana. ECF 20-1 at 2.

Even if mifepristone could still be permissibly shipped to providers for in-clinic dispensing if the Court entered the requested relief, the requested relief would serve a significant blow to

abortion access in non-party states, harming people nationwide.[8] Many patients around the country will be forced to travel long distances to healthcare settings to obtain mifepristone in-person, with long waits at clinics overrun with patients whose pharmacy access has been restricted by judicial order, and supply-chain disruptions may even cause a lapse in the availability of mifepristone. *See* ECF 1-50 at 58-59 (noting increase in prescribers based on removal of in-person dispensing requirement).[9] Still other patients may seek procedural abortions or even be forced to carry pregnancies to term against their will if access is restricted. *See, e.g.*, Ex. H at 9-11, 19-20.

In sum, this Court should not upend the status quo with its own nationwide regulatory regime that would harm public and private interests in the 49 states that are not a party to this suit.

CONCLUSION

For these reasons, the Court should deny Plaintiffs' motion for preliminary relief.

[8] *See, e.g.*, Ex. I at 2-6 (letter from University of Chicago professors detailing public health harms resulting from restricted access to abortion, including increased infant deaths and worse maternal health outcomes); Ex. J at 1-2 (letter from Boston University's School of Law's Program on Reproductive Justice and other groups detailing the link between restricting abortion access and incidents of inter-partner violence); Ex. K (letter from Legal Voice and other groups explaining that restricting abortion access puts "intimate partner violence survivors at risk").

[9] *See* Ex. B at 11 n.35, 21 n.76 (collecting authorities showing public health benefits of abortion, including, Leah Koenig *et al.*, *The role of telehealth in promoting equitable abortion access in the United States: spatial analysis*, 9 JMIR Public Health Surveillance e45671 (2023); and Erica Chong *et al.*, *Expansion of a direct-to-patient telemedicine abortion service in the United States and experience during the COVID-19 pandemic*, 104 Contraception 43, 44 (2021)).

UNITED STATES DISTRICT COURT
FOR THE WESTERN DISTRICT OF LOUISIANA
LAFAYETTE DIVISION

THE STATE OF LOUISIANA, by and through its Attorney General, LIZ MURRILL, and ROSALIE MARKEZICH, *Plaintiffs*, *v.* U.S. FOOD AND DRUG ADMINISTRATION, *et al*., *Defendants*.	Civil Action No. 6:25-cv-01491 Judge: David C. Joseph Mag. Judge: David J. Ayo

DECLARATION OF ROBERT J. KATERBERG IN SUPPORT OF PROPOSED INTERVENOR GENBIOPRO, INC.'S CONDITIONAL MEMORANDUM IN OPPOSITION TO PLAINTIFFS' MOTION FOR PRELIMINARY RELIEF

I, Robert J. Katerberg, declare, as follows:

1. I am a partner at the firm Arnold & Porter Kaye Scholer LLP and counsel for GenBioPro, Inc. ("GenBioPro"), a proposed intervenor in the above-captioned litigation. I am admitted to practice in the District of Columbia and have been permitted to appear pro hac vice on behalf of GenBioPro in this matter. ECF 32. I submit this declaration in support of GenBioPro's Conditional Memorandum in Opposition to Plaintiffs' Motion for Preliminary Relief.

2. Attached hereto as **Exhibit A** is a true and correct copy of the Defendant U.S. Food and Drug Administration's ("FDA's") 2023 Risk Evaluation Mitigation Strategy (REMS) Single Shared System for Mifepristone 200 MG, published March 2023.

3. Attached hereto as **Exhibit B** is a true and correct copy of a Citizen Petition that GenBioPro submitted to FDA on July 3, 2025, which FDA accepted on July 7, 2025, and to which it assigned docket number FDA-2025-P-2162.

4. Attached hereto as **Exhibits B-1–B-9** are the nine volumes of appendices to GenBioPro's July 3, 2025 Citizen Petition, docket number FDA-2025-P-2162.

5. Attached hereto as **Exhibit C** is a true and correct copy of FDA's January 16, 2026 response denying a citizen petition filed by the American Association of Pro-Life Obstetricians and Gynecologists, American College of Pediatricians, Christian Medical & Dental Associations, and Catholic Medical Association, to which FDA assigned docket number FDA-2025-P-3288.

6. Attached hereto as **Exhibit D** is a true and correct copy of FDA's December 17, 2025 interim response to GenBioPro's July 3, 2025 Citizen Petition, docket number FDA-2025-P-2162.

7. Attached hereto as **Exhibit E** is a true and correct copy of an article by Sophie Dilek, *et al.*, titled "The US Food and Drug Administration's Regulation of Mifepristone," published in The Journal of the American Medical Association (JAMA) on January 12, 2026.

8. Attached hereto as **Exhibit F** is a true and correct copy of the August 27, 2025 Comment submitted by the UCLA Law Center for Reproductive Health, Law, and Policy and UCSF Advancing New Standards in Reproductive Health on behalf of 263 reproductive health researchers in support of GenBioPro's Citizen Petition, docket number FDA-2025-P-2162.

9. Attached hereto as **Exhibit G** is a true and correct copy of the April 14, 2023 Declaration of Janet Woodcock, M.D., Principal Deputy Commissioner, FDA, submitted in support of the Federal Petitioners' Application for a Stay in the U.S. Supreme Court case captioned *FDA v. Alliance for Hippocratic Medicine*, No. 22A902 (U.S. Apr. 14, 2023).

10. Attached hereto as **Exhibit H** is a true and correct copy of a citizen petition submitted by the American College of Obstetricians and Gynecologists, Society of Family

Planning, and Society for Maternal-Fetal Medicine to FDA on January 21, 2025, which FDA accepted on February 4, 2025, and to which it assigned docket number FDA-2025-P-0377.

11. Attached hereto as **Exhibit I** is a true and correct copy of the October 6, 2025 Comment submitted by Lee Hasselbacher, JD, Department of Family Medicine, University of Chicago, and Debra Stulberg, MD, MAPP, Department of Family Medicine, University of Chicago in support of GenBioPro's Citizen Petition, docket number FDA-2025-P-2162.

12. Attached hereto as **Exhibit J** is a true and correct copy of the January 27, 2026 Comment submitted by Boston University School of Law's Program on Reproductive Justice, Immigrants' Rights and Human Trafficking Program, and the Racial Justice and Movement Lawyering Clinic in support of GenBioPro's Citizen Petition, docket number FDA-2025-P-2162.

13. Attached hereto as **Exhibit K** is a true and correct copy of the December 3, 2025 Comment submitted by Legal Voice, Family Violence Appellate Project, Sexual Violence Law Center, and Washington State Coalition Against Domestic Violence in support of GenBioPro's Citizen Petition, docket number FDA-2025-P-2162.

I declare under penalty of perjury that the above is true and correct to the best of my knowledge, information, and belief.

Dated: February 3, 2026

EXHIBIT A

Initial Shared System REMS approval: 04/2019
Most Recent Modification: 03/2023

Mifepristone Tablets, 200 mg
Progestin Antagonist

RISK EVALUATION AND MITIGATION STRATEGY (REMS)
SINGLE SHARED SYSTEM FOR MIFEPRISTONE 200 MG

I. GOAL

The goal of the REMS for mifepristone is to mitigate the risk of serious complications associated with mifepristone by:

a) Requiring healthcare providers who prescribe mifepristone to be certified in the Mifepristone REMS Program.

b) Ensuring that mifepristone is only dispensed by or under the supervision of certified prescribers, or by certified pharmacies on prescriptions issued by certified prescribers.

c) Informing patients about the risk of serious complications associated with mifepristone.

II. REMS ELEMENTS

A. Elements to Assure Safe Use

1. Healthcare providers who prescribe mifepristone must be specially certified.
   a. To become specially certified to prescribe mifepristone, healthcare providers must:
      i. Review the Prescribing Information for mifepristone.
      ii. Complete a *Prescriber Agreement Form*. By signing[1] a *Prescriber Agreement Form*, prescribers agree that:
         1) They have the following qualifications:
            a) Ability to assess the duration of pregnancy accurately
            b) Ability to diagnose ectopic pregnancies
            c) Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or to have made plans to provide such care through others, and ability to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary
         2) They will follow the guidelines for use of mifepristone (see b.i-vii below).
   b. As a condition of certification, prescribers must follow the guidelines for use of mifepristone described below:
      i. Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
      ii. Ensure that the healthcare provider and patient sign the *Patient Agreement Form.*

[1] In this REMS, the terms “sign” and “signature” include electronic signatures.

Reference ID: 5146641

iii. Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.

iv. Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.

v. Ensure that any deaths are reported to the Mifepristone Sponsor that provided the mifepristone, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of mifepristone that was dispensed to the patient.

vi. If mifepristone will be dispensed by a certified pharmacy:

1) Provide the certified pharmacy a signed *Prescriber Agreement Form*.

2) Assess appropriateness of dispensing mifepristone when contacted by a certified pharmacy about patients who will receive mifepristone more than 4 calendar days after the prescription was received by the certified pharmacy.

3) Obtain the NDC and lot number of the package of mifepristone the patient received in the event the prescriber becomes aware of the death of the patient.

vii. The certified prescriber who dispenses mifepristone or who supervises the dispensing of mifepristone must:

1) Provide an authorized distributor with a signed *Prescriber Agreement Form*.

2) Ensure that the NDC and lot number from each package of mifepristone dispensed are recorded in the patient's record.

3) Ensure that healthcare providers under their supervision follow guidelines i.-v.

c. Mifepristone Sponsors must:

i. Ensure that healthcare providers who prescribe their mifepristone are specially certified in accordance with the requirements described above and de-certify healthcare providers who do not maintain compliance with certification requirements.

ii. Ensure prescribers previously certified in the Mifepristone REMS Program complete the new *Prescriber Agreement Form*:

1) Within 120 days after approval of this modification, for those previously certified prescribers submitting prescriptions to certified pharmacies.

2) Within one year after approval of this modification, if previously certified and ordering from an authorized distributor.

iii. Ensure that healthcare providers can complete the certification process by email or fax to an authorized distributor and/or certified pharmacy.

iv. Provide the Prescribing Information and their *Prescriber Agreement Form* to healthcare providers who inquire about how to become certified.

v. Ensure annually with each certified prescriber that their locations for receiving mifepristone are up to date.

The following materials are part of the Mifepristone REMS Program:

- *Prescriber Agreement Form for Danco Laboratories, LLC*
- *Prescriber Agreement Form for GenBioPro, Inc.*
- *Patient Agreement Form*

Reference ID: 5146641

2. Pharmacies that dispense mifepristone must be specially certified
   a. To become specially certified to dispense mifepristone, pharmacies must:
      i. Be able to receive *Prescriber Agreement Forms* by email and fax.
      ii. Be able to ship mifepristone using a shipping service that provides tracking information.
      iii. Designate an authorized representative to carry out the certification process on behalf of the pharmacy.
      iv. Ensure the authorized representative oversees implementation and compliance with the Mifepristone REMS Program by doing the following:
         1) Review the Prescribing Information for mifepristone.
         2) Complete a *Pharmacy Agreement Form*. By signing a *Pharmacy Agreement Form*, the authorized representative agrees that the pharmacy will put processes and procedures in place to ensure the following requirements are completed:
            a) Verify that the prescriber is certified by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with the pharmacy.
            b) Dispense mifepristone such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in c) below.
            c) Confirm with the prescriber the appropriateness of dispensing mifepristone for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
            d) Record in the patient's record the NDC and lot number from each package of mifepristone dispensed.
            e) Track and verify receipt of each shipment of mifepristone.
            f) Dispense mifepristone in its package as supplied by the Mifepristone Sponsor.
            g) Report any patient deaths to the prescriber, including the NDC and lot number from the package of mifepristone dispensed to the patient, and remind the prescriber of their obligation to report the deaths to the Mifepristone Sponsor that provided the mifepristone. Notify the Mifepristone Sponsor that provided the dispensed mifepristone that the pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
            h) Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
            i) Maintain records of *Prescriber Agreement Forms*.
            j) Maintain records of dispensing and shipping.
            k) Maintain records of all processes and procedures including compliance with those processes and procedures.
            l) Maintain the identity of the patient and prescriber as confidential, including limiting access to patient and prescriber identity only to those personnel necessary to dispense mifepristone in accordance with the Mifepristone REMS Program requirements, or as necessary for payment and/or insurance purposes..
            m) Train all relevant staff on the Mifepristone REMS Program requirements.

Reference ID: 5146641

n) Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

b. Mifepristone Sponsors must:

i. Ensure that pharmacies are specially certified in accordance with the requirements described above and de-certify pharmacies that do not maintain compliance with certification requirements.

ii. Ensure that pharmacies can complete the certification process by email and fax to an authorized distributor.

i. Verify annually that the name and contact information for the pharmacy's authorized representative corresponds to that of the current designated authorized representative for the certified pharmacy, and if different, require the pharmacy to recertify with the new authorized representative.

The following materials are part of the Mifepristone REMS Program:

- *Pharmacy Agreement Form for Danco Laboratories, LLC*
- *Pharmacy Agreement Form for GenBioPro, Inc.*

3. Mifepristone must be dispensed to patients with evidence or other documentation of safe use conditions as ensured by the certified prescriber in signing the *Prescriber Agreement Form.*

a. The patient must sign a *Patient Agreement Form* indicating that the patient has:

i. Received, read and been provided a copy of the *Patient Agreement Form*.

ii. Received counseling from the healthcare provider regarding the risk of serious complications associated with mifepristone.

B. Implementation System

1. Mifepristone Sponsors must ensure that their mifepristone is only distributed to certified prescribers and certified pharmacies by:

a. Ensuring that distributors who distribute their mifepristone comply with the program requirements for distributors.

i. The distributors must put processes and procedures in place to:

1) Complete the certification process upon receipt of a *Prescriber Agreement Form* or *Pharmacy Agreement Form*.

2) Notify healthcare providers and pharmacies when they have been certified by the Mifepristone REMS Program.

3) Ship mifepristone only to certified pharmacies or locations identified by certified prescribers.

4) Not ship mifepristone to pharmacies or prescribers who become de-certified from the Mifepristone REMS Program.

5) Provide the Prescribing Information and their Prescriber Agreement Form to healthcare providers who (1) attempt to order mifepristone and are not yet certified, or (2) inquire about how to become certified.

ii. Put processes and procedures in place to maintain a distribution system that is secure,

Reference ID: 5146641

confidential and follows all processes and procedures, including those for storage, handling, shipping, tracking package serial numbers, NDC and lot numbers, proof of delivery and controlled returns of mifepristone.

iii. Train all relevant staff on the Mifepristone REMS Program requirements.

iv. Comply with audits by Mifepristone Sponsors or a third party acting on behalf of Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed for the Mifepristone REMS Program. In addition, distributors must maintain appropriate documentation and make it available for audits.

b. Ensuring that distributors maintain secure and confidential distribution records of all shipments of mifepristone.

2. Mifepristone Sponsors must monitor their distribution data to ensure compliance with the Mifepristone REMS Program.

3. Mifepristone Sponsors must ensure that adequate records are maintained to demonstrate that the Mifepristone REMS Program requirements have been met, including, but not limited to records of mifepristone distribution; certification of prescribers and pharmacies; and audits of pharmacies and distributors. These records must be readily available for FDA inspections.

4. Mifepristone Sponsors must audit their new distributors within 90 calendar days and annually thereafter after the distributor is authorized to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their distributor compliance if noncompliance is identified.

5. Mifepristone Sponsors must audit their certified pharmacies within 180 calendar days after the pharmacy places its first order of mifepristone, and annually thereafter audit certified pharmacies that have ordered mifepristone in the previous 12 months, to ensure that all processes and procedures are in place and functioning to support the requirements of the Mifepristone REMS Program. Mifepristone Sponsors will take steps to address their pharmacy compliance if noncompliance is identified.

6. Mifepristone Sponsors must take reasonable steps to improve implementation of and compliance with the requirements of the Mifepristone REMS Program based on monitoring and assessment of the Mifepristone REMS Program.

7. Mifepristone Sponsors must report to FDA any death associated with mifepristone whether or not considered drug-related, as soon as possible but no later than 15 calendar days from the initial receipt of the information by the Mifepristone Sponsor. This requirement does not affect the sponsors' other reporting and follow-up requirements under FDA regulations.

C. Timetable for Submission of Assessments

The NDA Sponsor must submit REMS assessments to FDA one year from the date of the approval of the modified REMS (01/03/2023) and annually thereafter. To facilitate inclusion of as much information as possible while allowing reasonable time to prepare the submission, the reporting interval covered by each assessment should conclude no earlier than 90 calendar days before the submission date for that assessment. The NDA Sponsor must submit each assessment so that it will be received by the FDA on or before the due date.

MIFEPREX® (Mifepristone) Tablets, 200 mg

PRESCRIBER AGREEMENT FORM

Mifeprex* (Mifepristone) Tablets, 200 mg, is indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation. Please see Prescribing Information and Medication Guide for complete safety information.

To ***become a certified prescriber***, you must:

- **If you submit Mifeprex prescriptions for dispensing from certified pharmacies**:
  - Submit this form to each certified pharmacy to which you intend to submit Mifeprex prescriptions. The form must be received by the certified pharmacy before any prescriptions are dispensed by that pharmacy.
- **If you order Mifeprex for dispensing by you or healthcare providers under your supervision:**
  - Submit this form to the distributor. This form must be received by the distributor before the first order will be shipped to the healthcare setting.
  - Healthcare settings, such as medical offices, clinics, and hospitals, where Mifeprex will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

Prescriber Agreement: By signing this form, you agree that you meet the qualifications below and will follow the guidelines for use. You are responsible for overseeing implementation and compliance with the Mifepristone REMS Program. You also understand that if the guidelines below are not followed, the distributor may stop shipping mifepristone to the locations that you identify and certified pharmacies may stop accepting your mifepristone prescriptions.

Mifepristone must be provided by or under the supervision of a certified prescriber who meets the following qualifications:

- Ability to assess the duration of pregnancy accurately.
- Ability to diagnose ectopic pregnancies.
- Ability to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Has read and understood the Prescribing Information for mifepristone. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free), or by visiting www.earlyoptionpill.com.

In addition to meeting these qualifications, you also agree to follow these guidelines for use:

- Ensure that the *Patient Agreement Form* is reviewed with the patient and the risks of the mifepristone treatment regimen are fully explained. Ensure any questions the patient may have prior to receiving mifepristone are answered.
- Ensure the healthcare provider and patient sign the *Patient Agreement Form*.
- Ensure that the patient is provided with a copy of the *Patient Agreement Form* and Medication Guide.
- Ensure that the signed *Patient Agreement Form* is placed in the patient's medical record.
- Ensure that any deaths of patients who received Mifeprex are reported to Danco Laboratories, LLC, identifying the patient by a non-identifiable reference and including the NDC and lot number from the package of Mifeprex that was dispensed to the patient.

Ensure that healthcare providers under your supervision follow the guidelines listed above.

- If Mifeprex will be dispensed through a certified pharmacy:
  - Assess appropriateness of dispensing Mifeprex when contacted by a certified pharmacy about patients who will receive Mifeprex more than 4 calendar days after the prescription was received by the certified pharmacy.
  - Obtain the NDC and lot number of the package of Mifeprex the patient received in the event the prescriber becomes aware of the death of a patient.
- If Mifeprex will be dispensed by you or by healthcare providers under your supervision:
  - Ensure the NDC and lot number from each package of Mifeprex are recorded in the patient's record.

I understand that a certified pharmacy may dispense mifepristone made by a different manufacturer than that stated on this Prescriber Agreement Form.

Healthcare Providers: *Counsel the patient on the risks of mifepristone. Both you and the patient must provide a written or electronic signature on this form.*

Patient Agreement:

1. I have decided to take mifepristone and misoprostol to end my pregnancy and will follow my healthcare provider's advice about when to take each drug and what to do in an emergency.
2. I understand:
   a. I will take mifepristone on Day 1.
   b. I will take the misoprostol tablets 24 to 48 hours after I take mifepristone.
3. My healthcare provider has talked with me about the risks, including:
   - heavy bleeding
   - infection
4. I will contact the clinic/office/provider right away if in the days after treatment I have:
   - a fever of 100.4°F or higher that lasts for more than four hours
   - heavy bleeding (soaking through two thick full-size sanitary pads per hour for two hours in a row)
   - severe stomach area (abdominal) pain or discomfort, or I am "feeling sick," including weakness, nausea, vomiting, or diarrhea, more than 24 hours after taking misoprostol
     — these symptoms may be a sign of a serious infection or another problem (including an ectopic pregnancy, a pregnancy outside the womb).

   My healthcare provider has told me that these symptoms listed above could require emergency care. If I cannot reach the clinic/office/provider right away, my healthcare provider has told me who to call and what to do.
5. I should follow up with my healthcare provider about 7 to 14 days after I take mifepristone to be sure that my pregnancy has ended and that I am well.
6. I know that, in some cases, the treatment will not work. This happens in about 2 to 7 out of 100 women who use this treatment. If my pregnancy continues after treatment with mifepristone and misoprostol, I will talk with my provider about a surgical procedure to end my pregnancy.
7. If I need a surgical procedure because the medicines did not end my pregnancy or to stop heavy bleeding, my healthcare provider has told me whether they will do the procedure or refer me to another healthcare provider who will.
8. I have the MEDICATION GUIDE for mifepristone.
9. My healthcare provider has answered all my questions.

MIFEPREX®(Mifepristone) Tablets, 200mg

PHARMACY AGREEMENT FORM

Pharmacies must designate an authorized representative to carry out the certification process and oversee implementation and compliance with the Mifepristone REMS Program on behalf of the pharmacy.

Healthcare settings, such as medical offices, clinics, and hospitals, where mifepristone will be dispensed by or under the supervision of a certified prescriber in the Mifepristone REMS Program do not require pharmacy certification.

By signing this form, as the Authorized Representative I certify that:

- Each location of my pharmacy that will dispense Mifeprex is able to receive *Prescriber Agreement Forms* by email and fax.
- Each location of my pharmacy that will dispense Mifeprex is able to ship Mifeprex using a shipping service that provides tracking information.
- I have read and understood the Prescribing Information for Mifeprex. The Prescribing Information is available by calling 1-877-4 EARLY OPTION (1-877-432-7596 toll-free) or online at www.earlyoptionpill.com; and
- Each location of my pharmacy that will dispense Mifeprex will put processes and procedures in place to ensure the following requirements are completed. I also understand that if my pharmacy does not complete these requirements, the distributor may stop accepting Mifeprex orders.
  - Verify that the prescriber is certified in the Mifepristone REMS Program by confirming their completed *Prescriber Agreement Form* was received with the prescription or is on file with your pharmacy.
  - Dispense Mifeprex such that it is delivered to the patient within 4 calendar days of the date the pharmacy receives the prescription, except as provided in the following bullet.
  - Confirm with the prescriber the appropriateness of dispensing Mifeprex for patients who will receive the drug more than 4 calendar days after the date the pharmacy receives the prescription and document the prescriber's decision.
  - Record in the patient's record the NDC and lot number from each package of Mifeprex dispensed.
  - Track and verify receipt of each shipment of Mifeprex.
  - Dispense mifepristone in its package as supplied by Danco Laboratories, LLC.
  - Report any patient deaths to the prescriber, including the NDC and lot number from the package of Mifeprex dispensed to the patient, and remind the prescriber of their obligation to report the deaths to Danco Laboratories, LLC. Notify Danco that your pharmacy submitted a report of death to the prescriber, including the name and contact information for the prescriber and the NDC and lot number of the dispensed product.
  - Not distribute, transfer, loan or sell mifepristone except to certified prescribers or other locations of the pharmacy.
  - Maintain records of *Prescriber Agreement Forms*, dispensing and shipping, and all processes and procedures including compliance with those processes and procedures.
  - Maintain the identity of Mifeprex patients and prescribers as confidential and protected from disclosure except to the extent necessary for dispensing under this REMS or as necessary for payment and/or insurance.
  - Train all relevant staff on the Mifepristone REMS Program requirements.
  - Comply with audits carried out by the Mifepristone Sponsors or a third party acting on behalf of the Mifepristone Sponsors to ensure that all processes and procedures are in place and are being followed.

Any new authorized representative must complete and submit the *Pharmacy Agreement Form*.

VIA ELECTRONIC SUBMISSION (WWW.REGULATIONS.GOV)

Division of Dockets Management
U.S. Food and Drug Administration
Department of Health and Human Services
5630 Fishers Lane, Rm. 1061
Rockville, MD 20852

CITIZEN PETITION

The undersigned submits this petition under Section 505 of the Federal Food, Drug, and Cosmetic Act ("FDCA") and 21 C.F.R. § 10.30 to request the Commissioner of Food and Drugs to: (1) refrain from taking any action that would reduce patient access to the drug mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone, absent new robust scientific or clinical evidence that meets applicable statutory standards warranting such a change; and (2) confirm that any steps that may be taken to modify, suspend, or withdraw FDA approval for mifepristone, including in response to any court order, will follow all applicable rules and procedures for any withdrawal or suspension required under the Administrative Procedure Act ("APA"), the FDCA, and implementing regulations, and that Petitioner will be permitted to continue to market and sell mifepristone in the United States until all such procedures have been completed.[1]

GenBioPro, Inc. ("Petitioner") markets a generic version of mifepristone, which provides patients with a safe, effective, and non-invasive medication option for terminating a pregnancy. Mifepristone was first approved by the Agency as safe and effective for medically terminating early pregnancies over two decades ago, when FDA approved a New Drug Application ("NDA") for mifepristone tablets marketed under the brand name Mifeprex®.[2] Petitioner has held an FDA-approved Abbreviated New Drug Application ("ANDA") to market generic mifepristone since 2019.[3] In the twenty-five years since the medication's approval, mifepristone's safety and efficacy have been confirmed time and again through FDA's repeated and rigorous review of the underlying scientific data and literature, as well as real-world clinical experience of the millions of American women who have safely terminated their pregnancies with the mifepristone regimen. The robust scientific and clinical record demonstrates that mifepristone is safely used under the mifepristone Risk Evaluation and Mitigation Strategy ("REMS") with Elements to Assure Safe Use ("ETASU") as currently framed. And, as FDA has repeatedly recognized, there is no scientific

[1] All articles, references, and sources cited herein are provided in an attached Appendix, in accordance with 21 C.F.R. § 10.20(c).

[2] U.S. Food & Drug Admin., Ctr. for Drug Evaluation & Rsch., NDA Approval Letter, NDA 020687 (Sept. 28, 2000), https://www.accessdata.fda.gov/drugsatfda_docs/appletter/2000/20687appltr.pdf.

[3] U.S. Food & Drug Admin., Ctr. for Drug Evaluation & Rsch., ANDA Approval Letter, ANDA 091178 (Apr. 11, 2019), https://www.accessdata.fda.gov/drugsatfda_docs/appletter/2019/091178Orig1s000ltr.pdf.

basis for allegations that administration of mifepristone causes harm to the environment. In light of mifepristone's longstanding safety and effectiveness profile, Petitioner respectfully requests that FDA take no action that would reduce or inhibit patient access to this important medication.[4]

Furthermore, as FDA is well aware, FDA's approvals regarding mifepristone have come under legal challenge, and efforts are underway to seek withdrawal of, or limitations on, Petitioner's ANDA approval. These unfounded attacks on FDA's well-reasoned and appropriate decisions pursuant to its congressional mandate are of grave concern to Petitioner, which has invested considerable effort and resources in reliance on FDA's prior regulatory actions with respect to mifepristone, with the understanding that any possible attempt to withdraw or take other actions with respect to an FDA approval are subject to well-established and legally required FDA processes. Accordingly, Petitioner respectfully requests confirmation that any steps to withdraw or limit FDA's approval of Petitioner's ANDA for mifepristone—whether in effectuation of a court order or otherwise—will follow all applicable procedures afforded by law and regulation to Petitioner as the ANDA holder and that FDA will permit Petitioner to continue marketing and selling mifepristone until those procedures have been completed, as required by law.

Petitioner is aware of recent statements by Department of Health and Human Services ("HHS") Secretary Robert F. Kennedy, Jr. that the Commissioner will undertake a "complete review" of mifepristone and will provide a recommendation to President Trump regarding the mifepristone label and REMS.[5] Petitioner requests that it be provided an opportunity to comment and provide input with respect to any such review, in accordance with Petitioner's rights as the ANDA holder for mifepristone. Additionally, Petitioner requests that, in the course of any such review, FDA ensure that all data reviewed are made public; that the Agency consider the entire body of evidence supporting mifepristone's safety and effectiveness, which reflects over two decades of robust scientific research and the experience of millions of patients; and that FDA consider the content of and attachments to this Petition as part of its review. As the expert agency charged by Congress with evaluating the safety and efficacy of drugs, FDA must adhere to its longstanding scientific and legal standards requiring objective safety data and transparent study methodologies, such that the Agency can continue to engage in scientifically sound, evidence-based decision-making on important matters affecting public health.

---

[4] If anything, the current scientific and medical record may support expanding patient access by revising aspects of the current REMS and ETASU.

E. CERTIFICATION 30

A. ACTION REQUESTED

Petitioner requests that, absent new peer-reviewed studies or otherwise robust scientific or clinical evidence warranting such action, FDA take no action that would reduce patient access to mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone, including but not limited to any of the following actions:

(1) revoking or suspending the 2000 approval of Mifeprex (NDA 020687) or the 2019 approval of generic mifepristone (ANDA 091178);

(2) adding new ETASU to the current REMS for mifepristone;

(3) reinstating former ETASU that are not part of the current REMS;

(4) making the existing ETASU more onerous;

(5) modifying the REMS or labeling for mifepristone in a manner that is not supported by robust scientific or clinical evidence;

(6) modifying the REMS or labeling for mifepristone based on any scientific or clinical evidence that has not been provided to Petitioner with sufficient time to comment on its validity, relevance, and application to any REMS or labeling modification; or

(7) otherwise restricting healthcare practitioner or patient access to mifepristone without adherence to statutory processes and standards.

Additionally, Petitioner requests that FDA confirm that:

(1) any withdrawal or other adverse action by FDA on the approval of Petitioner's ANDA for mifepristone—whether in effectuation of a court order or otherwise—will follow all applicable procedures and meet all standards afforded by law and regulation to Petitioner as the ANDA holder; and

(2) FDA will permit Petitioner to continue marketing and shipping mifepristone until such procedures have been completed.

B. STATEMENT OF GROUNDS

1. As FDA Has Repeatedly Found, The Safety and Efficacy of Mifepristone is Well-Established and Supported by Robust Scientific Data

As FDA is aware, mifepristone is a progestin antagonist indicated, in a regimen with misoprostol, for the medical termination of intrauterine pregnancy through 70 days gestation.[6] Under the FDA-approved dosing regimen, mifepristone is administered in a single oral dose, followed by buccal administration of misoprostol 24 to 48 hours after taking mifepristone. The label provides that patients should follow up with their healthcare provider approximately 7 to 14 days after taking mifepristone to confirm that complete termination of pregnancy has occurred. Since the medication's approval nearly twenty-five years ago, mifepristone has continued to exhibit a robust safety and efficacy profile, as demonstrated by its FDA approval history and countless peer-reviewed medical studies.

a. FDA Has Repeatedly Concluded Mifepristone is Supported by Substantial Evidence of Safety and Efficacy

For over two decades, FDA has consistently affirmed mifepristone's safety and effectiveness, grounded in rigorous scientific review and real-world data from millions of uses. As the body of evidence supporting its safety and efficacy has grown over time, FDA has appropriately updated mifepristone's conditions of use to remove unduly burdensome restrictions on patient access and the health care delivery system. At every stage, FDA's decisions have been

[6] MIFEPREX Prescribing Information (Mar. 23, 2023), https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s026lbl.pdf.

based on a comprehensive review of the entire body of scientific evidence, including peer-reviewed clinical studies and robust scientific data, as further outlined below.

(i) NDA Approval and REMS

Mifepristone was first approved by FDA under the brand name Mifeprex in 2000.[7] This approval was based on an extensive body of scientific data substantiating its safety and effectiveness, including three clinical studies involving approximately 2,500 patients.[8] The approval was granted under FDA regulations at 21 C.F.R Part 314 Subpart H, which allowed FDA to impose conditions it deemed necessary to ensure the product's safe use.

In 2008, at the request of several members of Congress, the U.S. Government Accountability Office ("GAO") reviewed FDA's approval of mifepristone and the Agency's oversight of the drug since approval.[9] GAO found that the mifepristone NDA was supported by a four-year analysis by FDA of three clinical studies involving mifepristone, other substantial scientific and medical data, and additional safety data from the prior extensive use of the drug overseas. GAO concluded that FDA's approval process and postmarket oversight of mifepristone was consistent with its processes and postmarket oversight for other Subpart H drugs.

When Congress adopted the REMS framework in 2007, it deemed each drug with existing Subpart H restrictions to have an approved REMS imposing the same restrictions.[10] Congress directed that ETASU imposed under REMS must "not be unduly burdensome on patient access to the drug," and, "to the extent practicable," must "minimize the burden on the health care delivery system."[11] In 2008, FDA reviewed the distribution restrictions set forth in the first FDA-approved label for mifepristone and concluded they were sufficient to constitute an acceptable REMS for

[7] U.S. Food & Drug Admin., Ctr. for Drug Evaluation & Rsch., NDA Approval Letter, NDA 020687 (Sept. 28, 2000), https://www.accessdata.fda.gov/drugsatfda_docs/appletter/2000/20687appltr.pdf. *See also* U.S. Food & Drug Admin., Ctr. for Drug Evaluation & Rsch., Medical Review (Sept. 28, 2000), https://www.accessdata.fda.gov/drugsatfda_docs/nda/2000/20687_Mifepristone_medr_P1.pdf and https://www.accessdata.fda.gov/drugsatfda_docs/nda/2000/20687_Mifepristone_medr_P2.pdf.

the drug.[12] In 2011, FDA approved a REMS for mifepristone providing for essentially the same requirements previously imposed under Subpart H.[13]

(ii) 2016 Changes

Fifteen years after FDA's initial approval of Mifeprex, Danco Laboratories, LLC ("Danco"), the NDA holder, submitted a supplemental NDA ("sNDA") to revise Mifeprex's label and REMS in light of the further development of extensive data from dozens of clinical studies.[14] FDA approved most of the proposed modifications in 2016,[15] including: (1) increasing the gestational age limit in the labeling from 49 days to 70 days;[16] (2) reducing the number of required

prescribe drugs (e.g., nurse practitioners).[18] Before granting the sNDA and REMS modification, FDA undertook a full review of all elements of the mifepristone REMS, finding that "[t]he safety profile of [mifepristone] is well-characterized over 15 years of experience, with known risks occurring rarely; the safety profile has not changed over the period of surveillance."[19] FDA found that medication abortion "has been increasingly used as its efficacy and safety have become well-established by both research and experience, and serious complications have proven to be extremely rare."[20] FDA also found that the rates of serious adverse events associated with the new regimen, including home administration of misoprostol, are "exceedingly low."[21]

In 2018, responding to another request from members of Congress, GAO reviewed FDA's approval of the 2016 changes. It found that FDA had reviewed numerous peer-reviewed published studies, articles and data that supported the efficacy and safety of the proposed changes and had

[21] 2016 FDA Medical Review at 62 (Mar. 29, 2016), https://www.accessdata.fda.gov/drugsatfda_docs/nda/2016/020687Orig1s020MedR.pdf.

also evaluated adverse event data associated with Mifeprex.[22] Specifically, GAO found that FDA had reviewed 19 studies that evaluated increasing the gestational age limit, which demonstrated efficacy rates of greater than 90% through 70 days gestation.[23] FDA also reviewed 15 studies that evaluated home administration of misoprostol, including a large literature review of 87 studies that included over 45,000 women. GAO noted that FDA found no evidence that home use of misoprostol increased rates of treatment failure or serious complications.[24] After reviewing 11 studies that evaluated different methods for follow-up care after mifepristone administration, FDA determined that various methods of follow-up, including home pregnancy testing and telephone visits, were acceptable alternatives to an in-clinic follow up.[25] Finally, FDA reviewed four studies addressing the ability of nonphysician health care providers to provide abortion care, finding that efficacy rates were at least 96% across all studies, regardless of gestational age or provider type.[26]

Petitioner is not aware of any peer-reviewed study or other robust evidence (clinical or epidemiological) that casts any doubt on these findings of either the FDA or GAO. Nor has FDA ever provided any contrary studies or evidence to Petitioner or asked Petitioner for comments on any such studies or evidence.

(iii) ANDA Approval

On April 11, 2019, FDA approved Petitioner's ANDA to manufacture and market generic mifepristone.[27] FDA's approval of Petitioner's ANDA reflects the Agency's consistent finding that mifepristone is safe and effective and was based on a robust review of vast amounts of data and hundreds of medical studies over more than two decades, including data submitted by Petitioner to support the approval of its ANDA. As required by the FDCA, Petitioner's generic mifepristone and Danco's Mifeprex must have substantively identical labels, in recognition of the fact that they are "bioequivalent" and have "the same therapeutic effect" and thus have the same benefits and risks.[28] FDA accordingly determined that the branded and generic mifepristone should share a single, shared REMS pursuant to 21 U.S.C. § 355-1(i). Petitioner is the sole supplier of generic mifepristone in the United States and currently supplies the majority of the mifepristone used domestically for medication abortions.

(iv) 2023 Changes

FDA more recently concluded that in-person dispensing of mifepristone is not necessary to ensure its safe use, following a comprehensive review of published scientific literature and adverse event data. From July 13, 2020 through January 2021, a court injunction barred FDA from enforcing the in-person dispensing requirement during the COVID-19 Public Health Emergency ("PHE").[29] In April 2021, as the COVID-19 PHE continued, FDA further stated it intended to exercise enforcement discretion with respect to the in-person dispensing requirement, finding that requiring a patient to visit a clinic to receive mifepristone could pose COVID-related safety risks to those patients and healthcare personnel.[30] FDA reached this decision following "a thorough scientific review" by experts within FDA's Center for Drug Evaluation and Research ("CDER"), who "evaluated relevant information, including available clinical outcomes data and adverse event reports."[31]

Throughout the remainder of 2021, FDA "undertook a full review" of the mifepristone REMS, evaluating published literature, safety information submitted to FDA during the COVID-19 PHE, adverse event data, the one-year assessment report for the mifepristone REMS, and information provided by advocacy groups, individuals, and the sponsors of the NDA and the ANDA.[32] In December 2021, FDA determined that the in-person dispensing requirement was not necessary and directed sponsors to initiate the process to modify REMS.[33] In particular, after reviewing adverse event data, FDA found no difference in adverse event rates between periods when the in-person dispensing requirement was being enforced and periods when the in-person dispensing requirement was not being enforced, suggesting that "mifepristone may be safely used without an in-person dispensing requirement."[34] FDA further concluded, based on published studies, that dispensing by mail does not jeopardize efficacy of medical abortion, finding that the

safety and efficacy outcomes reported in these studies were "within the ranges described in mifepristone labeling."[35]

Based on this comprehensive review of the evidence, FDA concluded that mifepristone "will remain safe and effective for medical abortion if the in-person dispensing requirement is removed, provided all the other requirements of the REMS are met, and pharmacy certification is

added."[36] FDA determined that this modification would "render the REMS less burdensome to healthcare providers and patients" and that the modified REMS will "continue to ensure that the benefits of mifepristone for medical abortion outweigh the risks."[37] FDA further recognized that removing the in-person dispensing requirement would allow "dispensing of mifepristone by mail via certified prescribers or pharmacies."[38] In January 2023, FDA approved the sponsors' applications to remove the in-person dispensing requirement from the REMS.[39]

Again, Petitioner is not aware of any peer-reviewed study or other robust scientific evidence (clinical or epidemiological) that casts any doubt on these findings. Nor has FDA ever provided any contrary studies or evidence to Petitioner or asked Petitioner for comments on any such studies or evidence. On the contrary, as discussed below, since December 2023, additional research has further confirmed that the dispensing of mifepristone via telehealth is safe and effective.

b. Mifepristone Remains Safe and Effective Under the Current REMS

Mifepristone's safety and efficacy profile has remained strongly supported across multiple iterations of the mifepristone REMS, including after removing the in-person dispensing requirement. As detailed above, the safety and efficacy of mifepristone is supported by a robust body of scientific evidence, reflecting vast amounts of data and hundreds of medical studies evaluating thousands of patients.[40] Moreover, mifepristone is recognized as a safe and effective option for abortion care by numerous clinical practice guidelines and best practices issued by professional groups and other reproductive health experts.[41]

Adverse events with mifepristone are extremely rare, as demonstrated by FDA's summary report of post-marketing adverse events through December 31, 2024.[42] In that report, FDA estimates that approximately 7.5 million women have used mifepristone in the U.S. for medical termination of pregnancy from its approval through December 2024. Among those millions of patients, there have been 36 reported deaths (which are included regardless of any causal attribution to mifepristone), corresponding to an approximate mortality rate of 0.00048%.[43] Moreover, as FDA has recognized, even that small percentage of deaths cannot be causally attributed to mifepristone because of concurrent use of other drugs, other medical or surgical treatments, co-existing medical conditions, and/or information gaps about patient health status and clinical management of the patient.[44]

Other adverse events also remain rare: from November 2012 through December 2024, adverse events were reported in 1,512 cases of mifepristone users in the entire nation, of which 288 required hospitalization (excluding deaths).[45] As the FDA-approved label recognizes, infections and bleeding can occur "very rarely following *spontaneous, surgical, and medical abortions*," and "[n]o causal relationship between the use of [mifepristone] and misoprostol and these events has been established."[46] Evidence suggests that the "critical risk factor" in the reported

cases of infection "is pregnancy itself."[47] Importantly, mifepristone is associated with significantly fewer, and less severe, complications than full-term pregnancy. Approximately 1.6% of women giving birth in U.S. hospitals experience severe maternal morbidity—including hemorrhage, eclampsia, sepsis, and organ failure—which can have significant short- and long-term health consequences.[48] In 2023, the maternal mortality rate was 18.6 deaths per 100,000 live births (0.0186%).[49]

As discussed above, FDA's decision to eliminate the in-person dispensing requirement was fully supported by the scientific evidence available as of December 2021. Since December 2021, further research has demonstrated that the dispensing of mifepristone via telehealth is safe and effective.[50] Again, Petitioner is not aware of any peer-reviewed study or other robust data (clinical

or epidemiological) that contradicts FDA's decision to remove the in-person dispensing requirement.

c. Unsubstantiated Claims by Abortion Opponents Do Not Justify Imposing Restrictions on Mifepristone Access

Despite mifepristone's well-established safety and efficacy profile—which has been borne out in hundreds of medical studies over more than two decades as well as use by millions of women—some ideological opponents of abortion have alleged that mifepristone carries unacceptable safety risks. Such opponents have urged FDA either to revoke its approval of mifepristone or to impose burdensome restrictions on patient access. As discussed further below, there is no scientifically robust evidence to support these spurious claims, which fall far short of the evidentiary standard required by the FDCA.

First, to withdraw the mifepristone approval, FDA would need to find that: (1) "*clinical or other experience, tests, or other scientific data* show that such drug is *unsafe for use* under the conditions of use upon the basis of which the application was approved," (2) "new evidence of *clinical experience*" or "*tests by new methods*" show that a drug is "*not shown to be safe for use* under the conditions of use upon the basis of which the application was approved," or (3) "new information" demonstrates a "*lack of substantial evidence* that the drug will have the effect it purports or is represented to have under the conditions of use prescribed, recommended, or suggested in the labeling thereof."[51] No such evidence exists with respect to mifepristone. Petitioner is not aware of any scientifically robust evidence—including clinical experience, tests, or data—showing that mifepristone is unsafe for use under its conditions of use. Nor is Petitioner aware of any new information that demonstrates a lack of substantial evidence of effectiveness. To the contrary, the overwhelming weight of scientific research and peer-reviewed studies demonstrate that mifepristone is safe and effective for the medical termination of intrauterine pregnancy through 70 days gestation.

Second, when evaluating a REMS for potential modification, FDA considers "new safety information."[52] The statute provides explicit instruction on the type of evidence that FDA may consider, defining "new safety information" to mean "information derived from a *clinical trial*, an *adverse event report*, a *postapproval study* . . . , or *peer-reviewed biomedical literature*; data derived from the *postmarket risk identification and analysis system* . . . ; or other *scientific data*

deemed appropriate by the Secretary."[53] Such information must address: (1) "a serious risk or an unexpected serious risk associated with the use of the drug that the Secretary has become aware of (that may be based on a new analysis of existing information) . . . *since the last assessment of the approved [REMS]* for the drug"; or (2) "the effectiveness of the approved [REMS] for the drug obtained *since the last assessment of such strategy*."[54] Petitioner is not aware of any such new clinical trial, adverse event report, postapproval study, peer-reviewed biomedical literature, or other scientific data that merits a modification to the mifepristone label or REMS to make them more restrictive or to reinstate previously removed requirements.[55]

Petitioner is aware that, in late April 2025 and early May 2025, the Ethics and Public Policy Center ("EPPC") issued two documents arguing that FDA should reverse its findings with respect to the mifepristone REMS and label and "reconsider its approval altogether."[56] Secretary Kennedy was expressly questioned about the April 2025 document at a recent congressional hearing where Senator Josh Hawley (a strong opponent of abortion) demanded that FDA undertake a complete review of mifepristone.

At the outset, it is important to note that EPPC is not a medical or scientific organization: EPPC describes its mission as "working to apply the riches of the Jewish and Christian traditions to contemporary questions of law, culture, and politics, in pursuit of America's continued civic and cultural renewal."[57] The EPPC documents on mifepristone were issued as part of the organization's "Life and Family Initiative," which "works nationwide to advance pro-life policies that protect unborn children by restricting abortion at the state and federal levels, via legislation,

---

[53] *Id.* (emphasis added)

[54] *Id.* (emphasis added).

[55] Some abortion opponents have advocated that FDA should re-impose the in-person dispensing requirement or otherwise modify the REMS to mitigate a purported risk that a pregnant individual could be forced or coerced to ingest mifepristone in order to induce an abortion. Any forced or coerced use of mifepristone would be inconsistent with the *existing* FDA-approved label and REMS, as well as both unethical and illegal. Petitioner is unaware of *any* study or data analyzing whether or to what extent such conduct has occurred in the United States, let alone linking such conduct to the recent REMS modification. Petitioner also is unaware of any evidence of such alleged activity indicated in the FDA Adverse Event Reporting System ("FAERS") database. In the absence of any such scientific evidence evaluating this purported risk, FDA cannot reinstate the in-person dispensing requirement or otherwise modify the REMS on the basis of this unfounded allegation. Moreover, if FDA believed such evidence existed, it would be incumbent on FDA to accord Petitioner, who worked with FDA to develop and finalize the current REMS, notice and an opportunity to comment on such material.

regulation, and litigation."[58] Similarly, the authors of the documents at issue, Jamie Bryan Hall and Ryan T. Anderson, are neither physicians nor medical scientists. Hall and Anderson state that the project was conducted by an unnamed "team" of data scientists, analysts, and engineers, with assistance from a group of unnamed physicians. Most critically, the documents were self-published on EPPC's website and not subject to peer review, meaning Hall and Anderson's methodology, data, and conclusions were never scrutinized by experts in the field for accuracy or reliability.

The EPPC documents are, in fact, deeply flawed and present no legitimate basis for FDA to revise the mifepristone REMS or to revoke its approval of the drug. We outline some (but not all) of those flaws below.

In the first document, Hall and Anderson claim that the unnamed team used an unnamed dataset to identify patients whose medical records contained a code for a medication abortion, a prescription for mifepristone, or a code for an abortion or unwanted pregnancy alongside coding consistent with a medication abortion. Among those patients, Hall and Anderson claim that10.93% allegedly also had some mention of some other purported adverse event within 45 days of the prior entry.[59] Hall and Anderson state that they identified "serious adverse events" using an undefined list of "relevant" diagnosis codes and procedure codes. They then grouped those codes into 10 categories, which include, among other categories: (1) emergency room visits (with abortion-related diagnosis and procedure codes); (2) other events that a group of unnamed doctors "judge to be life-threatening" (including ectopic pregnancy); (3) subsequent surgical abortion procedures; or (4) unspecified "other abortion complications," including "life-threatening mental health diagnoses."[60] These categories present several critical and likely fatal issues.

To begin, it is clear that Hall and Anderson did not follow accepted scientific practices in conducting their result-oriented analysis, including, but not limited to, use of a validated algorithm for probing the data. For example, counting abortion-related emergency room visits by themselves as serious adverse events is contrary to the FDCA and FDA guidance.[61] It is also inconsistent with real world evidence: studies have repeatedly demonstrated that the majority of patients with abortion-related emergency room visits receive observation care only.[62] Patients often visit

Upadhyay et al., *Abortion-Related Emergency Department Visits in the United States: An Analysis of a*

emergency rooms to receive care for normal uterine cramping and bleeding, to ask questions, or simply to confirm they are no longer pregnant. None of those scenarios would qualify as a serious adverse event under FDA's definition. In any event, it is well established in the scientific literature (and reflected in the mifepristone label) that a small number of patients will visit an emergency room following administration of mifepristone and misoprostol, and this evidence was available to, and considered by, FDA when it approved changes to mifepristone's labeling and REMS. Yet, emergency room visits constitute over 40% of the purported serious adverse events identified by Hall and Anderson.

Hall and Anderson also count any subsequent procedure to *complete* the abortion as a serious adverse event. But, again, it is well-known and expected that approximately 2-7% of patients will need a surgical procedure following mifepristone administration, and this possibility is already included in the FDA-approved mifepristone labeling.[63] Yet again, surgical abortion procedures account for over 25% of the purported serious adverse events identified by EPPC.

Hall and Anderson also include ectopic pregnancy as a serious adverse event, even though ectopic pregnancies are not caused by mifepristone. As already made clear in its labeling, mifepristone is contraindicated in patients with ectopic pregnancy because it is not effective for terminating such pregnancies; however, there is no evidence that mifepristone leads to unusual complications for women with ectopic pregnancies.[64] Yet Hall and Anderson claim, without support, that use of mifepristone in the case of ectopic pregnancy "poses extraordinary, heightened risk" to the patient's health.[65]

The largest category of alleged adverse events in the EPPC's findings—over half—is made up of unspecified "other abortion-specific complications." Hall and Anderson do not list the diagnosis or procedure codes used for this category, and hence it is impossible to determine the codes' relevance (if any) to mifepristone treatment.

[65] Jamie Bryan Hall & Ryan T. Anderson, Ethics & Pub. Pol'y Ctr., *Frequently Asked Questions About the Largest Study on Chemical Abortion* (May 7, 2025), https://eppc.org/wp-content/uploads/2025/05/Frequently-Asked-Questions-About-the-Largest-Study-on-Chemical-Abortion.pdf.

In the second document, Hall and Anderson claim that, among those patients identified as having received a medication abortion based on claims data, within a 45-day window, 3.22% had some entry suggesting repeated mifepristone administration, and 2.84% had some entry suggesting a subsequent procedure to complete the abortion. Hall and Anderson use these "findings" to assert that mifepristone has a "real-world failure rate" of 5.26%.[66] Again, there are several seriously problematic issues with this document. We highlight just two. First, as discussed above, it is known and expected that a small percentage of patients will need a surgical procedure following mifepristone administration to complete the abortion, and this possibility is already included in the mifepristone labeling. Second, Hall and Anderson do not explain how they identified the purported repeated use of mifepristone, or the steps taken (if any) to ensure such entries in the unnamed dataset did not merely reflect duplicate claims. Such entries may also reflect instances in which a patient received two mifepristone prescriptions but only ingested a single dose.

The failure of Hall and Anderson to disclose the "commercially available all-payer health insurance claims database"[67] underlying their "findings;" the methodology (if any) used to address misclassified or missing information; any steps taken to preserve data quality or remove duplicate claims; or the diagnosis and procedure codes used to identify adverse events make it impossible to independently verify or replicate the results. More specifically, EPPC's decision to withhold the identity of the claims database also makes it impossible for FDA, the mifepristone NDA and ANDA holders, the scientific and medical community at large, or anyone else to assess either the reliability or relevance of that dataset with respect to any decision on the approval or REMS requirements for the drug.

As FDA recognized in its guidance regarding the use of electronic health records and medical claims data ("EHR Guidance"), "existing electronic health care data were not developed for research purposes or to support regulatory submissions to FDA, [so] it is important to understand their potential limitations when they are used for that purpose."[68] One potential limitation recognized by FDA is that the purpose of medical claims data is to "support payment for care."[69] Accordingly, as FDA has stated, claims data "may not accurately reflect" the presence, characteristics, severity, or clinical management of a particular condition or event.[70]

[70] *Id.*

FDA has likewise cautioned that investigators should "identify whether the data sources cover all populations relevant to the study" and that "[d]ifferences in terminology and coding systems used in different health care systems" may affect the relevance of the data source.[71] There is no evidence suggesting Hall and Anderson gave any consideration to these issues or other potential limitations of their dataset. Until EPPC discloses the identity of the dataset it claims to have analyzed—and independent reviewers at FDA and the medical community are able to assess its relevance, reliability and integrity (or any of the more detailed data issues FDA has also specified in its EHR Guidance)—any use of (much less reliance on) EPPC's purported "findings" from that unidentified data would violate FDA's own standards and procedures.

In sum, the EPPC documents utterly fail to provide robust scientific evidence regarding the safety and effectiveness of mifepristone. The documents do not constitute "new safety information" for purposes of REMS modification assessments, which the FDCA requires to be derived from a clinical trial, adverse event reports, a postapproval study, peer-reviewed biomedical literature, FAERS data, or other scientific data.[72] To the extent that FDA considers these documents at all, FDA must also consider the overwhelming weight of scientific research and peer-reviewed studies that support mifepristone's safety and efficacy. In light of its many obvious scientific flaws—which are apparent even upon a facial review—the EPPC documents cannot provide a legitimate basis to restrict access to mifepristone—a drug which has been repeatedly verified as safe and effective for terminating early pregnancies through vast amounts of data, hundreds of medical studies, and use by millions of women over more than two decades.

d. FDA Must Avoid Undue Burdens on Patient Access to Mifepristone

The FDCA requires FDA to balance safety *and access* in adopting and revising a REMS.[73] Specifically, ETASU imposed under a REMS must "not be unduly burdensome on patient access to the drug," and, "to the extent practicable," must "minimize the burden on the health care delivery system."[74]

In its 2021 review of the mifepristone REMS, FDA correctly determined that removing the in-person dispensing requirement would "render the REMS less burdensome to healthcare providers and patients" and that the modified REMS would "continue to ensure that the benefits

[71] *Id.* at 5.

[72] 21 U.S.C. § 355-1(b)(3).

[73] 21 U.S.C. § 355-1(g)(4)(B) (authorizing FDA to require a sponsor to modify a REMS to "ensure benefits of the drug outweigh the risks of the drug" or "minimize the burden on the health care delivery system"); 21 U.S.C. § 355-1(f)(5) (requiring FDA to periodically evaluate whether ETASU "are not unduly burdensome on patient access to the drug" and "to the extent practicable, minimize the burden on the health care delivery system"). Congress was particularly concerned about access to REMS drugs for "patients who have difficulty accessing health care (such as patients in rural or medically underserved areas)." 21 U.S.C. § 355-1(f)(2).

[74] 21 U.S.C. § 355-1(f)(2).

of mifepristone for medical abortion outweigh the risks."[75] Since then, numerous peer-reviewed studies have confirmed that the availability of medication abortion through telehealth improves patient access to care.[76] In particular, studies have shown that telehealth provides an important care option for patients living in rural and medically underserved areas, who would otherwise have to travel long distances to receive in-person care. Telehealth also provides a particular benefit for patients who may find it difficult to take time off work or arrange for childcare in order to travel for abortion care.

FDA appropriately balanced patient safety and access when it determined that the mifepristone REMS should be modified in 2021. Reinstating the prior ETASU, such as the in-person dispensing requirement, would unduly restrict patient access to mifepristone without a legitimate patient safety rationale. Doing so would also violate the FDCA's mandate that REMS requirements be firmly rooted in scientific evidence and clinical data and no more burdensome than necessary to ensure safe use.

2. There is No Scientific Evidence Suggesting that Mifepristone Causes Harm to the Environment

FDA has previously and correctly rejected claims that mifepristone somehow causes harm to the environment, and there continues to be no evidence that would support restricting access to

mifepristone on this basis. Further, when granting the mifepristone NDA and ANDA, FDA complied with all applicable law and regulations regarding environmental reviews and consultations, including environmental assessment requirements.

As FDA is aware, opponents of medical abortion have alleged that mifepristone or its metabolites cause harm to the environment, despite the lack of any scientific evidence, including by filing the below citizen petitions:

(1) *Students for Life of America ("SFLA") Citizen Petition (Nov. 2022)*: This petition requested that FDA modify the REMS to require prescribers to include a medical waste bag and catch-kit with all mifepristone prescriptions to "alleviate some amount of human remains (this includes fetal remains) and Mifepristone contaminants in the nation's water supply."[77] SFLA's petition claimed that exposure to mifepristone in the nation's water can cause "teratologic repercussions or congenital anomalies."[78]

(2) *SFLA Citizen Petition (Apr. 2023)*: This petition requested that FDA revoke approval of the NDA, ANDA, and modifications to the REMS, on the basis that FDA failed to comply with the Endangered Species Act ("ESA") by not consulting with the United States Fish and Wildlife Service ("FWS") and National Marine Fisheries Service ("NMFS").[79] SFLA claimed that mifepristone in the water supply can have "detrimental effects on the fertility of animals, as well as having unknown detrimental effects on plant life and ecosystems."[80]

(3) *SFLA Citizen Petition (Aug. 2023)*: This petition requested that FDA revoke approval of the mifepristone NDA, ANDA, and modifications to the REMS, on the basis that FDA failed to comply with certain requirements of the Clean Water Act ("CWA").[81]

(4) *SFLA Citizen Petition (Dec. 2024)*: This petition requested that FDA "refrain from modifying the approved use of [m]ifepristone to include miscarriage care" until the Agency requires the provision of a medical waste bag and catch-kit and determines compliance with the CWA and ESA.[82]

[82] Citizen Petition from Students for Life of America, No. FDA-2024-P-5967 (Dec. 18, 2024), https://www.regulations.gov/document/FDA-2024-P-5967-0001.

FDA correctly rejected these requests.[83] There is no scientific evidence whatsoever that suggests mifepristone or the products of conception have any effect, let alone an adverse one, on the environment (including protected species, habitats, or water quality).

As FDA has recognized, the 2000 approval of Mifeprex and the 2019 approval of generic mifepristone complied with all environmental assessment requirements and demonstrated that mifepristone would have no adverse environmental effects.[84] FDA is required under the National Environmental Policy Act ("NEPA") to assess the environmental impacts of qualifying actions and ensure that the public is informed of these analyses.[85] When assessing "environmental effects and feasible alternatives for NEPA," an agency is accorded "substantial deference" as to the "depth and breadth of its inquiry."[86] Under FDA regulations, the approval of an NDA, ANDA, and certain supplements to these applications require at least the preparation of an environmental assessment ("EA"), unless the action qualifies for a categorical exclusion.[87] Action on an ANDA qualifies for a categorical exclusion from the requirement to prepare an EA "if the action does not increase the use of the active moiety."[88]

FDA's approval of the mifepristone NDA complied with all applicable EA requirements, and Petitioner properly claimed a categorical exclusion on its ANDA, meaning no additional EA was required. In 1996, the applicant for the mifepristone NDA submitted an EA in accordance with NEPA and applicable FDA regulations, which was reviewed by FDA to determine whether approval of mifepristone would have a significant environmental impact.[89] The EA evaluated the potential environmental impacts of the manufacture of the drug product, use of the drug product by patients (i.e., excretion by patients), and disposal of pharmaceutical waste. In accordance with FDA guidance, the EA calculated a projected environmental introduction concentration into the

aquatic environment from use of *much less than 1 part per billion* using default, conservative screening-level assumptions that all drug substance produced is used, there is even distribution throughout the United States per day, and there are no metabolism or depletion mechanisms.[90] The Material Safety Data Sheet also noted that mifepristone is "[b]iodegradable in natural media," meaning that mifepristone is not expected to accumulate in the environment because it will break down through the action of microorganisms.[91] Based on these materials, FDA made a finding of no significant impact, concluding that mifepristone "can be manufactured, used and disposed of *without any expected adverse environmental effects*," that "[a]dverse effects are not anticipated upon endangered or threatened species," and that approval of the NDA "will not have a significant effect on the quality of the human environment."[92] In support of its ANDA, Petitioner appropriately claimed a categorical exclusion under 21 C.F.R. § 25.31(a) because action on its ANDA would not increase use of the active moiety.

In rejecting the aforementioned citizen petitions, in January 2025, FDA reaffirmed that the 1996 EA complied with NEPA and FDA's regulations, concluding that "FDA appropriately assessed the potential impact on the human environment from excretion by patients who use mifepristone and determined that there would be no significant effects on the quality of the human environment."[93] FDA concluded that the 1996 EA and FDA's finding of no significant impact "show that 'remnants of mifepristone' are not causing harm to the environment and to people through environmental pathways**,** and also show, by extension, that metabolites from patients using mifepristone have not been 'causing teratologic repercussions or congenital anomalies in animals like birth defects.'"[94]

The findings from the 1996 EA were also reaffirmed by a new environmental analysis conducted by FDA. In January 2025, FDA conducted its own environmental analysis, using publicly available data on current usage rates of mifepristone and applying the default

environmental calculations described in FDA's current environmental guidance. This analysis reaffirmed the findings from the 1996 EA: FDA concluded that its "conservative calculations" using estimates of current use rates of mifepristone "show an exposure level that is *so low that is it predicted to have no effect on the environment*, including threatened and endangered species."[95] As FDA recognized, the SFLA petitions "provide[d] *no evidence* showing that bodily fluid from patients who have used mifepristone (a one-time, single-dose drug product) is causing harm to the nation's aquatic environment."[96] FDA further stated that the Agency is not aware of any evidence "suggesting that products of conception pose an environmental hazard to the water supply" or that "products of conception from induced abortions differ from the naturally occurring products of conception from spontaneous abortions."[97] No new evidence contradicts FDA's conclusions. And, if FDA now believes such evidence exists, it must accord Petitioner notice and an opportunity to comment on such material.

Separately, FDA also correctly concluded that the ESA and CWA do not impose requirements on FDA's approval of drug applications. In rejecting the April 2023 SFLA citizen petition, FDA correctly explained that it does not have "discretionary Federal involvement or control" over approvals of the type that would trigger obligations under ESA Section 7; accordingly, it is not required to consult with FWS or NMFS before approving an NDA or ANDA.[98] Additionally, in rejecting the August 2023 SFLA citizen petition, FDA explained that the CWA does not apply to FDA's approval of mifepristone, because excretion of mifepristone, its metabolites, or any products of conception into wastewater would not be considered a "discharge" or nonpoint "runoff" under the CWA.[99] It remains the case today that the ESA and CWA are inapplicable to FDA's approval of drug applications. If FDA adopts the position that these regimes somehow impact the approval of mifepristone, Petitioner must be accorded notice and opportunity to comment on and challenge such an unfounded interpretation.

* * *

In summary, FDA's approval of mifepristone and the current REMS reflects its judgment that the drug is safe and effective and has a favorable benefit-risk balance under the current conditions of use. FDA's decisions regarding mifepristone have been based on the agency's review of vast amounts of data and hundreds of medical studies over more than two decades. Further, FDA's decisions regarding mifepristone have twice been found to be legally and factually valid by the GAO.

Accordingly, FDA should take no action that would reduce patient access to mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone, as such actions are not scientifically or medically warranted, or consistent with applicable law.

3. Any FDA Withdrawal of Petitioner's ANDA Approval Must Follow All Applicable Procedures Afforded by Law and Regulation

As FDA is well aware, FDA's longstanding approvals regarding mifepristone have come under legal challenge. These ill-advised and unfounded attacks on FDA's decisions pursuant to its congressional mandate are of grave concern to Petitioner, which has invested considerable effort and expense in reliance on FDA's past regulatory actions with respect to mifepristone, and with the understanding that any withdrawal of an FDA approval is subject to a well-established FDA regulatory process. Petitioner therefore must respectfully insist that any steps to withdraw or otherwise restrict FDA's approval of Petitioner's ANDA for mifepristone as currently labeled—whether in effectuation of a court order or otherwise—follow all applicable procedures afforded by law and regulation, and that FDA permit Petitioner to continue marketing and selling mifepristone under current conditions of use until those procedures have been completed.

a. FDA's Approval of Petitioner's ANDA is Facing a Legal Challenge

On November 18, 2022, the Alliance for Hippocratic Medicine filed a complaint in the U.S. District Court for the Northern District of Texas challenging FDA's approvals of Danco's NDA for Mifeprex and Petitioner's ANDA for mifepristone, as well as other FDA actions related to mifepristone. On April 7, 2023, the district court granted in part the plaintiffs' preliminary injunction motion, purporting to "stay[] the effective date of FDA's September 28, 2000, [a]pproval of mifepristone" and subsequent actions on mifepristone that the plaintiffs challenged, including the REMS modifications in 2016 and 2021 and the approval of Petitioner's ANDA in 2019.[100] That order, however, was stayed pending appeal; on June 13, 2024, the Supreme Court ultimately held that the plaintiffs lacked Article III standing to challenge FDA's actions relating to mifepristone.[101] The case was subsequently remanded to the district court.[102]

But that was not the end of the legal threat to Petitioner's ANDA. On remand, intervenor-plaintiff States in the lawsuit, now captioned *Missouri v. FDA*, have alleged that FDA "lacked legal authority" when approving Petitioner's ANDA.[103] Intervenor-plaintiffs have asserted that Petitioner's ANDA approval "must be held unlawful, stayed, set aside, vacated, and preliminarily and permanently enjoined."[104] Because Petitioner's ANDA for generic mifepristone remains under

---

[101] *FDA v. All. for Hippocratic Med.*, 602 U.S. 367 (2024).

[102] *All. for Hippocratic Med. v. FDA*, 117 F.4th 336, 340 (5th Cir. 2024).

[103] Amended Complaint ¶ 764, *Missouri v. FDA*, No. 2:22-cv-223-Z (N.D. Tex. Jan. 16, 2025), ECF No. 217.

[104] *Id.* ¶ 787.

attack, Petitioner is acutely interested in FDA's adherence to all applicable procedures governing any potential withdrawal of approved drug applications.[105]

As a result of this legal threat, Petitioner has previously and repeatedly insisted that FDA confirm that any withdrawal of approval for Petitioner's ANDA for mifepristone would follow all applicable procedures afforded by law to Petitioner as the ANDA holder, and that FDA would permit Petitioner to continue marketing and selling mifepristone until those procedures have been completed. Petitioner communicated these requests in letters to FDA in March and April 2023, as it considered the potential impact of the district court's order in *Alliance for Hippocratic Medicine v. FDA*.[106] FDA responded to one such letter by declining to provide the assurances sought by Petitioner, instead stating that FDA would "need to review the Court's opinion and order before determining what steps may be necessary to comply with it."[107] FDA did not respond to Petitioner's other communications on this topic.

b. Statute and Regulations Require FDA to Follow Specific Procedures to Withdraw an ANDA

Petitioner believes that FDA should confirm that any steps to withdraw the approval of Petitioner's ANDA for mifepristone—whether in purported effectuation of a court order or otherwise—will follow all applicable procedures afforded by law and regulation to Petitioner as the ANDA holder, and that Petitioner may continue marketing and selling mifepristone until those procedures have been completed.

(i) *Statutory Withdrawal Procedures*

Any withdrawal of Petitioner's ANDA must comport with the statutory provisions governing the withdrawal of an approved drug application. Congress granted FDA, and FDA alone, the authority to oversee the withdrawal of an approved drug application.[108] Withdrawal requires a finding by FDA that one of the relevant statutory criteria has been met, as well as "due notice and opportunity for hearing to the applicant."[109] As discussed above, under the FDCA, and

[105] Petitioner has intervened in the *Missouri v. FDA* lawsuit to defend against the Intervenor-plaintiff States' unfounded attacks on the ANDA approval and other FDA regulatory actions, including on the basis that the lawsuit is procedurally improper for multiple reasons. As Petitioner has made clear in its filings in the case, Intervenor-plaintiffs' legal challenges should be dismissed.

[108] 21 U.S.C. § 355(e).

[109] *Id.*

as relevant here, the Secretary of HHS may withdraw approval of an application *only* if the Secretary finds that:

> [C]linical or other experience, tests, or other scientific data show that such drug is unsafe for use under the conditions of use upon the basis of which the application was approved . . . [or] on the basis of new information before him with respect to such drug, evaluated together with the evidence available to him when the application was approved, that there is a lack of substantial evidence that the drug will have the effect it purports or is represented to have under the conditions of use prescribed, recommended, or suggested in the labeling thereof.[110]

The Secretary, in turn, has delegated the responsibility for making the requisite finding to the FDA Commissioner.[111] Any withdrawal of a drug approval on safety or efficacy grounds therefore requires a finding that the evidence demonstrates that the drug's benefit-risk balance requires withdrawal. As the Supreme Court has emphasized, the FDCA does "not provide any mechanism other than the Commissioner's suspension authority under [section 355(e)], whereby an NDA once effective could cease to be effective."[112]

(ii) FDA Regulations on Withdrawal Procedures

The regulations that implement 21 U.S.C. § 355(e)'s requirements of notice and opportunity to be heard set out the specific and detailed procedures FDA must follow when withdrawing a drug approval. In addition to notice and the opportunity for a hearing on a proposal to withdraw a drug, FDA regulations also expressly permit the applicant to submit studies, data, and other information.[113] Specifically with regard to the holder of an ANDA such as Petitioner, the regulations require an opportunity to submit written comments and, if a hearing is granted, the opportunity to participate and to submit written objections to an initial decision.[114]

The participation of the manufacturer in withdrawal proceedings is crucial to upholding the legitimacy of (and public confidence in) FDA's decision-making. Moreover, manufacturers such as Petitioner are often the most knowledgeable party regarding the drug's use, safety profile, and the related health care delivery systems. The due process protections embodied within these statutory and regulatory procedures are also constitutionally necessary for the protection of Petitioner's property interest in its mifepristone ANDA.

[114] 21 C.F.R. § 314.151.

(iii) Authority to Suspend Approval Without Pre-Deprivation Process

While the FDCA permits the suspension of an ANDA without pre-deprivation process, this power may be used only in exceptional circumstances.[115] Such suspension requires a finding of "an imminent hazard to the public health."[116] FDA regulations, in turn, provide that an "imminent hazard to the public health" is considered to exist only when "the evidence is sufficient to show that a product or practice, posing a *significant threat* of danger to health, creates a public health situation: (1) that should be corrected immediately to *prevent injury* and (2) that should not be permitted to continue while a hearing or other formal proceeding is being held."[117]

The legislative history of the suspension statute makes clear that this authority is to be used only in extraordinary situations. Congress believed that the suspension authority, "which could have grave effects upon a manufacturer and upon the confidence of the public in a drug which might later be found appropriate for continued availability to physicians, should only be exercised under the most extreme conditions and with the utmost care."[118] In the event that FDA finds an "imminent hazard" and orders the immediate suspension of an application approval, the approval holder is entitled to immediate procedural protections, including "prompt notice," and "an expedited hearing."[119] The holders of any ANDAs whose approval rests on a suspended NDA must be allowed to participate in the post-suspension proceeding for the NDA.[120]

c. Suspension of Mifepristone Outside FDA Procedure Would Be Unlawful

To date, there has been no finding of imminent hazard made with respect to mifepristone—nor could there be given the mountain of replicated scientific data establishing the drug is safe and effective as used by millions of women for over twenty years in the United States. Therefore, without the requisite "imminent hazard" finding—and the procedural protections that accompany such a finding—FDA may not deprive Petitioner of its protected property interests in marketing its ANDA for mifepristone.

HHS and FDA's procedures for withdrawing or suspending drug approvals are far more than regulatory formalities. In addition to harming the constitutional rights of NDA and ANDA holders, suspension of approvals outside FDA and HHS's express procedures disrupts the evidence-based mandate of FDA. It undermines public confidence in FDA's approval of drugs by incorrectly suggesting that FDA approval is not grounded in scientific principles or by implying

[115] 21 U.S.C. § 355(e)

[116] *Id.*

[117] 21 C.F.R. § 2.5 (emphasis added).

[118] 108 Cong. Rec. 17366 (Aug. 23, 1962).

[119] 21 U.S.C. § 355(e); *see* 21 C.F.R. § 314.150(a)(1).

[120] 21 C.F.R. § 314.150(a)(1).

that FDA misinterpreted those scientific principles in such a way that a drug must be immediately pulled from the market.

Crucially, since FDA's approval of Petitioner's ANDA in 2019, FDA has never presented Petitioner with any scientific evidence that would justify withdrawal or suspension of its approval. Petitioner must be afforded an opportunity to be heard on any such evidence prior to any withdrawal or suspension.

In sum, the statutory and regulatory procedures governing the withdrawal and suspension of an application approval are necessary to protect Petitioner's property interests in its mifepristone ANDA, as well as the patient desire for medication access. Accordingly, Petitioner requests that FDA confirm that any withdrawal of the approval of Petitioner's ANDA for mifepristone, or any other action that would impair the approval or labeling—whether in effectuation of a court order or otherwise—must follow all applicable procedures afforded by law and regulation to Petitioner as the ANDA holder, and that Petitioner may continue marketing and selling mifepristone until those procedures have been completed.

4. Conclusion

For the foregoing reasons, Petitioner respectfully requests that FDA:

(1) refrain from taking any action that would reduce patient access to mifepristone and/or increase the burdens associated with prescribing or dispensing mifepristone; and

(2) confirm that any FDA withdrawal of approval for mifepristone, including in response to any court order, will follow all applicable rules and procedures for any withdrawal, suspension or other action under the APA, the FDCA, and implementing regulations, and that Petitioner will be permitted to continue to market and sell mifepristone in the United States until those procedures have been completed.

C. ENVIRONMENTAL IMPACT

We claim categorical exclusion under 21 C.F.R. § 25.31. Therefore, an environmental impact analysis is not required.

D. ECONOMIC IMPACT

Pursuant to 21 C.F.R. § 10.30(b), an economic impact statement will be submitted upon request of the Commissioner.

E. CERTIFICATION

The undersigned certifies that, to the best knowledge and belief of the undersigned, this petition includes all information and views on which the petition relies, and that it includes representative data and information known to the petitioner which are unfavorable to the petition.

the Executive Calendar, I ask unanimous consent that they be ordered to lie on the Secretary's desk, for the information of any Senator.

The PRESIDING OFFICER. The nominations will lie on the desk, as requested by the Senator from Maine.

The nominations are as follows:

Howard F. Stevenson, and sundry other officers of the Marine Corps, for temporary appointment to the grade of colonel;

Willard F. Angen, and sundry other officers, for promotion in the Regular Army of the United States;

Jacquard H. Rothschild, for reappointment as a temporary brigadier general in the Army of the United States and for reappointment as colonel in the Regular Army of the United States;

Edward J. Osborne, and sundry other persons, for appointment in the Regular Army;

Franklin H. Andrew, Jr., and sundry other distinguished military students, for appointment in the Regular Army of the United States; and

Lawrence A. Adams, Jr., and sundry other officers for promotion in the Regular Air Force.

The PRESIDING OFFICER. If there be no further reports of committees, the clerk will state the nominations placed on the Secretary's desk.

COAST AND GEODETIC SURVEY

The Chief Clerk proceeded to read sundry nominations in the Coast and Geodetic Survey.

The PRESIDING OFFICER. Without objection, the nominations will be considered en bloc; and, without objection, they are confirmed en bloc.

U.S. COAST GUARD

The Chief Clerk proceeded to read sundry nominations in the U.S. Coast Guard.

The PRESIDING OFFICER. Without objection, the nominations will be considered en bloc; and, without objection, they are confirmed en bloc.

Without objection, the President will be immediately notified of the confirmation of all nominations confirmed today.

LEGISLATIVE SESSION

Mr. MANSFIELD. Mr. President, I move that the Senate resume the consideration of legislative business.

The motion was agreed to; and the Senate resumed the consideration of legislative business.

Mr. MANSFIELD. Mr. President, is there further morning business?

The PRESIDING OFFICER. Is there further business in the morning hour? If there is no further business, morning business is concluded.

DRUG INDUSTRY ACT OF 1962

Mr. MANSFIELD. Mr. President, I ask unanimous consent that the unfinished business be laid before the Senate.

The PRESIDING OFFICER. The bill will be stated by title for the information of the Senate.

The CHIEF CLERK. A bill (S. 1552) to amend and supplement the antitrust laws with respect to the manufacture and distribution of drugs, and for other purposes.

The PRESIDING OFFICER. Is there objection to the request by the Senator from Montana?

There being no objection, the Senate resumed the consideration of the bill.

PRIVILEGE OF THE FLOOR

Mr. EASTLAND. Mr. President, I ask unanimous consent that during the consideration of the drug bill, Mr. Jerome N. Sonosky, special assistant to the Assistant Secretary for Legislation of the Department of Health, Education, and Welfare, be allowed the privilege of the Senate floor.

The PRESIDING OFFICER. Without objection, it is so ordered.

Mr. MANSFIELD. Mr. President, I ask unanimous consent that Mr. Clarence M. Dinkins, chief counsel of the Patents Subcommittee, be authorized to be present on the floor of the Senate during the discussion of the bill today.

The PRESIDING OFFICER. Without objection, it is so ordered.

Mr. MANSFIELD. Mr. President, I suggest the absence of a quorum.

The PRESIDING OFFICER. The clerk will call the roll.

The Chief Clerk proceeded to call the roll.

Mr. MANSFIELD. Mr. President, I ask unanimous consent that the order for the quorum call be rescinded.

The PRESIDING OFFICER (Mr. BURDICK in the chair). Without objection, it is so ordered.

Mr. MANSFIELD. Mr. President, I ask unanimous consent that the time used for the call of the roll not be charged to the time on either side under the unanimous-consent agreement.

The PRESIDING OFFICER. Is there objection to the request by the Senator from Montana? The Chair hears none, and it is so ordered.

Mr. EASTLAND. Mr. President, on behalf of the Committee on the Judiciary, I ask unanimous consent to withdraw the substitute amendment contained in the bill as reported to the Senate on July 19 last, and that the additional substitute amendment reported on the 21st of August be considered in lieu thereof. Under the Senate precedents, this latter substitute amendment would be deemed to be the original text for the purpose of amendment.

The PRESIDING OFFICER. Is there objection to the request by the Senator from Mississippi? The Chair hears none, and it is so ordered.

Mr. MANSFIELD. Mr. President, will the Senator yield?

Mr. EASTLAND. I yield.

Mr. MANSFIELD. Mr. President, I ask unanimous consent that the time under the control of the majority leader be allotted to the chairman of the committee which reported the bill.

The PRESIDING OFFICER. Is there objection to the request by the Senator from Montana? The Chair hears none, and it is so ordered.

Mr. EASTLAND. Mr. President, S. 1552 as reported by the Committee on the Judiciary to the Senate on July 19, 1962, together with the additional amendments voted by the committee on August 20, 1962, is the result of long and intensive study. Under the chairmanship of the senior Senator from Tennessee [Mr. KEFAUVER], beginning in 1959, the Antitrust and Monopoly Subcommittee studied the drug industry for many months, with particular emphasis on prices, profits, and patent matters. The Senator from Tennessee [Mr. KEFAUVER] then introduced S. 1552, in April 1961, and the subcommittee held additional hearings from July 1961 to February 1962 on this bill. On March 8, 1962, the subcommittee reported out a revised bill. The full committee then referred the bill to the Patent Subcommittee for study of the patent provisions. In reporting the bill back to the full committee, the Patent Subcommittee withheld for further consideration two of the patent provisions and suggested amendments of the third provision.

The Judiciary Committee then spent many weeks in executive sessions going over the bill line by line, sentence by sentence, and section by section. In addition to the suggestions from the two subcommittees, the committee was guided by the recommendations of the President in his consumer message of March 14, 1962, and in his letter dated April 10, 1962, to the chairman of the Judiciary Committee.

After this intensive study, the committee approved a bill which in its opinion struck a reasonable and workable balance among the conflicting views of the Department of Health, Education, and Welfare, the majority and minority of the Antitrust Subcommittee, the pharmaceutical industry, and the medical profession. The committee felt that it covered the recommendations of the President in his letter of April 10 in every respect except one, the recommendation for legislation to establish special controls for habit-forming barbiturates and amphetamines, a matter on which the committee took no action because a bill on this subject is now pending before the Committee on Labor and Public Welfare.

The bill was reported to the Senate on July 19, 1962. Thereafter, as a result of the tragic thalidomide episode, the committee undertook a further review of the Food, Drug, and Cosmetic Act and the text of the pending bill on the calendar to determine whether additional amendments were necessary and appropriate. On August 4 the President submitted seven amendments to the bill. Beginning on August 6 the committee held a number of meetings at which these amendments were carefully reviewed. As a result the committee voted unanimously, on August 20, to recommend a number of amendments to the bill previously reported.

In general, the principal features of the bill as it would be amended by the committee amendments would accomplish the following:

First. Provide for cooperation between the Patent Office and the Department of Health, Education, and Welfare on questions relating to drug patents.

Second. Insure greater Government supervision of drug manufacturers by

(a) requiring every plant to be registered; (b) strengthening the inspection authority and requiring inspection of each plant at least once in every 2 years; and (c) authorizing the seizure of a drug if, regardless of its quality, it is made under inadequate methods, facilities or controls.

Third. Require that a new drug be shown to be effective, as well as safe, before it is cleared for the market, and authorize withdrawal of such a drug from the market if new evidence shows it to be ineffective.

Fourth. Strenghen the authority to withdraw a new drug from the market on safety grounds, and include a provision, in the event of an imminent hazard to the public health, for immediate suspension from the market pending a hearing.

Fifth. Add to the Secretary's existing authority to issue regulations to control the testing of new drugs before they are placed on the general market, by giving him specific authority to require records and reports as to data obtained as the result of investigational use of, and clinical experience with, both new drugs and antibiotics.

The committee drafted a drug bill responsive to the recommendations of the administration and to the needs of the American people. It will provide a framework under which industry and Government, working together, can continue to make available improved medicines and new medicines that are safe and useful. It will preserve the system of incentives which has made U.S. industry the most inventive and the most productive and will guarantee continued American prominence in this field.

SUMMARY OF THE PROVISIONS OF S. 1552 AS AMENDED BY THE COMMITTEE AMENDMENTS OF AUGUST 20, 1962

On the desk of each Senator appears Senate Report No. 1744 of July 19, the further amendments adopted by the Judiciary Committee on August 20, and a supplementary report explaining the committee amendments of August 20. I believe it would be helpful if I summarized the provisions of the bill, together with the committee amendments of August 20, 1962.

INFORMATION OF PATENTS FOR DRUGS

Section 2, which is not affected by the August 20 amendments, would amend the Federal Food, Drug, and Cosmetic Act to establish the basis for assistance from the Department of Health, Education, and Welfare to the Patent Office on questions relating to drug patents submitted by the Commissioner of Patents. It is designed to achieve the kind of collaboration that is in effect between the Patent Office and the Agriculture Department in connection with patents on plants. Any information on drugs furnished by the Secretary of Health, Education, and Welfare would be advisory. The final decision as to patentability would be left to the Commissioner of Patents, as has been the practice in the past. With such help from the Department of Health, Education, and Welfare, the Commissioner of Patents will be better equipped to make the decision as to whether a new drug represents the kind of genuine technical advance and new-product competition that should continue to be stimulated by patent rights.

This section of the bill is in lieu of three proposals in the bill as reported by the Antitrust Subcommittee to the full committee. One of such provisions would have imposed compulsory licensing on every drug patent; the committee did not feel that this proposal, which would drastically affect patent rights, should be included in legislation at this time, particularly in view of the testimony that it would seriously reduce the incentives to incur the risks of conducting research and developing new products for the market. Another would have created a new test of patentability for certain drug products; the committee felt that this provision raised so many technical questions that it should not be included in the bill as reported out. The third patent provision would have required all agreements relating to drug patents to be filed in the Patent Office; the committee felt that such proposals should be considered in the light of proposals with respect to patent agreements in general, not limited to drugs, and should therefore not be a part of S. 1552. Indeed, a bill on the subject of filing patent settlement agreements has been passed by the House and has been referred to the Senate Judiciary Committee.

REGISTRATION OF PRODUCERS OF DRUGS

Section 3, which was affected in only minor and technical respects by the August 20 amendments, calls upon every person who owns or operates any establishment for the manufacture, preparation, propagation, compounding, or processing of a drug or drugs to register each year with the Secretary of Health, Education, and Welfare. The Secretary is directed to inspect each such establishment at least once every 2 years. The purpose of this section is to enable the Secretary of Health, Education, and Welfare to be able to identify every manufacturer of prescription and nonprescription drugs and facilitate the inspection of each establishment. It is not a licensing system. The committee decided that it was not necessary, and would be inadvisable, to establish a system of licensing drug plants and operators. The committee felt that this registration provision, coupled with the added inspection authority in section 4 of the bill and the quality manufacturing controls in section 5 of the bill, were preferable to the provisions recommended by the subcommittee which would have set up a complete per-drug-per-plant licensing system.

FACTORY INSPECTION

Section 4, as it would read under the August 20 amendments, broadens the authority of the Food and Drug Administration to inspect establishments in which prescription drugs are made or held. The basic new authority is stated in such sweeping terms that it is necessary to set forth certain limitations necessary to exclude access to data that should be allowed to be held in confidence. Thus, it is provided that financial data, sales data other than shipment records, and pricing data shall be protected from inspection. There would also be a protection for personnel data other than data as to qualifications of technical and professional personnel performing functions subject to the act. Also protected from inspection would be a company's research data, other than records and reports of the type required by the regulations issued under the new drug and antibiotic sections of the act. The object of these limitations is to give the Government adequate power to insure high standards of manufacture and distribution without delving into the unrelated private affairs of a company, or exposing matters at the heart of its capacity to survive and grow in a highly competitive industry. In addition, it would be specified that this additional inspection authority does not extend to pharmacies, medical practitioners, and persons engaged in research, teaching, or chemical analysis.

A further amendment would permit the Food and Drug Administration to obtain injunctions against refusals to permit inspection.

QUALITY MANUFACTURING CONTROLS

Section 5, as it would read under the August 20 amendments, is designed to assure that drugs are manufactured according to good manufacturing practice. It would deem a drug to be adulterated and thus subject to seizure if made under facilities, methods, or controls that are inadequate to assure that the drug meets the specifications of a quality product. Adulteration could also be found if such facilities, methods, or controls were not operated or administered in conformity with good manufacturing practice.

Since the competitive position of responsible manufacturers depends in large part on the confidence of the medical profession and the public, it will be in their own interest to maintain high standards of current good manufacturing practice which will provide a readily determinable basis for enforcement proceedings against any substandard operator. The Secretary could use his general rulemaking authority under section 701(a) of the act to announce what he, in the administration of the act, considers to be good manufacturing practice insofar as methods, facilities, controls, and their operation and administration are concerned. As in the case of other regulations, the courts in the final analysis will pass upon the scope and effect of such regulations.

NEW DRUG CLEARANCE PROCEDURES

Section 6, in the context of the August 20 amendments, changes the procedure on original clearance of new drug applications. Under the present law, such applications become effective, and the drug thus cleared for the market, unless the Food and Drug Administration acts to block the drug within a period of 60 days—extendable to 180 days—after the filing of the application. The bill would change this procedure so that no new drug application would be cleared until

the Food and Drug Administration had issued an affirmative approval. Within the 180-day period after the filing of an application, it would have to be either approved or notice given for opportunity for a hearing. If the applicant within 30 days after such notice requests a hearing, the hearing must be commenced within 120 days after the notice and be conducted on an expedited basis.

These provisions give the Food and Drug Administration greater flexibility in the light of the volume of new drug applications, the more complex nature of new drugs, and the shortage of personnel for study and investigation. The 180-day maximum and the provision for expedited hearings will help to assure that no useful drug will be held off the market for an inordinate period because of bureaucratic inertia or inability to act. It is hoped that the Food and Drug Administration will, as it now does, advise the applicant as soon as practicable after the filing, of any deficiencies it observes in the completeness of the material presented. It is also hoped that in the administration of this new provision, there will continue to be close cooperation and liaison between the Food and Drug Administration and the new drug applicants so that the flow to the market of safe and effective new drugs will not be excessively retarded.

Section 6 would also designate the U.S. court of appeals, instead of the district courts, as the forum for appeal from the Secretary's orders under the new drug procedures.

RECORDS AND REPORTS AS TO EXPERIENCE ON NEW DRUGS AND ANTIBIOTICS

Section 7, which was not affected by the August 20 amendments, authorizes the Secretary to issue regulations requiring manufacturers to maintain records and to make reports as to investigational and clinical experience with new drugs and antibiotics, as requested by the administration. It should be pointed out in this connection that, under the act as it now reads, new drugs and antibiotics cannot be marketed or moved in interstate commerce unless they have passed the applicable tests and been cleared. The statute directs the Secretary to establish regulations exempting such products from these prohibitions to the extent necessary for investigational use. In issuing such regulations, the Food and Drug Administration could, under existing law, impose conditions relating to records and reports. In fact, the Food and Drug Administration has recently issued new regulations bearing on this subject. However, in view of the President's recommendations of April 10, the committee felt it desirable to add language specifically referring to records and reports.

EFFECTIVENESS AND SAFETY OF NEW DRUGS

Section 8 of the bill, as it would read under the August 20 amendment, makes major changes—in addition to the procedural changes in section 6—in the new drug provisions of the act.

DEFINITION OF "NEW DRUG"

The term "new drug" is presently defined as one not generally recognized to be safe for the claimed uses or one, which while so recognized, has not been used for a material time or to a material extent for such uses. The bill would expand this definition so that the term "new drug" would also include not generally recognized to be effective for the claimed uses or one, which while so recognized, has not been used for a material time or to a material extent for such uses. Thus, every brandnew product, and every new claim for an existing product, would be subject to the tests and procedures established in section 505 of the act.

NEW GROUNDS FOR REJECTION OF NEW DRUG APPLICATION

Section 505(d) of the act sets forth certain grounds for refusing to approve new drug applications. Since 1938 the grounds have been expressed in terms of failure to pass safety tests, without reference to the effectiveness of the drug for the uses claimed. Under the bill, there would be added the test of effectiveness. The committee recognized that legitimate differences of opinion may exist among responsible clinicians with respect to the effectiveness of a particular new drug. Experience has shown that a majority of so-called experts has often been wrong in initially condemning a new drug, just as new inventions in other fields are usually regarded with skepticism and often with hostility. The new ground for rejection of a new drug application is therefore expressed in terms of "a lack of substantial evidence," evaluated on the basis of all the information before him, that the drug will have the effect claimed for it. The term "substantial evidence" is defined in terms of the kind and quality of the investigations that must support the claims.

The bill would also provide for rejection of a new drug application upon a finding that the proposed labeling is false or misleading.

NEW GROUNDS FOR WITHDRAWAL OF APPROVAL

Section 505(e) of the act sets forth the grounds for withdrawal of approval of a new drug application. Since 1938 the grounds have been expressed in terms of lack of safety of the drug, without reference to the effectiveness of the drug for the uses claimed. The bill would accomplish the following:

First. Clarify and expand the authority to withdraw approval on safety grounds so that the manufacturer would continue to have the burden of showing that the drug is safe, as he has on the original submission.

Second. Provide for withdrawal of approval if on the basis of new evidence, evaluated with the evidence at the time of approval, the Secretary finds that there is a lack of substantial evidence that the drug will have the effects claimed. This is a corollary of, and subject to the definition of "substantial evidence" in, the provisions for rejection of a new drug application on the original submission.

Third. Permit withdrawal of approval upon a finding that the manufacturer has failed to establish a system for maintaining required records, or repeatedly or deliberately failed to maintain such records or make required reports, or refused access to such records.

Fourth. Permit withdrawal of approval upon a finding that the methods, facilities, and controls are not adequate and were not made adequate within a reasonable time after notice of inadequacy.

Fifth. Permit withdrawal of approval upon a finding that the labeling is false or misleading and was not corrected within a reasonable time after notice.

Withdrawal of approval of any new drug application on the basis of the foregoing grounds would be preceded by a hearing and an order with findings on the basis of the record. In addition, however, the bill includes a provision for immediate suspension of approval upon a finding of an imminent hazard to the public health; in this case, the applicant would have to be given prompt notice and an opportunity for an expedited hearing. The committee believes that this authority, which could have grave effects upon a manufacturer and upon the confidence of the public in a drug which might later be found appropriate for continued availability to physicians, should only be exercised under the most extreme conditions and with the utmost care. For that reason, it is provided that it may be exercised only by the Secretary or the Acting Secretary. I feel that it would be desirable, wherever possible, for the Secretary, before taking action, not only to confer with the manufacturer, but also to consult a committee of experts appointed by the National Research Council. It should not be forgotten also that there may be other remedies available to the Secretary to cope with the situation instead of using the potentially lethal weapon of immediate suspension.

TRANSITIONAL PROVISIONS

As a result of the change in the definition of "new drug" and the addition of the new effectiveness test, it is necessary to include transitional provisions. Under these provisions, the new effectiveness test, in the case of drugs previously cleared under a new drug application, will apply only to new or amended claims unless the application is withdrawn or suspended. Withdrawal on the ground of a lack of substantial evidence of effectiveness will not apply, for a period of 2 years, to existing claims, unless the approval of any of the claims is withdrawn on other grounds. Established drugs which have never been required to go through new drug procedures will not be affected by the new effectiveness test insofar as their existing claims are concerned.

NAMES ON LABELS AND LABELING

Section 9 of the bill, as it would read under the August 20 amendment, would require the label of a drug to bear the established name of the drug, the established name of each active ingredient, and, in the case of prescription drugs, the quantity of each active ingredient. On the label, and on any labeling on which the drug or any ingredient thereof is named, if a trade name is used for the

drug or the ingredient, the established name of the drug or the ingredient, as the case may be, must be shown in type at least half the size of the type used for the trade name. The term "established name" is defined as the name designated by the Secretary—under the authority granted in section 10 of the bill—or if there is none so designated, the name recognized in an official compendium, or if there is no such official name, the common or usual name.

These provisions preserve trademark rights, which give incentives to strive for excellence surpassing minimum standards. At the same time, they will make sure that established names are used so that physicians and pharmacists can more readily identify the characteristics of the product and more readily consider the use of competitive products where appropriate. The committee rejected proposals that would have required such subordination of trade names that the important functions of trademarks would have been weakened. There must be no loss of incentive for the manufacturer to build a reputation based on integrity and quality of product. In the pharmaceutical industry, above all, the individual manufacturer's pursuit of excellence is to be encouraged, not discouraged. Trade marks and trade names represent an important factor in assuring that this pursuit never flags.

DESIGNATION OF NAMES OF DRUGS

Section 10, which was not affected by the August 20 amendments, has to do with the designation of names of drugs. The Secretary of Health, Education, and Welfare is authorized to designate the name for any drug if he determines that such action is necessary or desirable in the interest of usefulness and simplicity. He is also directed to review existing names recognized in the official compendia to determine whether any revision is necessary or desirable in the interest of usefulness and simplicity. This provision is substantially as reported by the Antitrust Subcommittee.

INFORMATION TO PHYSICIANS

Section 11 would require manufacturers of prescription drugs to transmit to practitioners who request information about a drug, true and correct copies of all printed matter which is required to be included in any package in which that drug is distributed. This is to insure that every physician has ready access to full information about a drug. It would also require the Secretary to distribute such material to doctors, hospitals, medical schools, and libraries.

In addition, section 11 would add a new provision to the act applicable to the content of prescription drug advertising and other descriptive printed matter. This provision would require that such matter include the established name printed prominently and in type at least half as large as that used for any trade name. It would also require inclusion of the formula showing the quantity of each ingredient. Finally, it would require information relating to side effects, contraindications, and effectiveness; in this respect, the Secretary would be under a mandate to issue regulations setting forth the information to be included. Since heretofore the Federal Trade Commission has had jurisdiction of advertisements it would be provided that upon the issuance of regulations with respect to prescription drug advertising under the Food, Drug, and Cosmetic Act, such advertisements would, with respect to the matters covered by the new provision, be removed from the coverage of the Federal Trade Commission Act.

CERTIFICATION OF ANTIBIOTICS

Section 12 of the bill, as it would read under the August 20 amendments, extends batch certification controls, now applicable to five named antibiotics, to all other antibiotics. In the same connection, the provision of the act relating to exemptions of covered antibiotics from the batch certification controls would be strengthened by setting forth considerations which the Secretary must take into account in determining whether to grant an exemption. In order to keep exempted and covered manufacturers on an equal competitive basis, it would be made clear that, in labeling or advertising, an exempted manufacturer could represent that the product has been exempted and a covered manufacturer could represent that the product has been certified.

Mr. President, I believe that the committee has come up with a good drug bill which will protect the American people. Mr. President, I urge the passage of S. 1552 as amended by the committee.

Mr. KEFAUVER. Madam President——

The PRESIDING OFFICER (Mrs. NEUBERGER in the chair). Does the Senator from Tennessee have control of the time on his side?

Mr. KEFAUVER. Yes. Madam President, I yield myself 20 minutes.

The PRESIDING OFFICER. The Senator from Tennessee is recognized for 20 minutes.

Mr. KEFAUVER. Madam President, a parliamentary inquiry.

The PRESIDING OFFICER. The Senator from Tennessee will state it.

Mr. KEFAUVER. Senate bill 1552 was reported from the Judiciary Committee on July 19. An additional amendment, in the nature of a substitute, changing many sections of the bill, was reported on August 21. Do I correctly understand that, by unanimous consent, the August 21 amendment in the nature of a substitute has replaced the bill reported on July 19 which originally was before the Senate?

The PRESIDING OFFICER. That is correct.

Mr. KEFAUVER. Is the amendment in the nature of a substitute, reported on August 21, now the pending question, and is it subject to amendment?

The PRESIDING OFFICER. That is correct.

Mr. KEFAUVER. Madam President, I have heard that yesterday a unanimous-consent agreement was entered into. I trust that we shall be able to conclude the debate within the time allowed by the unanimous-consent agreement. However, several Senators have informed me that they wish to speak; and for fear that they might not have sufficient time under the limitation in the agreement, I ask unanimous consent that any time left over, during consideration of the amendments, may be added to the time available for general debate on the bill.

The PRESIDING OFFICER. Is there objection?

Mr. HRUSKA. Madam President, reserving the right to object, would that include any amendments which may be submitted, but are not now pending? If so, I can anticipate that the debate might be extended 3 or 4 additional days, and that it would be in violation of the spirit of the unanimous-consent agreement.

Mr. KEFAUVER. I do not know of any amendments which would be offered, but which are not now pending, although certainly I cannot say. But I do not think we shall go beyond the time. Several Senators have complained to me that they might not have sufficient time in which to speak. I have not complained.

Mr. HRUSKA. I suggest, Madam President, that the Senator from Tennessee withhold his request for unanimous consent until a later time.

Mr. KEFAUVER. Very well.

Mr. HRUSKA. Because, I say frankly, I do not know where that request might lead; and at this time we are not short of time.

Mr. KEFAUVER. Very well; I shall do that.

Mr. HRUSKA. I thank the Senator from Tennessee.

Mr. KEFAUVER. Madam President, the speech by the distinguished Senator from Mississippi [Mr. EASTLAND], the chairman of the Judiciary Committee, has accurately defined the provisions of the substitute which was reported on August 21. I wish to take this occasion to say that insofar as the Food and Drug Act is concerned, I think this measure is a good one. It is not as strong in some respects as I should like it to be. It is not as strong in some respects as the President recommended in the seven recommendations in his letter of August 3, or as has been recommended in the latest presentation in executive session by representatives of the Food and Drug Administration.

But this measure constitutes a genuine effort on the part of the majority and the minority of the Judiciary Committee—regardless of what may have happened in the past—and on the part of the President, the Food and Drug Administration, and the staff of the committees—to whom I pay the very highest tribute—and on the part of the industry itself to bring the food and drug law up to date and make it effective and modernized. If ever there was a law which needed to have new teeth put into it and needed to be modernized and made more effective, it is the food and drug law.

In my opinion, the bill now before us will assure the people of the United States safer, more effective and better prescription drugs; that physicians will have more accurate information as to

drugs; that false and misleading statements as to the efficacy and side effects in advertising and promotion material will be eliminated, that physicians will receive recent and accurate information about drugs, and that prescribing by generic names will be made simpler and safer.

The bill gives the Food and Drug Administration much needed powers. It will also go far toward preventing repetition of the near calamity with respect to the drug thalidomide, about which we have read so much, was kept off the market largely by the heroic efforts of Dr. Frances Kelsey.

Drugs are big business, sales of drugs and appliances being more than $3 billion a year, or more than the amount received by doctors.

If the bill is passed, drugs will be safer, purer, and more reliable; they will be more properly tested; and information going to physicians will be more accurate as to side effects, warnings, and contradictions.

I want to compliment all who have had anything to do with bringing out this bill. There has been give and take. There has been an honest effort to bring out a good bill so far as the food and drug provisions of the bill are concerned. I endorse it. I think it is in the public interest. I think it should be passed immediately, for the protection of the public.

If Senators will turn to the original bill, introduced on April 12, 1961, of which I had the privilege of being the chief sponsor, and of which the Senator from Michigan [Mr. HART] was a cosponsor, they will find the bill as originally introduced, with lines drawn through it. As a result of hearings by the Antitrust and Monopoly Subcommittee, refined certain changes and revisions were made.

The original bill was stronger, in most respects, than the bill we have before us at the present time, but the bill we have before us is good legislation and it is strong legislation.

On page 23 of the report of the Judiciary Committee filed on July 19, Senators will find the bill reported by the full committee on that date.

Then, as we all know, on August 3 the President of the United States sent a letter to the Chairman of the Judiciary Committee, the Senator from Mississippi [Mr. EASTLAND], in which he made seven excellent recommendations for strengthening the bill that had been reported by the full committee, the history of which is well known.

The chairman of the full committee immediately instituted hearings, day after day, for the consideration of the President's recommendations. They were considered seriously on their merits, with the aim of getting the best possible bill.

There was some give and take. Concessions were made by all sides. Some recommendations were weakened, but not fatally so. Others were even strengthened.

Thus, the bill is the product of a fine, genuine, and cooperative effort. I want to compliment every Senator who has had anything to do with this bill since the President's recommendations of August 3 came to the Judiciary Committee. Without going into detail, I shall try to state briefly what the bill does.

The first section requires that the Commissioner of Patents—who passes on patents for drugs, but who, unfortunately, does not have pharmacologists or doctors in the Patent Office to inspect and test drugs—may call upon the Secretary of Health, Education, and Welfare to furnish full and complete information concerning any drug application, and the Secretary of Health, Education, and Welfare is authorized and directed to do so. The Secretary, of course, may draw upon the doctors of the National Institutes of Health or other doctors in the Department of Health, Education, and Welfare. This information will be supplied to the Commissioner of Patents for his consideration in passing upon whether or not a drug should be patented.

The next section provides for registration. Companies engaged in the manufacture of drugs are required to file with the Secretary of Health, Education, and Welfare their names and places of business.

With respect to the factory inspection provision, section 4, as matters now stand, Food and Drug Administration inspectors are unable, unless the factory permits, to get certain types of information or have access to certain types of records. This provision is not as strong as had been recommended, but should be generally satisfactory. It applies to pharmacies only to the extent that a pharmacy is engaged in manufacture of drugs.

The provision for factory inspection does not apply to proprietary, that is, over-the-counter drugs. There has been some misunderstanding as to what I said, as chairman of the subcommittee, in connection with proprietary drugs. I did say that the investigation, as started back in 1959, was concerned with the ethical drug industry. The companies we wanted to examine were all manufacturers of ethical drugs, and, of course, some of them also manufactured proprietary drugs. As time went on, I said that certain sections of the bill did not apply to proprietary drugs. But, since some ethical drugs become proprietary drugs, it is difficult to arbitrarily make a distinction in all of the provisions of the food and drug law between proprietary drugs and ethical drugs.

Then, the bill which was filed on April 12, 1961, in some respects did apply to proprietary drugs. Yet, although hearings began in August 1961 and went through February 1962, representatives of the proprietary drug producers did not ask to testify. Then, after the hearings were over, they protested that they had not had a chance to be heard.

It must be recognized that in proprietary drugs there is not the same level of concentration. The consumer is not captive. A person who wants a proprietary drug can shop around. There are usually several different products, selling at different prices. There are several different brands of aspirin, for instance, or mouthwash, or other such products.

In contrast, in ethical drugs, when the doctor writes the prescription in terms of a trade name, the patient has no alternative. He has to purchase the brand which the doctor prescribes and pay for it. As I have said before, in ethical drugs, he who orders does not buy and he who buys does not order. This is not true in proprietary drugs. There the buyer and the orderer are the same.

Furthermore, proprietary drugs are not as dangerous, or otherwise they would not be sold across the counter.

Nonetheless, the factory inspection provision, in my opinion, should apply to proprietary drugs, but since whatever the reason, they did not have a hearing, I agreed to their exclusion from this bill, but I have filed a separate and companion bill applying the factory inspection provision to proprietary drugs. If they are included in the House bill, of course, that provision will go into conference.

Effectiveness, as well as safety, should apply to new proprietary drugs, but proprietaries now on the market are not to be subject under the present bill to the provisions requiring them, upon notice by the FOA, to support their claims for effectiveness. I think they should be so required. That is a matter which can be remedied in conference or by other legislation.

I think that there is validity to the suggestion that proprietary drugs should not have to disclose their exact formula, which may constitute a trade secret.

Quality manufacturing controls are covered in section 5. This provision has been strengthened considerably in comparison to the bill which was reported in July. It is not as strong as the President recommended, or as was recommended by the majority members of the Antitrust and Monopoly Subcommittee. The Department of Health, Education, and Welfare believes it to be adequate and I hope they are proved to be correct.

On this point the bill which the Senate is now considering differs from the bill recommendation by the majority of the Antitrust and Monopoly Subcommittee in that the original bill would have set up certain positive and explicit standards which anybody who wished to get into business would have had to meet. It would certainly have prevented "bathtub operators" from getting into the business and making improper drugs.

In respect to the manufacture of vaccines and other products a license must be secured upon a showing that the manufacturer is qualified to make that particular kind of drug. Under the original bill this same approach of licensing would have been extended to all drugs. It is a good approach.

The present approach calls for a combination of registration, a good inspection system and quality manufacturing controls. If the manufacturers do not live up to these provisions, their products can be seized by the Food and Drug Administration. This is an alternative

with which we are going along. It does represent a great improvement over what exists at the present time.

The next section covers the new drug clearance procedure. As has been stated, many drugs have been approved for sale on the market when they should not have been. Senators can look at page 43 of the report of the Committee on the Judiciary of July 19, 1962, and there they will find a list of drugs which have been approved for marketing but then had to be withdrawn because of serious side effects. Some have caused cataracts, blood disorders, kidney ailments, even death. Though not as dramatic as thalidomide, their side effects were serious.

The reason why some of these drugs have gotten onto the market is that the Food and Drug Administration simply did not have time to consider them, to test them, and to get all of the information needed with respect to the drugs before the time limit ran out and the drug was entitled under the present law to be put on the market automatically.

As stated by the chairman of the committee, the time period would be extended from 60 to 180 days. Thereafter, a 30-day notice could be given of a hearing. A hearing could be held. It would have to be commenced in 90 days. Then, if the new drug application were denied, the company would have a right to go to the U.S. court of appeals.

There would be no mandatory requirement that the Food and Drug Administration allow a drug to be put on the market automatically. There would have to be affirmative action by the Secretary, either approving or disapproving the application or giving notice of a hearing.

Section 7 relates to records and reports as to experience with new drugs and antibiotics. This section would require the keeping of records of experience on new drugs and antibiotics. A company would have to keep records as to the effectiveness and as to the side effects of drugs, and the Food and Drug Administration would have access to that information.

This has been one of the great failures in the past. Records have not been available to the Food and Drug Administration, it could not learn, for example, how many cases of aplastic anemias have been reported to a company because the records were not available to it. This can be a very effective provision.

The next section, section 8, relates to effectiveness and safety of new drugs.

The present situation, as was pointed out by former Secretary Ribicoff, of the Department of Health, Education, and Welfare, is that since 1913 manufacturers of drugs for hogs and other animals have been required to show not only that they were safe but also that they were efficacious for what it was claimed they would do. That has never been the rule as to prescription drugs used by human beings. Animals, but not humans, have been assured of receiving effective drugs.

This section would require, in addition to proof of safety, a showing by substantial evidence, by experts who are experienced in making investigations of the drug involved, that the drug will not only be safe but also will have the effect it purports or is represented to have.

The PRESIDING OFFICER. Does the Senator from Tennessee wish to extend his allotted time? His 20 minutes have expired.

Mr. KEFAUVER. Madam President, I yield myself an additional 15 minutes.

What I have described should have been done a long time ago. It is obviously very much in the public interest.

Theoretically—and it has almost happened in some cases—a certain almost completely inert drug might be safe, and claims might be made for its being efficacious for a certain purpose. Where safety is not involved the Food and Drug Administration has not had a basis for disapproving this new drug application.

Where a product does little or no good at all, physicians, because of claims by manufacturers, might be induced to give them to patients when they ought to be giving them older, proven effective medicines instead. Hence the proposal would be a great step toward the protection of the public health.

Another portion of the section would authorize the immediate suspension of a drug if there were an imminent hazard to public health. For example, suppose thalidomide had gotten on the market, and it was then found, as has unfortunately happened, that thousands of horribly deformed children were being born. Under that provision the Food and Drug Administration could immediately take the drug off the market if a hearing would be held after the action.

There are additional grounds for the withdrawal of a new drug from the market—if the manufacturer does not keep the proper records, or does not correct improper control procedures within a reasonable length of time, or does not comply with other provisions of that section.

Section 9 deals with the conspicuousness of official, or generic, names. We hope that as to nonpatented drugs, the bill will bring prices down substantially. Already as a result in part of the hearings before the Subcommittee on Antitrust and Monopoly, States and hospitals are buying drugs by generic names rather than by trade name. Mr. Ribicoff pointed out that in Connecticut hundreds of thousands of dollars had been saved. Sometimes when a drug is purchased by generic name, the price is one-half or one-third of what it would be under a trade name. Hospitals are buying drugs by generic name. The U.S. Government is buying drugs by generic name. In some cases, it is getting them for one-tenth of what it would otherwise pay if bought by trade name, even though they may be made by the same company and be exactly the same drug.

In times past the generic name has been printed in very small letters, both in advertisements and on the label. One must get a magnifying glass to see the generic name at times. It is often to be found in the corner somewhere in microscopic type. Often, it is simply omitted entirely. We recommended in the Subcommittee on Antitrust and Monopoly that the generic name be printed in letters as large as the trade name. Unfortunately, however, some generic names are very long. Finally, as a compromise, it was agreed that the Secretary should establish regulations that the generic name must be carried in print at least half as large as the trade name on the label as well as in advertisements.

Doctors would be able to see more readily the generic name of drugs, if they are in larger type. Knowing that all drug plants are inspected fully and have good control procedures, and that necessary safeguards are provided, there should be no doubt in the minds of any reasonable physicians that when they buy drugs by generic name instead of trade name, they are getting good and safe drugs.

With reference to section 10, as matters now stand, some drugs have no generic names; some have two or three. It is the company which coins the generic name. The U.S. Pharmacopoeia tries to persuade manufacturers to agree to generic names, and it has done a fine job. The AMA is setting up a committee to work on that subject. But, at the present time, unless the company agrees, nothing can be done about it. Under this section after the U.S. Pharmacopoeia has worked with the company and has been unable to reach a satisfactory generic name, the Secretary of HEW would have the standby authority to establish the generic name. In addition the Secretary would be required to make reviews of all the generic names—some of which are several inches long and entirely unpronounceable—and provide more simplified generic names so that physicians can remember, pronounce, and spell them.

Under section 11 advertisements must be accurate with respect to what it is said a drug will do. An advertisement must state the side effects and effectiveness, or a summary thereof, which must be approved by the Secretary of Health, Education, and Welfare.

This relates to advertisements in journals, promotion material, and any other similar type of material, including what is carried on the label, including the accompanying material.

We found cases concerning drugs that were addictive and in which nothing at all was said about side effects, and also cases in which drugs had other harmful side effects, but it was explicitly stated that there were no adverse side effects. That has been misleading to the physician. This proposal is a very important part of the bill. It will provide the physicians with honest and useful information.

There was an outdated provision in the law that longstanding antibiotics had to be batch-tested. But the new antibiotics, introduced since the law was passed, and are more in need of batch-testing than the old ones, were not covered. Section 12 requires the testing of all antibiotics, unless, as a

result of experience, the Secretary of Health, Education, and Welfare finds that any particular one no longer needs to be tested.

Madam President, insofar as the Food and Drug Administration is concerned, I think we have here a good bill, which will do the job required of it.

Later I shall discuss three amendments. If Senators will examine the individual views of the Senator from Colorado [Mr. CARROLL], the Senator from Connecticut [Mr. DODD], the Senator from Michigan [Mr. HART], the Senator from Missouri [Mr. LONG] and myself—the majority members of the Antitrust and Monopoly Subcommittee—in the earlier committee report, beginning at page 33, they will see the amendments that we had in mind offering at that time.

I wish to say that the first three have been adequately taken care of after reconsideration of the bill by the Judiciary Committee, following the President's recommendations. Later on I shall offer an amendment, which I believe will be acceptable, to make it possible for the Food and Drug Commissioner or to require, if he deems it necessary, the testing of a new drug on animals before it is actually given to human beings. If thalidomide had been tested on rabbits, before the drug was introduced, the resulting deformities of baby rabbits would have been discovered so that this whole catastrophe would have been avoided in the countries where it occurred. Apparently, some thalidomide children are being born in the United States also.

The second amendment relates to making available the agreements with reference to the settlement of interference proceedings in the Patent Office, so that the Department of Justice and the Federal Trade Commission can see if the Sherman Act or other antitrust laws have been violated.

This amendment, dealing with interference proceedings, would do much to bring the price of prescription drugs down, because we have found that in many cases when several companies apply for a patent, they agree that one of them will get it, and the others withdraw. Then the company that gets the patent usually licenses the others, but they all sell at the same high price.

The third amendment would require compulsory licensing after 3 years of a qualified applicant upon the payment of 8-percent royalty and open a finding by the Federal Trade Commission that the drug is sold by the manufacturer to the druggist at more than 500 percent of the production and research cost.

Madam President, I wish at this point to pay tribute to the very competent staff who worked in the entire investigation, including Dr. John Blair, Horace Flurry, Paul Rand Dixon—before he left the subcommittee—Dr. E. Wayles Browne, Jr., Dr. Irene Till Hamilton, Mrs. Lucille Wendt, Mrs. Emily Zayyani and Miss Jo Anne Youngblood. Their work was supplemented from time to time in particular aspects by excellent contributions from Bernard Fensterwald, Jr., Mrs. Dorothy Goodwin, Winslow Turner, George Clifford, Dr. Walter Measday, Herman Schwarts and Paul Green. I also wish to express appreciation for the work of the minority staff members—Peter Chumbris, Ronald Raitt, Nicholas Kittre and James Bailey. All worked devotedly on all or some parts of this long and difficult investigation.

The PRESIDING OFFICER. The time of the Senator has expired.

Mr. KEFAUVER. I yield myself 15 minutes on the bill.

The staff started its staff work early in 1959. The first hearing was held on December 7, 1959. For some 2 years we held investigatory hearings, and for almost another year we held hearings on the bill itself. There has been a great deal of acrimony, and much criticism has been heaped upon the chairman and upon some of the majority members of the staff. But we felt we were doing a good job. As far as I am concerned, that is past history. The record is available for anyone who is interested.

I believe that anyone who reads the 13 volumes of hearings in the investigation and the 7 volumes of hearings on the bill as well as the report, will find them detailed and accurate. I have had the privilege of heading many investigations, but I have never known a staff that has worked more effectively, conscientiously and accurately.

Every figure and every statement, aside from typographical or inadvertent errors, is based on fact. The tables and charts are accurate. I cannot pay too high a tribute to those who did the work.

To show what was taking place in the Food and Drug Administration, in May 1960 we held hearings with reference to Dr. Henry Welch, who had been the head of the Antibiotic Section of the Food and Drug Administration. There had been some rumors that he had been receiving honorariums for editorial work in connection with several medical publications, in one of which he was associated with Dr. Felix Marti-Ibanez. John Lear, science editor of the Saturday Review, wrote some articles about it. Mr. John Connor, the president of the Merck Co., and then the chairman of the Pharmaceutical Manufacturers Association, became alarmed about a possible conflict of interest. In 1956 Mr. Connor called it to the attention of the Food and Drug officials. Apparently he did not have the full facts. Perhaps he could not get them. Then the Food and Drug Administration released a statement to the effect that Dr. Welch was not going to accept any large fees in the future. But they never asked him how much he had received. During our hearings, we found that he had received some $280,000 from the magazine of which he was half owner, based on reprints of articles paid for by the very companies that he was supposed to be regulating.

It was estimated that half went to the cost of publishing the reprints, and the other half was divided 50–50 between him and Dr. Felix Marti-Ibanez. At about the time of our hearings into the matter he resigned. The matter now is the subject of a grand jury investigation.

I have always thought that the Food and Drug Administration, and its head, Mr. George Larrick, should have pursued the matter further and received the full information at the time the situation was first brought to their attention several years earlier. But that is past history. That kind of conflict of interest is highly reprehensible. I am confident there are no present similar cases in the Food and Drug Administration.

When Mr. Flemming, then Secretary of Health, Education, and Welfare, appeared before our committee, he stated he would appoint two committees, the Bronk committee, which made an outside or "scientific" investigation and the Kendall committee which made an "inside" investigation. They did a great deal of work, but I do not know exactly what if anything, has been done as a result of their recommendations and reports.

During our investigatory hearings the pharmaceutical manufacturers testified that everything was all right as it was. They were against everything we proposed. The companies and their associates, in their advertisements and public relations, were very critical of the staff of the committee. But it should be said to their credit that when the bill was introduced in April 1961—and the bill was not one recommended by the Food and Drug Administration, although the Food and Drug officials later recommended most of its provisions.

The bill was aimed at reducing the unreasonably high prices of drugs, at providing safer, sounder, more dependable drugs, and at insuring advertising that was truthful concerning the purpose of drugs and their side effects for the benefit of physicians and the Nation.

The bill before the Senate accomplishes two of those objectives. It does not accomplish anything with respect to lowering the price of patented drugs. The patent provisions were eliminated.

It should be said to the credit of the pharmaceutical manufacturers that when they returned to testify on the bill, they accepted about three-fourths of the provisions of the bill. They had become convinced that some reforms were needed.

In contrast, representatives of the American Medical Association who testified on the bill, stated that in this entire omnibus bill there was nothing which they could support. In my opinion, 90 percent of the doctors of the Nation, including members of the American Medical Association, favor the bill which is now before the Senate. Many members of the AMA appeared before the committee, including members of its own council on drugs, outstanding physicians and specialists in their respective fields, to favor the bill. I pay tribute to those outstanding physicians who took the time and trouble to come here to help us with our investigation and to produce a good bill.

The committee covered all the important ethical drugs, including the steroids, oral antidiabetic drugs, tranquilizers, and antibiotics—the wonder drugs which cost so much money.

That distinguished medical journal, the New England Journal of Medicine carried series of six editorials endorsing and recommending the passage of most of the bill.

The report on the drug investigation, including the individual views of several members of the subcommittee, was circulated in March 1961, and finally filed on June 27. It contains a wealth of information about the entire drug field.

Before introducing the bill, as a result of the investigation, I spoke with the distinguished senior Senator from Alabama [Mr. HILL], chairman of the Committee on Labor and Public Welfare, and pointed out to him that, as of that time, three of the provisions dealt with antitrust or patent matters within the jurisdiction of the Committee on the Judiciary, and that others dealt with the Food and Drug Act. I discussed with him recommending that the FDA section be referred to the Committee on the Judiciary. The Senator from Alabama replied that he was very busy with other legislative matters and would be glad to have the Committee on the Judiciary handle that part of the bill. So he joined with me in asking that the Parliamentarian refer the bill to the Committee on the Judiciary, and it was so referred. The Senator from Alabama is an outstanding leader on problems of health research, both in the Committee on Labor and Public Welfare and the Committee on Appropriations. His backing, help, and suggestions have been appreciated throughout the investigation. There have been no committee conflicts.

Because two of the provisions in the original bill related to patent policy, I spoke with the distinguished senior Senator from Arkansas [Mr. MCCELLAN], chairman of the Subcommittee on Patents, and he agreed that the Subcommittee on Antitrust and Monopoly should handle the whole matter. He said he was busy with other problems, particularly in the Committee on Government Operations, and that he would be glad to have the Subcommittee on Antitrust and Monopoly proceed with that part of the investigation. Thus, our subcommittee heard the testimony of a number of patent lawyers with respect to the patent sections, and the results of that investigation are contained in the report.

Representative CELLER introduced a companion bill in the House of Representatives on the same day the bill was introduced in the Senate.

The bill now before the Senate accomplishes two of the stated objectives of the subcommittee. In January 1962, in his message to the Congress, the President of the United States said that action should be taken to reduce the high cost of prescription drugs. Following that came the President's consumer message of March 13, 1962, describing in general language desirable objectives in connection with drugs.

About that time, the then Secretary of Health, Education, and Welfare, Mr. Ribicoff, made an excellent statement before our committee, endorsing strongly all the food and drug provisions of the bill. Although he thought that the patent and antitrust provisions of the bill were generally in the public interest, and he favored the objectives which they sought, he said they were not within the jurisdiction of his Department and that he would not, therefore, wish to express an official position with respect to them. Throughout the time he was Secretary of Health, Education, and Welfare, he gave the subcommittee consistent and strong backing. Mr. Larrick, Commissioner of the Food and Drug Administration, testified in favor, generally, of the food and drug provision. Likewise, he did not express any position as to the patent or the antitrust sections of the bill.

The bill was considered by the Antitrust and Monopoly Subcommittee. I wish to thank the Senator from Nebraska [Mr. HRUSKA] and the Senator from Illinois [Mr. DIRKSEN] for suggesting improvements in the bill at that time. But when the bill was reported, it was approved by a vote of 5 to 3, along party lines.

Then the bill was sent to the full Judiciary Committee. As everyone knows, the three patent sections then were referred to the Subcommittee on Patents, which recommended against two of them and in favor of one of them. But the full Judiciary Committee eliminated all three.

Senators are familiar with what occurred in July in the Judiciary Committee, which resulted in the reporting of the bill and the submission of a report on July 19.

The PRESIDING OFFICER. The time the Senator from Tennessee has yielded to himself has expired.

Mr. KEFAUVER. Madam President, I yield myself 5 additional minutes.

The PRESIDING OFFICER. The Senator from Tennessee is recognized for 5 additional minutes.

Mr. KEFAUVER. Madam President, as I have said, everyone has cooperated now in trying to bring before us a very fine bill, insofar as the food and drug provisions are concerned.

On April 10, the President wrote a letter in which he generally recommended the bill as reported by the Antitrust and Monopoly Subcommittee. I ask unanimous consent that the letter be printed at this point in the RECORD.

There being no objection, the letter was ordered to be printed in the RECORD, as follows:

THE WHITE HOUSE,
Washington, D.C., April 10, 1962.

Hon. JAMES O. EASTLAND,
U.S. Senate,
Washington, D.C.

Dear SENATOR: In the message I sent to the Congress on March 14, I called attention to the need for new legislative authority to advance and protect the interests of consumers in the marketing of drugs.

S. 1552, which is now pending before your committee, incorporates the major recommendations I made. It will strengthen and broaden existing laws in the food and drug field, contribute toward better, safer and less expensive medicines, and establish a better system of enforcement. As you know, the bill is the outgrowth of 28 months of intensive investigation and hearings by your Subcommittee on Antitrust and Monopoly. I believe that early passage of this legislation will substantially improve the ability of the drug industry to serve the Nation and help provide consumers with quality drugs at low, competitive prices.

I understand that the members of the Subcommittee on Patents have decided that the compulsory licensing feature of the legislation requires further study and consideration. I would hope that this would not, however, delay enactment of the other provisions of the bill—provisions which will establish necessary safeguards to assure the reliability and effectiveness of drugs placed on the market, provide for standardization of drug names, and thereby encourage physicians to prescribe drugs by nonproprietary rather than by brand names, require disclosure of adverse as well as beneficial effects of drugs in drug promotion, and assure consideration of therapeutic effectiveness in the granting of patents for drugs that are modifications of other drugs.

The message I sent to the Congress made several other suggestions which, it would seem to me, might appropriately be included in the bill now before your committee. They are:

1. Drug manufacturers should be required to keep records on and report to the Department of Health, Education, and Welfare any indications of adverse effects from the use of a new drug or antibiotic.

2. The Department of Health, Education, and Welfare should be empowered to withdraw approval of a new drug on the basis of a substantial doubt of its efficacy or safety.

3. The provisions requiring drug manufacturers to maintain facilities and controls to assure the reliability of their product, and to institute more effective inspection to determine whether drugs are being manufactured in accordance with the law, cannot feasibly be limited to a particular class of drugs and should therefore be made applicable to over-the-counter as well as prescription drugs.

4. An enforceable system of preventing the illicit distribution of habit-forming barbiturates and amphetamines should be provided.

The need for these amendments is based upon the accumulated years of experience of the Food and Drug Administration, and they appear to be properly within the scope of the subject matter dealt with in the extensive hearings of the Subcommittee on Antitrust and Monopoly.

In addition, I recommend two minor procedural changes:

1. In the section having to do with the rendering of advisory opinions by the Department of Health, Education, and Welfare to the Patent Office on the therapeutic effect of modifications and combinations, I suggest that the requirement providing the applicant with an opportunity for a plenary hearing be deleted. Under the provisions of S. 1552 in its earlier form, the Secretary's finding was conclusive and therefore should have required a formal hearing. But since the bill in its present form requires no binding decision to be made by the Secretary, the requirement of the hearing seems inappropriate and would tend to unduly delay the rendition of the Secretary's purely advisory opinion to the Commissioner. The action of the Commissioner is, of course, subject to well established de novo judicial review.

2. The provision requiring the filing of patent agreements with the Commissioner of Patents should more properly be in the form of an amendment to the Patent Act rather than the Sherman Act.

I have asked the Department of Health, Education, and Welfare to transmit to you promptly any additional recommendations to strengthen, clarify, or improve the bill that it may have and that will not require

additional hearings or substantially delay action on the bill.

It would not appear that the consideration of these proposed changes should occasion any further delay in the approval of this important measure.

With the above changes, S. 1552 adequately deals with the most pressing problems in the drug field, and it is my sincere wish that it be enacted during the current session of the Congress. Your cooperation and assistance to this end will be greatly appreciated.

Sincerely,

JOHN F. KENNEDY.

Mr. KEFAUVER. Madam President, we are also familiar with the fact that on August 4 the President wrote to the Senator from Mississippi [Mr. EASTLAND] a subsequent letter, making seven specific recommendations. Since then, regardless of what happened before, there has been a genuine effort, on all sides, to work out a strong, effective bill; and that has been done. The results of this effort are set forth in the supplemental report which I hope Senators will read—part 2 of Senate Report No. 1744.

In May, on the recommendation of the Food and Drug Administration, a bill was introduced by Representative OREN HARRIS, the chairman of the House Committee on Interstate and Foreign Commerce. That bill has many provisions similar to those in the measure now before us, although there are a number of differences. I am gratified that Representative HARRIS is holding hearings on that bill. I hope that as a result of the hearings and as a result of the conference to be held between the House and the Senate, the bill will be passed by both Houses of the Congress and will be sent to the President.

Madam President, in concluding this part of my presentation, let me say there are many important measures before the Congress, but none is more important than this for the protection of the public.

Madam President, we are about to accomplish a great deal; and I wish to thank the majority members and the minority members and the staff members of the subcommittee and the full committee. I wish to say that in recent weeks Tom Collins of the full Judiciary Committee has virtually worked his heart out; and I desire to thank all who have made this measure possible.

The PRESIDING OFFICER. The time the Senator from Tennessee has yielded to himself has expired.

Mr. SCOTT. Madam President, to the committee amendment, I offer an amendment which I send to the desk and ask to have stated.

The PRESIDING OFFICER. The amendment to the committee amendment will be stated.

The LEGISLATIVE CLERK. In the committee amendment on page 2, in line 23, it is proposed to strike out "December 31" and insert "June 30."

Mr. KEFAUVER. Madam President, I had difficulty hearing the amendment read. Is it offered to the bill?

Mr. SCOTT. Madam President, if the Senator from Tennessee will let me proceed for a moment with my remarks I think he will understand my purpose in offering the amendment. I expect to withdraw it at the conclusion of my remarks.

Mr. EASTLAND. Madam President, let me ask how long the Senator from Pennsylvania wishes to speak.

Mr. SCOTT. Between 15 and 20 minutes.

Mr. EASTLAND. Madam President, I ask unanimous consent that the Senator from Pennsylvania may proceed for 20 minutes. If consent is given, it will not be necessary for him to offer the amendment, which I judge is only a pretext.

Mr. KEFAUVER. Madam President, reserving the right to object, let me say—as I have previously stated—that several Senators were disappointed at the time limitation which was applied. Under the circumstances, why do we not let the Senator from Pennsylvania speak on his amendment?

Mr. SCOTT. I have no objection, if I can obtain unanimous consent to speak for 15 or 20 minutes on the bill.

Mr. EASTLAND. Madam President, I have propounded a unanimous-consent request.

The PRESIDING OFFICER. Is there objection to the request of the Senator from Mississippi?

Mr. HUMPHREY. Madam President, I shall be compelled to object; otherwise, there would be no use in having the unanimous-consent agreement entered into. The Senator from Pennsylvania has offered an amendment, and he is entitled to speak on it.

The PRESIDING OFFICER. Objection is heard.

Mr. DIRKSEN. Madam President, if the distinguished Senator from Pennsylvania will withdraw his amendment—for I suppose it is only a pro forma amendment——

Mr. SCOTT. That is correct.

Mr. DIRKSEN. If he will withdraw it, I will yield him 20 minutes on the bill.

Mr. SCOTT. I shall be happy to do so, with the understanding that the distinguished Senator from Illinois will yield me 20 minutes on the bill.

Mr. DIRKSEN. Madam President, I yield the Senator from Pennsylvania 20 minutes on the bill.

The PRESIDING OFFICER. The Senator from Pennsylvania is recognized for 20 minutes on the bill.

Mr. SCOTT. Madam President, I now withdraw my amendment.

The PRESIDING OFFICER. The amendment of the Senator from Pennsylvania is withdrawn.

Mr. SCOTT. Madam President, in my opinion this is a good bill. It has been carefully considered at great length in the subcommittees and in the Judiciary Committee. Many provisions of the original bill have been revised, altered, or omitted, in favor of carefully drawn legislation.

The President's wishes in regard to certain amendments, which have been referred to as the President's amendments, have been recognized and carried out in a bipartisan fashion. As a result, we now have what I believe is a far better bill than the original one, by virtue of the care and attention which have been given to the bill by the members of the committee, and also by reason of the expert assistance which has been rendered to us by the staff members.

COMMITTEE STAFFING

Madam President, in referring to the staff, I should like to address myself to the entire problem of minority staffing. I manage as well as I can with the assistants I have, and I have been considerately treated by the chairmen of my committees. We have a large and busy office, although we are not always able to do all that I should like to do as a Senator. But certainly it is true that if there were more minority staff members on the committees of which I am a member and on the other committees, more constructive contributions might be made by those of us on the minority side.

It is a most important problem if Congress is to meet its obligation to provide adequate research and staff assistance on a fair and equitable basis to members of both parties. As one who has served as a Member of both the House of Representatives and the Senate, I observe that this situation has too long suffered from neglect and indifference.

All Senators are familiar with the objectives of the Legislative Reorganization Act of 1946 in regard to committee staffs. The staffs were to be nonpartisan, and selected and promoted solely on the basis of merit. The report accompanying the act recommended that committee staff personnel "should be appointed without regard to political affiliation and should not be dismissed for political reasons." The intention was to establish a type of legislative civil service headed by a director of congressional personnel, but this body amended the act, empowering each committee of the Senate and House to choose its staff by majority vote. The ideal of the professional nonpartisan staff remained as the core of the resources—including the Legislative Reference Service and Legislative Counsel—that were to enable Congress to fulfill its historic and proper function in the legislative process.

Ernest S. Griffith, dean of the School of International Service of the American University, and former Director of the Legislative Reference Service of the Library of Congress, commented optimistically on the position of the Congress following the Legislative Reorganization Act. He suggested that—

> Congress has mastered, or has provided itself with the tools to master, the problem of assuring itself an unbiased, competent source of expert information and analysis which is its very own. By the same token it has mastered the problem of recapturing its constitutional role as the independent policy determiner, a self-respecting coequal of the bureaucracy, its legal master in policy matters, and in practice its competent partner or its intelligent critic. Congress has done this without sacrificing its own amateur standing as the elected representatives of the people. This has been no small contribution to the content of governance in a complex and technical age.

Since this has by no means occurred, I take a much less sanguine view of our situation. Not only have we failed to

Safety and effectiveness of self-managed medication abortion provided using online telemedicine in the United States: A population based study

Abigail R.A. Aiken,[a,] Evdokia P. Romanova,[b] Julia R. Morber,[c] and Rebecca Gomperts[b]*

Published online 17 February 2022
https://doi.org/10.1016/j.lana.2022.100200

Summary

Background As access to clinical abortion care becomes increasingly restricted in the United States, the need for self-managed abortions (i.e. abortions taking place outside of the formal healthcare setting) may increase. We examine the safety, effectiveness, and acceptability of self-managed medication abortion provided using online telemedicine.

Methods We retrospectively examined records of the outcomes of abortions provided by the sole online telemedicine service providing self-managed medication abortion in the U.S. We calculated the prevalence of successful medication abortion (the proportion who ended their pregnancy without surgical intervention); the prevalence of serious adverse events (the proportions who received intravenous antibiotics and blood transfusion); and assessed whether any deaths were reported to the service. We also examined the proportions who were satisfied and felt self-management was the right choice.

Findings Between March 20th 2018 and March 20th 2019, abortion medications were mailed to 4,584 people and 3,186 (70%) provided follow-up information. Among these, 2,797 (88%) confirmed use of the medications and provided outcome information, while 389 (12%) confirmed non-use. Overall, 96.4% (95% CI 95.7% to 97.1%) of those who used the medications reported successfully ending their pregnancy without surgical intervention and 1.0% (CI 0.7%-1.5%) reported treatment for any serious adverse event. Among these, 0.6% (CI 0.4% to 1.0%) reported receiving a blood transfusion, and 0.5% (CI 0.3% to 0.9%) reported receiving intravenous antibiotics. No deaths were reported to the service by family, friends, the authorities, or the media. Among 2,268 who provided information about their experience, 98.4% were satisfied and 95.5% felt self-management was the right choice.

Interpretation Self-managed medication abortion provided using online telemedicine can be highly effective with low rates of serious adverse events. In light of increasingly restricted access to in-clinic abortion in the U.S., it may offer a safe and effective option for those who cannot access clinical care.

Keywords: Abortion; Self-managed; Online telemedicine; United States

Introduction

Abortion access is approaching cross-roads in the United States. The Supreme Court is currently considering an enacted Mississippi law that bans abortion at 15 weeks' gestation[1] and recently allowed a 6-week ban in effect in Texas to stand.[2] Although the right to choose established by *Roe v. Wade* in 1973 still currently stands, access to abortion in the clinic setting is moving further out of reach due to restrictive state legislation. One hundred and eight abortion restrictions were enacted in state legislatures in 2021, more than any other year since *Roe*.[3] These laws make clinical abortion harder to access by imposing waiting periods and medically unnecessary medical tests on patients and requiring clinics and providers to conform to unnecessary administrative regulations.[3]

Research in context

Evidence before this study

In many U.S. states, access to abortion in the clinic setting is becoming increasingly restricted. In the face of dwindling access, there is evidence that people in the United States are self-managing their abortions (i.e. sourcing and conducting them outside of the formal healthcare setting). While self-managed abortions have been happening in North America for centuries using botanicals, and later misoprostol, one important contemporary method of self-management is the use of online telemedicine to provide the abortion medications mifepristone and misoprostol. No studies, however, have examined the safety, effectiveness, and acceptability of self-managed medication abortion using this model in the United States. We conducted a systematic search of MEDLINE and PubMed using the MeSH terms 'Abortion', 'Self-managed', 'United States', 'Safety' and 'Effectiveness' with no language or date restrictions, and found no relevant reports as of September 2021. Using data from the sole online telemedicine organization that provides self-managed medication abortion to people in the United States, we provide here an analysis of the reported outcomes of self-managed abortions provided between March 20th 2018 and March 20th 2019. We report both the proportion that resulted in successful termination of pregnancy and the proportion that resulted in serious adverse events. We also describe the acceptability of these self-managed abortions based on user experience.

Added value of this study

This study presents the first evidence that self-managed medication abortion provided through online telemedicine in the United States is effective, acceptable to users, and has a very low rate of serious adverse outcomes. This evidence adds to a global body of data showing that self-managed medication abortion is safe and effective. In this study, 70% of those to whom medications were shipped provided follow-up information about their abortions, and among these 2,797 (88%) confirmed use of the medications and provided outcome information, while 389 (12%) confirmed non-use. Among those who used the medications, 96% were able to end their pregnancies without surgical intervention from a clinical provider, a rate comparable with the in-clinic setting. Treatment for serious adverse events was uncommon with 1% receiving a blood transfusion or intravenous antibiotics. No deaths were reported to the service by family, friends, the authorities, or the media. Among the 2,268 people who provided information about their experience, 98% expressed satisfaction with their abortion experience and 96% said it was the right choice.

Implications of all the available evidence

As restrictive abortion legislation continues to create substantial barriers to in-clinic abortion in many U.S. states, abortion self-managed outside of the formal healthcare setting is an important option for those who cannot or prefer not to access clinical care. This study provides key evidence for clinicians, policymakers, and the public that safe, effective, self-managed medication abortion is available in the United States. However, people who self-manage are still vulnerable to legal risks and in some states unjust prosecutions have occurred. Rather than being subject to criminalization, self-managed abortion should be a legitimate part of a spectrum of options for abortion care that must be made available in the United States.

Recent research suggests that one possible consequence of increasing barriers to in-clinic abortion is that more people will self-manage.[4,5] A self-managed abortion is one that takes place outside of the formal healthcare setting, and includes a spectrum of methods, such as the abortion pills mifepristone and/or misoprostol, menstrual extraction, botanicals, herbs, vitamins, beverages, and ingestion of toxic substances and physical injury. Self-managed abortion has been happening in North America for centuries and recent estimates suggest that approximately 7 percent of U.S. women have attempted a self-managed abortion in their lifetime.[6]

An important consideration for people who self-manage is the safety and effectiveness of the method they are using. Since 2018, self-managed abortion using mifepristone and misoprostol has been available through online telemedicine in the U.S. via a non-profit service called Aid Access.[7] The service received 57,506 requests from people in the U.S. in its first two years of operation.[4] While clinic-based and physician-led telemedicine models that provide medication abortion within the formal healthcare setting are also available in some U.S. states,[8–10] Aid Access is distinct from these service models because it offers self-managed abortion, operating outside of the formal U.S. healthcare setting in all 50 states. Provision of self-managed medication abortion using similar services, such as Women on Web and Women Help Women, has been explored in other countries,[11–13] but outcomes have not been studied in any U.S.-based population. Using data from Aid Access, the objective of this study is to examine the safety, effectiveness, and acceptability of self-managed medication abortion provided via online telemedicine in the U.S.

Methods

Data

Aid Access currently provides medication abortion up to 10 weeks gestation at the time of request, which is made using an online consultation form. A doctor reviews the form to ensure no contraindications and provides a prescription of 200mg mifepristone to be taken orally and 800mcg misoprostol to be taken sublingually, along with an additional 800mcg of

misoprostol for use if needed, according to the World Health Organization (WHO) recommended dosage regimen for medication abortion.[14] A partner organization then mails the medications along with usage instructions. A donation of $110 to support the service is requested, but those who cannot afford it are asked to donate what they can. An online non-clinical helpdesk team is available to answer questions. Four weeks after receipt of the medications, users are invited to report their abortion outcomes using an online evaluation form or via an email to the helpdesk.

Our dataset includes all U.S. residents to whom abortion medications were shipped between March 20th 2018 and March 20th 2019. Since Aid Access is the sole organization of its kind serving the U.S., our sample represents the universe of people in the U.S. self-managing a medication abortion using online telemedicine outside the formal healthcare system. De-identified data from the online consultation form, follow-up form, and emails were provided by Aid Access. All individuals in the sample consented to the anonymized use of their data at the aggregate level for research purposes.

The online consultation form includes self-reported information about age, weeks' gestation, parity, feelings about the decision to have an abortion, any medical contraindications, whether or not a person has had an ultrasound scan for the current pregnancy, knows someone who can be with them during their abortion, and lives within 60 min of a hospital. We categorized age as "Under 20 years", "20–24 years" and into 5-year increments thereafter, with a final group of "40 years and over". Gestation was reported as "< 7 weeks" or "7–10 weeks", which represents gestation at the time of the consultation. Those who did not have an ultrasound scan used a pregnancy calculator based on their last menstrual period. Number of children was reported numerically, and we constructed categories of "0" and "1 or more". Feelings about the decision to have an abortion were reported as "I can cope with my feelings regarding my decision" and "I have some worries about my decision and would like further information". Those who expressed worries were directed to appropriate sources of information. Medical history questions included the presence of any contraindications (e.g. bleeding disorders, inherited porphyrias, allergies to mifepristone or misoprostol) or medical conditions that required additional medical screening (e.g. having an IUD in place or having a suspected STI).

The evaluation form is based on similar follow-up instruments used in the clinical setting and is sent to participants 4 weeks after receipt of the medication. Available information included the number who confirmed delivery of the medications, the number who confirmed whether or not they used the medications, and the outcome of the pregnancy or abortion. Those who confirmed using the medications were asked about gestation at the time of use, whether or not they were still pregnant, whether or not they received any clinical intervention to help end the pregnancy (Dilation and Curettage (D&C) or vacuum aspiration), and any other treatment they received for a possible serious adverse event following their abortion. Those who confirmed not using the medications were asked about the outcome of their pregnancy.

Analysis

We compared available clinical and demographic characteristics among those who provided follow-up information and those who did not. We conducted chi-squared difference of proportions tests using an alpha level of 0.05 to indicate statistical significance to check for any systematic differences between the two groups that might affect the outcome of their abortions.

Among those for whom self-reported information on outcomes was available, we examined these in the overall sample as well as constructing two groups: those reported a gestation of 10 weeks or fewer at the time of using the pills, and those who reported a gestation of over 10 weeks. This threshold was chosen to allow comparison with outcomes of medication abortion in the clinic setting, where the mifepristone-misoprostol combined regimen is approved by the FDA through 70 days gestation.[15] While requestors must be 10 weeks pregnant or less at the time of filling out the consultation form, the medications may take 1–3 weeks to arrive and thus some individuals may be over 10 weeks at the time of use. We first examined the proportion who reported that they were no longer pregnant, and then the proportion for whom medication abortion was successful according to the standard definition of success in the Medical Abortion Reporting of Efficacy (MARE) Guidelines, *i.e.* the proportion who were able to expel their pregnancy without the need for surgical intervention.[16] Next, we examined the prevalence of reported serious adverse events, following to the extent possible the categories defined by Cleland et al.[17] Information was available on receipt of IV antibiotics and blood transfusion and we also assessed whether any deaths were reported, recognizing that we are relying on reporting by friends, family members, the authorities, or the media. We calculated point-estimates and exact binomial 95% confidence intervals (CI) both for the overall population and for the binary gestation categories available in our dataset. To compare outcomes between the two gestation groups we used Fisher's exact test and considered findings statistically significant at an alpha level of 0.05.

The follow-up form also included a series of "yes/no" questions asking about the abortion experience, including satisfaction with the service, and whether: using it had been the right choice; affording the full donation (which at the time of data collection was $90) had been difficult; enough information had been provided about

the abortion process; and enough support was available from family and friends. We calculated the proportions of people answering "yes" and "no" to each question.

Data analysis was conducted using Stata version 15.1.[18] The Institutional Review Board of the University of Texas at Austin approved the study.

Role of the funding source

Neither funding source that supported the investigators during the study had any involvement in study design, data collection, analysis or interpretation, and had no role in the writing of this manuscript or the decision to submit for publication.

Results

Between 20th March 2018 and 20th March 2019, Aid Access provided mifepristone and misoprostol by mail to 4584 people. Among these, 3,186 provided follow-up information for a follow-up rate of 70% (Figure 1). Of those who provided follow-up information, 2797 (88%) confirmed use of the medications and provided information on the outcome of their abortion, while 389 (12%) confirmed non-use of the medications. Reasons for non-use included spontaneous pregnancy loss (45%), accessing abortion care in a clinic (21%), deciding to continue the pregnancy (19%), shipping delays (6%), having self-managed using another method (3%), the pregnancy being a false alarm (3%); and experiencing symptoms of an ectopic pregnancy, for which they reported receiving clinical treatment (0.5%). An additional 3% did not specify a reason for not using the medications.

The demographic and clinical characteristics of those who provided follow-up information vs. those who did not are shown in Table 1. Among those who provided follow-up, 94.9% reported being under 7 weeks pregnant at the time of requesting the service. The majority (63.1%) were aged under 30. Virtually all (99.4%) felt OK about their decision to have an abortion and none had any contraindications to abortion medications. A greater proportion of those who provided follow-up were aged 20 or over (89.1% vs. 85.4%, $p < 0.01$), already had children (58.1% vs. 48.4%, $p < 0.001$), and had not received an ultrasound scan prior to their abortion (90.4% vs. 87. 6%, $p=0.005$). There were no significant differences in any characteristic, including gestation, that might reasonably bias the follow-up group towards more favorable outcomes.

Among those who confirmed use of the medications ($n=2,797$), 2402 (86%) reported being under 10 weeks pregnant, while 395 (14%) reported being 10 weeks pregnant or more. Overall, 99.0% of all those who used the medications reported having ended their pregnancies (Table 2), and 96.4% reported a successful medication abortion (i.e., ending their pregnancies with no surgical intervention). There was no significant difference by gestation in the proportion reporting ending their pregnancies (99.1% vs. 98.2%, $p=0.097$), but those who were less than 10 weeks pregnant had a lower rate of surgical intervention compared to those who were 10 weeks or more (2.0% vs. 6.1%, $p < 0.001$). Overall, among the 72 people who reported receiving a procedure to help end their pregnancy, 54 received D&C, 12 received aspiration, and 6 did not specify procedure type. No ectopic pregnancies were reported among those who confirmed use of the medications.

Potentially serious adverse events were not common (Table 3). Overall, 29 people (1.0%) reported experiencing any serious adverse event. Of these, 18 people (0.6%) reported receiving a blood transfusion and 15 (0.5%) reported receiving IV antibiotics (4 people reported receiving both). No deaths were reported by family, friends, clinicians, the authorities, or the media. Rates of adverse events overall were more common among those who reported a gestation of 10 weeks or more as compared with those who were less than 10 weeks (2.3% vs. 0.8%, $p=0.009$).

Among the 2797 people who provided follow-up information, 2268 (81%) reported on the acceptability of their self-management experience (Table 4). Almost

Discussion

We used a data set containing all available outcomes of self-managed medication abortions provided through online telemedicine, outside the formal healthcare system, in the U.S. for one year. We found that abortions self-managed using this model were highly effective, with reported success rates comparing favorably with medication abortions carried out up to 10 weeks within the formal U.S. healthcare setting.[19] The reported prevalence of serious adverse events was very low, and the users of service reported high levels of satisfaction.

Our results offer the first insight into the outcomes of self-managed medication abortions provided using online telemedicine in the U.S. The high effectiveness rates and low prevalence of serious adverse events we found mirror findings from other countries where medication self-management is used.[20–22] We note that although most people in our study did not receive an ultrasound, they reported awareness of the duration of their pregnancy at the time of medication use. These findings are in line with prior evidence suggesting that last menstrual period is an accurate method for determining gestation in early pregnancy[23] and WHO guidelines, which clearly specifies that ultrasound is not a necessary pre-requisite for medication abortion.[14]

Our findings also add to evidence on the safety and effectiveness of self-managed medication abortion beyond 10 weeks. While rates of surgical intervention were higher among the small proportion in our study who used the medications after 10 weeks compared to those at 10 weeks or under, almost all were able to end their pregnancies and the rate of successful medication abortion was similar to other studies examining medication abortion in the late first trimester,[24] and medication self-management after 13 weeks using an accompaniment model.[25] Those self-managing after 10 weeks in our study also tended to have experienced shipping delays and some received modified instructions according to the WHO protocol for medication abortion at 12 weeks and over[14] and additional support from Aid Access. In addition, no ectopic pregnancies were reported after using the medications and indeed a small number were diagnosed quickly by the service at the time of initial contact.

This study has several limitations. The first is that abortion outcomes were self-reported by people who self-managed. However, since these abortions take place outside of the formal healthcare system, self-reporting is by definition the only possible method of follow-up. Moreover, a previous large randomized controlled trial showed that self-assessment of the outcome of medication abortion was non-inferior to clinical follow-up, indicating that people are capable of determining on their own whether or not their abortion has been successful.[26] Since an examination of the outcomes of medication abortions taking place outside the formal healthcare setting cannot be dealt with by a randomized controlled trial or clinical trial, we have drawn on the best available "real world" data to answer these important questions.

Second, although the 70% follow-up rate in this study is incomplete, it is on par with or better than many clinical studies, since most outcomes are only recorded if patients decide to follow up with the clinic.[27]

Outcome	All gestations (*N*=2268)* Frequency (percent)
Felt satisfied with the service	2,231 (98.4)
Felt self-management using the service was the right choice	2,166 (95.5)
Felt had enough information on how to use pills	2,225 (98.1)
Felt had enough information on what to expect to see and feel	2,118 (93.4)
Felt had enough support from family/friends	1,837 (81.0)
Had difficulty affording the full requested donation	1,401 (61.8)

***Table 4*: Experiences reported by people who self-managed a medication abortion through Aid Access (*N*=2268).**
* 529 people who confirmed using medications did not provide information on acceptability outcomes.

Moreover, we took a more conversative approach than most clinical studies in that we did not consider those for whom no outcome data were available as presumed successful abortions. Third, while self-reporting could be subject to recall or social desirability bias, the short time period between the abortion and the collection of follow-up information should minimize recall bias.

While treatment for serious adverse events was a rarely reported outcome in our study, rates were still higher than those reported in studies of abortions taking place in the clinical setting.[19,28] We note, however, that we are not able to verify whether the treatment received by users of the service who did engage with the formal healthcare system was appropriate to their situation. For example, most of those who reported receiving surgical intervention also received antibiotics, which may have been given prophylactically or to treat an existing infection. Studies in other countries have shown that rates of intervention and additional treatment during clinical abortion follow-up are highly variable, especially in countries where hospital staff are not trained to care for abortion patients.[29] While we did examine whether any deaths were reported to the service, we were of course unable to fully assess whether any deaths occurred in the group that did not provide follow-up information.

It is also important to consider the rates of self-reported adverse events shown in this study in the context of the other possible outcomes for people in the U. S. who cannot access in-clinic abortion care. Between 200,000 and 1.2 million unsafe abortions are estimated to have taken place per year in the U.S. in the 1950s and 1960s pre-*Roe*, with the resulting burden of morbidity and mortality falling disproportionately on racially minoritised people.[30] While we do not expect the same prevalence of unsafe abortion today, we cannot assume that none will occur. Moreover, those forced to carry a pregnancy to term would also be at higher risk than those who self-manage using Aid Access. Rates of hemorrhage postpartum in the U.S. are over five times higher than those reported in this study, with Black women at disproportionately high risk.[31,32]

The trajectory of highly restricted access to in-clinic abortion in the U.S. and the future possibility of full abortion bans in some states means that self-managed abortion is likely to become an increasingly used alternative. The FDA recently permanently suspended the in-person dispensing requirement on mifepristone, paving the way for expanded clinic-based telemedicine abortion services. However, at least 19 states already have laws banning telemedicine for medication abortion and in these jurisdictions the FDA ruling will have little effect.[33] These states are the also the ones with the highest rates of requests to Aid Access.[4] In the majority of U.S. states, self-management is not illegal, and clinicians who may provide follow-up care have no reporting obligation.[34] It is important to note, however, that there have been 24 cases of unjust prosecution for alleged self-management since 2000, with populations already subject to increased surveillance and biased treatment, including people with low incomes and racially minoritised people, at highest risk.[35] While legal risks remain, our findings demonstrate that self-management using medications provided through online telemedicine is a safe, effective, and acceptable option for people in the U.S. and thus it is both an important method of harm reduction and a means of preserving reproductive autonomy.

Contributors

ARAA conceived of the original research question. All authors contributed to the study design. RG, ER, and JM compiled and provided the de-identified Aid Access data. ARAA conducted the statistical analyses and prepared the tables and figures. ARAA and RG did the initial data interpretation. ARAA, wrote the first draft of the manuscript. All authors contributed to final data interpretation and contributed to and approved the final draft of the manuscript. ARAA and RG verified the underlying data. All authors had full access to all the data and all authors accept responsibility to submit the manuscript for publication. No medical writers were involved in the preparation of the manuscript.

Data sharing statement

Authors are not able to directly provide access to data. Any direct requests submitted to Aid Access will be dealt with according to their internal policies and procedures.

Declaration of interests

ARAA reports grant support from the Society of Family Planning (Grant # SFPRF12-MA1) and received infrastructure support from the National Institutes of Health (Grant # P2CHD042849). ARAA is a Council Member of the British Society of Abortion Care Providers (BSACP). RG is the Founder and Director of Aid Access, ED is a helpdesk coordinator at Aid Access, and JM interned at Aid Access during her program of study at VU.

Role of the funding source

None of the sources of funding had any involvement in data collection, analysis or interpretation, and no role in the writing of this manuscript or the decision to submit for publication. None of the authors were paid to write this article by a pharmaceutical company or other agency. All authors had full access to the full data in the study and accept responsibility for publication.

ABSTRACT

OBJECTIVES

To assess self reported outcomes and adverse events after self sourced medical abortion through online telemedicine.

DESIGN

Population based study.

SETTING

Republic of Ireland and Northern Ireland, where abortion is unavailable through the formal healthcare system except in a few restricted circumstances.

POPULATION

1000 women who underwent self sourced medical abortion through Women on Web (WoW), an online telemedicine service, between 1 January 2010 and 31 December 2012.

MAIN OUTCOME MEASURES

Successful medical abortion: the proportion of women who reported ending their pregnancy without surgical intervention. Rates of adverse events: the proportion who reported treatment for adverse events, including receipt of antibiotics and blood transfusion, and deaths reported by family members, friends, or the authorities. Care seeking for symptoms of potential complications: the frequency with which women reported experiencing symptoms of a potentially serious complication and the proportion who reported seeking medical attention as advised.

RESULTS

In 2010-12, abortion medications (mifepristone and misoprostol) were sent to 1636 women and follow-up information was obtained for 1158 (71%). Among these, 1023 women confirmed use of the medications, and follow-up information was available for 1000. At the time women requested help from WoW, 781 (78%) were <7 weeks pregnant and 219 (22%) were 7-9 weeks pregnant. Overall, 94.7% (95% confidence interval 93.1% to 96.0%) reported successfully ending their pregnancy without surgical intervention. Seven women (0.7%, 0.3% to 1.5%) reported receiving a blood transfusion, and 26 (2.6%, 1.7% to 3.8%) reported receiving antibiotics (route of administration (IV or oral) could not be determined). No deaths resulting from the intervention were reported by family, friends, the authorities, or the media. Ninety two women (9.3%, 7.6% to 11.3%) reported experiencing any symptom for which they were advised to seek medical advice, and, of these, 87 (95%, 87.8% to 98.2%) sought attention. None of the five women who did not seek medical attention reported experiencing an adverse outcome.

CONCLUSIONS

Self sourced medical abortion using online telemedicine can be highly effective, and outcomes compare favourably with in clinic protocols. Reported rates of adverse events are low. Women are able to self identify the symptoms of potentially serious complications, and most report seeking medical attention when advised. Results have important implications for women worldwide living in areas where access to abortion is restricted.

WHAT IS ALREADY KNOWN ON THIS TOPIC

In many countries where abortion through the formal healthcare system is restricted, self sourced medical abortion through online telemedicine provides an alternative to methods such as sharp objects or noxious substances

Little is known about the safety and effectiveness of medical abortion provided through this online pathway

Previous studies have been limited by small sample sizes, high losses to follow-up, and inability to examine self screening for potentially serious complications

WHAT THIS STUDY ADDS

This study is based on women's self reports of outcomes and complications of medical abortion and provides the best evidence to date that self sourced medical abortion through online telemedicine is highly effective and that rates of adverse events are low

Reported rates of successful medical abortion are comparable with protocols in clinics, and women report successfully self screening for potentially serious complications and seeking medical assistance when necessary

For the millions of women worldwide living in areas where access to abortion is restricted, the findings show the vital role played by self sourced medical abortion in providing an option with high effectiveness rates and few reported adverse outcomes

Introduction

About a quarter of the world's population lives in countries with highly restrictive abortion laws.[1] Women in these countries often resort to unsafe methods to end their pregnancies. Globally, each year an estimated 43000 women die as a result of lack of access to safe legal abortion services through their countries' formal healthcare systems.[2] Millions more have complications.[3] Worldwide, the fourth leading cause of maternal mortality is unsafe abortion.[4]

Yet in many countries, self sourced medical abortion provides a vital alternative to dangerous methods such as using sharp objects or noxious substances. Women source mifepristone and misoprostol (or misoprostol alone) themselves and use the medications outside the formal healthcare system. In some settings, women buy the medications from pharmacies or markets.[5] In other settings, they can self source using online telemedicine

BMJ: first published as 10.1136/bmj.j2011 on 16 May 2017. Downloaded from https://www.bmj.com/ on 28 April 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

initiatives that provide medications as well as help and support by email or instant messaging.[6]

One setting in which online telemedicine has dramatically changed women's access to abortion is in the Republic of Ireland and Northern Ireland. Abortion laws in both the Republic and Northern Ireland are among the most restrictive in the world.[1] Abortion is allowed only to save a women's life and, in Northern Ireland only, her permanent physical and mental health.[7 8] Although Northern Ireland is part of the UK, the Northern Irish legislature did not adopt the 1967 Abortion Act, which legalised abortion carried out by registered medical practitioners in England, Scotland, and Wales. As a result, abortion under most circumstances remains illegal there under the Offences Against the Person Act of 1861, which provides a maximum penalty for the woman undergoing the abortion of life imprisonment.[9]

Women from the Republic and Northern Ireland who do not want to, or feel they cannot, continue with a pregnancy have traditionally had three options: those with the requisite financial and logistical means can travel abroad to access abortion in a clinic, while those who do not must either self induce using an unsafe method or continue their unwanted pregnancy. For the past decade, however, women of all financial means have also had the option to self source early medical abortion through online telemedicine.[10 11]

Despite having been used by thousands of women in the Republic and Northern Ireland[11] and tens of thousands of women worldwide,[12] little is known about the outcomes of these self sourced medical abortions. Two existing studies have examined data from telemedicine initiatives: one across various settings[6] and the other in Brazil.[13] These studies showed encouraging results with respect to efficacy but were limited by small sample sizes and relatively high losses to follow-up. Moreover, no study has examined whether women are able to safely manage their own abortions by identifying the symptoms of serious complications and presenting for medical advice when appropriate.

Using data from an online telemedicine initiative, we conducted a population based analysis of women in the Republic of Ireland and Northern Ireland who self sourced medical abortion during a three year period. We examined self reported outcomes and complications after medical abortion through online telemedicine and assessed women's ability to self screen for the symptoms of potentially serious complications of abortion and their propensity to seek medical attention. In light of current policy debates,[9 14] the Republic and Northern Ireland provide a particularly important and timely opportunity to examine women's self reported outcomes.

Methods

We examined data from Women on Web (WoW), a non-profit organisation that provides early medical abortion through online telemedicine in countries where access to safe abortion is restricted. The service is currently available for women up to 10 weeks' gestation at the time of request. To make a request, women fill out a consultation form on the WoW website (www.womenonweb.org/en/i-need-an-abortion).[15] A doctor reviews the medical information on the form and, if clinical criteria are met, provides a prescription according to the WHO recommended dose regimen for medical abortion.[16] Mifepristone and misoprostol are sent through the mail by a partner organisation. Women either make a donation to support the service or, if they cannot afford to do so, the service is donated to them. Real time instruction about how to use the medications, as well as help and support during and after the abortion process, are provided by a multilingual specially trained helpdesk team.[6] Women are invited to share their experiences four weeks later using an online evaluation form or by emailing the helpdesk.

Our dataset includes all women in the Republic and Northern Ireland who filled out an online consultation form and to whom mifepristone and misoprostol were sent from 1 January 2010 to 31 December 2012. We chose this date range for three reasons. Firstly, although WoW began providing online telemedicine abortion in 2006, changes to the software used to handle requests mean that data are available only from 1 January 2010 onwards. Secondly, in January 2013, a change to the evaluation form reduced the level of detail available on symptoms of potential complications and help seeking behaviour. Thirdly, WoW was the only telemedicine service operating in the Republic and Northern Ireland in 2010-13. Our sample therefore represents all women accessing medical abortion through online telemedicine during this period. Overall, 2150 women contacted the WoW helpdesk to request an abortion from 1 January 2010 to 31 December 2012. Among these, 514 cancelled their request or discontinued contact with the helpdesk, and no medications were sent to them. The analytic sample size was determined by the number of women remaining to whom medications were sent and who subsequently confirmed using them and provided follow-up information about the outcome of their abortion.

We did not distinguish between women who live in the Republic and Northern Ireland in our analyses. All women living in the Republic who access abortion through WoW have their medications sent to an address outside the Republic because the import by mail of prescription medications is prohibited and all incoming medications are confiscated by Irish customs.[17] Some women from the Republic are already aware of the customs situation and select Northern Ireland as their country of origin on the consultation form. The border between the two countries, however, is, at present, barely discernible and fully open to travel. Moreover, the practicalities women face in terms of accessing abortion in the two countries is similar.

The online consultation form includes self reported information about age, weeks' gestation, feelings about the decision to have an abortion, and any medical contraindications or conditions requiring additional screening. We categorised age as <20, 20-24, and into 5 year increments thereafter, with a final group of ≥45.

BMJ: first published as 10.1136/bmj.j2011 on 16 May 2017. Downloaded from https://www.bmj.com/ on 28 April 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

doi: 10.1136/bmj.j2011 | BMJ 2017;357:j2011 | the bmj

Gestational age was reported as <7 weeks' or 7-9 weeks', which represents gestational age at the time of the consultation. During the time period of our study, WoW collected data on gestational age according to these categories to reflect the change in the registered use of mifepristone from up to 7 weeks' to up to 9 weeks' gestation in 2009.[18] In our sample, 58% of women reported having gestational age confirmed through ultrasonography, and the remainder used a pregnancy calculator based on the date of their last menstrual period, which has been shown to be an accurate method of determining gestational age for early medical abortion.[19] The estimated time for the medications to arrive in the Republic/Northern Ireland is between five and seven days, and 94% of women who used them reported doing so less than a week after they arrived. Thus, while we do not have information on women's exact gestational ages at the time they took the medications, we can estimate that for most women it was less than two weeks after the consultation.

Feelings about the decision to have an abortion were reported as "I can cope with my feelings regarding my decision" and "I have some worries about my decision and would like further information." Women who expressed worries were directed to appropriate sources of information. Questions on medical history included the presence of any contraindications (such as bleeding disorders, inherited porphyrias, allergies to mifepristone or misoprostol) or medical conditions that required additional medical screening (such as hypertension and diabetes).

We retrieved follow-up information for as many women as possible through either an evaluation form sent out four weeks after the medications were sent or email follow-up through the helpdesk. The evaluation form is based on similar follow-up instruments used in the clinical setting. Available information included the number of women who confirmed delivery of mifepristone and misoprostol, the number who confirmed whether or not they had used the medications, and, among those who confirmed use, the outcome of the abortion. The number of women who confirm using the medications is inevitably lower than the number to whom the medications are sent because some experience a spontaneous miscarriage, decide travel to obtain an abortion abroad, decide to continue with their pregnancy, or simply do not respond to follow-up from the helpdesk.

Women who confirmed using the medications were asked whether or not they are still pregnant, whether they received any surgical intervention (dilatation and evacuation or vacuum aspiration), and whether they received any other treatment after their abortion, including antibiotics and blood transfusion. Women were also asked if they experienced any symptoms of potentially serious complications, including: "bleeding requiring more than two maxi pads an hour for more than two hours"; "fever over 39°C or abnormal vaginal discharge"; and "persistent pain continuing for several days after the abortion." They were then asked whether they went to a hospital or to see a doctor. WoW advises women to seek medical attention if any of the above symptoms arise.

For women who completed medical abortion at home and for whom self reported information on outcome was available, we first examined the age distribution, gestational age, feelings about abortion, and prevalence of contraindications and comorbidities. We then examined the proportion for whom medical abortion was successful according to the standard definition of success in the Medical Abortion Reporting of Efficacy (MARE) Guidelines—that is, the proportion who were able to expel their pregnancy without the need for surgical intervention.[20] Next, we examined the prevalence of reported adverse events, following to the extent possible the categories defined by Cleland and colleagues.[21] Information was available on antibiotics, blood transfusion, and death. The highly politicised nature of abortion in the Republic and Northern Ireland means that any death suspected to be related to abortion would be extremely high profile news. We think it is likely that WoW would either have known if the woman in question had accessed their service or would have been notified by the authorities or the woman's family or friends. Finally, we examined the prevalence with which women reported symptoms of possibly serious complications and the frequency with which those who reported such symptoms sought medical attention.

Data analysis was conducted with Stata version 13.1 (StataCorp. 2013. College Station, TX). We calculated point estimates and exact binomial 95% confidence intervals for the overall population and for the binary categories of gestational age available in our dataset. Characteristics and outcomes by category of gestational age were compared with the Fisher-Freeman-Halton test and Fisher's exact test, respectively. Findings were considered significant at an α level of 0.05. Anonymised data were provided to us by WoW.

Patient involvement

Patients were not involved in the design or conduct of the study. The follow-up that WoW provides, however, is designed to deal with the priorities and experiences of women who access the service. Thus, though this study is an analysis of secondary, anonymised data, with no direct participant involvement, the research questions were informed by the needs of women who rely on WoW to access abortion.

Results

From 1 January 2010 to 31 December 2012, WoW sent 200 mg mifepristone and 1200 µg misoprostol to 1636 women living in the Republic and Northern Ireland (fig 1). Among these, 1181 women confirmed subsequent use or non-use of the medications. Among the remainder, 24 women confirmed delivery but offered no further follow-up information, while 431 neither confirmed delivery nor offered further follow-up information. Among the 1181 women who confirmed use or non-use of the medications, 1023 used the pills, and 158 did not. Follow-up information on abortion outcome (that is, whether or not a woman was still pregnant after using

BMJ: first published as 10.1136/bmj.j2011 on 16 May 2017. Downloaded from https://www.bmj.com/ on 28 April 2025 by guest. Protected by copyright, including for uses related to text and data mining, AI training, and similar technologies.

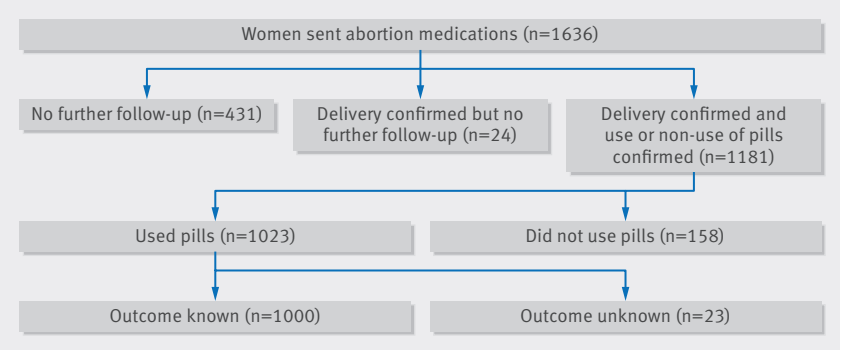

Fig 1 | **Women accessing medical abortion through WoW (Women on the Web)**

the medications) was available for 1000 of the 1023 women who confirmed use of the medications. Thus, outcome data were available for 1158 women who were sent mifepristone and misoprostol, representing 71% follow-up. Reasons for not using the medications included having had a spontaneous miscarriage in the meantime, accessing abortion through another pathway such as travelling abroad, and deciding to continue the pregnancy. One woman elected not to use the medications because she discovered her pregnancy was ectopic. No other ectopic pregnancies were reported either before or after use of the medications.

Among the 1000 women who used the medications and for whom we had information about the outcome of the abortion, 781 (78%) reported being <7 weeks pregnant at the time of requesting help from WoW, and 219 (22%) reported being 7-9 weeks pregnant (table 1). Almost a third (n=306) of women were aged 30-34, 236 were 35-39, and 195 were 25-29, 79 were aged ≤24, and 184 were ≥40. Virtually all (997) reported being able to cope with their decision to have an abortion. None had any contraindications to medical abortion, and 23 had a medical condition that required extra screening to ensure that it could be carried out safely. Comparison of the characteristics of the 1158 women for whom follow-up information was available versus the 478 women for whom no follow-up information was available showed no clinically or statistically significant differences between the two groups (see appendix).

Virtually all women (99.2%, 95% confidence interval 98.4% to 99.7%) reported having ended their pregnancies, and 94.7% (93.1% to 96.0%) reported a successful medical abortion (that is, ending their pregnancies with no surgical intervention) (table 2). Women with a reported gestational age of 7-9 weeks at the time they requested an abortion more commonly reported receiving a surgical intervention than women with a reported gestational age of <7 weeks (7.3% (4.2% to 11.6% *v* 3.7% (2.5% to 5.3%), respectively, P=0.04). There were, however, no statistically or clinically significant differences by gestational age in the proportions reporting a successful medical abortion (95.4% (93.7% to 96.8%) *v* 92.2% (87.9% to 95.4%); P=0.09).

Among the 1000 women for whom information about the outcome of their abortion was available, information about adverse events and symptoms of potentially serious complications was available for 987 (99%). Rates of self reported treatment for adverse events were low: 3.1% (95% confidence interval: 2.1% to 4.4%)

Table 1 | **Medical and demographic characteristics of women conducting self sourced medical abortion through online telemedicine. Figures are number (percentage) of women**

Characteristic	All gestations (n=1000)	<7 weeks' gestation (n=781)	7-9 weeks' gestation (n=219)	P value
Age (years):				
<20	4 (0.4)	3 (0.4)	1 (0.5)	0.17

Table 2 | Outcome of abortion reported by women conducting medical abortion through online telemedicine. Figures are number of women (percentage, 95% confidence interval)

Abortion outcome	All gestations (n=1000)	<7 weeks' gestation (n=781)	7-9 weeks' gestation (n=219)	P value
Pregnancy				
No longer pregnant	992 (99.2, 98.4 to 99.7)	774 (99.1, 98.2 to 99.6)	218 (99.5, 97.5 to 100.0)	1.0
Surgical intervention				
Reported surgical intervention*	45 (4.5, 3.3 to 6.0)	29 (3.7, 2.5 to 5.3)	16 (7.3, 4.2 to 11.6)	0.04
Successful medical abortion				
No longer pregnant and no surgical intervention	947 (94.7, 93.1 to 96.0)	745 (95.4, 93.7 to 96.8)	202 (92.2, 87.9 to 95.4)	0.09

*Dilatation and evacuation; vacuum aspiration.

Table 3 | Treatment for adverse events reported by women conducting medical abortion through online telemedicine. Figures are number of women (percentage, 95% confidence interval)

Treatment	All gestations (n=987)	<7 weeks' gestation (n=768)	7-9 weeks' gestation (n=219)	P value
Antibiotics	26 (2.6, 1.7 to 3.8)	19 (2.5, 1.5 to 3.8)	7 (3.2, 1.3 to 6.5)	0.63
Blood transfusion	7 (0.7, 0.3 to 1.5)	4 (0.5, 0.1 to 1.3)	3 (1.4, 0.3 to 4.0)	0.19
Death	0 (0, 0.0 to 0.4)	0 (0, 0.0 to 0.5)	0 (0, 0.0 to 1.7)	1.0
Any adverse event	31 (3.1, 2.1 to 4.4)	21 (2.7, 1.7 to 4.1)	10 (4.6, 2.2 to 8.2)	0.19

reported any treatment for a possible adverse event (table 3). Overall, 2.6% (1.7% to 3.8%) reported receiving antibiotics by any route of administration, 0.7% (0.3% to 1.5%) reported receiving a blood transfusion, and no deaths were reported by family, friends, the authorities, or the media. Rates of reported adverse events were not significantly more prevalent in the 7-9 week group than in the <7 weeks group (4.6% (2.2% to 8.2%) *v* 2.7% (1.7% to 4.1%), respectively, P=0.19).

Among the 987 women for whom we had information on self reported symptoms, 9.3% (95% confidence interval 7.6% to 11.3%) reported experiencing symptoms of a potentially serious complication (table 4). The prevalence of reporting any such symptom was higher in the 7-9 weeks group than the <7 weeks group (13.7% (9.4% to 19.0%) *v* 8.1% (6.2% to 10.2%), respectively, P=0.02). Bleeding requiring more than two maxi pads an hour for more than two hours was the most commonly reported of the symptoms (5.2%, 3.9% to 6.7%). Overall, 95% (87.8% to 98.2%) of women who reported symptoms of a potentially serious complication for which they were advised to seek medical assistance said they went to a hospital or clinic. There were no substantive or significant differences in the proportions of women who sought advised medical attention by reported gestational age (94% (84.3% to 98.2%) in the <7 weeks group *v* 96.7% (82.8% to 99.9%) in the 7-9 weeks group, P=1.0). None of the five women who did not seek medical help reported an adverse outcome or treatment for a complication, and none of the women who did not report symptoms of a potentially serious complication reported an adverse event.

Discussion

Among women in the Republic of Ireland and Northern Ireland, early medical abortion provided through online telemedicine was highly effective. The reported rate of successful medical abortion compares favourably with the rates of those carried out within the formal healthcare system, both when mifepristone and misoprostol are administered in clinic and when mifepristone is administered in clinic and misoprostol is taken at home.[22] The reported prevalence of adverse events is low, and, critically, when women reported experiencing symptoms of a potentially serious complication, almost all reported seeking medical attention as advised.

Limitations and strengths of study

The main limitation of our study is that we relied on women's self reports with respect to the outcome and complications of abortion. Many studies in the clinical setting, however, have the same limitation as women often do not return to the clinic and either self report by phone or are simply lost to follow-up. Moreover, as the women in our study are by definition conducting their

Table 4 | Reported symptoms and care seeking for potentially serious complications among women conducting medical abortion through online telemedicine. Figures are number of women (percentage, 95% confidence interval)

	All gestations	<7 weeks' gestation	7-9 weeks' gestation	P value
Reported symptoms:				
No of women	987	768	291	—
Bleeding >2 maxi pads/hr for >2 hours	51 (5.2, 3.9 to 6.7)	33 (4.3, 3.0 to 6.0)	18 (8.2, 4.9 to 12.7)	0.02
Fever >39°C or abnormal vaginal discharge	17 (1.7, 1.0 to 2.7)	10 (1.3, 0.6 to 2.4)	7 (3.2, 1.3 to 6.5)	0.07
Persistent pain continuing several days after abortion	24 (2.4, 1.6 to 3.6)	19 (2.5, 1.5 to 3.8)	5 (2.3, 0.8 to 5.3)	1.0
Any of above symptoms	92 (9.3, 7.6 to 11.3)	62 (8.1, 6.2 to 10.2)	30 (13.7, 9.4 to 19.0)	0.02
Advised to seek medical care given reporting any of above symptoms:				
No of women	92	62	30	—
Sought medical care as advised	87 (95.0, 87.8 to 98.2)	58 (94.0, 84.3 to 98.2)	29 (96.7, 82.8 to 99.9)	1.0

abortions outside the formal healthcare setting, self report is the only possible method of follow-up. While self reporting could be subject to recall or social desirability bias, the short time period between the abortion and the collection of follow-up information should minimise recall bias. A previous large randomised controlled trial showed that self assessment of the outcome of medical abortion was non-inferior to clinical follow-up, indicating that women are capable of determining on their own whether or not their abortion has been successful.[23] Although judgment of the symptoms of potentially serious complications is subjective, and not all will actually be indicative of an adverse event, it is reassuring that virtually all women who reported experiencing such symptoms said they sought medical advice. It is also unlikely that women had much incentive to give inaccurate reports of adverse events or complications. WoW was their main source of advice during their abortion, and so women who reported problems tended to have communicated with the helpdesk.

Another important limitation is that we were unable to ascertain whether the treatment women received for potential adverse events was appropriate and necessary. Previous work has shown that rates of surgical intervention after medical abortion provided through online telemedicine vary widely by setting.[24] The surgical intervention rate of 4.5% that we found is similar to equivalent rates found in studies of medical abortion in the clinical setting (which typically range from 3% to 5%).[22] It is possible, however, that providers in countries where abortion is highly restricted might intervene inappropriately because of lack of experience or overcautious management. They could also cause further complications through unnecessary or inappropriate interventions, and we are unable to distinguish these from adverse events relating to the abortion itself (for example, surgical intervention could lead to the need for a blood transfusion). The rate of reported receipt of an antibiotic in our sample was higher than previous reports of receipt of intravenous antibiotics after medical abortion in a clinic.[21] We could not distinguish between antibiotics administered intravenously versus orally, the latter being much more common after medical abortion. Additionally, some healthcare professionals might provide oral antibiotics "just in case" or for an incidentally discovered urinary tract or sexually transmitted infection. Our rate of reported blood transfusion was also higher than in previous large studies of abortion in a clinic[21 25] but still low at less than 1%. We also lacked information on two other adverse events−−hospital admission and emergency room treatment.[21] Previous studies, however, have shown considerable overlap between these events and the receipt of blood transfusion or antibiotics,[26] both of which we were able to include.

Key strengths of our study include the large sample size and high follow-up rate, which is comparable with or, in some cases, better than studies of abortion within the formal healthcare setting.[27] Additionally, we included data on the entire population of women in the Republic and Northern Ireland who accessed medical abortion through online telemedicine. While we must acknowledge the limitations of necessary reliance on self reporting and incomplete follow-up, the questions we sought to answer about medical abortion provided outside the formal healthcare system in a setting where abortion is highly restricted cannot be dealt with by a randomised controlled trial, clinical trial, or prospective cohort study. We have drawn on the best available "real world" data to answer these important questions.

We consider that the rates of reported complications and successful abortion in our study might be conservative estimates. A previous study using telephone follow-up among a smaller sample of women who self sourced their own abortions using WoW shows that those to whom medications were sent but who did not spontaneously provide follow-up information by email or an online evaluation form were less likely to have experienced complications and more likely to have had a successful medical abortion.[6] This possibility must still be balanced against the biases discussed above. We are also unable to definitively identify gestational age at the time of abortion, and some women might have had higher gestational ages than they were willing to disclose or might have experienced delays in receipt of the medications. Thus, we might reasonably expect the reported rates of adverse events to be slightly higher than those reported in clinical studies of medical abortion,which generally include gestational ages up to a maximum of 7 or 9 weeks.[21 22 25 26] Moreover, a systematic review of the safety of regimens of medical abortion at home up to 8 weeks' gestation indicates average rates of transfusion of 0.1%, which although higher than for studies of medical abortion in a clinic, is still considered low.[22]

It is also important to view the rates of self reported adverse events shown in this study in the context of the other options available to women in the Republic and Northern Ireland who have an unwanted pregnancy. The complication rates we found are lower than the risk of equivalent complications during delivery in the UK.[28] They are also much lower than the equivalent risks associated with unsafe methods of abortion.[3] While some could also raise ethical questions about the provision of medications without formal in person consultation with a doctor, it is worth noting that similar models of telemedicine are used in the US to prescribe and dispense numerous other medications (with the exception of controlled substances)[29] and that both mifepristone and misoprostol are on the WHO list of essential medicines.[30] Additionally, one might view the provision of abortion medications by telemedicine as an ethical response to the unethical practice of criminalising women for choosing abortion. A growing body of literature documents the negative health impacts experienced by women denied a wanted abortion and forced to continue an unwanted pregnancy compared with those who were able to access an abortion.[31 32] In 2016, the United Nations Human Rights Council found Ireland in violation of its human rights obligations, stating that its abortion laws subject women to "suffering and discrimination."[33]

Applicability

Our results might not be generalisable to all settings where women self source using online telemedicine. A recent review of the acceptability of self managed abortion in both legal and legally restricted contexts emphasises the role of local attitudes surrounding abortion on women's experiences.[34] Higher levels of education and medical knowledge as well as better access to healthcare compared with women in developing settings might mean that women in the Republic and Northern Ireland are more likely to use the medications correctly and to seek follow-up care. The stigma surrounding abortion experienced by Irish women, however, is considerable. Women in both countries face the possibility of prosecution and jail sentences if they are found to have conducted an abortion at home. Recently, several women in Northern Ireland have been charged after being reported to the authorities by housemates or medical staff.[35 36] Women who have had a self sourced abortion and those who have had an early pregnancy loss are clinically indistinguishable, but these events raise the concerning possibility of a chilling effect, whereby women might be reluctant to seek care for fear of being reported.

On average, women who access abortion through online telemedicine are older than women who access abortion in a clinic setting in the UK.[37] This difference might be because younger women are less likely to recognise their pregnancy sufficiently early to choose medical abortion if they have not been pregnant before, or they might be more likely to be able to travel abroad to access abortion because of parental assistance or fewer childcare commitments, or they might already be overseas pursuing higher education. Alternatively, older women might be more likely to have had abortions or deliveries before and thus be more confident about self managing their abortion at home. A previous study examining the decision making and experiences of Irish women who self sourced medical abortion through WoW indicated that some do so because they lack the financial or social resources to travel elsewhere.[11] Thus, our sample could be less socioeconomically advantaged than women who travel to access abortion care. The same study also showed, however, that others access abortion through online telemedicine because they prefer the privacy of using the medications at home, they lack the required documentation to travel, or they prefer medical abortion to a surgical alternative.[11]

Implications and conclusions

Our results have important implications for the perception of abortion self sourced outside the formal health system using online telemedicine. Firstly, they clearly show that not at all abortions taking place outside the law are unsafe abortions. Secondly, they add an important dimension to existing evidence that women themselves report abortion through online telemedicine as a positive experience with benefits for health and wellbeing.[11] Millions of women worldwide live in countries where self sourced medical abortion is a potentially lifesaving option, and strengthening services outside the formal healthcare setting could be a vital component of strategies to reduce maternal mortality from unsafe abortion. Finally, given the trajectory of abortion policy in Europe and the US, the visibility and importance of self sourced medical abortion will continue to increase. There are already reports of women seeking abortion outside the formal healthcare setting in the US.[38] Investigating women's experiences, preferences, outcomes, and unmet needs in various settings is a critical goal for future research.

Contributors: ARAA conceived the original research question, conducted the statistical analyses and prepared the tables and figures, and wrote the first draft of the manuscript. ARAA, RG, and JT contributed to the study design. RG and ID provided the de-identified data. ARAA and JT did the initial data interpretation. All authors contributed to final data interpretation, revised first and subsequent drafts critically for intellectual content, and approved the final manuscript. All authors, external and internal, had full access to all of the data (including statistical reports and tables) in the study and take responsibility for the integrity of the data and the accuracy of the data analysis. ARAA is guarantor.

Funding: This study was funded by a grant from the Society of Family Planning (SFPRF10-JI2) and was supported in part by the Eunice Kennedy Shriver National Institute of Child Health and Human Development of the NIH through grant R24HD04284 to the population research centre at the University of Texas at Austin, and in part by grant P2C HD047879 to the office of population research at Princeton University. The funders played no role in the study design; in the collection, analysis, and interpretation of data; in the writing of the report; or in the decision to submit the article for publication. The authors are completely independent from the funding sources. The content of this article is solely the responsibility of the authors and does not necessarily represent the official views of the Society of Family Planning or the National Institutes of Health.

Competing interests: All authors have completed the ICMJE uniform disclosure form at www.icmje.org/coi_disclosure.pdf and declare grants from the Society of Family Planning (ARAA) and infrastructure support from the National Institutes of Health (JT and ARAA); RG is founder and director of Women on Web, ID is a prescribing physician for Women on Web, JT serves on the Board of the Women on Web Foundation; no other relationships or activities that could appear to have influenced the submitted work.

Ethical approval: The University of Texas at Austin institutional review board reviewed and approved study protocols and declared the use of the de-identified database for research purposes exempt from full board review. All women consented to the anonymised use of their data at the aggregate level for research purposes.

Transparency: The lead author affirms that the manuscript is an honest, accurate, and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any discrepancies from the study as planned (and, if relevant, registered) have been explained

Data sharing: No additional data available.

Objective To compare outcomes before and after implementation of medical abortion (termination of pregnancy) without ultrasound via telemedicine.

Design Cohort analysis.

Setting The three main abortion providers.

Population or sample Medical abortions at home at ≤69 days' gestation in two cohorts: traditional model (in-person with ultrasound, n = 22 158) from January to March 2020 versus telemedicine-hybrid model (either in person or via telemedicine without ultrasound, n = 29 984, of whom 18 435 had no-test telemedicine) between April and June 2020. Sample (n = 52 142) comprises 85% of all medical abortions provided nationally.

Methods Data from electronic records and incident databases were used to compare outcomes between cohorts, adjusted for baseline differences.

Main outcome measures Treatment success, serious adverse events, waiting times, gestation at treatment, acceptability.

Results Mean waiting time from referral to treatment was 4.2 days shorter in the telemedicine-hybrid model and more abortions were provided at ≤6 weeks' gestation (40% versus 25%, $P < 0.001$). Treatment success (98.8% versus 98.2%, $P > 0.999$), serious adverse events (0.02% versus 0.04%, $P = 0.557$) and incidence of ectopic pregnancy (0.2% versus 0.2%, $P = 0.796$) were not different between models. In the telemedicine-hybrid model, 0.04% were estimated to be over 10 weeks' gestation at the time of the abortion; all were completed safely at home. Within the telemedicine-hybrid model, effectiveness was higher with telemedicine than in-person care (99.2% versus 98.1%, $P < 0.001$). Acceptability of telemedicine was high (96% satisfied) and 80% reported a future preference for telemedicine.

Conclusions A telemedicine-hybrid model for medical abortion that includes no-test telemedicine and treatment without an ultrasound is effective, safe, acceptable and improves access to care.

Introduction

Improved access to care for induced abortion (termination of pregnancy) would deliver significant advantages for both healthcare systems and the women who use them. There is clear evidence that restricting access to abortion does not reduce abortion rates, it simply makes the procedure less safe.[1,2] Improving access is likely to benefit those who are

GBP-PET00026

most vulnerable,[3] especially in resource-poor settings or where care has to be self-funded. In its 2019 guideline on abortion care, the National Institute for Health and Care Excellence (NICE) stated that improving access to abortion was a key priority.[4]

Telemedicine, the use of information and communication technologies to improve patient outcomes by increasing access to care and medical information,[5] has been noted to decrease costs and increase convenience and safety.[6] It is an established service delivery model for abortion care in many settings[7] and it is recommended to improve access.[4] The COVID-19 pandemic required urgent action to ensure delivery of essential health services, with the Royal College of Obstetricians and Gynaecologists (RCOG) publishing guidelines to safeguard abortion care in the UK.[8] These guidelines profoundly changed the way medical such care is delivered in Great Britain. Prior to the emergence of COVID-19, all patients seeking medical abortion were required to attend in-person to receive an ultrasound scan and have mifepristone administered within the clinic. Under the new guidelines, consultations were encouraged to take place by telephone or video call; an ultrasound scan was required only if indicated. By 30 March 2020, all the governments in Great Britain had issued emergency legal orders to allow mifepristone to be used at home along with misoprostol up to 10 weeks' gestation.[9–11] These approvals permitted abortion providers to implement a fully telemedical service delivery model, including 'no test medical abortion' and direct-to-patient delivery of abortifacient medications.

Great Britain's new pathway for no-test medical abortion is unusual among existing models because it is fully remote: no clinic visit, tests or ultrasound scan are performed and both mifepristone and misoprostol are delivered by mail or collected from a clinic for use at home. This new service model thus presents an important opportunity to evaluate a potentially better way to provide medical abortion that could improve access and reduce the barriers posed by in-person care.[12] We examined and compared the effectiveness, safety and acceptability of medical abortion provided up to 10 weeks' gestation before and after the widespread implementation of no-test telemedicine.

Methods

Population and cohorts

The study population comprised all patients who accessed an early medical abortion (EMA) at the three largest abortion providers in England – British Pregnancy Advisory Service (BPAS), MSI Reproductive Choices (MSUK) and the National Unplanned Pregnancy Advisory Service (NUPAS) – 2 months before and after the service model change. Medical abortion is defined as the use of medications to terminate a pregnancy without primary surgical intervention and 'EMA' applies to these procedures, commonly within the first trimester.[13] The recommended EMA regimen uses the anti-progestogen mifepristone in an oral dose of 200 mg, then, after 24–48 hours, 800 mcg of the prostaglandin analogue misoprostol by the sublingual, vaginal or buccal route. In the UK, an additional dose of misoprostol is recommended if expulsion has not occurred 3–4 hours after the first dose.[8,14] Prior to telemedicine, patients would have returned to clinic to receive this, but in the new model the additional dose was provided in the treatment pack. Patients are advised to call the abortion provider on their 24-hour phone service in the event of any problems, if bleeding is unexpectedly light or heavy, if pregnancy symptoms fail to resolve quickly or if a low-sensitivity pregnancy test (1000 IU) is positive 3 weeks after using misoprostol. This information is conveyed in a variety of formats, including verbally at consultation, in writing and through on-line resources. Women are offered self-assessment with a low-sensitivity pregnancy test to determine success of the abortion, with instructions to report back to the abortion provider if there are any ongoing issues or a positive test, in line with national guidelines[15] and high quality evidence that self-assessment is safe, effective and preferred by women.[16]

Our dataset consisted of information on EMAs extracted directly from each provider's electronic records and included fully de-identified patient clinical and demographic characteristics. Each providers' clinical incident database was cross-referenced to patients in each cohort to determine rates of unsuccessful medical abortion and adverse events. All data were extracted 6 weeks after the end of the study period to ensure the reporting of complications was as complete as possible. We also consulted with regulators and national agencies to ensure that we accounted for incident reports made directly to them. The independent regulator of all health and social care services in England, the Care Quality Commission (CQC), confirmed that all cases reported directly to them through various routes, for example, statutory notifications and the central NHS database of patient safety incident reports (the National Reporting and Learning System [NRLS] and the Strategic Executive Information System [StEIS]), were known to the providers.

Two cohorts were defined. The 'traditional' cohort comprises all patients having an EMA between 1 January and 1 March 2020, prior to service model change. All patients in this cohort received an in-person assessment and an ultrasound scan, had mifepristone administered in the clinic, and were supplied with misoprostol for use at home. The 'telemedicine-hybrid' cohort comprises all patients accessing an EMA between 6 April and 30 June 2020, in a 2-month period after the service model change at each

provider. Patients in this cohort were offered a consultation via phone or video call, during which an assessment of eligibility for treatment via telemedicine was made. Patients were deemed eligible for no-test medical abortion via telemedicine if they had a low risk of ectopic pregnancy and their self-reported last menstrual period (LMP) indicated a gestation of <10 weeks. Medications were then delivered to patients via post or were made available for collection from a clinic for use at home. Those deemed ineligible for no-test medical abortion via telemedicine had an in-person assessment with ultrasound as per the 'traditional' model. After the in-person assessment, medications for this group were then provided from the clinic for home use. The medications provided to both groups in the hybrid cohort were the same. Providers followed organisation-specific evidence-based policies informed by the RCOG[8] and associated decision aid[17] (Figures 1 and 2) and earlier RCOG and NICE guidelines.[14,15]

Outcome measures

Access

Waiting time and gestation at treatment were used to assess how the two models impacted access. Waiting time was defined as the interval from first contact with the abortion provider to when medication was dispensed (either in-person in clinic or posted). Gestation was recorded as that applicable on the date mifepristone was dispensed or provided. Analysis was of mean gestation and the proportion of abortions performed at ≤6 weeks' gestation.

Effectiveness

Effectiveness was defined as the proportion of medical abortions that were successful. Success was defined according to the MARE Guidelines as successful expulsion of an intrauterine pregnancy without need for surgical intervention,[13] using the sub-categories as listed in Table 2.

Safety

Safety was defined according to the proportions of medical abortions that involved one or more significant adverse events. We defined significant adverse events as haemorrhage requiring transfusion, significant infection requiring hospital admission, major surgery and death. We also examined the incidence of ectopic pregnancy and when it was diagnosed in the care pathway. For the analysis of ectopic pregnancies, we included all abortion consultations rather than all abortions provided because some patients with suspected ectopic pregnancies were referred to Early Pregnancy Assessment Units (EPAU) and did not proceed to abortion. All patients referred for further diagnostics (e.g. serial human chorionic gonadotropin [βhCG] monitoring) but who had no further treatment are included in the ectopic pregnancy group, although a proportion of these will be pregnancy of unknown locations (PULs), which includes failed early intrauterine pregnancies. We analysed the proportion of cases where treatment was reported to have occurred at ≥10 weeks' gestation in the telemedicine-hybrid cohort.

Acceptability

Given the constraints of delivering healthcare during COVID-19, it was not possible to follow up all patients to capture patient-reported outcomes. Two of the providers (BPAS and MSUK) collected patient feedback during the study period. Patients were invited to provide feedback 1–3 weeks after treatment, either by telephone using a structured interview tool (MSUK)[18] or using an online form (BPAS).[19] We analysed data on questions reporting on satisfaction, future preference and privacy. Although the questions were similar, only the MSUK survey included questions on the privacy of teleconsultation. All contact was by a non-clinician who had not been involved in the patient's care.

Analysis

The primary analysis was to assess whether the telemedicine-hybrid model was non-inferior to the traditional model. We compare effectiveness and safety in the two cohorts by testing the hypotheses that the telemedicine-hybrid model is less effective and has a higher complication rate.

We first compared patient demographic and clinical characteristics between the cohorts to assess the need to covariate-adjust our hypothesis tests for systematic differences in the two groups that might affect outcomes of abortion. All hypothesis tests were covariate adjusted for patient age, race/ethnicity, gestational age, parity and prior abortions using logistic regression and weighted risk differences.[20]

We evaluated effectiveness by testing the alternative hypothesis that the rate of successful medical abortion in the telemedicine-hybrid cohort is lower than in the traditional cohort using a covariate-adjusted test of difference in proportions. We also performed a Chi-square test to evaluate whether the distribution of unsuccessful abortion subcategories differed between the cohorts. We evaluated safety by testing the alternative hypothesis that significant adverse events occurred at higher rates in the telemedicine-hybrid cohort than in the traditional cohort using a covariate-adjusted hypothesis test for difference of proportions. We reported one-sided *P*-values for both of these tests. We also evaluated whether the prevalence of ectopic pregnancies managed before EMA and after EMA were different between the traditional and telemedicine-hybrid cohorts using Chi-square difference of proportion tests.

The secondary analysis was to compare effectiveness and safety of medical abortion for patients who received

Figure 1. Summary of early medical abortion care management during COVID-19 pandemic (adapted with permission from RCOG Coronavirus [COVID-19] Infection and Abortion Care – Information for Healthcare Professionals[8]).

fully remote no-test telemedicine versus in-person care in the telemedicine-hybrid cohort, primarily to assess whether any differences between the cohort service models were driven by one particular group. We performed covariate-adjusted hypothesis tests under the null hypothesis of equal effectiveness and equal rates of significant adverse events in the telemedicine versus in-person groups.

All analyses were performed using R, version 3.6.2 (R Foundation for Statistical Computing, c/o Institute for Statistics and Mathematics, Vienna, Austria). Statistical significance was defined using an alpha level of 0.05.

Ethics approval

The study was reviewed by the Institutional Review Board (IRB) at the University of Texas at Austin, and a determination was made that the research did not meet the criteria for human subject research as defined in the Common Rule (45 CFR 46) or FDA Regulations (21 CFR 56). Each provider ensured compliance with their own internal ethics and governance systems. This study is classed as service evaluation by the NHS Health Research Authority[21] and therefore did not require review by an NHS Research Ethics Committee (REC).[22] The principles of the STROBE statement, and the MARE supplement, were followed.[13] Patients were not involved in the development of the study.

Results

In total, 52 142 medical abortions were provided during the study period: 22 158 in the traditional cohort and 29 984 in the telemedicine-hybrid cohort. Among those that took place in the telemedicine-hybrid cohort, 18 435 (61%) were provided via telemedicine and 11 549 (39%) in-person. Our sample represents 85% of the total number of medical abortions performed in England and Wales during the study period.[23] The clinical and demographic characteristics of patients in the two cohorts are described in Table 1.

Table 1. Clinical and demographic characteristics in the traditional and telemedicine-hybrid cohorts (n = 52 142). n (%)

Patient characteristics	Traditional (n = 22 158)	Telemedicine-hybrid (n = 29 984)	P-value
Mean gestational age in weeks (SD)	6.4 (1.3)	6.0 (1.4)	<0.001
Gestational age at treatment*			
≤6 weeks	5582 (25.2)	11 947 (39.8)	<0.001
>6 weeks	16 576 (74.8)	18 037 (60.2)	
Mean age in years (SD)	27.8 (6.6)	28.5 (6.7)	<0.001
Ethnicity			
Asian	2038 (9.2)	2652 (8.8)	<0.001
Black	1656 (7.5)	2282 (7.6)	
Multiracial	1004 (4.5)	1361 (4.5)	
White	15 840 (71.5)	20 910 (69.7)	
Other	489 (2.2)	638 (2.1)	
Unknown	1131 (5.1)	2141 (7.1)	
Previous abortions			
0	13 098 (59.1)	16 741 (55.8)	<0.001
1+	9060 (40.9)	13 243 (44.2)	
Parity			
0	10 133 (45.7)	11 741 (39.2)	<0.001
1+	12 025 (54.3)	18 243 (60.8)	
Mean waiting time in days (SD)*	10.7 (19.9)	6.5 (13.5)	<0.001

*After checking for normality, these variables were non-parametric and therefore two-sample Wilcoxon tests were used.

Access

Mean waiting time to treatment declined from 10.7 days (SD 19.9) in the traditional pathway to 6.5 days (SD 13.5) in the telemedicine-hybrid cohort ($P < 0.001$). Mean gestational age at treatment also declined in the telemedicine-hybrid cohort, resulting in 40% of abortions performed at 6 weeks' gestation or less versus 25% in the traditional cohort ($P < 0.001$).

Effectiveness

Rates of successful medical abortion were high under both service delivery models (Table 2) – 98.2% in the traditional cohort versus 98.8% in the telemedicine-hybrid cohort. We found no evidence of a lower success rate with the telemedicine-hybrid pathway ($P > 0.999$). The distribution of the different sub-categories of unsuccessful medical abortion did not differ between the cohorts ($P = 0.268$).

Safety

Significant adverse events in both cohorts were rare (Table 3). Haemorrhage requiring transfusion was reported in eight (0.04%) cases in the traditional cohort and in seven (0.02%) cases in the telemedicine-hybrid cohort. No cases of significant infection requiring hospital admission, major surgery or death were reported. We found no evidence that significant adverse events were higher in the telemedicine-hybrid cohort ($P = 0.557$).

The overall incidence of ectopic pregnancy was equivalent in both cohorts – 39 (0.2%) in the traditional cohort and 49 (0.2%) in the telemedicine-hybrid cohort, $P = 0.796$ (Table 4). The proportions managed after EMA were not significantly different between the cohorts (0.01% in the traditional pathway and 0.03% in the telemedicine-hybrid pathway, $P = 0.123$). There were 11 cases (0.04%) in the telemedicine-hybrid cohort where the gestational age after abortion was reported by the patient or an admitting hospital as being greater than the expected 10 weeks. In all these cases, the abortion was completed at home without additional medical complications.

Acceptability

Patient-reported outcome data were available from 2453 respondents: 96% were 'satisfied' or 'very satisfied' with their care, or rated their experience as 'good' or 'very good'; 80% reported that they would choose telemedicine in the future or that it was their preferred option, with 13% choosing in-person care and the remainder being unsure. No patient reported that they were unable to consult in private using teleconsultation (n = 1243).

Table 2. Comparison of effectiveness of medical abortions conducted in the traditional and telemedicine-hybrid cohorts (n = 52 142). n (%)

Outcome	Traditional n = 22 158	Telemedicine-hybrid n = 29 984	P-value
Successful medical abortion	21 769 (98.2)	29 618 (98.8)	1.0
Unsuccessful medical abortion	389 (1.8)	366 (1.2)	
Continuing pregnancy: treated with surgical management	161 (0.7)	150 (0.5)	0.268
Continuing pregnancy: opted to continue or unknown	3 (0.01)	8 (0.03)	
Retained products treated with surgical management (ERPC)	225 (1.0)	208 (0.7)	

As explained in the methods section, the P-value for successful medical abortion is the co-variate-adjusted P-value (i.e. all differences in patient clinical and demographic characteristics, including gestational age, are controlled for) and was calculated using a hypothesis test where the null hypothesis is that the traditional cohort has the same effectiveness rate as the telemedicine-hybrid cohort and the alternative hypothesis is that the traditional cohort has a higher effectiveness rate than the telemedicine-hybrid cohort. The P-value for unsuccessful medication abortion is the Chi-square test of whether the distribution of types of failure differ between the cohorts.

Table 3. Comparison of significant adverse events following medical abortions conducted in the traditional and telemedicine-hybrid cohorts (n = 52 142). n (%)

Outcome	Traditional (n = 22 158)	Telemedicine-hybrid (n = 29 984)	P-value
Haemorrhage requiring transfusion	8 (0.04)	7 (0.02)	0.557
Infection requiring hospital admission	0 (0.0)	0 (0.0)	
Major surgery	0 (0.0)	0 (0.0)	
Death	0 (0.0)	0 (0.0)	

As explained in the methods section, the P-value was calculated using a hypothesis test where the null hypothesis is that the traditional cohort has the same rate of adverse events as the telemedicine-hybrid cohort and the alternative hypothesis is that the traditional cohort has a lower rate of adverse events than the telemedicine-hybrid cohort.

Table 4. Significant outcomes among patients presenting for medical abortion in the traditional and telemedicine-hybrid cohorts (n = 52 218). n (%)

Outcome	Traditional (n = 22 197)	Telemedicine-hybrid (n = 30 021)	P-value
Ectopic managed pretreatment	37 (0.17)	39 (0.13)	0.796
Ectopic managed post-treatment	2 (0.01)	10 (0.03)	0.123
Gestational age later than expected*	0 (0.0)	11 (0.04)	N/A

The column numbers include patients who presented for an EMA but did not receive one because their ectopic pregnancy was identified pretreatment.
*The column numbers for the gestational age later than expected category are the same as those in Table 3, (all EMAs performed in the two cohorts, i.e. n = 52 142).

Secondary outcome measures

Comparison of clinical outcomes for the telemedicine versus in-person groups in the telemedicine-hybrid cohort is shown in Tables S1–S3. Rates of successful medical abortion were higher in the telemedicine group (99.2% versus 98.1%, $P < 0.001$), but rates of significant adverse outcomes were not significantly different between the two groups – three (0.02%) for telemedicine versus four (0.03%) for in-person ($P = 0.532$).

Discussion

Main findings

We found that no-test medical abortion via telemedicine without routine ultrasound up to 10 weeks' gestation is an effective, safe and acceptable service model. Clinical outcomes with telemedicine are equivalent to in-person care and access to abortion care is better, with both waiting times and gestational age at the time of the abortion significantly reduced. Although gestation could be influenced by different behaviour during the pandemic, resulting in earlier presentation, in most other areas of healthcare, access has been severely impacted, with waiting times increasing substantially,[24] and so reductions in both seem relevant. Even small reductions in waiting time are significant – NICE noted that a reduction of 1 day resulted in annual savings of £1.6 million to the health services in England owing to reduced complications and fewer needing to opt for a surgical abortion.[4] Further evidence that the new telemedicine-hybrid model improves access comes from a study showing that the rate of women seeking abortion medication outside the formal healthcare setting was significantly reduced in the UK following its implementation.[25] The implication is that those previously too vulnerable to

© 2021 The Authors. *BJOG: An International Journal of Obstetrics and Gynaecology* published by John Wiley & Sons Ltd.

attend in-person have been able to access care through telemedicine, potentially benefitting from the safeguarding, counselling and contraceptive services provided by regulated providers.[26]

Our study confirms previous literature that medical abortion is safe and effective. Our findings of low rates of significant complications and failure are similar to those reported from other high quality studies.[27,28] The slight increase in effectiveness we observed in the group that received telemedicine – even after controlling for lower average gestational age compared with the in-person group – may be due to the ability of patients to control better the time at which they took the medication.

The telemedicine-hybrid model resulted in very low rates of undiagnosed ectopic pregnancy and later than expected gestations. Although the rate of ectopic pregnancy in the general population in the UK and USA is reported as 1–2%,[29,30] the rate reported among patients having a termination of pregnancy is 10 times lower,[31] which is consistent with our findings. Ultrasound is not used to screen for ectopic pregnancy in the general population – it is only used where signs and symptoms suggest a need.[30] Routine screening of symptom-free women is associated with a high false-positive rate when the prevalence of ectopic pregnancy is low, as is the case in women seeking abortion, and therefore it is unlikely there would be significant benefits.[32] There is no clinical justification for maintaining this inconsistency in care between women wishing to continue their pregnancies and those choosing EMA.[33,34]

However, given that over 200 000 people access abortion care each year in the UK alone, some will inevitably have an asymptomatic ectopic pregnancy and so will proceed with having mifepristone and misoprostol either through telemedicine or after a false-negative scan. The essential issue for safety is that these are detected prior to causing harm rather than prior to beginning the medical abortion treatment; treatment with mifepristone and misoprostol in itself will have no effect on an underlying ectopic pregnancy. Indeed, the reduction in waiting times afforded by the telemedicine model may facilitate earlier detection than traditional pathways where women present later or are sent away to give additional time to visualise an intrauterine pregnancy on scan. Proceeding with early medical abortion without a scan may permit earlier diagnosis of a developing ectopic pregnancy owing to increased surveillance and index of suspicion, for example where there is minimal bleeding after misoprostol.[8,15]

The proportion of cases where gestational age was later than expected based on LMP was low, as might have been expected given the evidence that women can determine the gestational age of their pregnancy with reasonable accuracy by LMP alone.[33] Nevertheless, inadvertent treatment of gestations over 10 weeks is inevitable and, consistent with our findings, the consequences for most are unlikely to be medically significant.[35] The 10-week gestation limit in the English government's approval order is arbitrary and is not based on evidence of safety or effectiveness. The Scottish government did not stipulate a limit, leaving the decision to the discretion of the clinician in consultation with their patient. Moreover, the reported success of self-managed terminations of pregnancy at >12–24 weeks' gestation is 93%, with safety similar to that expected in earlier gestations.[36,37]

Strengths and limitations

Although the study is not a clinical trial, we were able to evaluate the outcomes of both the telemedicine-hybrid and traditional in-person services as they operate in the real world, and we were able to adjust for key covariates. A key strength of the study is the generalisability of our findings, given that our sample included 85% of all medical abortions provided in England and Wales during the study period.

The main limitation of this study is that we were unable actively to follow up patients after their abortion. There is a potential gap in the consistency of reporting incidents, due to some complications not meeting the threshold of serious incidents, multiple routes of entry into the NHS and informal communication between the NHS and abortion providers. Although it is possible that some patients presented to other providers and a significant adverse event was not reported in our dataset, the risk management and reporting systems within the NHS are well defined, with serious incidents being routinely shared. The governing body of the NHS in England alerted all commissioners of the need to report incidents relating to telemedicine and there were review meetings of key stakeholders to ensure compliance. No additional cases were identified from regulators that were not already recorded by the providers' clinical incident processes. More importantly, there is no reason that any under-reporting would be systematically more likely in either cohort to introduce bias. Although patient behaviour may have been altered in the pandemic, it seems unlikely patients would not have reported problems to their provider given that there is immediate access to help via 24-hour telephone services. It is also possible that with NHS acute services (e.g. early pregnancy units) harder to access, patients would be more likely to engage with their abortion provider first. Finally, evidence from an equivalent population to ours in Scotland gave almost identical results. This was a smaller cohort study that followed up all patients (n = 663) and cross-checked NHS hospital records (reporting successful medical abortion 98%, haemorrhage requiring transfusion 0%, infection requiring hospital admission 0%, choosing telemedicine again in future 71%).[39]

Interpretation

NICE conducted a systematic review and recommended using telemedicine to improve access to medical abortion care.[3] Several models for using telemedicine to facilitate medical abortion have been described but most existing trials are small, and many required attendances to have medicines administered, an ultrasound scan or blood tests.[7,38] Our study is the first to assess a real-world no-test telemedicine abortion care pathway in a national population. This new national model demonstrates how a permissive framework for medical abortion can deliver significant quality improvements to those needing to access abortion care.

Conclusion

This large study of 52 142 medical abortions demonstrates that incorporating no-test telemedicine into the care pathway is not inferior to the traditional pathway where all patients are seen in person and have an ultrasound scan. There are advantages – waiting times and gestation at abortion are reduced and it is highly rated by patients. There was no evidence of worse outcomes in failure rate, haemorrhage, need for surgery or failure to detect ectopic pregnancy. In the 0.04% of cases where the abortion appeared to have been provided at over 10 weeks' gestation, these were all completed at home without additional medical complications. Given the advantages of improving access to care, especially in vulnerable groups and in resource-poor healthcare systems or where patients have to fund their own care, the evidence is compelling that no-test telemedicine should become routine in the provision of abortion care.

Disclosure of interests

All authors have completed the ICMJE uniform disclosure form at www.icmje.org/coi_disclosure.pdf and declare: no support from any organisation for the submitted work; no financial relationships with any organisations that might have an interest in the submitted work in the previous 3 years; no other relationships or activities that could appear to have influenced the submitted work beyond that described under the roles held by each individual. AA – Member of the Council of the British Society of Abortion Care Providers (BSACP); NG and JS – nothing to disclose; PL – Co-author/committee member of national guidelines cited in this paper from RCOG and NICE; member RCOG abortion taskforce; council member of British Society of Abortion Care Providers (BSACP); Medical Director of BPAS; JL – Co-author/committee member of national guidelines cited in this paper from RCOG and NICE; co-chair of RCOG Abortion Taskforce and British Society of Abortion Care Providers (BSACP); primary employment includes work as termination of pregnancy care provider as a consultant gynaecologist and medical director. Completed disclosure of interests forms are available to view online as supporting information.

Contribution to authorship

AA – Initial concept, developing study protocol, data analysis, writing first draft and subsequent revisions, verification of data. Overall responsibility for data analysis and principal investigator. Guarantor; NG – Developing study protocol, revision of draft paper. Overall responsibility for conduct of study including data collection at NUPAS; PL – Initial concept, developing study protocol, writing first draft and subsequent revisions. Overall responsibility for conduct of study including data collection at BPAS; JL – Initial concept, developing study protocol, writing first draft and subsequent revisions, co-ordination and liaison. Overall responsibility for conduct of study including data collection at MSUK; JS – Data analysis including statistical advice, writing first draft and subsequent revisions, verification of data.

Details of ethics approval

The study was reviewed by the Institutional Review Board (IRB) of the University of Texas at Austin and a determination was made on 21 April 2020 that the research did not meet the criteria for human subjects research as defined in the Common Rule (45 CFR 46) or FDA Regulations (21 CFR 56). Each provider ensured compliance with their own internal ethics and governance systems. The principles of the STROBE statement, and the MARE supplement, were followed.[13]

Funding

This study was supported in part by the Eunice Kennedy Shriver National Institute of Child Health & Human Development of the National Institutes of Health (NIH) through Center Grant P2CHD042849, awarded to the Population Research Center at The University of Texas at Austin. The content of this article is solely the responsibility of the authors and does not necessarily represent the official views of the NIH.

Acknowledgements

We would like to thank the Care Quality Commission (CQC), NHS England and NHS Improvement (NHSE & I), and the National Child Mortality Database (NCMD) for their advice and assistance in ensuring all complications reported within NHS systems have been included. We are also enormously grateful to the many people who helped to ensure access to essential healthcare for women needing an abortion not only continued, but was improved during the COVID-19 pandemic. There are too many to list individually, but we would like to especially thank the following who not only helped to implement a complete service change within a few weeks, but also made this paper

Data-sharing statement

The collated datasets, which include participant data with anonymised identifiers, are held by AA at the University of Texas. Consideration will be given to sharing this with bona fide researchers on application. The original data reside with the co-authors' own institutions. Although the data are de-identified, some relate to very rare events and could therefore result in identification. Therefore data on complications, and data arising from clinical incident reports, will be subject to the same access restrictions as those of the organisation supplying it.

Transparency statement

The authors affirm that the manuscript is an honest, accurate and transparent account of the study being reported; that no important aspects of the study have been omitted; and that any discrepancies from the study as originally planned (and, if relevant, registered) have been explained.

Data availability

Data available on request due to privacy/ethical restrictions.

ABSTRACT: Medication abortion, also referred to as medical abortion, is a safe and effective method of providing abortion. Medication abortion involves the use of medicines rather than uterine aspiration to induce an abortion. The U.S. Food and Drug Administration (FDA)-approved medication abortion regimen includes mifepristone and misoprostol. The purpose of this document is to provide updated evidence-based guidance on the provision of medication abortion up to 70 days (or 10 weeks) of gestation. Information about medication abortion after 70 days of gestation is provided in other ACOG publications [1].

Background

Epidemiology

An estimated one in four women in the United States will have an abortion in her lifetime. In 2017, an estimated 60% of abortions in the United States occurred at or before 10 weeks of gestation and medication abortion comprised 39% of all abortions [2]. Between 2006 and 2015, there was a shift in the timing of abortion, with abortions taking place at earlier gestational ages; this is likely due, in part, to availability of medication abortion [3]. From 2014 to 2017, the number of nonhospital facilities that provided medication abortion increased by 25% [2]. A recent survey of American College of Obstetricians and Gynecologists (ACOG) Fellows and Junior Fellows found that 14% had provided medication abortion in the prior year [4].

Medication Abortion

GBP-PET00038

The medication abortion regimen supported by major medical organizations nationally and internationally includes two medications, mifepristone and misoprostol [5] [6]. If mifepristone is unavailable, then a misoprostol-only regimen is an acceptable alternative [5]. Mifepristone is a selective progesterone receptor modulator that binds to the progesterone receptor with an affinity greater than progesterone itself but does not activate the receptor, thereby acting as an antiprogestin [7]. Mifepristone's known actions on a uterus during pregnancy include decidual necrosis, cervical softening, and increased uterine contractility and prostaglandin sensitivity [8] [9]. Misoprostol is a prostaglandin E1 analogue that causes cervical softening and uterine contractions. It is approved by the FDA for oral administration to prevent gastric ulcers in individuals who take anti-inflammatory drugs on a long-term basis, and it is included in the FDA-approved labeling of mifepristone for use in abortion [10].

The FDA currently restricts mifepristone access under the risk evaluation and mitigation strategy (REMS) program, which includes a requirement that the drug be "dispensed to patients only in certain health-care settings, specifically clinics, medical offices, and hospitals, by or under the supervision of a certified prescriber" [10]. However, the REMS restrictions for mifepristone do not make the care safer, are not based on medical evidence or need, and create barriers to clinician and patient access to medication abortion [4] [11] [12]. The American College of Obstetricians and Gynecologists advocates the removal of REMS restrictions for mifepristone [12].

Clinical Considerations and Recommendations

How should patients be counseled about abortion methods?

GBP-PET00039

Only when patients have considered their options and decided to have an abortion does the discussion about the different methods become clinically relevant. Patients who choose abortion should be counseled about all methods available as well as the risks, advantages, disadvantages, and the different features of these options **5** **6** . Most patients who initially are unsure about the method will have some preference after counseling **13** . Generally, patients are satisfied with the method they choose **12** **14** **15** . Patients who choose medication abortion tend to do so because of a desire to avoid a procedural intervention; a perception that medication abortion is safer, more natural, and private compared with uterine aspiration; or a combination of these reasons **16** . Compared with uterine aspiration, medication abortion takes longer to complete and requires more active patient participation as the pregnancy expels outside of a clinical setting. The uterine aspiration procedure for a first-trimester abortion takes place most commonly in one visit, is slightly more effective, and allows for direct assessment of pregnancy tissue by the clinician.

What information and counseling should be provided to patients who are considering medication abortion?

Eligibility and Contraindications

Most patients at 70 days of gestation or less who desire abortion are eligible for a medication abortion. There are medical conditions for which a medication abortion may be preferable to uterine aspiration. Such examples include uterine fibroids that significantly distort the cervical canal or uterine cavity **17** **18** , congenital uterine anomalies **19** , or introital scarring related to infibulation **20** . Patients with asthma are candidates for medication abortion because misoprostol does not cause bronchoconstriction and actually acts as a weak bronchodilator **21** . Multiple gestation pregnancy is not a contraindication; patients with twin gestations can be treated with the same regimens as those with singleton gestations **22** .

Medication abortion is not recommended for patients with any of the following: confirmed or suspected ectopic pregnancy, intrauterine device (IUD) in place (the IUD can be removed before medication abortion), current long-term systemic corticosteroid therapy, chronic adrenal failure, known coagulopathy or anticoagulant therapy, inherited porphyria, or intolerance or allergy to mifepristone or misoprostol **23** . Patients with significant comorbidities may still have a medication abortion but may need more monitoring during the process depending on the stability of the conditions. The safety of medication abortion in patients with anemia is unknown because studies have excluded patients with anemia who have hemoglobin levels of less than 9.5 or 10 g/dL. Although the transfusion rates associated with medication abortion are low (less than 0.1%), they exceed those reported for uterine evacuation procedures in early pregnancy (0.01%) **24** **25** . Patients may also not be good candidates for medication abortion if they are unable or unwilling to adhere to care instructions, desire quick completion of the abortion process, are not available for follow-up contact or evaluation, or cannot understand the instructions because of comprehension barriers.

What to Expect

Most patients who have a medication abortion will experience bleeding and cramping, which are necessary for the process to occur. Patient counseling should emphasize that bleeding likely will be much heavier than menses (and potentially with severe cramping).

Adverse effects can occur after mifepristone administration but are more typically experienced after misoprostol administration. Adverse effects commonly associated with misoprostol use include nausea (43–66%), vomiting (23–40%), diarrhea (23–35%), headache (13–40%), dizziness (28–39%), and thermoregulatory effects such as fever, warmth, hot flushes, or chills (32–69%) **26** **27** **28** **29** . The incidence of each adverse effect varies by regimen used, the dose and route of administration of the prostaglandin analogue, and the gestational age.

GBP-PET00041

Patient counseling before medication abortion should include discussion of when patients should contact their clinician in the case of heavy bleeding (soaking more than two maxi pads per hour for 2 consecutive hours) and when to access urgent intervention **5** **6** **30** . In rare cases, patients who undergo medication abortion may need to obtain an additional intervention, such as uterine aspiration. If the prescribing clinician does not perform the intervention, it is medically appropriate to provide a referral. In patients who receive mifepristone and vaginal misoprostol, the need for intervention within the first 24 hours of treatment is rare, occurring in 0.2% of patients **31** . The need for intervention is based on how the patient is feeling and whether the bleeding seems to be slowing. For patients with heavy bleeding, a baseline hemoglobin or hematocrit, if known, may also influence when to seek urgent care. Overall, less than 1% of patients will obtain an emergency intervention for excessive bleeding **13** **14** **15** **32** , and the need for blood transfusion is rare (0.1% of patients or less) **24** **33** . Should a rare medical emergency arise, patients should be advised to seek care at the closest emergency facility.

Teratogenicity and Ongoing Pregnancy

Before undergoing medication abortion, patients should be counseled regarding the teratogenicity of misoprostol in the event of an unsuccessful medication abortion. All patients with a continuing pregnancy after using mifepristone and misoprostol should be provided with all pregnancy options and a thorough discussion of the risks and benefits of each. Most individuals with a continuing pregnancy opt to complete the abortion, but patients should be supported in their choice of how to proceed. No evidence exists to date of a teratogenic effect of mifepristone **34** . However, misoprostol can result in congenital anomalies, such as limb defects with or without Möbius' syndrome (ie, facial paralysis), when used during the first trimester **35** **36** **37** **38** **39** . Because misoprostol is the common agent used with every medication abortion regimen, clinicians should counsel all patients regarding potential teratogenic effects.

In the very rare case that patients change their mind about having an abortion after taking mifepristone and want to continue the pregnancy, they should be monitored expectantly **40** . There is no evidence that treatment with progesterone after taking mifepristone increases the likelihood of the pregnancy continuing **41** **42** . However, limited available evidence suggests that use of mifepristone alone without subsequent administration of misoprostol may be associated with an increased risk of hemorrhage **43** .

What evaluation and ancillary testing are needed before a medication abortion?

GBP-PET00042

Before medication abortion is performed, the clinician should confirm pregnancy and estimate gestational age. For patients with regular menstrual cycles, a certain last menstrual period within the prior 56 days, and no signs, symptoms, or risk factors for ectopic pregnancy, a clinical examination or ultrasound examination is not necessary before medication abortion. Rh testing is recommended in patients with unknown Rh status before medication abortion, and Rh D immunoglobulin should be administered if indicated **44** . In situations where Rh testing and Rh D immunoglobulin administration are not available or would significantly delay medication abortion, shared decision making is recommended so that patients can make an informed choice about their care. Other laboratory evaluations are not routinely indicated but may be required by local and state laws **2** . Preoperative assessment of hemoglobin or hematocrit is indicated only when anemia is suspected.

Most abortion care globally is provided without ultrasound examination. Although most U.S.-based studies have used ultrasonography to confirm gestational age and intrauterine location of the pregnancy, more recent evidence has shown that a patient's certain last menstrual period when within the prior 56 to 63 days is accurate **45** **46** **47** **48** . In one study, use of certain last menstrual period alone would have resulted in medication abortion being provided to only 26 of 3,041 (0.8%) patients with pregnancies beyond 70 days of gestation **45** .

A potential concern when providing early abortion services is the possibility of an undiagnosed ectopic pregnancy. The overall ectopic pregnancy rate in the U.S. general population is low and declining and is approximately 6 per 1,000 pregnancies among insured patients and 14 per 1,000 among patients who receive Medicaid **49** **50** . However, in studies of patients who seek abortion, ectopic pregnancy rates generally are lower. A U.S. study of uterine evacuation procedures performed at less than 6 weeks of gestation found the ectopic pregnancy rate to be 5.9 per 1,000 pregnancies **51** at a time when the national rate was three times higher **52** . The largest published study of first-trimester medication abortion patients involved 16,369 patients with pregnancies of 49 days of gestation or less and yielded a calculated ectopic pregnancy rate of 1.3 per 1,000 pregnancies **53** . Although ectopic pregnancy among individuals who seek early abortion is rare, patients with a medical history of ectopic pregnancy, medical risk factors (prior tubal surgery, pregnancy with progestin-only or IUD contraception use) or symptoms (ie, unilateral pain, vaginal bleeding) suggestive of ectopic pregnancy should have pretreatment clinical evaluation, which may include ultrasonography **5** **6** .

Most patients with clinical indications for an ultrasound examination before medication abortion can be initially screened with transabdominal ultrasonography, reserving transvaginal ultrasonography for situations in which further clarification is required **54** **55** . If ultrasonography is medically indicated, transabdominal ultrasonography is sensitive for diagnosing the presence or absence of a gestational sac in patients who are not obese **54** . A randomized trial that compared the use of transabdominal ultrasonography with transvaginal ultrasonography for eligibility assessment before medication abortion found that 80% of patients who received initial transabdominal ultrasonography did not require further testing to proceed with medication abortion, thus avoiding use of more invasive and resource-intensive screening with transvaginal ultrasonography **55** .

Recommendations on whether Rh D immune globulin should be given to patients before medication abortion in early pregnancy are primarily based on expert opinion because available evidence is limited **6** **56** . Rh D alloimmunization that is left undiagnosed and untreated can lead to significant perinatal morbidity and mortality in future pregnancies **57** . And, guidelines from ACOG and various other major medical societies include recommendations for Rh D immune globulin prophylaxis for Rh D-negative patients undergoing medication abortion within the first 12 weeks of gestation **44** **58** **59** **60** . For patients undergoing medication abortion before 10 weeks of gestation, some experts recommend against routine Rh testing and anti-D prophylaxis **6** or advise that forgoing Rh typing and Rh prophylaxis can be considered **61** . Research regarding Rh alloimmunization during early pregnancy continues to evolve **62** . However, based on currently available indirect evidence and the theoretical risk of Rh D alloimmunization in future pregnancies, ACOG recommends Rh D immune globulin prophylaxis for Rh D-negative patients undergoing medication abortion. In situations where Rh testing and anti-D prophylaxis are not available or would significantly delay medication abortion, shared decision making is recommended so that patients can weigh the benefits and risks of their options and make an informed decision about their care.

What regimens are used for medication abortion, and how do they compare in effectiveness for treatment?

GBP-PET00044

Combined mifepristone–misoprostol regimens are recommended as the preferred therapy for medication abortion because they are significantly more effective than misoprostol-only regimens. If a combined mifepristone–misoprostol regimen is not available, a misoprostol-only regimen is the recommended alternative **5** **63** **64** . Mifepristone is approved by the U.S. FDA to be used with misoprostol for medication abortion through 70 days of gestation **23** , but evidence also exists to support use with more advanced gestations **1** **5** . The recommended medication abortion regimens are listed in **Table 1** . With all regimens, the mifepristone dose is the same: 200 mg taken orally. The misoprostol portion of the regimen is more variable in terms of dose, route, and timing. Oral use of misoprostol is not recommended because it may result in lower overall efficacy **65** . In general, patients prefer a shorter interval between the two medications **66** . These regimens have been extensively studied and are similarly safe and effective **5** . Offering options provides patients with flexibility in the timing of abortion and the ability to avoid possible adverse effects related to the misoprostol route. Gastrointestinal adverse effects are less common when misoprostol is administered vaginally as compared with regimens that use oral, buccal, or sublingual misoprostol **65** **67** . Buccal and sublingual administration cause similar adverse effects, with the sublingual route associated with a higher rate of chills **68** .

Table 1. Medication Abortion Regimens Up to 70 Days of Gestation

Regimen	Mifepristone Dose	Misoprostol Dose	Interval Between Drugs
Preferred			
Combination, FDA-approved*	200 mg (orally)	800 micrograms (buccally)	24–48 h
Combination, WHO recommended†	200 mg (orally)	800 micrograms (vaginally, sublingually, or buccally)	24–48 h
Alternative			
Misoprostol only	N/A	800 micrograms (vaginally, sublingually, or buccally)	Repeat every 3 h for up to 3 doses‡

Abbreviations: h, hours; FDA, U.S. Food and Drug Administration; N/A, not applicable; WHO, World Health Organization.

GBP-PET00045

Complete abortion rates with all regimens are highest at earlier gestational ages **Table 2** . *Medication abortion failure* (defined as the need for uterine aspiration because of ongoing pregnancy or retained tissue) increases with advancing gestational age through 70 days of gestation **Table 2** , although failure rates remain low even at this point. Clinicians should counsel patients that medication abortion failure rates, especially continuing pregnancy rates, increase as gestational age approaches 10 weeks.

Table 2. Outcome by Gestational Age After Mifepristone 200 mg and Misoprostol for Outpatient Medication Abortion

	Misoprostol Dose	Interval Between Mifepristone and Misoprostol (h)	Gestational Age			
			≤49 days	50–56 days	57–63 days	64–70 days
Complete abortion	800 micrograms buccally[*]	24–48	98.1%	96.8%	94.7%	92.7%
	800 micrograms vaginally[†‡§‖¶‡‡]	24–72	98.3–99.7%	95.3–98.6%	95.1–98.3%	94.9%

Who is qualified to provide medication abortion, and in what settings can medication abortion be provided?

Any clinician with the skills to screen patients for eligibility for medication abortion and to provide appropriate follow-up can provide medication abortion. Clinicians who wish to provide medication abortion services should be trained to perform uterine evacuation procedures or should be able to refer to a clinician who has this training **5** **69** .

In addition to physicians, advanced practice clinicians, such as nurse–midwives, physician assistants, and nurse practitioners, possess the clinical and counseling skills necessary to provide first-trimester medication abortion **70** . Randomized trials in Mexico, Nepal, and Sweden have consistently found that patients randomized to receive medication abortion under the care of a nurse or nurse–midwife had a statistically equivalent risk of complete abortion compared with those under the care of a physician, without increased risk of adverse events **71** **72** **73** . In some U.S. states, advance practice clinicians can provide medication abortion; however, many states require that a physician perform an abortion and prohibit provision of medication abortion by nonphysician clinicians **2** .

According to the requirements of the FDA REMS program, clinicians who want to prescribe mifepristone must complete a “prescriber agreement form” before ordering and dispensing mifepristone, and the clinician and patient need to sign a “patient agreement form” before the drug is dispensed **10** .

The actual location of where a patient takes the medication abortion drugs has evolved over time. Although the FDA REMS program for mifepristone continues to require dispensing in the clinician's office, the U.S. labeling for mifepristone no longer indicates that the medication should be used only in the clinician's office **10** . Patients can safely and effectively use mifepristone at home for medication abortion **74** **75** **76** **77** . A clinician can prescribe misoprostol and pain medications or can maintain an office supply and directly dispense to the patient. Patients can safely and effectively self-administer misoprostol at home for medication abortion **5** **78** **79** **80** .

GBP-PET00047

Medication abortion can be provided safely and effectively by telemedicine with a high level of patient satisfaction, and telemedicine improves access to early abortion care, particularly in areas that lack a health care practitioner **81** **82** . Telemedicine involves the use of video and information technology to provide a medical service at a distance. Medication abortion through telemedicine has been evaluated in observational studies and found to be equally effective as an in-person visit **33** **83** **84** **85** . In an analysis of nearly 20,000 medication abortions, adverse events were rare (0.3% overall) and did not differ between those who choose telemedicine or in-person services **33** **84** . Patients who choose telemedicine medication abortion are significantly more likely to say they would recommend the service to a friend compared with those who have an in-person visit (90% versus 83%) **83** . Telemedicine also may help reduce the rate of delays to care because of barriers in access to abortion care in remote areas **82** . After medication abortion through telemedicine was introduced in Iowa, a significant reduction in second-trimester abortion was reported, and patients in remote parts of the state were more likely to obtain a medication abortion **82** . Despite this evidence, some states have passed legislation that bans the use of telemedicine to provide medication abortion **86** .

Should prophylactic antibiotics be used in medication abortion?

The routine use of prophylactic antibiotics is not recommended for medication abortion **6** . Following concern about serious, rare, and deadly infection with clostridial bacteria in patients undergoing medication abortion, it has since become evident that no specific connection exists between clostridial organisms and medication abortion **87** **88** . Uterine infection with medication abortion is uncommon, and published data do not support the routine use of prophylactic antibiotics in medication abortion. In a systematic review of 65 studies of heterogeneous design (prospective, retrospective, and randomized), the overall proportion of diagnosed or treated infection after medication abortion was 0.9% in more than 46,000 patients **89** . In these studies, as in most studies of abortion by uterine evacuation, the diagnostic criteria for infection were variable, leading to possible overestimation of infection.

GBP-PET00048

Although serious infections occur rarely in patients after medication abortion, clinicians need to be aware of the signs and symptoms. Tachycardia, severe abdominal pain, or general malaise with or without fever that occur more than 24 hours after misoprostol administration should increase suspicion of a serious infection **90** . Clostridial toxic shock often resembles a flu-like illness, so clinicians should have a high level of suspicion for infection when symptoms consistent with flu are present **90** . Patients with such infections typically have hemoconcentration and significant leukocytosis without fever and can rapidly progress to refractory hypotension and death **91** .

What is the recommended pain management approach for patients undergoing medication abortion?

Nonsteroidal anti-inflammatory drugs are recommended for pain management in patients who undergo a medication abortion. Pain management during medication abortion is an important consideration because many patients report pain that requires analgesia. Studies of pain control and medication abortion have found that the duration of pain for most patients is no longer than 24 hours after misoprostol administration **92** **93** . The most severe pain occurs approximately 2.5–4 hours after misoprostol use and lasts about 1 hour **94** . One randomized trial found that ibuprofen taken when needed was more effective than acetaminophen to reduce pain associated with medication abortion **95** . Another randomized trial found ibuprofen given prophylactically at the time of misoprostol administration did not significantly reduce pain associated with medication abortion compared with ibuprofen taken when needed **93** . Nonsteroidal anti-inflammatory drugs do not appear to counteract misoprostol or affect the success of the medication abortion **96** . Opioids have not been found to decrease the amount or duration of maximum pain associated with medication abortion up to 70 days of gestation **94** . Other medications, like pregabalin, have been studied for pain control but have not been effective **97** .

Patients should be sent home with appropriate instructions for analgesia with over-the-counter medications. If opioids are requested or desired, the Centers for Disease Control and Prevention (CDC) advises that “clinicians should prescribe the lowest effective dose of immediate-release opioids and should prescribe no greater quantity than needed for the expected duration of pain severe enough to require opioids” **98** .

What kind of assessment is recommended after medication abortion?

GBP-PET00049

Routine in-person follow-up is not necessary after uncomplicated medication abortion. Clinicians should offer patients the choice of self-assessment or clinical follow-up evaluation to assess medication abortion success. If medically indicated or preferred by the patient, follow-up evaluation can be performed by medical history, clinical examination, serum human chorionic gonadotropin (hCG) testing, or ultrasonography **5** **6** **99** .

The type of follow-up visit after medication abortion has evolved over time. The mifepristone FDA label includes recommendations for follow up **23** . However, some patients choose not to return for follow-up; this likely is due to the high success rates and because patients are able to self-assess abortion completion **100** **101** **102**.

Remote Assessment and Self-Assessment

Follow-up can be performed by telephone at 1 week, with subsequent at-home urine pregnancy testing at 4 weeks after treatment, which avoids the need for the patient to go to a facility **103** **104** **105** **106**. Most studies have used a short series of questions that ask patients whether they have experienced bleeding and cramping (including how much and for how long) and whether they still feel pregnant or if they think the pregnancy has passed **104** **107**. When the clinician and the patient think that expulsion has occurred based on symptomatology, they are correct 96–99% of the time **104** **108**. Although urine pregnancy testing alone with standard high-sensitivity or low-sensitivity tests has not been shown to be a viable alternative to other forms of follow-up, newer semiquantitative or multilevel at-home urine hCG tests have shown promise in accurately identifying ongoing pregnancies after medication abortion **109** **110** **111** **112**.

Clinical Follow-Up

When a patient obtains in-person follow-up after medication abortion, transvaginal ultrasonography is commonly used, although it is not required **5** . Incorrect interpretation of ultrasound examination results can lead to unnecessary interventions such as an unneeded uterine aspiration **5** . If an ultrasound examination is performed at follow-up after medication abortion, the sole purpose is to determine whether the gestational sac is present or absent. The measurement of endometrial thickness or other findings do not predict the need for subsequent uterine aspiration **113**. In research trials, when a transvaginal ultrasound examination shows no evidence of a gestational sac 1 week after mifepristone use, only 1.6% of patients needed subsequent uterine evacuation **113**.

GBP-PET00050

Serum hCG testing before treatment and 1 week after treatment is another option for follow-up examination after medication abortion; however, data about use of this approach are lacking for gestations beyond 63 days. This strategy may be more effective than ultrasonography to confirm abortion completion in patients who were below the threshold for visualization of a gestational sac at the time of their medication abortion **114**. Patients do not need to return to the same facility; they can obtain serum hCG testing at a convenient location **114** **115**. The patient should then be informed of the result. A serum hCG level decrease of at least 80% over 6–7 days after initiating treatment with mifepristone and misoprostol indicates a successful abortion **114**. In a randomized trial of in-clinic transvaginal ultrasound examination or serum hCG testing follow-up, 24.5% of patients were lost to follow-up, there were no significant differences reported in unplanned visits and interventions by 2 weeks (6.6% versus 8.2%, respectively) or in uterine evacuation rates by 4 weeks (4.4% and 1.4%, respectively) **116**.

How is incomplete medication abortion or ongoing pregnancy managed?

Guidelines for intervention vary for patients who have delayed expulsion, an incomplete medication abortion (ie, persistent gestational sac on ultrasonography without evidence of embryonic cardiac activity or retained tissue), or an ongoing pregnancy (ie, continuing development with embryonic cardiac activity).

Delayed Expulsion

After induced or spontaneous expulsion, the uterus will normally contain sonographically hyperechoic tissue or “thick” endometrial stripe that consists of blood, blood clots, and decidua. Rarely does this ultrasound finding in patients who have undergone medication abortion indicate a need for intervention. In the absence of excessive bleeding or pain by patient report, clinicians can monitor such patients based on symptoms.

Incomplete Medication Abortion

GBP-PET00051

An incomplete medication abortion can be treated with a repeat dose of misoprostol, uterine aspiration, or expectant management, depending on the clinical circumstances and patient preference **23** **30** **117** **118**. Studies indicate that even with a retained sac at 2 weeks after medication abortion, intervention is unnecessary, and that expulsion will typically occur in the ensuing weeks **30** . However, some patients with incomplete expulsion will have bothersome symptoms, such as prolonged and irregular bleeding episodes. Patients with incomplete medication abortion 1 week after treatment can safely receive another dose of misoprostol **28** **118** or repeat misoprostol doses can be used for a persistent gestational sac **117**. Patients who prefer not to wait or do not desire medical management can choose to have a uterine evacuation at any time.

Ongoing Pregnancy

Ongoing pregnancy after medication abortion can be treated with a repeat dose of misoprostol or uterine aspiration, depending on the clinical circumstances and patient preference. In an analysis of data from two randomized trials with 14 cases of ongoing pregnancy, treatment with a repeat dose of misoprostol, 800 micrograms administered vaginally, resulted in expulsion of the products of pregnancy in five cases (36%); in an additional four cases (29%), gestational cardiac activity was no longer present at the next follow-up visit **118**. If gestational cardiac activity persists at follow-up after a second dose of misoprostol, uterine aspiration should be performed.

What is the recommended timing of contraception initiation after medication abortion?

Patients undergoing medication abortion who desire contraception should be counseled that

- almost all contraceptive methods, except IUDs and permanent contraception, can be safely initiated immediately on day 1 (mifepristone intake) of medication abortion.
- all contraceptive methods can be safely initiated after successful medication abortion.

Patients who select depot medroxyprogesterone acetate (DMPA) for contraception should be counseled that administration of DMPA on day 1 of the medication abortion regimen may increase the risk of ongoing pregnancy **119**.

GBP-PET00052

Providing desired contraception as soon as possible to patients undergoing medication abortion enables the greatest flexibility in care and decreases barriers to initiating contraception. The CDC and World Health Organization (WHO) support the initiation of almost all methods of contraception on day 1 of the medication abortion or on the same day as mifepristone administration **5** **6** **120**. Permanent contraception procedures may be performed once abortion is confirmed complete.

Concern has been raised that the immediate use of hormonal contraception that contains progestins could theoretically interfere with medication abortion efficacy. Etonogestrel implant use does not affect medication abortion outcomes **121** **122**. However, DMPA injection at the time of mifepristone administration may slightly increase the risk of an ongoing pregnancy **119**. In a randomized trial that evaluated the effects of DMPA injection timing on medication abortion outcomes, ongoing pregnancy was more common among those randomized to receive DMPA injection on the day of mifepristone administration compared with those who received DMPA at a follow-up visit (3.6% versus 0.9%; 90% CI, 2.7 [0.4–5.6]), although the proportion undergoing aspiration for any reason did not significantly vary (6.4% versus 5.3%; 90% CI, 1.1 [−2.8 to 4.9]) **119**. Patients should be counseled about this small risk of ongoing pregnancy, which needs to be weighed against the risk of potentially not receiving their desired method of contraception.

Patients do not experience a higher rate of IUD expulsion with placement in the first week after medication abortion as compared with 3 to 6 weeks later **123** **124**. However, IUD placement within 6 weeks after medication abortion is associated with a higher expulsion rate compared with IUD placement remote from pregnancy; the time frame after 6 weeks at which this rate decreases is unknown. Placement of a copper or levonorgestrel IUD close to the time of abortion results in improved uptake of a desired IUD compared with placement at an additional follow-up visit several weeks after the abortion **123** **124** **125**, although overall use rates at 6 months may not differ **126**. The IUD expulsion risk should be weighed against the potential for more patients to receive their desired IUD if it is placed sooner rather than later.

How should patients be counseled about the effect of medication abortion on future fertility and pregnancy outcomes?

GBP-PET00053

Patients can be counseled that medication abortion does not have an adverse effect on future fertility or future pregnancy outcomes **5** **6** . Studies consistently demonstrate that medication abortion has no negative effect on future fertility or pregnancy outcomes. A study from China found that patients who had a prior mifepristone abortion had lower odds of preterm birth compared with those who had never been pregnant (adjusted OR, 0.77; 95% CI, 0.61–0.98), and the frequencies of low-birth-weight infants and mean lengths of pregnancy were similar in both groups **127** . No significant differences were reported in risk of preterm delivery, frequency of low-birth-weight infants, or mean infant birth weight in the comparisons of patients who had previous mifepristone abortion and patients who had uterine evacuation. In a registry-based study from Scotland, no association was found between prior abortion and subsequent preterm birth during the period 2000–2008, when 68% of abortions were medication-induced **128** .

Summary of Recommendations

The following recommendations are based on good and consistent scientific evidence (Level A):

- Combined mifepristone–misoprostol regimens are recommended as the preferred therapy for medication abortion because they are significantly more effective than misoprostol-only regimens. If a combined mifepristone–misoprostol regimen is not available, a misoprostol-only regimen is the recommended alternative.

- Clinicians should counsel patients that medication abortion failure rates, especially continuing pregnancy rates, increase as gestational age approaches 10 weeks.

- Any clinician with the skills to screen patients for eligibility for medication abortion and to provide appropriate follow-up can provide medication abortion.

- Patients can safely and effectively use mifepristone at home for medication abortion.

- Patients can safely and effectively self-administer misoprostol at home for medication abortion.

GBP-PET00054

- Nonsteroidal anti-inflammatory drugs are recommended for pain management in patients who undergo a medication abortion.

- Routine in-person follow-up is not necessary after uncomplicated medication abortion. Clinicians should offer patients the choice of self-assessment or clinical follow-up evaluation to assess medication abortion success. If medically indicated or preferred by the patient, follow-up evaluation can be performed by medical history, clinical examination, serum human chorionic gonadotropin (hCG) testing, or ultrasonography.

- If an ultrasound examination is performed at follow-up after medication abortion, the sole purpose is to determine whether the gestational sac is present or absent. The measurement of endometrial thickness or other findings do not predict the need for subsequent uterine aspiration.

The following recommendations are based on limited or inconsistent scientific evidence (Level B):

- Medication abortion is not recommended for patients with any of the following: confirmed or suspected ectopic pregnancy, intrauterine device (IUD) in place (the IUD can be removed before medication abortion), current long-term systemic corticosteroid therapy, chronic adrenal failure, known coagulopathy or anticoagulant therapy, inherited porphyria, or intolerance or allergy to mifepristone or misoprostol.

- Before undergoing medication abortion, patients should be counseled regarding the teratogenicity of misoprostol in the event of an unsuccessful medication abortion.

- Before medication abortion is performed, the clinician should confirm pregnancy and estimate gestational age. For patients with regular menstrual cycles, a certain last menstrual period within the prior 56 days, and no signs, symptoms, or risk factors for ectopic pregnancy, a clinical examination or ultrasound examination is not necessary before medication abortion.

- Most patients with clinical indications for an ultrasound examination before medication abortion can be initially screened with transabdominal ultrasonography, reserving transvaginal ultrasonography for situations in which further clarification is required.

GBP-PET00055

- Medication abortion can be provided safely and effectively by telemedicine with a high level of patient satisfaction.

- The routine use of prophylactic antibiotics is not recommended for medication abortion.

- An incomplete medication abortion can be treated with a repeat dose of misoprostol, uterine aspiration, or expectant management, depending on the clinical circumstances and patient preference.

- Ongoing pregnancy after medication abortion can be treated with a repeat dose of misoprostol or uterine aspiration, depending on the clinical circumstances and patient preference.

- Patients undergoing medication abortion who desire contraception should be counseled that

  - almost all contraceptive methods, except IUDs and permanent contraception, can be safely initiated immediately on day 1 (mifepristone intake) of medication abortion.

  - all contraceptive methods can be safely initiated after successful medication abortion.

- Patients who select depot medroxyprogesterone acetate (DMPA) for contraception should be counseled that administration of DMPA on day 1 of the medication abortion regimen may increase the risk of ongoing pregnancy.

- Patients can be counseled that medication abortion does not have an adverse effect on future fertility or future pregnancy outcomes.

The following recommendations are based primarily on consensus and expert opinion (Level C):

- Patients who choose abortion should be counseled about all methods available as well as the risks, advantages, disadvantages, and the different features of these options.

- Most patients at 70 days of gestation or less who desire abortion are eligible for a medication abortion.

GBP-PET00056

- Patient counseling before medication abortion should include discussion of when patients should contact their clinician in the case of heavy bleeding (soaking more than two maxi pads per hour for 2 consecutive hours) and when to access urgent intervention.

- All patients with a continuing pregnancy after using mifepristone and misoprostol should be provided with all pregnancy options and a thorough discussion of the risks and benefits of each.

- In the very rare case that patients change their mind about having an abortion after taking mifepristone and want to continue the pregnancy, they should be monitored expectantly.

- Rh testing is recommended in patients with unknown Rh status before medication abortion, and Rh D immunoglobulin should be administered if indicated. In situations where Rh testing and Rh D immunoglobulin administration are not available or would significantly delay medication abortion, shared decision making is recommended so that patients can make an informed choice about their care.

- Clinicians who wish to provide medication abortion services should be trained to perform uterine evacuation procedures or should be able to refer to a clinician who has this training.

Medication abortion up to 70 days of gestation. ACOG Practice Bulletin No. 225. American College of Obstetricians and Gynecologists. Obstet Gynecol 2020;136:e31–47.

The MEDLINE database, the Cochrane Library, and the American College of Obstetricians and Gynecologists' own internal resources and documents were used to conduct a literature search to locate relevant articles published between January 2000 and February 2020. The search was restricted to articles published in the English language. Priority was given to articles reporting results of original research, although review articles and commentaries also were consulted. Abstracts of research presented at symposia and scientific conferences were not considered adequate for inclusion in this document. Guidelines published by organizations or institutions such as the National Institutes of Health and the American College of Obstetricians and Gynecologists were reviewed, and additional studies were located by reviewing bibliographies of identified articles. When reliable research was not available, expert opinions from obstetrician–gynecologists were used.

Studies were reviewed and evaluated for quality according to the method outlined by the U.S. Preventive Services Task Force:

- I Evidence obtained from at least one properly designed randomized controlled trial.
- II-1 Evidence obtained from well-designed controlled trials without randomization.
- II-2 Evidence obtained from well-designed cohort or case–control analytic studies, preferably from more than one center or research group.
- II-3 Evidence obtained from multiple time series with or without the intervention. Dramatic results in uncontrolled experiments also could be regarded as this type of evidence.
- III Opinions of respected authorities, based on clinical experience, descriptive studies, or reports of expert committees.

Based on the highest level of evidence found in the data, recommendations are provided and graded according to the following categories:

Level A—Recommendations are based on good and consistent scientific evidence.

Level B—Recommendations are based on limited or inconsistent scientific evidence.

Level C—Recommendations are based primarily on consensus and expert opinion.

ABSTRACT

Objectives: To compare outcomes among patients who did or did not have pre-abortion ultrasound or pelvic exam before obtaining medication abortion (MA) via direct-to-patient telemedicine and mail.
Study design: We analyzed data from participants screened for enrollment into the TelAbortion study at five sites from March 25 to September 15, 2020. We compared participants who had preabortion ultrasound or pelvic exam ("test-MA") to those who did not ("no-test MA"). Outcomes were: abortion not complete with pills alone (i.e., had procedure intervention or ongoing pregnancy), ongoing pregnancy separately, ectopic pregnancy, hospitalization and/or blood transfusion, and unplanned clinical encounters. We used propensity score weighting and multivariable logistic regression to adjust for baseline characteristics.
Results: Our analysis included 287 participants who had no-test MA and 125 who had test-MA. Abortion was not complete with pills alone in 16of 287 (5.6%) no-test MA patients compared to 2of 123 (1.9%) test-MA patients (adjusted risk difference [aRD] = 4.3%, 95% confidence interval [CI]: 1.4%–7.1%). No ectopic pregnancies were detected. Groups did not differ regarding hospitalization and/or blood transfusion ($p = 0.76$) or ongoing pregnancy diagnosis ($p = 0.59$). Unplanned clinical encounters were more common in no-test MA patients (35of 287, 12.5%) than test-MA patients (10of 125, 8.0%, aRD = 6.7%, 95% CI: 0.5%–13.1%).
Conclusions: Compared to patients who had pre-abortion ultrasound, patients who had no-test MA via telemedicine were more likely to have abortions that were not complete with pills alone and/or unplanned clinical encounters. However, both no-test and test-MA patients had similar and very low rates of ongoing pregnancy and hospitalization or blood transfusion.
Implications: Omitting pre-abortion ultrasound before provision of medication abortion via telemedicine does not appear to compromise safety or result in more ongoing pregnancies. However, compared to patients who have preabortion ultrasound, patients who do not have pre-abortion tests may be more likely to seek post-treatment care and have procedural interventions.

1. Introduction

The COVID-19 pandemic triggered intense interest in delivery of abortion care by telehealth. Clinical guidelines for medication abortion (MA) in the United States [1–3] and elsewhere [4], were revised to enable providers to communicate with patients virtually to assess eligibility and evaluate outcomes using history and

self-administered urine tests without examination, ultrasound, or laboratory tests, and to deliver abortion medications by mail. In some countries that have adopted all of these elements, most people can now legally obtain MA without leaving their homes. Recent retrospective studies from the United Kingdom and Canada indicate that this approach is highly acceptable to patients and can decrease waiting times for MA without compromizing safety or efficacy [5–8].

Information on the safety and efficacy of a fully remote MA approach in the US is critical for informing regulatory and programmatic decisions about MA service provision in this country. Our ongoing TelAbortion study has offered MA by direct-to-patient telemedicine and mail to people in multiple US states for the past 5 years [9,10]. Although the investigational plan had required participants to obtain an ultrasound or pelvic exam before shipment of MA drugs, when the COVID crisis worsened in 2020, some study investigators began waiving this requirement, as well as all laboratory tests, when they judged that doing so was safe and necessary to protect the participant's wellbeing. In this analysis, we used data from the TelAbortion study to explore the effect of this approach on clinical outcomes, service delivery parameters, and participant satisfaction.

2. Materials and methods

TelAbortion is a prospective, multicenter single-arm trial initiated in 2016 designed to assess the safety and feasibility of providing medication abortion via direct-to-patient telemedicine and mail. Details of the protocol are described elsewhere [9,10].

Individuals expressing interest in the TelAbortion service first had a conversation with site staff via telephone or video conference to learn more about study procedures and undergo preliminary eligibility screening. After providing signed informed consent (documented via electronic signature), each participant had a videoconference with a study clinician who assessed eligibility for treatment. In early March, in response to exigencies of the COVID-19 pandemic, study clinicians at 5 of the 9 sites began on a case-by-case basis to provide treatment without screening ultrasound, which had previously been uniformly used in the study. These five sites enrolled participants in 10 jurisdictions: Colorado, Georgia, Illinois, Maine, Maryland, Minnesota, Montana, New Mexico, New York, and District of Columbia. In selecting patients for this simplified service, clinicians followed recently released clinical guidelines [3]; although specific criteria were not uniform, an ultrasound was typically not required if the patient reported a sure menstrual period starting within the past 69 days and had no symptoms of or risk factors for ectopic pregnancy. In addition, clinicians omitted ultrasound only if they judged that the process of obtaining the test would compromise the welfare of the patient, e.g., by delaying the abortion. With or without a screening ultrasound, if the gestational duration was ≤69 days and the participant was eligible for MA, the participant selected a plan for follow-up tests (ultrasound, serum HCG measurements, or home urine pregnancy test), and the clinic mailed a package containing abortion medications and instructions. Participants were told to take mifepristone (200 mg orally) followed by misoprostol (800 or 1600 mcg, at the clinician's discretion). The clinician assessed abortion outcome using information provided by participants via telephone call or online survey. Participants or their insurance carriers were charged for all services they received from study sites and from any non-study facilities. Participants also completed an exit questionnaire via phone or on-line survey about satisfaction of the TelAbortion service and out-of-pocket costs.

This analysis includes all enrolled participants who were screened at the five sites that were omitting preabortion tests for some patients between March 24, 2020 and September 15, 2020. Patients included in this analysis must have also taken mifepristone, reported the last menstrual period (LMP) onset date, and had a known abortion outcome based on tests or history alone. March 24, 2020 was the screening date of the first participant after the onset of the COVID-19 pandemic who had a "no-test MA," i.e., MA without pretreatment ultrasound or pelvic exam. We included only the first TelAbortion had by each individual during this interval.

Our aim was to compare post-treatment clinical, service delivery, and acceptability outcomes of two groups of participants: those who had no-test MA ("no-test MA" group) and those who had a pre-treatment ultrasound or pelvic exam ("test-MA" group). We examined five clinical outcomes: abortion not complete with pills alone (defined as the patient having a procedure such as aspiration to complete the abortion and/or had a viable pregnancy documented by ultrasound at any time during follow-up); diagnosis of ongoing pregnancy separately; diagnosis of ectopic pregnancy; unplanned clinical encounters (i.e., instances when a patient sought in-person medical care related to the abortion and the visit was not planned before package shipment); and serious adverse events (hospitalization or blood transfusion). We examined 2 service delivery outcomes to determine if no-test MA helped the telemedicine process move quicker and enable patients to initiate MA sooner: interval > 7 days between the initial participant contact with study staff and package shipment; and gestational duration > 63 days (per LMP onset) at the time of mifepristone ingestion. We assessed the latter only among participants with gestational duration ≤ 63 days from LMP onset to first contact. Finally, we examined three acceptability outcomes: participant-reported satisfaction with the overall TelAbortion service; future preference for abortion care (i.e., TelAbortion or in-person scare); and out-of-pocket abortion-related costs (categorized as ≤ $100, $101-250, $251-400, $400-550, > $550).

We compared clinical outcomes between test-MA and no-test MA groups using unadjusted and adjusted logistic regression models to estimate risk differences (RDs) with 95% confidence intervals (CIs). The adjusted models included propensity scores using inverse probability of treatment weights to address potential confounding between groups. We calculated propensity scores using logistic regression to model the probability of having no-test MA based on the following variables: age group, race/ethnicity, education, number of previous pregnancies (0, 1, ≥ 2), gestational age (GA) by LMP at time of videoconference (≤ 42, 43–63, or > 63 days), urban or rural residence (using U.S. Census designation), distance from participant's residence to the study site, insurance used to pay for the abortion service, and study site. We assessed whether propensity score weighting achieved balance among baseline characteristics between study groups by calculating standardized differences before and after weighting; a standardized difference of -0.1 to 0.1 indicated adequate balance [11]. Our multivariable logistic regression models of clinical outcomes were weighted on the propensity score and included the following covariates for double robust estimation on these characteristics: site, GA at videoconference, and any variable not adequately balanced by propensity score weighting.

We used the same method for analysis of service delivery outcomes, except that in the outcome of GA > 63 days at time of mifepristone ingestion, we used GA by LMP at first contact with the site in lieu of GA at videoconference in the propensity score calculation and multivariable model of the outcome.

For acceptability outcomes, we used a Fisher's exact test to compare participant-reported satisfaction and future preference for abortion care by study group. For out-of-pocket costs, we analyzed the range estimates reported by no-test MA and test-MA patients and stratified by whether insurance was used to pay for any part of abortion care. We used univariable and multivariable log-binomial regression to determine if no-test MA participants were less likely

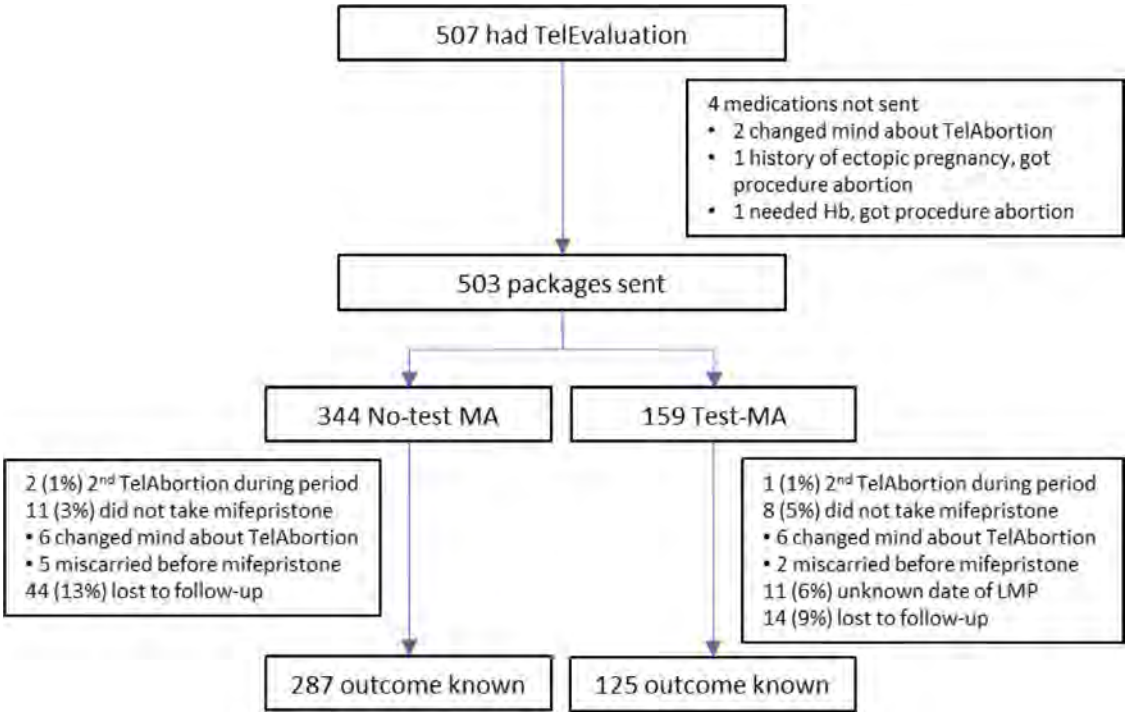

Fig. 1. U.S. TelAbortion study population included in analysis comparing use of no-test medication abortion (no-test MA) and use of preabortion ultrasound or pelvic exam before medication abortion (Test-MA), March 24 – September 15, 2020.

than test-MA participants to report out-of-pocket costs exceeding $400 for abortion-related care. The multivariable regression model included adjustment for use of insurance and the cost of abortion service charged by sites. We chose the $400 threshold for this outcome because it was the cost category closest to the median cost of service charged by sites (median: $375, range $250–450).

We conducted sensitivity analyses of clinical outcomes to examine whether results were robust after excluding participants who: (1) had abortion outcome determined based on history alone (i.e., without ultrasonography, serum HCG measurement, or HSPT); (2) had GA > 63 days or (3) had GA ≤ 35 days by LMP at time of the videoconference; (4) had extreme low or high propensity scores (< 0.1 or > 0.9, Figure A.1). We also examined the potential influence of study attrition by (5) including participants who were lost to follow-up assuming all did not have the outcome in question.

We conducted all analyses using SAS version 9.4 (SAS Institute Inc., Cary, NC, USA). The study was approved by the Advarra Institutional Review Board and is registered with clinicaltrials.gov (NCT02513043).

3. Results

Sites mailed 503 TelAbortion packages during the analysis period (Fig. 1). We excluded 91 (18%) occurrences because participants did not provide a LMP date, did not take mifepristone, or did not have a recorded abortion outcome. Our final analysis included 287 no-test MA and 125 test-MA participants. The two groups differed in many characteristics (Table 1). For example, compared to test-MA participants, no-test MA participants were more likely to be aged ≥35 years, be non-Hispanic Black, have above high school education, and have GA ≤ 42 days. No-test MA participants were less likely than test-MA participants to live ≥ 150 miles from the study site and have GA > 63 days. The proportion of participants having no-test MA at each site ranged from 47.4%–84.3%. After weighting on propensity scores, the groups were balanced on all characteristics except urban/rural residence (Table A.1); therefore, we included urban/rural residence in multivariable logistic regression models of clinical and service delivery outcomes.

All 412 participants had outcome information on unplanned clinical encounters (Table 2). Two participants in the test-MA group were known to have had a clinical encounter, but sites were unable to obtain information on abortion outcome, blood transfusion, or hospitalization, thus they were excluded from analysis of those outcomes. Overall, 392of 410 (95.6%) participants had a complete MA with pills alone. Abortion was not complete with pills alone for more patients in the no-test than in the test-MA group (5.6% and 1.6%, respectively). In adjusted analysis, the likelihood of this outcome was significantly higher by 4.3 percentage points (95% CI: 1.5, 7.1) among no-test MA participants. Among the 18 participants who had an abortion that was not complete with pills alone (i.e., had a procedure intervention and/or ongoing pregnancy), 5 received care at an emergency room or urgent care center, 6 received care at an office or clinic not affiliated with the study site, and seven received care at a center affiliated with the study site. More patients in the no-test MA group (12of 274, 4.2%) than in the test-MA group (0of 123) had procedure interventions for reasons not specifically noted as ongoing pregnancy ($p < 0.01$, data not shown). We found no statistically significant difference between groups regarding ongoing pregnancy alone or likelihood of serious adverse events, and no ectopic pregnancies were detected. Among the 3 participants with serious adverse events (i.e., hospitalization and/or blood transfusion), two individuals in the no-test MA group received procedure interventions and blood transfusions during emergency room visits and one individual in the test-MA group was hospitalized due to fever and abdominal pain and later discharged after showing improvement on antibiotics and fluids. The proportion of participants who had unplanned clinical encounters after treatment was significantly higher (6.7%; 95% CI: 0.5, 13.1) in the no-test MA group than the test-MA group. Sensitivity analyses showed consistent re-

Table 3
Effect of no-test approach to medication abortion on acceptability outcomes in TelAbortion study, March 25 to September 15, 2020

	No-test MAn (%)	Test-MAn (%)	*p* value[a]
Satisfaction with TelAbortion service	N = 256	N = 112	
Very satisfied	228 (89.0%)	99 (87.5%)	$p = 0.50$
Satisfied	25 (9.8%)	14 (12.5%)	
Unsatisfied	0	0	
Very unsatisfied	3 (1.2%)	0	
Future preference	N = 255	N = 111	
In-person care	9 (3.5%)	5 (4.5%)	$p = 0.14$
TelAbortion	233 (91.4%)	105 (94.6%)	
No preference	13 (5.1%)	1 (0.9%)	

No-test MA, no-test medication abortion; Test-MA, test medication abortion.
[a] Fisher's exact test.

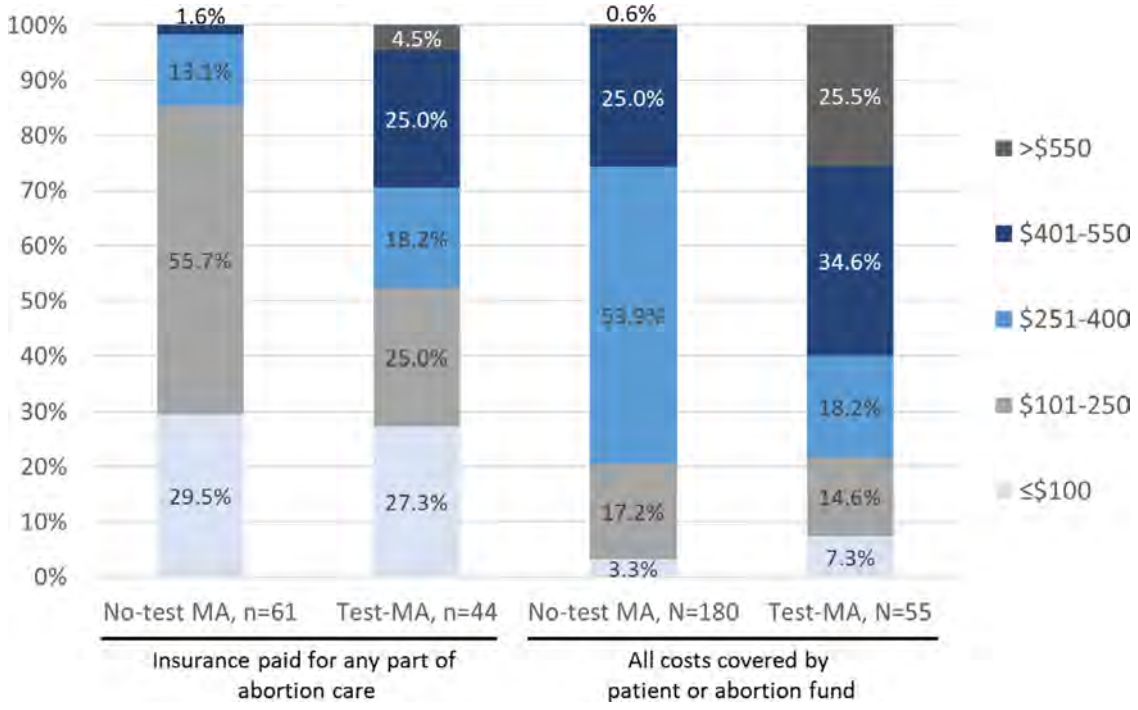

Fig. 2. Patient reported out-of-pocket costs by patients receiving no-test medication abortion (no-test MA) and those who had pre-abortion ultrasound or pelvic exam (test-MA) in the TelAbortion study.

sults, though the association of no-test MA and unplanned clinical encounters was not statistically significant when excluding participants with extreme propensity scores and including participants lost to follow-up (Figure A.2).

Our adjusted analysis of service delivery outcomes indicated significant or borderline significant differences between groups. Compared to test-MA participants, the proportion of participants who obtained their medications > 7 days after initial contact was 21.2 percentage points (95% CI: 9.1, 33.4) lower in the no-test MA group than the test-MA group (Table 2). Similarly, among participants with GA ≤ 63 days at first contact with sites, the proportion who took mifepristone at GA > 63 days was 6.2 percentage points (95% CI: -0.2, 12.6) lower in the no-test MA group than the test-MA group.

In the analysis population, 256 no-test MA and 112 test-MA participants completed exit questionnaires (Table 3), including 67 (26.2%) no-test MA and 16 (14.3%) test-MA via online survey. More than 98% of participants in both groups reported being very satisfied or satisfied with the TelAbortion service, and > 91% in both groups said they would prefer TelAbortion for a future abortion. Among the 340 participants who reported out-of-pocket costs, those who had no-test MA reported lower out-of-pocket costs whether or not they used insurance (Fig. 2). After controlling for insurance used and site-specific costs of the abortion service, significantly fewer no-test MA (47of 241, 19.5%) than test-MA patients (46of 99, 46.5%) reported out-of-pocket costs exceeding $400 ($p <$ 0.01, data not shown).

4. Discussion

This analysis of patients receiving MA via direct-to-patient telemedicine and mail shows both benefits and drawbacks of no-test MA. Over 94% of patients in both no-test MA and test-MA groups had a complete MA with pills alone, which is comparable to success rates previously reported of mifepristone and misoprostol regimens [12–14]. Self-reported patient satisfaction was excellent for both no-test MA and test-MA patients, and we show evidence that no-test MA may enable patients to access MA via telemedicine sooner and at lower cost. However, no-test MA patients were more likely to have unplanned in-person clinical encounters and an abortion that was not complete with pills alone.

Our analysis found no evidence that no-test MA leads to an increased risk of outcomes of particular clinical concern (i.e., ongoing pregnancy, hospitalization or blood transfusion, ectopic pregnancy); these results are consistent with other studies [5,15,16]. However, our findings show that approximately 4.3% more no-test MA patients may have an intervention compared to patients who have pre-abortion tests. This differs from results of a large retrospective cohort study from the United Kingdom that examined use of telemedicine MA with no-test MA which showed that patients who have no-test MA may have higher MA success rates compared to patients who have screening ultrasonography [5]. This discrepancy may be explained by differences in how information was gathered on abortion outcome; while the UK study used program data and clinical incident reports for abortion outcome determination, our analysis includes data collected prospectively with rigorous efforts to obtain outcome information from participants. In our study, it is possible that no-test MA patients had slightly higher intervention and encounter rates due to concerns and anxiety related to providers and patients adapting to the new clinical practice; there may have been differences in counseling that made no-test MA patients more likely to seek care, and study providers may have been more likely to encourage no-test MA patients to seek in-person evaluation during follow-up contacts.

Notably, patients who had pre-abortion screening tests had an intervention rate of 1.6% which is lower than the average rate of 3%to 7% reported in studies of first-trimester MA [12–14,17]. This could indicate a reduced likelihood of patients seeking care during the COVID-19 pandemic. Such tendencies in delays or avoidance of care-seeking due to COVID-19 concerns has been documented in the general U.S. population [18]. This impact of reduced care-seeking would apply to patients in both no-test MA and test-MA groups, with the higher rate of care-seeking and interventions observed in the no-test MA group occurring for reasons hypothesized above.

Our results also show benefits of no-test MA in facilitating provision of MA sooner through telemedicine and reducing the cost burden. Previous studies show that cost is an important barrier to abortion access, and this disproportionately impacts people in states where Medicaid and other insurance plans may not cover abortion care [19,20]. By reducing out-of-pocket costs, use of no-test MA could facilitate more equitable expansion of access to MA via telemedicine.

This analysis has limitations. First, patients were not randomized to receive no-test MA or test-MA and the two groups differed on factors that may affect outcomes. To address this, we used propensity score weighting with double robust estimation on key variables and we also conducted numerous sensitivity analyses that showed our results to be robust under various scenarios; however, there could be residual confounding. Second, our sample size of 412 patients from five clinical sites is rather small, especially considering the rare nature of some clinical outcomes. However it is notable that, despite our small sample size, we did document significant differences in the study groups for more common outcomes. Our analysis is strengthened by the prospective data collection, consistent study monitoring, and low loss-to-follow-up. The geographic diversity of the study population within the US increases generalizability.

The COVID-19 pandemic led to profound changes in MA service provision, including increased use of no-test MA within both telemedicine and in-person services [16,21,22]. Overall, our results support the continued use of no-test MA since treatment success rates remain high and we saw no increase in more serious outcomes in this population. Our analysis also shows that no-test MA patients may have more post-MA interventions than patients who had preabortion tests; this increase could be temporary as providers and patients become more comfortable with clinical protocol changes, as has been shown with use of telemedicine more broadly [23]. Additional rigorous research and evaluation of no-test MA would help further elucidate the consequences of these shifts in practices.

ABSTRACT

Objectives: This study aimed to compare medication abortion outcomes among people screened without or with ultrasound or pelvic examination.

Study design: We used data collected from March 24, 2020, to September 27, 2021, at five TelAbortion Project sites that provided medication abortion with mifepristone and misoprostol by mail. Using logistic regression weighted on propensity scores, we compared outcomes in participants who had neither ultrasound nor examination before treatment (No-Test group) or had such tests (Test group). We analyzed outcomes separately for participants screened early in the analysis period (before September 15, 2020) or later. Outcomes included procedural abortion completion or ongoing pregnancy, serious adverse events, and unplanned posttreatment abortion-related clinical visits.

Results: Among 416 participants in the early period, the No-Test group had a significantly higher risk than the Test group of procedural abortion completion or ongoing pregnancy (5.6% vs 0.9%, risk difference 4.6%, 95% CI 1.5%, 7.7%) and abortion-related clinical visits (13.3% vs 6.3%; risk difference 7.0%; 95% CI 1.1%, 12.8%). Among 364 participants screened later, the risk of procedural abortion completion or ongoing pregnancy did not differ by group, while unplanned abortion-related clinical visits were less common in the No-Test group (9.9% vs 20.5%; risk difference −10.6%; 95% CI −20.1%, −1.1%). The risk of serious adverse events did not differ by group in either period.

Conclusions: When providers first began omitting ultrasound or pelvic examination before medication abortion, the practice was associated with increased risks of failure of complete abortion and posttreatment clinical visits; however, these increased risks resolved over time.

Implications: Medication abortion without pretreatment ultrasound or examination is effective and safe. This model should be routinely offered to eligible patients.

1. Introduction

In recent years, guidelines for first-trimester medication abortion (MA) with mifepristone and misoprostol have been updated to allow eligibility screening based on history alone without pretreatment sonography or pelvic examination [1,2]. A systematic review of 21 studies published in 2023 [3] as well as a large study published subsequently [4] concluded that effectiveness and complication rates were similar to rates reported in studies of patients who had pretreatment ultrasound. However, only two of the 22 studies compared outcomes in patients receiving MA with or without ultrasound contemporaneously in the same setting. One study [5], which included 327 patients treated in Hawaii in 2020, reported no differences in the unadjusted proportions of patients who required

additional treatment to complete the abortion, who visited a hospital or emergency department, or who had significant adverse events. The second study [6] was an analysis that we performed using data from 412 people who received MA in 2020 through the TelAbortion Project [7–9], a set of two prospective, multicenter, case series studies that evaluated provision of MA by telemedicine and mail. After adjusting for baseline differences, we found that participants without pretreatment ultrasound were less likely to complete the abortion with medications alone (risk difference 4.3%, $p < 0.01$) and more likely to have unplanned posttreatment clinical visits (risk difference 6.7%, $p = 0.03$). However, 94% of participants who did not have pretreatment ultrasound had a complete MA without intervention, and we saw no evidence that screening ultrasound was associated with an increased risk of ongoing pregnancy, hospitalization, or transfusion.

Despite these supportive findings, many clinicians in the United States still have reservations about history-based screening [10–12]; indeed, as of September 2023, it was legally prohibited in some 16 states, including states where abortion is legal and available [13]. Additional evidence documenting its safety and effectiveness may be helpful. The TelAbortion Project enrolled hundreds of additional participants after the period of our study described above. Here, we present an update of the prior analysis that includes the additional data.

2. Materials and methods

As described previously [7–9], people seeking MA through the TelAbortion Project were screened for MA eligibility by study clinicians using videoconference. Sites mailed mifepristone 200 mg and misoprostol 1600 mcg to consenting eligible participants with instructions to take the mifepristone followed within 48 hours by misoprostol. Providers used their standard practice regarding misoprostol dose (800 or 1600 mcg) and route for individual participants. Sites followed participants until abortions were complete and adverse events resolved. Study 1 was conducted under an Investigational New Drug Application filed with the United States Food and Drug Administration (FDA) and ran from 2016 through April 2021. Study 2 was not filed with FDA and ran from late 2020 through September 2021. The overlap reflected the changing regulatory requirements for dispensing mifepristone at that time [14]. The studies were conducted at the same sites and were essentially identical except that the gestational duration (GD) limit for treatment was 63 days in Study 1 and 70 days in Study 2, and the Study 1 protocol included an explicit requirement for pretreatment ultrasound, whereas the Study 2 protocol did not. Despite the Study 1 ultrasound requirement, clinicians at some sites began in March 2020 to omit the ultrasound when deemed necessary for patient welfare during the coronavirus disease 2019 (COVID-19) pandemic. Study 2 did not provide specific criteria for confirming eligibility without ultrasound; each clinician followed their institution's abortion policies. Studies 1 and 2 were approved by the Advarra Institutional Review Board and Allendale Investigational Review Board, respectively, and were registered with clinicaltrials.gov (NCT02513043 and NCT04599725, respectively).

The present analysis followed the same general methods described in our prior paper [6]. Our aim was to compare clinical and service delivery outcomes of participants who had neither an ultrasound nor pelvic examination before treatment ("No-Test" group) and those who had such a test ("Test" group). We used final data from TelAbortion participants screened between March 24, 2020 (the screening date of the first participant after the onset of the COVID-19 pandemic who had a No-Test MA) and September 27, 2021 (the screening date of the last TelAbortion Project participant enrolled) at the five project sites that contributed to our prior paper [6]. These data differ slightly from those used in that paper because of new information obtained since that time. Three of the five sites were Planned Parenthood affiliates (Planned Parenthood of the Rocky Mountains, Planned Parenthood of Montana, and Planned Parenthood North Central States), and the other two were independent (Maine Family Planning, carafem). Collectively, they provided abortion in 10 jurisdictions: Colorado, Georgia, Illinois, Maine, Maryland, Minnesota, Montana, New Mexico, New York, and District of Columbia. We excluded data from the two other sites that did not provide no-test abortions during the time of our prior analysis because the focus of this update paper was to determine whether the findings of the prior paper changed over time. The two excluded sites performed only 26 no-test abortions. As in the prior paper, we excluded participants who did not report the onset date of the last menstrual period (LMP) or who did not ingest mifepristone. If a participant had multiple eligible abortions during the analysis period, we included only the first. We also excluded participants from outcome analyses if we or the site investigator determined that follow-up was insufficient for ascertainment of that outcome.

The clinical outcomes were (1) abortion completed by a procedure or an ongoing pregnancy diagnosed by ultrasound during follow-up; (2) diagnosis of ongoing pregnancy separately; (3) serious adverse events (hospitalization, blood transfusion, or death); and (4) any unplanned abortion-related in-person clinical visit. To ascertain the last of these, both authors independently reviewed data from every in-person posttreatment visit to a medical facility or laboratory and coded it as abortion related if it was motivated by a concern about a medical problem or symptom related to the abortion or it resulted in detection of an abortion-related problem requiring further evaluation or treatment. These criteria were similar to those used for the prior paper [6]. The service delivery outcomes were (1) interval > 7 days between the participant's initial contact with study staff and medication shipment and (2) mifepristone ingestion > 63 days after LMP. The latter analysis excluded participants whose LMPs began > 63 days before initial contact.

As in the prior paper, we estimated unadjusted and adjusted risk differences with 95% CIs to compare outcomes between the No-Test and Test groups. Because we noted different results in participants screened during the period of our previous analysis (on or before September 15, 2020) and those screened later, we analyzed the data separately from the two periods, which we here refer to as Periods 1 and 2, respectively. We generated adjusted risk differences and 95% CIs from logistic regression models with inverse probability of treatment weights to address the imbalance of baseline confounders between groups. First, we calculated propensity scores using logistic regression to model the probability of omitting pretreatment ultrasound or pelvic examination based on the following variables: age group, race/ethnicity, education, number of previous pregnancies (0, 1, ≥2), linear and quadratic terms for GD by LMP at videoconference, urban/rural residence (using US Census designation), distance from participant's residence to the study site (< 150 miles, ≥150 miles), insurance used to pay for the abortion), and study site. In Period 2, the propensity score calculations also included a measure of calendar time, specifically whether the screening date was on or before April 13, 2021, vs later; April 13, 2021, was the date the FDA announced that mailing mifepristone was permitted during the COVID-19 pandemic. Our logistic regression models of clinical outcomes were weighted on propensity scores using stabilized inverse probability of treatment weights. We used the same analysis method for service delivery outcomes, except that in the outcome of mifepristone ingestion > 63 days after LMP, we used GD by LMP at first contact with the site instead of GD at videoconference in propensity score estimation.

To explore temporal trends with more granularity and to better understand how changes in health-seeking behavior over the course of the pandemic may have impacted our results, we divided Period 2 into two subperiods (Periods 2a and 2b) using the April 13, 2021,

cutoff date. We then used the propensity score weighting method described above to estimate adjusted proportions of participants with clinical outcomes in the No-Test and Test groups in each subperiod and created plots for each group showing the change in these proportions across Period 1 (March 24, 2020, to September 15, 2020, the period of the prior analysis), Period 2a (September 16, 2020, to April 13, 2021, the date of the FDA announcement), and Period 2b (April 14, 2021, to September 27, 2021, the screening date of the last participant enrolled in the study).

We conducted sensitivity analyses of clinical outcomes to examine whether results were robust after excluding participants who had abortion outcome determined based on history alone (i.e., without ultrasonography, serum human chorionic gonadotropin (HCG) measurement, or high-sensitivity urine pregnancy test). We also examined the influence of study attrition using multiple imputations with fully conditional specification to generate outcome values for people excluded due to loss-to-follow-up; we generated 20 data sets with missing outcomes imputed based on modeling the same variables used to calculate propensity scores, performed outcome analysis on each data set, and calculated pooled effect estimates.

We conducted analyses using SAS version 9.4 (SAS Institute Inc., Cary, NC, USA).

3. Results

The five study sites provided 1013 TelAbortions to participants screened from March 24, 2020, through September 27, 2021 (Fig. 1). Our analysis excluded 79 (8%) participants because the participant did not take mifepristone, did not report an LMP onset date, or had a previous abortion during the study period. We excluded an additional 154 (15%) participants because follow-up data on clinical outcomes were unavailable. The analysis population comprised 416 participants screened in Period 1 and 364 participants screened in Period 2, including 289 (62%) who had No-Test MA in Period 1 and 170 (47%) with No-Test MA in Period 2.

Pretreatment characteristics of the two groups differed by study group and period. In both periods, participants in the No-Test group were older and earlier in gestation (Table 1). In Period 1, No-Test participants were more likely to be non-Hispanic Black and to live within 150 miles from the study site, but these differences were not apparent in Period 2. Conversely, education did not differ significantly by group in Period 1, but the No-Test participants were more educated in Period 2.

Overall, 740 (95%) of 777 participants with known abortion outcomes had complete abortions without a procedure (Table 2). Complete abortions were confirmed by ultrasound, serum HCG tests, or urine pregnancy test in 654 (88%) of these 740 participants and by history alone in the rest. In the No-Test group, the proportion with test confirmation was significantly higher among participants screened in Period 1 than those screened in Period 2 (93% vs 83%, $p < 0.01$), but did not differ by period in the Test group. One participant in the No-Test group had scant bleeding after treatment and was found by ultrasound to have an ectopic pregnancy. The participant was hospitalized and had surgical treatment Three days after mifepristone ingestion. Two other participants were hospitalized for bleeding and discharged within One day.

Among participants screened in Period 1, the adjusted proportion of those who did not have complete abortions without a procedure was higher in the No-Test group than the Test group (5.6% vs 0.9%, risk difference 4.6%, 95% CI 1.5%, 7.7%, Table 3). The adjusted proportion of participants who had unplanned, abortion-related clinical visits was also higher in the No-Test group in Period 1 (13.3% vs 6.3%, risk difference 7.0%, 95% CI 1.1%, 12.8%). In contrast, in Period 2, we found no significant difference between groups regarding the adjusted proportion who did not have complete abortions without a

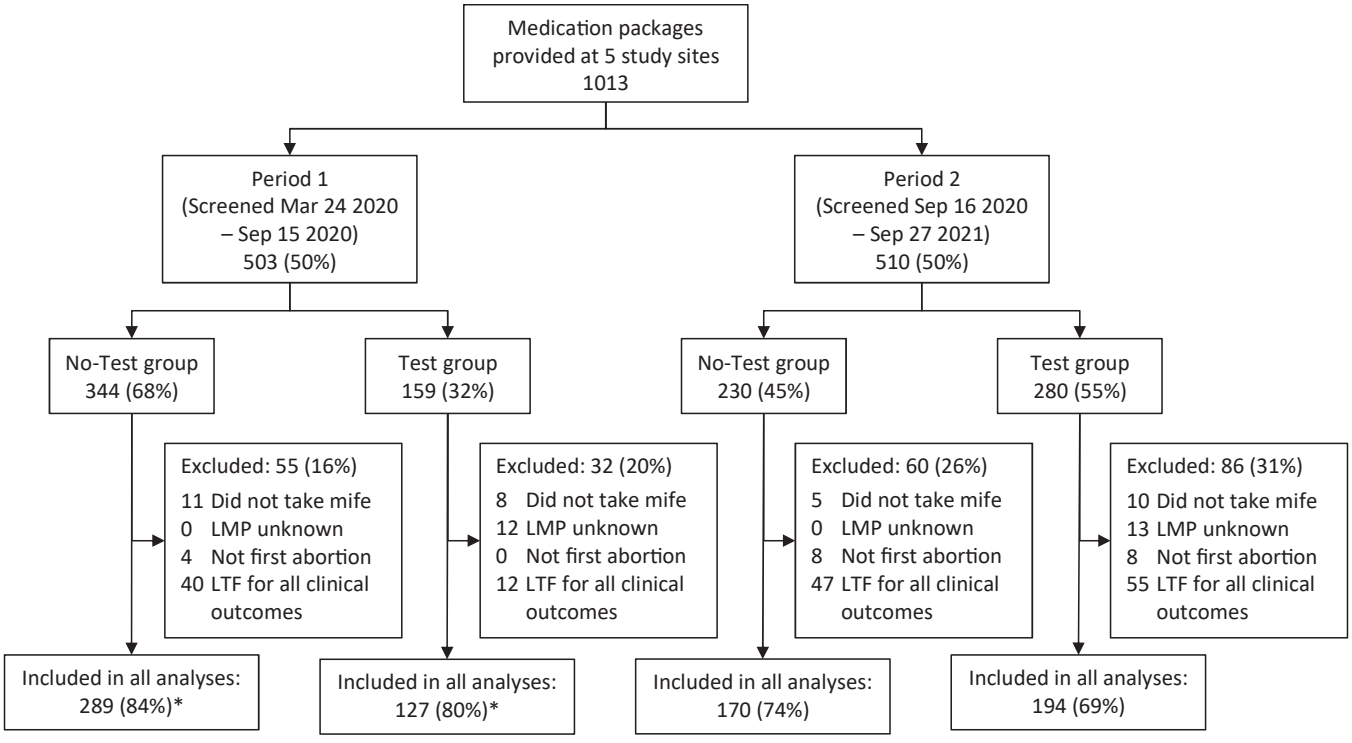

Fig. 1. Study population flowchart, United States, 2020–2021.
Percents are based on the number in the preceding box. The reasons for exclusion are hierarchical in the order listed; each excluded participant is counted only once.
*The numbers of participants in this time interval are more than the corresponding numbers in our prior paper (287 and 125 in the No-Test and Test groups, respectively) [5] because new information obtained after that paper indicated eligibility.
LMP, last menstrual period; LTF, lost to follow-up; mife, mifepristone.

GED, General Education Development; GD, gestational duration; LMP, onset of last menstrual period.
[a] The number of participants in this time interval is four more than the number in our prior paper [5] because new information obtained after that paper indicated eligibility.
[b] p-values calculated using χ^2 test of association.
[c] Participants could choose multiple responses. We coded each participant as Hispanic if that choice was checked, and otherwise as indicated.
[d] GD at provision of medications ranged from 25 to 72 d after last menses onset in the No-Test group and from 33 to 78 d by ultrasound in the Test group.

procedure (risk difference −1.2%, 95% CI −5.0%, 2.7%). Those in the No-Test group were significantly less likely than those in the Test group to have unplanned, abortion-related clinical visits (9.9% vs 20.5%, risk difference −10.6%, 95% CI −20.1%, −1.1%). Risks of other clinical outcomes did not differ significantly by group in either period. Unadjusted results are presented in Appendix A Table 1. Sensitivity analyses that excluded individuals with abortion outcomes determined based on history alone and that used multiple imputation to estimate outcomes for those excluded due to loss-to-follow-up yielded similar results (data not shown).

Participants in the No-Test group were significantly more likely to have eligibility confirmed and abortion medications mailed within Seven days after screening; the adjusted risk differences were > 13 percentage points in both periods (Table 3). The adjusted proportion of participants who took mifepristone more than 63 days gestation did not differ significantly between groups. Based on all information obtained before and after treatment, no participant is known to have ingested mifepristone at > 80 days of gestation.

In the Test group, the adjusted proportion of participants who did not have complete abortions without a procedure and who had unplanned, abortion-related clinical visits both increased across the duration of the study, from Period 1 to Period 2a and to Period 2b (Fig. 2). In the No-Test group, the proportions of participants with these outcomes were highest in Period 1 when the no-test approach was new to sites, then declined in Period 2a and rose in Period 2b. These outcomes were more common in the No-Test group than in the Test group in Period 1, but in Period 2a and 2b, these outcomes were more common the Test group. The risk of these outcomes rose substantially in both groups over the course of Period 2.

4. Discussion

This updated analysis corroborates some key findings from our earlier paper [6]. Specifically, it confirms that providing MA to people selected using history alone, without pretreatment ultrasound or pelvic examination, was not associated with increased risks

Table 2
Clinical outcomes in analysis population, by study group, United States, 2020–2021, *N* = 779

Characteristic	Period 1 (screened Mar 24 to Sep 15, 2020)[a]				Period 2 (screened Sep 16, 2020, to Sep 27, 2021)			
	No-Test		Test		No-Test		Test	
	n	%	*n*	%	*n*	%	*n*	%
Abortion outcomes								
Total with known outcomes	289		125		169		194	
Complete abortion without procedure	273[a]	94	123	97	161	95	183[a]	94
Confirmed by test[b,c]	253	93	111	90	133	83	157	86
Confirmed by history alone[c]	20	7	12	10	28	17	26	14
Procedure to terminate pregnancy	15	5	1	1	8	5	11	6
Ongoing pregnancy	4	1	1	1	5	3	4	2
Ectopic pregnancy	0	0	0	0	1	1	0	0
Other reason	11	4	0	0	2	1	7	4
Ongoing pregnancy not aborted	1	< 1	1	1	0	0	0	0
Serious adverse events								
Total with known outcomes	289		125		169		194	
Hospitalization	0		1	1	1	< 1	1[d]	< 1
Transfusion	2	1	0		0		1[d]	< 1
Deaths	0		0		0		0	
Unplanned, abortion-related, in-person visits								
Total with known outcomes	288		126		170		193	
Visits	36	13	12	10	21	12	38	20
Emergency department visits	9	3	5	4	5	3	13	7

Two participants in the Test group in the earlier period and one in the No-Test group in the later period were excluded from the analyses of abortion outcomes and serious adverse events because they had insufficient follow-up. One participant in each group in the earlier period and one in the Test group in the later period were excluded from the visits analysis because they had insufficient follow-up.

[a] One participant in the No-Test group and three in the Test group received misoprostol not supplied by the study and thus may have taken more than 1600 mcg misoprostol in total.

[b] Complete abortion confirmed by ultrasound, serum HCG tests, or urine pregnancy test.

[c] Proportion is among those with complete abortion without procedure.

[d] One participant had both a hospitalization and a transfusion.

of failure to terminate ongoing pregnancy or of posttreatment serious adverse events. Moreover, No-Test group participants were more likely to receive treatment within a week after initially contacting the study site.

Importantly, our new results appear to mitigate the findings of possible drawbacks of No-Test MA reported in our prior paper [6]. Among participants screened in the period of the prior study, those in the No-Test group were significantly more likely than those in the Test group to require a procedure to fully complete the abortion and to have unplanned clinical visits for abortion-related reasons. However, these elevated risks did not persist: in the later study period, abortion outcomes were similar in the two groups, and the No-Test group was less likely to have unplanned abortion-related visits after treatment. This marked temporal change cannot be directly explained by our data, but we note that the earlier period included the initial months of the COVID-19 pandemic, during which

Table 3
Adjusted risk difference in clinical and service delivery outcomes between No-test and Test groups in TelAbortion study, United States, 2020–2021, *N* = 780

GD at mifepristone ingestion > 63 d[c]				
No-Test	22/283 (9.0%)	−6.2% (−14.5%, 2.2%)	7/154 (10.7%)	−0.3% (−11.0%, 10.4%)
Test	22/118 (15.2%)		28/168 (10.9%)	

GD, gestational duration.

Proportions and risk differences are adjusted using inverse probability of treatment weighting (IPW) with stabilized weights. Propensity scores in IPW models were generated based on modeling the likelihood of having a No-Test MA based on age group, race/ethnicity, education, number of previous pregnancies, GD, urban/rural residence, distance from participant's residence to the study site, insurance used to pay for the abortion, and study site. Propensity score generation in the later period also incorporated screening date (≤April 13, 2021, vs ≥April 14, 2021).

[a] Two participants in the Test group in the earlier period and one in the No-Test group in the later period were excluded because they had insufficient follow-up for this outcome.

[b] One participant in each group in the earlier period and one in the Test group in the later period were excluded because they had insufficient follow-up.

[c] Analysis includes only participants with GD ≤63 d by LMP at first study contact. Model includes GD at first contact instead of GD at time of videoconference.

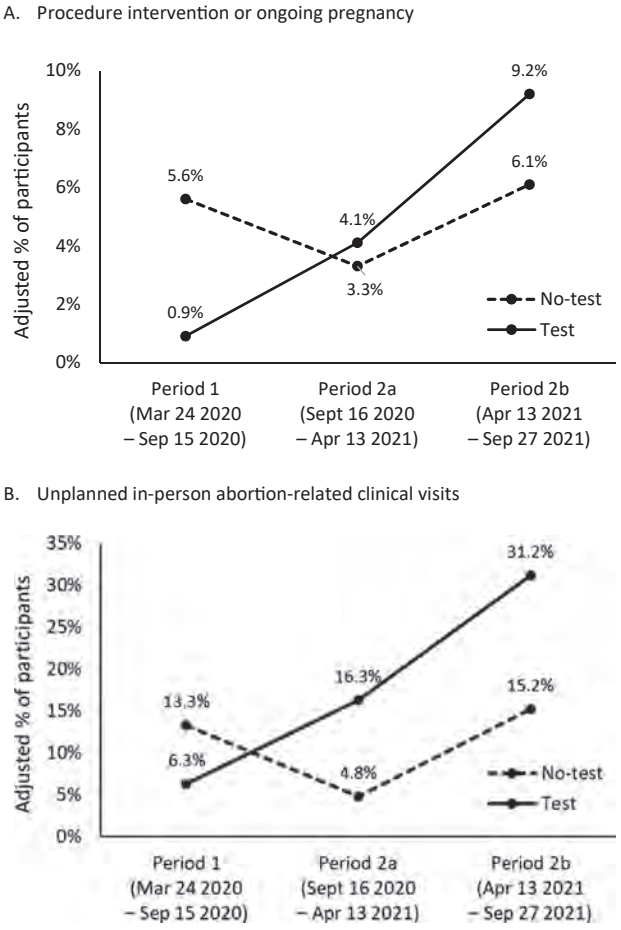

Fig. 2. Adjusted proportion* of participants with selected outcomes by study group over time, United States, 2020–2021, $N = 780$. A. Procedure intervention or ongoing pregnancy. B. Unplanned in-person abortion-related clinical visits.
*Adjusted proportions calculated from logistic regression models with inverse probability of treatment weighting (IPW). Propensity scores in IPW models were generated based on modeling the likelihood of having a No-Test MA based on age group, race/ethnicity, education, number of previous pregnancies, gestational duration, urban/rural residence, distance from participant's residence to the study site, insurance used to pay for the abortion, screening date, and study site.

physical distancing was strongly recommended to minimize infection risk [15]. We postulate that this recommendation may have resulted in a transient reduction in the frequency of in-person visits for nonserious problems in the Test group. However, because the no-test approach was novel in the United States in 2020 [16], unfamiliarity with the protocol may have led providers to encourage participants in the No-Test group to seek follow-up in person despite the pandemic. Subsequently, as pandemic concerns waned, participants in the Test group may have resumed a more typical pattern of in-person care for posttreatment concerns. In contrast, in the No-Test group, as experience with the no-test protocol grew, participants and their providers may have become more comfortable managing problems without in-person evaluation. Moreover, people who choose to have abortions without pretreatment tests may in general be inclined for many reasons to forgo in-person health care unless critically needed. These explanations are supported by our visual analysis of temporal trends and suggest that the favorable findings of the new data should reflect the expected pattern going forward.

The strengths of this study include prospective collection of data according to a standardized protocol, geographic diversity, the fairly high follow-up rate of 83% for all outcomes, and confirmation of complete abortion using objective tests in 88% of participants with that outcome. The study was not randomized, but we used robust methods to adjust for baseline differences between groups. However, the sample size was relatively small. Furthermore, abortions were provided by telemedicine and mail; the results may not apply to patients who have in-person care.

Currently, the FDA-approved label for mifepristone [17] lacks clarity regarding the advisability of using clinical history alone, without ultrasound or physical examination, to assess eligibility for provision of the drug. Although this screening approach can, in rare cases, result in treatment of someone with undetected advance gestation or ectopic pregnancy [18], our analysis strengthens the substantial evidence supporting the safety and effectiveness of this practice [3], as well as its benefit in accelerating treatment provision. We hope that these findings help prompt mifepristone manufacturers to submit and FDA to approve a label revision that explicitly reflects this evidence. Meanwhile, providers should routinely offer the no-test option to suitable patients following evidence-based guidelines [1,2,19].

ABSTRACT

Background Medical abortion provided via telemedicine is becoming more widely available, potentially decreasing travel time for in-person abortion evaluation.

Methods We conducted a retrospective chart review of all outpatient medical abortions from October 2016 through December 2019 at our academic medical centre in Portland, Oregon, USA. Using mifepristone administration logs, we identified patients who underwent abortion via direct-to-patient telemedicine or in clinic. Both groups had pre-abortion ultrasound examination. We extracted patient characteristics and geographic data to compare travel distance to clinic, ultrasound facility, and nearest advertised abortion clinic. We compared time from first contact until mifepristone ingestion and gestational age at mifepristone ingestion.

Results Median distance from mailing address to clinic for 80 telemedicine and 124 clinic medical abortions was 95 (range 4–377) and 12 (range 0–184) miles (p<0.01). Distance travelled to ultrasound facility was shorter for telemedicine patients (median 7 miles, range 0–150 vs 12 miles, range 0–184; p<0.01) excluding outliers >200 miles. Distance to nearest advertised abortion clinic was equal between groups (median 7 miles, p=0.4). Time to mifepristone administration (ingestion) was longer (11 vs 6 days; p<0.01) and median gestational age was higher (49 vs 44 days; p=0.01) for telemedicine.

Conclusions Telemedicine increases the reach of abortion providers and provides care to more geographically distant patients. Patients chose telemedicine abortion even when they had an equidistant option, suggesting that patients value telemedicine for reasons other than geographic convenience. This telemedicine delivery model that included ultrasound testing prior to abortion resulted in up to a 5-day delay in abortion initiation, which was not clinically significant.

Key messages

- Telemedicine expands geographic access to abortion in Oregon and Washington and does not result in clinically significant delayed care even when requiring ultrasound examination.
- Patients may choose to undergo abortion via telemedicine, even when an abortion clinic is geographically convenient.

INTRODUCTION

Compared with other regions of the United States (US), abortion is relatively accessible in the Pacific Northwest: in Oregon and Washington combined, there are more than 50 abortion clinics with regularly available appointments.[1] Despite the abundance of providers, most abortion clinics are located in urban centres, with 10% of reproductive-aged women in Washington and 23% in Oregon living in a county without an abortion clinic.[1] The provision of medical abortion is also limited by the US Food and Drug Administration (FDA), including an explicit requirement for dispensing mifepristone in a medical office or hospital and prohibition of pharmacy dispensing.[2] This requirement limits the ability to provide medical abortion via telemedicine, even while use of telemedicine is a rapidly expanding mode of healthcare administration globally.

In 2016, the TelAbortion Study began offering medical abortion via direct-to-patient telemedicine, dispensing mifepristone via mail under an Investigational New Drug application.[3] Patients complete pre-screening tests at local facilities, meet with a provider via videoconference, and receive the medication via mail.[3]

Currently, the TelAbortion Study is the only legally recognised way patients in the US can access medical abortion without entering a physical abortion clinic.[4] Telemedicine alleviates barriers to medical abortion such as the need to secure childcare or take time off work, and improves access for geographically remote patients by decreasing travel time and cost.[5–9]

We sought to compare demographic and geographic characteristics between patients choosing TelAbortion (telemedicine) versus clinic medical abortion at our urban, academic Family Planning Clinic in the Pacific Northwest. We questioned whether distance from an abortion clinic was farther for those undergoing TelAbortion and whether those choosing TelAbortion experienced later care due to a multistep process when ultrasound is a pre-abortion requirement.

METHODS

Study design

We performed a retrospective chart review of all medical abortions initiated at the Family Planning Clinic at Oregon Health & Science University (OHSU) between 1 October 2016 and 31 December 2019 to compare patient and procedural characteristics by method of care delivery: telemedicine or clinic.

Comparison groups

During the study period, our site provided medical abortion both via TelAbortion (telemedicine) and in clinic, self-selected by the patient.[3] Patients interested in telemedicine accessed a TelAbortion website and hotline to begin the study screening process, which included a requirement to be in Oregon or Washington for the videoconference and to receive medications via mail. They completed a gestational dating ultrasound at the facility of their choice. We accepted both formal and informal reports, given there was documentation of the ultrasound date, finding of intrauterine pregnancy, and gestational size. Unless Rhesus (Rh)-type was known, patients completed Rh-testing at the location of their choice. Patients visited with a provider through videoconference and received standard pre-abortion counselling and consent. After confirming eligibility and enrollment, we mailed abortion medications directly to the patient. Patients who called the main Family Planning Clinic phone number requesting medical abortion were scheduled in clinic. The clinic scheduler did not routinely offer TelAbortion, but referred patients to the study as requested. Patients presenting in clinic for medical abortion received ultrasound, Rh-typing, and mifepristone while on site. We sent additional prescriptions, including misoprostol, to the patient's chosen pharmacy.

During the study period, TelAbortion operated under two different billing models. From October 2016 to June 2018, TelAbortion patients underwent a video evaluation visit and obtained all medications at no cost, and received US$50 for study completion. Patients who called the main clinic telephone number were not informed that TelAbortion was available for no cost. After July 2018, the TelAbortion study transitioned to routinely billed care where patients or their insurance were responsible for all costs associated with medical abortion: ultrasound, Rh-typing and follow-up tests, as well as the video evaluation visit and medications. This change aligned the TelAbortion payment model with the clinic payment model.

For inclusion in this chart review, we used research and clinic mifepristone dispensing logs to identify eligible cases of induced medical abortion at <10 weeks' gestation, excluding patients aged <18 years, or without confirmed intrauterine pregnancy or non-viable pregnancies. These criteria matched the inclusion criteria of the TelAbortion study. We then compared patient characteristics and distance to care between those who initiated medical abortion via telemedicine versus in clinic. The Institutional Review Board at OHSU approved a waiver of consent.

Data collection

We collected variables from the electronic health record and entered data directly into REDCap (Research Electronic Data Capture).[10] Variables included age, race, ethnicity, mailing address, ultrasound facility address, gravidity/parity and gestational age based on ultrasound. We also collected time variables such as: date of first contact, defined as the first time the patient specifically requested abortion services, date of mifepristone delivery as determined from postal tracking, and self-reported date of mifepristone administration (ingestion). Gestational age was calculated by ultrasound or by last menstrual period if gestational age on ultrasound was non-specifically documented. We did not collect insurance data since many TelAbortion patients did not provide their primary insurance information when choosing to self-pay. For repeat abortions, we only included the first abortion. We included patients who were lost to follow-up in all analyses except those related to unknown mifepristone ingestion date.

For distance calculations, we used the patient mailing address listed in the electronic health record at the time of chart review. We marked addresses as 'confirmed' for the abortion date if the patient did not have a repeat visit in our healthcare system after their abortion, as addresses are confirmed or updated as necessary at every visit. Address data for patients without repeat visits are more reliable, as their documented address could not have been updated since the time of abortion. We categorised mailing addresses by county and as urban or rural as defined by 2010 Census Urbanized Areas or 2010 Census Urban Clusters.[11]

We identified abortion clinics by searching Google Maps for 'abortion clinic'. Abortion providers at our institution reviewed this list carefully for known clinics and we excluded clinics that did not advertise abortion on their website.

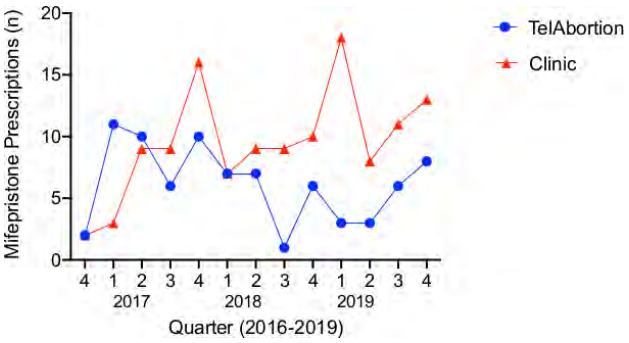

Figure 1 Mifepristone prescriptions written per quarter from October 2016 through December 2019 by method of delivery: TelAbortion (n=80) or clinic (n=124). This figure includes 21 TelAbortion patients with unknown dates of mifepristone ingestion (21/80, 26.3%). All clinic patients had known dates of mifepristone ingestion. There was not a significant difference in trend between either delivery method over time.

Statistical analysis

The primary outcome was the proportion of patients traveling ≥25 miles for abortion care based on method of care delivery: TelAbortion versus clinic. We selected this cut-off because a 25-mile radius from our clinic covers the Portland metro area. Based on case numbers over time at our Family Planning Clinic, in this convenience sample we estimated needing approximately 50% TelAbortion patients compared with clinic patients (60 vs 120) to be able to see at least a 15% difference between groups for the proportion travelling more than 25 miles for their abortion care.

We exported collected data to STATA Version 16.1 for analysis (StataCorp LP, College Station, TX, USA). We compared TelAbortion versus clinic groups using t-tests for continuous variables, chi square for categorical variables, and Wilcoxon rank sum tests to compare medians for non-parametric distributions. We considered a value of $p<0.05$ a significant result.

Distances were calculated using the 'georoute' programme in STATA which uses the HERE application programming interface to calculate the driving distance between two locations.[12] We compared median distances using the Wilcoxon rank sum test. We defined distance to care differently for the two groups. For TelAbortion patients, we measured distance to care as distance from mailing address to their respective ultrasound facility. We did not include distance to a laboratory since not all TelAbortion patients required testing and many were able to obtain this at a similar location to the ultrasound. For clinic patients, we measured distance to care as distance from mailing address to our Family Planning Clinic. We planned to exclude patients from this distance analysis if they did not have a mailing address listed or if they travelled more than 200 miles for care. We recognised that significantly large distances occurred in unique situations, such as obtaining an ultrasound while travelling out of state.

We also compared median distance from the patient's mailing address to the nearest advertised abortion clinic. We further used this list of advertised abortion clinics to determine the proportion of patients with a mailing address in a county without an abortion clinic.

Secondary outcomes included patient and procedure characteristics, including time from first clinic contact to mifepristone ingestion date.

RESULTS

From October 2016 through December 2019, 204 medical abortions were performed at OHSU through the Family Planning Clinic: 80 via TelAbortion (38.9%) and 124 in clinic (61.1%). There was a gap in service delivery of TelAbortion at the time of transition from free to billed visits in the third quarter of 2018, but otherwise there was not a significant difference in trend between either delivery method over time (figure 1).

Demographic outcomes

On average, patients in both groups were 30 years old and had a mailing address in an urban area. While overall demographic characteristics between the two groups were similar, there were some notable differences in race. The TelAbortion group had a higher proportion of White/Caucasian patients and the clinic group had a higher proportion of Asian patients (table 1). Patients undergoing TelAbortion were more likely to have a prior induced abortion (table 1). Mean time from first contact for scheduling to mifepristone administration was longer for TelAbortion (11 vs 6 days; $p<0.01$). Over three-quarters of TelAbortion patients received mifepristone via mail within 2 days of prescription signature (61/80, 76.3%, range 1–8). Median time from mifepristone delivery to mifepristone ingestion for TelAbortion patients was 2 (range 1–8) days. Date of mifepristone ingestion was not reported by 21 TelAbortion patients (26.3%). All clinic patients ingested mifepristone on the date of prescription signature. Median gestational age was clinically similar at mifepristone ingestion (49 vs 44 days; $p=0.01$). A similar proportion of TelAbortion and clinic patients initiated abortion after 63 days' gestation.

Geographic outcomes

We excluded four TelAbortion patients and three clinic patients from distance analyses, as their distance to care was greater than 200 miles. We excluded one additional clinic patient from these analyses due to missing address (total excluded: 5.0% vs 3.2%). Excluding these patients, median distance from address to our Family Planning Clinic was 95 (range 4–377) miles for TelAbortion and 12 (range 0–184) miles for clinic patients ($p<0.01$). However, median distance travelled for care was only 7 (range 0–150) miles for TelAbortion versus 12 (range 0–184) for clinic patients ($p<0.01$). Fewer TelAbortion patients had to travel ≥25 miles for their abortion care (5/76, 6.6% vs 26/120, 21.7%;

Table 1 Demographic characteristics of patients undergoing medical abortion via TelAbortion or in clinic in our retrospective study of care delivery method (n=204)

§Gestational size based on ultrasound measurements or last menstrual period if unmeasured.

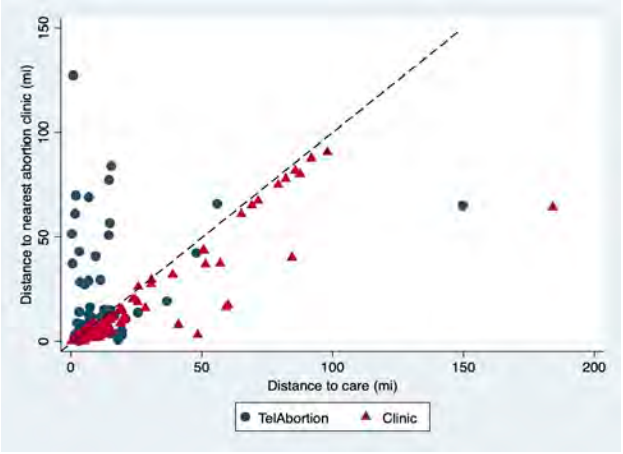

Figure 2 Distance to care versus distance to nearest abortion clinic, excluding four TelAbortion patients and three clinic patients who traveled >200 miles for care, and one clinic patient with unknown address. TelAbortion (n=76) and clinic patients (n=120) live similar distances to the nearest abortion clinic, but TelAbortion patients travelled a shorter distance to receive abortion care. The dashed line provides a reference for where abortion care chosen and nearest abortion clinic are equidistant. Points above the reference line represent individuals who are located farther away from an abortion clinic than the distance they travelled for abortion care. Points below the reference line represent individuals whose nearest abortion clinic is farther away than the distance they travelled for abortion care.

p=0.01). Median distance from mailing address to the nearest advertised abortion clinic was 7 (range 0–127) miles for TelAbortion and 7 (range 0–91) miles for clinic patients (p=0.4) (figure 2). Figure 2 depicts the relative distance to care versus distance to nearest abortion clinic for each individual.

TelAbortion patients were more likely than clinic patients to live in a county without an advertised abortion clinic (19/76, 25.0% vs 19/120, 15.8%; p=0.11). Similarly, more TelAbortion patients than clinic patients had a mailing address ≥25 miles from an abortion clinic (19/76, 25.0% vs 20/120, 16.7%; p=0.15).

Of the 76 TelAbortion patients included in distance analyses, 49 (64.5%) had free telemedicine visits and recived US$50 TelAbortion study compensation and 27 (35.5%) underwent routinely billed care or self-pay with no compensation. These two groups had similar distances to care. We also found similar distance results when analysing data only from patients with confirmed addresses.

DISCUSSION

In our cross-sectional study comparing characteristics and geographic location of medical abortion patients in Oregon and Washington, we found that patients who underwent TelAbortion had mailing addresses farther away from our Family Planning Clinic than patients who underwent medical abortion in person. This finding supports previous hypotheses that telemedicine may increase the reach of abortion providers and provide care to more geographically distant patients.[3]

Interestingly, TelAbortion patients and clinic patients were located similar distances from their nearest advertised abortion clinic, suggesting that distance from an abortion clinic may not be the primary reason patients opt for care via telemedicine, at least in this region. More than 90% of TelAbortion patients did not have to travel more than 25 miles for an ultrasound, demonstrating that ultrasound is a geographic option for most patients.

Telemedicine patients lived similar distances to an abortion clinic as their clinic counterparts, yet they still chose telemedicine. Although our results come from a single site, our findings demonstrate that TelAbortion offers something appealing to patients beyond simple geographic convenience, such as confidentiality, anonymity or facility hours that are more convenient.

We hypothesise that direct-to-patient care may reduce the need for childcare and lower additional abortion-related expenses, thus removing significant barriers for some patients. Patients may prefer flexible timing for mifepristone administration or ultrasound examination. Patients may also feel an increased sense of privacy meeting with their provider from their home, avoiding protestors and limiting exposure to COVID-19. Cost may be a further deciding factor for many patients. Telemedicine creates new financial options by allowing women without abortion coverage to use their insurance for ultrasound and laboratory tests. Alternately, patients may not decide where to undergo abortion based on full knowledge of the process specifics, such as appointment length, ultrasound requirements or cost. Full transparency about these details can help patients make an informed choice.

A limitation of this study is our inability to confirm that the mailing address listed in the electronic health record was the patient's physical address at the time of the abortion. However, repeat analyses including only patients whose addresses could be confirmed yielded similar results. It is also possible that we underestimated distance, as we did not include distance to a laboratory in our analyses and excluded those >200 miles from care. Due to limitations of a chart review, we were unable to collect further socioeconomic data to determine if TelAbortion improves abortion access for specific groups. We could not determine if patients choosing TelAbortion could have accessed in person care if telemedicine was not available, and we did not assess reasons for choosing a particular method.

Our TelAbortion study site followed the same workflow for both telemedicine and clinic patients. Appointments were available after a similar intake process, with the same providers, during the same hours, and with the same after-hours resources. Despite needing to coordinate multiple steps and wait for mifepristone to arrive via mail, TelAbortion patients only had a 5-day delay in abortion initiation. We could not determine if patients would have experienced further delays without this option. We do not think this 5-day difference is clinically significant, but assessment of timeliness of access is important in future studies. While ultrasound may be geographically feasible for women in our region, requiring an ultrasound may contribute to the delay and create a medically unnecessary emotional, social or financial burden for patients. Programmes should not require ultrasound examination for documentation of gestational age for most patients, as medical abortion can be performed safely without ultrasonography.[13–15]

TelAbortion increases abortion availability by creating another option that may be more acceptable and satisfactory to some patients than physically presenting to a nearby clinic. Despite close proximity to an abortion clinic, patients still chose TelAbortion, even when it meant travelling farther for care and experiencing a 5-day delay in abortion initiation. Further research should investigate reasons for choosing telemedicine and barriers to choosing telemedicine, as these factors may help shape policy and provide guidance for increasing equitable access to abortion.

"It Was So Easy in a Situation That's So Hard": Structural Stigma and Telehealth Abortion

Andréa Becker[1,2], Celina Doria[3], Leah R. Koenig[1], Jennifer Ko[1], and Ushma Upadhyay[1]

Abstract

For decades, sociological research has examined the role of stigma in contributing to health disparities, yet such research seldom grapples with the interplay between individuals and structures. There is a particular paucity of research on abortion that concurrently examines individual experiences with stigma and structural barriers. In this article, we use telehealth abortion as a case, which now accounts for one in five abortions in the United States. We conducted 30 interviews and approach the data using a structural stigma framework in tandem with conceptualizations of felt, internalized, and enacted stigma. Findings advance a sociological theory of structural abortion stigma: a combination of structural barriers, internalized beliefs, and interpersonal shame. Telehealth reduces structural barriers to abortion and mitigates internal and interpersonal experiences of stigma. The latter is achieved by the ability to avoid the traditional abortion clinic, which many interviewees view as the site where stigma is produced and experienced.

Keywords

abortion, inequality, reproduction, stigma, telehealth

> For the regular [American Medical Association] AMA physicians, the limitation of abortion became one way of asserting their own professional domination over other medical practitioners. In their crusading, these physicians had translated the social goals of cultural and professional dominance into moral and medical language. They lobbied long and hard to convince legislators of the danger and immorality of abortion. (Conrad and Schneider 1980:12)

Abortion in the United States is a highly common medical experience, and yet it has been subject to a unique stigmatization process. This stigma has translated to decades of anti-abortion legislation, which came to a tipping point in 2022 after the *Dobbs v. Jackson Women's Health Organization* Supreme Court decision overturned *Roe v. Wade*. Abortion has largely been overlooked by sociologists as a site of theoretical exploration despite representing a growing structural problem with major implications for social inequality and health disparities. Specifically, only seven articles on abortion have been published in top sociological journals since the year 2000 (Kimport and Kreitzer 2023). And yet, analyzing abortion care provides a critical case for exploring key questions within sociology regarding stigma as well as medicalization,

cultural norms, gender and sexuality, social movements, and structural inequality.

In fact, in a now canon text in sociology, Conrad and Schneider (1980) utilize the case of abortion to develop a theory on medicalization and deviance—two central themes in sociology. As their work argues, abortion became moralized in the mid-nineteenth century United States to professionalize medicine and assert dominance over alternative healers and midwives. This history clashes with a common assumption in the cultural imaginary that "[a]bortion was always defined as deviant and illegal in America prior to the Supreme Court's landmark decision in 1973" (Conrad and Schneider 1980:11) The assumption that abortion has always been (and thus will always be) defined as deviant has allowed for abortion care to be marginalized by two key social institutions: medicine and the law. Abortion care in the United States has long been siloed to a limited number of freestanding clinics that are frequented by protestors, which further denotes abortion as separate from "ordinary" gynecological and reproductive health care. Abortion is incredibly common; 25% of pregnancies end in abortion (Jones 2024). However, abortion training is largely left out of medical school curriculums: Half of medical schools offer no formal training on abortion or only a single lecture (Burns and Shaw 2020). The lack of training in tandem with the stigma and violence against abortion providers for doing "dirty work" have led to decreased numbers of providers over time (Joffe 2010). Legislation is also regularly passed to limit access to abortion via politically motivated abortion bans, the closing of physical clinics, and the exclusion of abortion from insurance plans and Medicare (Cohen and Joffe 2020). Taken together, individual beliefs about abortion being immoral or worthy of stigma become codified structurally such that abortion is continually medically inaccessible and under legislative attack.

However, most sociological work on abortion focuses on the individual level, including examinations of the ideological underpinnings of abortion stigma (Kumar, Hessini, and Mitchell 2009; Luker 1984) and analyses of abortion patients' internalized feelings of shame (Becker 2019; Cockrill and Nack 2013), fear of being stigmatized (Hanschmidt et al. 2016), and secrecy behaviors (Cowan 2017). This work is largely separate from work on the structural barriers to abortion, which primarily come from the field of public health and focus on barriers to care (Biggs et al. 2020; Upadhyay, Cartwright, and Grossman 2022; Upadhyay, McCook et al. 2021). In this article, we advance a sociological theory on "structural abortion stigma," which refers to the ways in which the stigmatization of abortion operates on the macro (state- and nation-wide legislation) level and in turn manifests in the meso (medical institutions, interpersonal interactions) and micro (individual) levels. In the process, this article provides a sociological framework for how cultural norms and stigma around abortion coalesce to create structural inequity to abortion access. As we argue, the social conditions, organizations, systems, and policy around abortion produce the individual-level phenomena that scholarship on abortion stigma tend to focus on. Moreover, by focusing on telehealth abortion as a case, we demonstrate how telehealth—a practice that is becoming an increasingly established norm in health care—can mitigate the effects of stigma across other cases.

BACKGROUND

Barriers to Abortion Care

Barriers to abortion care are manifold because its provision is often constrained by ideological political decisions rather than driven by scientific evidence. Patients in need of abortion care must often travel for care—whether to the other side of the city or across state lines—because its provision is excluded from the formal health care system (Kimport and Rasidjan 2023). Therefore, access hinges on a patient's socioeconomic status given limitations in many states on private insurance coverage for abortion and the Hyde Amendment, which bars abortion coverage for patients in many states on Medicare and Medicaid (Dennis, Blanchard, and Cordova 2011). Beyond paying for the abortion itself, other costs arise in the form of travel, time off work, the cost of childcare and dependent care, and the cost of lodging, particularly for those living in states with waiting periods, which require 24 to 72 hours in between an initial clinic visit and the abortion itself (Upadhyay, Cartwright, and Grossman 2022). Gestational limits are also a substantial barrier, particularly for those experiencing pregnancy complications at later gestations, and few clinicians provide abortions at later gestations (Foster, Dobkin, and Upadhyay 2013). Moreover, abortion medications are under intense legal scrutiny, including the recent Supreme Court case *U.S. Food and Drug Administration v. Alliance for Hippocratic Medicine* (2024), which experts had anticipated would severely limit access to mifepristone, the first of two medications typically used in a

medication abortion. Lastly, after the *Dobbs* decision that overturned *Roe v. Wade*, abortion bans in various states have led to the criminalization of abortion for patients, providers, or both. This criminalization carries over to self-managed abortion. The criminalization of abortion, in part, distinguishes structural stigma of abortion from structural barriers. Using structural stigma as a lens elucidates the ways that these various barriers to care are a codification of stigma, which ultimately further perpetuate abortion stigma. Although sweeping legislation and increased public education are key for reducing barriers and stigma at the individual level, this article will indicate the ways that telehealth abortion mitigates and disrupts various manifestations of structural abortion stigma.

Telehealth Abortion as a Case

We develop a theoretical framework of structural abortion stigma by using telehealth abortion—in which the entire medication abortion process occurs remotely—as a case. Key cultural, technological, and legislative changes in the past three years have led to increased salience of telehealth abortion. First, the onset of the COVID-19 pandemic necessitated and normalized innovations in remote health care, allowing fully remote telehealth models to expand. Next, at the height of the pandemic, the U.S. Food and Drug Administration permanently lifted restrictions on in-person dispensing of mifepristone (Belluck 2021). These changes permitted the formation of virtual clinics—abortion clinics without an affiliated brick-and-mortar facility—whereas previously, only some brick-and-mortar clinics offered telehealth. Additionally, despite previous regulations, new data collected during this time showed that telehealth medication abortion provision is equally safe and effective as in-clinic medication abortion, including telehealth abortion without an ultrasound or other form of in-person test (Anger et al. 2021; Upadhyay, Koenig et al. 2024; Upadhyay, Koenig, and Meckstroth 2021; Upadhyay, Raymond et al. 2022).

Moreover, the reversal of *Roe v. Wade* in 2022 resulted in many states outright banning abortion, leading to the closing of clinics in those states and longer wait periods in protected-access states, leading to an increased demand for abortion care beyond brick-and-mortar clinics (Society of Family Planning 2023). With these various sociocultural and legislative changes in motion, growing proportions of patients are expected to rely on telehealth abortion in the coming years (Aiken and Upadhyay 2022). From April 2022 to December 2022, for instance, there was a 137% increase in the number of virtual clinic abortions (Society of Family Planning 2023). Presently, one in five abortions are provided via telehealth (Society of Family Planning 2024). Furthermore, in past work, we found that telehealth allowed patients before the *Dobbs* decision to avert a median of 10 miles and 25 minutes of round-trip driving and 1 hour 25 minutes of round-trip public transit time (Koenig et al. 2023). After *Dobbs*, entire regions of the country are now abortion deserts (Cartwright et al. 2018), and travel time to the nearest abortion facility is significantly greater, with Black, Indigenous, and other people of color experiencing the greatest increases in travel time to abortion facilities (Rader et al. 2022).

Sociological scholarship has failed to grapple with the increasing salience of telehealth. Medical and public health literature has long discussed the capacity for telehealth to produce better health outcomes for patients, gather better data, and reduce health expenditures (Edwards et al. 2014; Toole 2013; WHO Global Observatory for eHealth 2011). However, sociological work tends to critique the meaning of telehealth and other digital health technologies, focusing on how telehealth changes the provision of health care and extends the medical gaze and surveillance into patient homes (Lupton 2013, 2014; Lupton and Maslen 2017). We conceive of telehealth at a unique intersection of medicalization and demedicalization (Halfmann 2012; Torres 2014; Zola 1972) given that it involves interacting with a licensed medical provider while simultaneously circumventing the physical clinic. Abortion via telehealth challenges central assumptions about how abortion needs to be provided—in a clinic, after ultrasounds and other tests, often after a waiting period—and provides a hybrid experience of medicalized and demedicalized care: the privacy and comfort of demedicalized at-home care with the supervision and direction of medicalized care.

In this article, we fill a critical gap in sociology scholarship through our focus on the use of telehealth for a stigmatized health practice. We argue that telehealth is a way to mitigate stigma. We find that obtaining abortion care by telehealth aids patients in managing the various cultural, societal, and policy-based manifestations of abortion stigma by circumnavigating the need to enter a clinic—a space that can heighten feelings of stigma for some—and by reducing the barriers to care that we argue are the product of stigma. Telehealth largely eliminates disruptions to one's schedule and associated cost and allows patients to feel more in control and experience a greater degree of privacy. As such, by examining the benefits

of telehealth abortion, we advance a sociological framework for structural abortion stigma—the ways that structural barriers coalesce with abortion stigma to produce structural inequality and a structural stigmatization of abortion.

Stigma

The stigmatization of health behaviors is a complex social process that can lead to poor health outcomes and lower quality of health care provision (Hatzenbuehler, Phelan, and Link 2013; Link and Phelan 2001; Norris et al. 2011). Although stigma has been applied to various realms of medicine, including mental illness and sexually transmitted disease, abortion stigma continues to be undertheorized (Hanschmidt et al. 2016). This lacuna in the literature leaves questions regarding the effects of abortion stigma and how individuals navigate and manage abortion stigma. In particular, there is a paucity in examinations of the structural manifestations of abortion stigma, which Kumar et al. (2009) introduced. Instead, there is substantial focus on stigma on the individual level, with little theoretical connections made between barriers to access and the codification of stigma on a structural level and between the individual and institutions.

In a special issue on structural stigma, Hatzenbuehler and Link (2014:2) defined structural stigma as "societal-level conditions, cultural norms, and institutional policies that constrain the opportunities, resources, and well-being of the stigmatized." In this article, we apply this theoretical framework to the realm of abortion—a highly stigmatized health care treatment—to advance social scientific literature on stigma. Abortion fits squarely within the study of structural stigma because cultural norms and policies not only constrain the well-being of and resources for abortion patients but also "[create] environments that have increased threat, punishment" (Richman and Lattanner 2014:95) for patients and providers alike. Although abortion is relatively simple to provide and demonstrably safe, the societal and cultural conditions have transformed access to abortion into what Cohen and Joffe (2020) refer to as "an obstacle course."

Moreover, we apply Hatzenbuehler and Link's (2014) conceptualization of structural stigma in tandem with Herek, Gillis, and Cogan's (2009) three levels of stigma: enacted, felt, and internalized levels of stigma. Enacted stigma refers to "overt behavioral expressions" (Herek et al. 2015:21), which in the case of abortion stigma can include the targeted violence and harassment ubiquitous across physical abortion clinics. Felt stigma refers to an individual's "expectations about the probability" (Herek et al. 2015:20) of being the target of the overt expressions of enacted stigma. This level of stigma has a particular bearing on people's behaviors because it causes individuals to engage in coping strategies to avoid or reduce the risk of discrimination. In the case of abortion, this can manifest as keeping an abortion secret or seeking to avoid a physical clinic through self-managed abortion or telehealth. The final level of stigma in Herek et al.'s (2009) framework is internalized stigma, which occurs when an individual accepts the beliefs underpinning stigma as part of their own value system. In the case of abortion, internalized stigma could manifest as shame or guilt.

Although the prevailing trend in abortion stigma literature fails to account for the way that structures and individuals interact, there are notable exceptions. In the first, Kimport and Rasidjan (2023) describe the emotional burden on individuals when forced to travel for an abortion to surpass local restrictions. In the context of Ireland, Broussard (2020) expounds on the way that structural abortion stigma manifests in peoples' embodied experiences with abortion, with the barriers to care manifesting as internalized stigma. Moreover, Coleman-Minahan et al. (2021) argued that "multilevel" abortion stigma is reinforced by the judicial bypass process, required in Texas of young people seeking abortion without parental consent. Abortion stigma also inhibits the quality of care received by patients, as found in a scoping review conducted by Sorhaindo and Lavelanet (2022), and can lead people to unsafe abortion methods to maintain keeping the procedure a secrecy (Cárdenas et al. 2018). Lastly, various researchers have examined how abortion stigma can lead to subpar and judgmental care from providers in various non-U.S. contexts, including Peru, Nepal, Senegal, and South Africa (Favier et al. 2018; Palomino et al. 2011; Puri et al. 2012; Suh 2018). In this present article, we build on this nascent work by using telehealth abortion as a case to advance a theory on structural abortion stigma while elucidating the way telehealth mitigates structural stigma for individual patients.

DATA AND METHODS

We conducted 30 in-depth interviews with individuals who had a telehealth medication abortion between May 31, 2021, and January 17, 2022. Participants were purposively sampled from the California Home Abortion by Telehealth Study, a

longitudinal evaluation of the safety, effectiveness, and acceptability of telehealth abortion care provided by three U.S. virtual clinics: Abortion on Demand, Choix, and Hey Jane (Koenig et al. 2023, 2024; Upadhyay, Koenig et al. 2024). These services offer fully remote, synchronous and/or asynchronous medication abortion care. Although the eligibility criteria differed slightly among the three providers, patients were generally eligible for medication abortion care if they lived in an approved state and their pregnancy duration was less than 70 days (assessed by date of last menstrual period or by ultrasound).[1] The services ranged in price from $199 to $289. Once their eligibility was approved by a licensed medical provider, patients received abortion medications via a mail-order pharmacy. Patients also received follow-up messages via secure text message or phone after receiving the medications. At the time of this study, Abortion on Demand, Choix, and Hey Jane served a combined 20 states and Washington, D.C., across the continental United States, primarily in the West and Northeast but with 2 states in the Midwest and 5 in the South.

Sample

We recruited 30 individuals (Table 1) who had a telehealth medication abortion with one of the three participating virtual clinics to participate in semistructured interviews. In a previous stage of the study, we conducted three longitudinal surveys with 1,600 individuals: a baseline survey at abortion intake, a second survey approximately one week after intake, and a final survey four weeks after intake. Individuals were eligible to participate in an interview if they had completed the series of longitudinal surveys and agreed to be contacted again in the future regarding an interview, resulting in a subsample of 1,260 individuals. We then used a purposive sampling method to account for a diverse interview sample in terms of race and ethnicity and age and to include those who required additional medical care after taking the abortion medications.

Interview participants ranged in age from 16 to 39, with an average age of 27, and 5 participants were adolescents (19 years or younger). In terms of race and ethnicity, 9 identified as non-Latinx White, 6 as Asian, 5 as non-Latinx Black, 5 as Latinx, and 5 as multiracial. Three participants reported requiring additional medical care after taking abortion medications. Participants were recruited from 11 states (CA, CO, GA, IL, MA, MN, NY, NJ, PA, RI, VA), representing all four regions in the country—West, Northeast, Midwest, and South. In terms of abortion history, 18 participants reported 0 prior abortions on the intake survey, and 12 reported 1 or more prior abortions.

Table 1. Sample Characteristics ($N = 30$).

Characteristics	Participants
Age (years)	
Range	16–39
Average	27
Race-ethnicity	
White	8
Black	5
Latinx	5
Asian	6
Multiracial	5
Complications	3

Procedures

Interviews were conducted remotely via Zoom by the first, second, and third authors between July and September 2022. The in-depth interviews followed a semistructured interview guide of 20 questions. The questions addressed the factors that contributed to participants' decisions to choose telehealth medication abortion and their overall experience of telehealth abortion. Sample questions included: "How did you first hear about telehealth abortion?" "What appealed to you about this service?" "Did you consider or call a brick-and-mortar clinic first?" "Can you tell me about your experience taking the abortion medications?" and "What kinds of things did you like and not like about the telehealth service?" The interviews lasted between 40 and 90 minutes. Patients provided informed consent for participation in the interview and audio recording. Interviews were audio recorded via Zoom and transcribed verbatim. Participants were compensated with a $50 electronic debit card for their participation. All procedures were reviewed and approved by the University of California, San Francisco's institutional review board.

Analysis

The data were coded by the first and second authors using a flexible coding approach on Dedoose. Flexible coding is a rigorous method of qualitative data analysis that uses both deductive and inductive approaches to coding and theory development (Deterding and Waters 2018). During the first stage

of data analysis, the authors began by developing a codebook that categorized broad topics that were addressed in the interviews (e.g., "reason for abortion," "reason for telehealth," "feelings about abortion"). To allow for flexibility, the authors also identified emergent codes from the text and refined existing codes based on ongoing analysis. Once the overarching theme of "structural abortion stigma" was selected, the first and second authors conducted axial coding to identify key subthemes (e.g., "financial barriers," "fear of the clinic," "internalized stigma"). Divergences in coding were discussed by the research team to ensure congruence across coding during the entire process of data analysis.

RESULTS

To utilize telehealth abortion as a case for advancing a theory on structural abortion stigma, we present the findings in the following two sections. First, we review the ways that telehealth mitigates structural barriers to abortion care—how telehealth removes travel to potentially distant physical clinics and, in the process, reduces logistical and financial hurdles. These findings build on a growing body of work on the benefits of telehealth and a long-standing literature on structural barriers to abortion care. Next, we present novel findings on how telehealth manages various manifestations of stigma—internalized, felt, and enacted—by circumnavigating the physical clinic and the visibility of being an abortion patient. Taken together, these findings contribute to a theoretical framework for structural abortion stigma.

How Telehealth Mitigates Structural Barriers

For many participants, telehealth medication abortion services increased access to needed health care. Structural barriers to accessing abortion care were mitigated by being able to obtain medication abortion through telehealth, from reduced waiting times and more affordable prices to the eliminated need to travel. Telehealth felt "convenient" and "easy" for participants, often resulting in positive abortion experiences.

Participants emphasized how telehealth reduced barriers to accessing abortion by offering fast and convenient care. Unlike brick-and-mortar clinics, participants felt that telehealth services more quickly accommodated their appointments and shipped medications. For example, Rachel, an 18-year-old White woman living in Illinois, explained the barriers she faced while looking for care at physical clinics:

> So when I had called Planned Parenthood, I had to have a first appointment, which would've been in a month, I think, and then a second appointment after that. And…I didn't want to wait that long. And also it was very expensive to go there. So that was mostly why I didn't go with that one. And then I called around to other clinics too, like OBs, and they either said that they didn't deal with that kind of stuff or that they didn't take my insurance.

Long wait times for appointments at physical clinics were a major barrier to accessing care for participants. Telehealth mitigated this barrier by offering the ability to quickly schedule appointments. Elaine, a 27-year-old multiracial law student in New Jersey, felt that telehealth removed multiple barriers to care, particularly those related to wait times and travel. She explained:

> Well, I really do think it kind of just boiled down to the difficulty of, not that I couldn't get somewhere, but finding somewhere that had an appointment available and having an appointment to pick because most of them didn't have appointments anytime soon. It was weeks away, month away, month and a half, whatever. And then trying to figure out what classes do I have that day? Do I have something else going on? Do I have something I have to do the next day? Well, if I need the car, does my boyfriend have work that day? Things like that. Telehealth was like, I could just take care of it. I didn't even have to go anywhere…it was so much easier.

Many participants also appreciated how telehealth mitigated other logistical barriers to accessing abortion care, such as taking time off work or finding childcare. Sara, a 34-year-old White woman living in Massachusetts, succinctly explained: "Honestly, I liked the fact that I didn't have to take any time off work. I didn't have to go anywhere. Didn't have to worry about all that." Similarly, Tess, a 39-year-old White woman who lives in Rhode Island with her husband and son, shared how the telehealth model provided a much more convenient way to complete her abortion at home:

> Having to take an extra day off would have added such a massive hindrance to the whole procedure. Being able to do this on my time, on

> my schedule, from my home, so I didn't have to get childcare coverage or take time off from work. So the convenience of it was huge. . . . It was easy. There were no hoops to jump through. It was: Google search, set up an appointment, pay for it, get the stuff done. Not: find the clinic, go make the appointment, have somebody take you to the appointment, find childcare to cover while you're going to the appointment. So the convenience, the ease of telehealth was good.

Telehealth also removed another critical structural barrier: traveling to a physical clinic. For many participants, the ease of accessing abortion care through telehealth was not simply a convenience; rather, it was a necessity. This was the case even in patients living in legal, protected states. Whether participants lacked reliable transportation or lived in abortion deserts, the telehealth model aided participants in accessing needed care from home. Had Alyssa, a 24-year-old Black woman, not lived in New York—where abortion care is generally more accessible—completing her abortion would have been "impossible." She explained:

> It's something that I could just do right on my phone. So I feel like for a lot of people, especially someone like myself, I didn't have a car, which I was in New York at the time. But if I was in another state, that probably would've made things a lot harder for me or made it impossible for me to go to a clinic. So I feel like that's a good option for people who maybe don't have reliable transportation, are able to get to an actual clinic.

Similarly, Michelle, a 36-year-old Black woman living in New Jersey, shared her experience:

> The area where I live, there are literally no abortion providers whatsoever. And I did not have the actual time to travel to the area where they do have actual abortion providers in person . . . and at the time, I was working. Some weeks, it was seven days a week. And myself, I didn't physically have the time to get [to the nearest abortion clinic]. But I was, "If I have to take sick time, I'll do it. And I'm going to have to go far."

Although Michelle may have been willing and able to travel to a clinic to receive care, the telehealth model removed the burden of travel and made abortion care more accessible.

This accessibility was crucial given that many other participants were simply unable to travel. In particular, participants living in rural areas faced numerous structural barriers to accessing abortion care. Katie, an 18-year-old White woman in rural Minnesota explained: "The closest [abortion clinic] was in [the nearby city], and that's probably a two-and-a-half-hour drive. I didn't want to go alone, so it would've just been harder to have to figure out me and my mom's schedule to be able to both go together." Similarly, Adriana, a 15-year-old Latina living in central California, described the difficulties she faced when trying to access abortion care: "The nearest clinic that was open was two hours away. There used to be [a clinic in my town], but there hasn't been one in a while." Further complicating her experience, Adriana also mentioned that she had not told her parents about the pregnancy or abortion. Thus, being too young to drive herself coupled by a lack of transportation or family support, "to find an excuse and a way to go that far [to a clinic] was just too hard."

Another recurring theme across all interviews was the affordability of telehealth medication abortion. Cost is one of the greatest barriers to abortion care and a key reason why many participants sought out telehealth as opposed to medication abortions at physical clinics. Participants felt surprised by the affordability of telehealth services. Rebeca, a 19-year-old Latina in New York, explained: "I felt like it was affordable because I've heard that abortions could be up to $800 . . . but I was like, '$250? That's not bad. I'll do that. I'll pay for it.' To me it felt like a good price. It's realistic." Similarly, Angelica, a 38-year-old White woman in California, described her shock at learning the cost of an abortion at her local in-person clinic, leading her to explore telehealth options:

> Compared to having to go to a clinic and meet someone in person, [telehealth] was a lot cheaper. Because . . . I think it was about $800 or maybe even a little more [at the local clinic]. So that kind of shocked me. I didn't think it would be so much. I didn't know. So I can't remember exactly how much it was with [the telehealth service]—maybe a couple of hundred or something—so, by comparison, it was a lot cheaper. And I didn't mind paying it because you're paying for the convenience of it and just being able to be at home.

For Annie, a 28-year-old Asian woman in California, the affordability of telehealth was particularly

important because she did not have health insurance at the time of her abortion. She explained:

> I felt like, compared to [other options] in the area, it was very affordable…[and] the closest [abortion] clinic was an hour away from me. And even then, the earliest appointment that I could get was probably two weeks. There was no guarantee that when I got there I wouldn't have to wait longer as well…I feel like time-wise, it was very effective for me. And also, cost-wise, it was as well. It was very expensive at [another health clinic]. I don't remember the exact price, but having to pay for the consultation and then having to pay for the medication, as well. And at the time, I didn't have health insurance to be doing something like that.

The affordability of telehealth abortion was critical given that many participants cited financial hardship as a key reason they wanted the abortion. For example, Sara, the 34-year-old White woman living in Massachusetts, succinctly noted: "One of the main reasons we aren't having another child right now is because we're broke. So I mean, [telehealth] was a few hundred bucks compared to [a more expensive in-clinic procedure]."

To understand the ways in which telehealth mitigated financial burdens, consider Maya, a 20-year-old multiracial woman in California. When Maya found out she was pregnant, she was already working two jobs to make ends meet. Due to these financial hardships and lack of family support, Maya knew that having a child "would be a huge struggle." Although she knew abortion was the right decision, she noted the cost of abortion care as a significant barrier. She explained:

> When I first found out that I was pregnant, I wasn't in the right financial means to have the child. And I knew even if I did choose to have it, it would be a really hard struggle for me. And so, then when I decided to go through with [the abortion], I was considering going to [an abortion clinic], but then when I went over there for the prices and stuff, I was just kind of iffy about it.

After working "long hours just trying to be able to get the money," Maya was able to pull together enough funds to pay for the telehealth medication abortion. Without telehealth, Maya would have likely encountered even more delays in care in order to afford a more expensive in-clinic procedure. These participants' experiences demonstrate how telehealth mitigates structural barriers by reducing logistical and financial burdens, affording them the ability to have the abortions they wanted and needed.

Avoiding the Clinic, Managing Stigma

In addition to structural barriers, many participants discussed the benefit of telehealth as a way of avoiding interpersonal and individual experiences of stigma by avoiding physical abortion clinics, which many participants view as the primary site where abortion stigma is experienced. In these accounts, entering the physical clinic represents facing abortion stigma across various levels—from having to drive to a different city or state or to a remote part of town to encountering anti-abortion protesters outside to physically being in a room as an abortion patient and requesting abortion pills face-to-face. Having a telehealth option circumnavigated these various facets of abortion care. As such, in addition to telehealth as a means of navigating costs, travel, and logistics, avoiding the physical clinic also allows one to manage internalized, felt, and enacted abortion stigma—together comprising structural abortion stigma. This adds insight into the ways that individuals' feelings of shame about a stigmatized health procedure can be mitigated by removing a primary place where abortion stigma is experienced.

As an example of how telehealth allows for the managing of abortion stigma across these various levels, consider Tess, the 39-year-old White woman who lives in Rhode Island with her husband and son mentioned previously. She was able to schedule and have her abortion while balancing her two-hour daily commute to work and being the primary caregiver to her son. In addition, access to telehealth aided in managing or avoiding internalized, enacted, and felt stigma. For instance, despite identifying as "pro-choice," she holds shame in choosing an abortion for herself. When probed about what she meant about her abortion evoking "hard feelings," she said the following through tears:

> I had to confront a lot of internal biases that I didn't really even know that I had, where I didn't deserve an abortion because financially, I could afford another child. I had to confront this internal bias that I had that abortions are for people on hard times…and that, as an intelligent person, I feel like I should have known better. I should have made smarter choices, and these are consequences that come up from them. So, that's hard…because this was a life.

While Tess was sifting through these complicated emotions—or internalized abortion stigma—she felt certain that an abortion was the correct choice for her and her family. The telehealth model aided in Tess managing these feelings and reducing additional layers of abortion stigma. She mentioned being comforted by the ability to avoid the physical clinic and potential protestors in making "an uncomfortable situation somewhat less uncomfortable."

> I didn't want to face the idea of there being protestors…you see all the footage of people standing outside and harassing people, and I'm already dealing with a super hard decision. I don't need people screaming in my face. I was nervous about that. So when I Googled and I found out that you can just do this via web interview, over the phone, I was like, I'm here for it.

Indeed, many participants mentioned anticipating stigma by having to confront protestors and anti-abortion signage outside of the clinic, with the severity of anti-abortion vitriol impossible to predict. Lindsey, a 30-year-old Asian American woman living in Colorado who had a previous in-clinic abortion in Louisiana—where abortion has long been highly restricted—said the following about the benefits of telehealth abortion:

> Just imagine living in a red state, and people are screaming and yelling at you and showing you these photoshopped pictures of babies being vacuumed out of women's wombs. That could be terrifying. And not having to experience that and being able to do an abortion in the comfort of your own home and your own space and being private about it and having, I guess, the choice to be private, I think that's great.

As Lindsey indicates in this excerpt, telehealth allows for a greater degree of privacy and comfort by being able to have the abortion process from one's home—specifically, "the choice to be private." In addition, Lindsey's quote indicates that telehealth mitigates both felt and enacted stigma by avoiding the feeling of anticipating being stigmatized when accessing a physical clinic and avoiding the enacted stigma in the form of protestors.

In addition to the presence of protestors, many participants mentioned that simply entering the physical clinic sparked negative emotions from the physicality of the space itself. For instance, consider Emily, a 24-year-old Asian American woman living in California. Earlier on in our interview, she mentioned that the ability to have the process remotely, and particularly the option to use the secure messaging feature, caused "less guilt" about the abortion. When asked to elaborate, she said the following about avoiding the physical clinic:

> If you go to a clinic then there's people that are outside of it with signs saying that it's bad and I don't have to deal with that or be confronted with it. It helped me in the process of not having to go to a clinic…and just having to be in the clinic is kind of just very depressing just in itself…I don't know. It just feels weird because there's putting names to faces and they know why I'm there rather than just doing it online. And you have someone that's there for you if you need help, but you're not sitting there looking at someone. So there's kind of less guilt into it.

As this quote indicates, for Emily and others in the study, being physically in the clinic, embodying "the abortion patient," conjures negative feelings due to multiple factors in addition to having to confront protestors. In such cases, receiving abortion care mediated through a phone or computer screen lessens internalized stigma or other negative feelings associated with an abortion because being seen in person by providers, other patients, and any potential onlookers seems to increase feelings of stigma.

In addition, as participants explained, having a telehealth option allows a greater degree of secrecy regarding the abortion, allowing patients increased control about who to disclose the abortion to. This, in turn, mitigates feelings of stigma. Rebeca, the 19-year-old Latina living in New York, for instance, said she appreciated telehealth because "I wouldn't want people to know that I'm having an abortion at the time. It's still something I'm not really proud of, so I would want it to be as secretive as possible." In this case, secrecy helps manage internalized stigma. The desire for privacy and secrecy is particularly the case for those living in small towns or rural areas. Take, for instance, Katie, the 18-year-old living in Minnesota. In addition to managing having an abortion while being a teenager living with her parents, Katie was also managing the fear of being seen and recognized at a location that provides abortions. As she said:

> When I go to the clinic, I know a lot of the nurses, the office people, so I just didn't want them to know what I was doing. And then, potentially, I know they can't say anything, but I mean you never really know, and I didn't want to

> be viewed different, I guess. So, that's why I wanted to keep it more confidential and not have to worry about someone seeing or hearing or saying something about it.

Indeed, anonymity and being in one's home were repeatedly mentioned as the benefits of telehealth. As Lindsey recounted:

> Just being able to do it in the safety of your own home and being absolutely 100% anonymous. They don't know what you look like. I mean, they know your name and they know your information, but they're not going to see you out on the street and be like, "Hey, she got an abortion." You know?

Advances in telehealth therefore disrupt stigma processes by removing the embodied element of receiving stigmatized health care, which could have implications beyond abortion, including other types of sexual and reproductive health or even mental health.

Additionally, although sociological literature on structural barriers and on stigma tend to be separate, many participants alluded to the structural barriers themselves being a source of stigma. This contributes to a sociological theory of structural abortion stigma by demonstrating a cycle in which abortion stigma leads to structural barriers, which then implicitly lead to abortion stigma. In the following excerpt, Michelle describes the connection between the reduction in structural barriers and the reduction in stigma, both of which telehealth provides.

> I don't think that it would be such a devastating process if Abortion on Demand or services like it were easily available and accessible to women. Because it destigmatized it a lot for me. Destigmatized it to the point where I've actually recommended it…ever since then, I'm, "You should go to this Abortion on Demand site…" Because it was such an easy process. It made it, like I said, like you can go get this done without it being an epic poem of emotion and having to figure out, am I going to be able to walk through the doors of some place? And it was so easy. I don't even know how many other people know about it. And that's why I want people to know. It's a safe place to get something done that could very well be very unsafe if you don't know that you have this option.

As Michelle describes, it is often the structural barriers of abortion that cause receiving this health care to be "a devastating process" or even "an epic poem of emotion." The process itself of having to find a physical clinic, plan a trip, and anticipate and/or encounter protestors fuels feelings of shame and sadness given the marginalization of the procedure. In fact, in the following excerpt, Michelle describes feeling surprised by her lack of negative emotions despite initially feeling very guilty about not continuing the pregnancy.

> I worried often, for the time during and afterwards, that I wasn't more emotionally connected to the process. Why am I not crying? Why am I not sad? Why am I not feeling like a bad person? And the answer is, because I didn't have to feel like a bad person. I didn't have to seek thousands of miles or millions of dollars' worth of care in order to get this thing done. And when I got it done, I felt physically safe. I felt physically taken care of.…But the fact that I don't have to deal with the mental consequences thereafter, that is probably where I place most of the value here. Because a lot of women that I have talked to are, "I feel so guilty that I've done this years later." And I sometimes have forgotten that I've done it. And I don't mean to sound callous, but this was not a pregnancy that I was ever going to be able to carry to term healthfully.

As this findings section demonstrated, there is a need for a theory of abortion stigma that combines structural barriers with internal and interpersonal experiences of stigma. The barriers themselves are a result, or codification of, individual-level abortion stigma, and the barriers then lead to feelings of abortion stigma for individuals receiving this care (in addition to providers, although the present study does not speak to this element of abortion stigma).

DISCUSSION

Our findings demonstrate the importance of understanding experiences with a telehealth model for abortion care. More broadly, this article makes important contributions to social scientific literature on stigma and health inequality. We found that a telehealth model aided patients not only in accessing abortion via reduced costs, time, and logistical hurdles but also in the managing of internalized, enacted, and felt stigma. Using telehealth abortion as a case, we connect barriers to care with the individual and interpersonal experiences of stigma to advance the theoretical concept of structural abortion stigma—a combination of structural barriers,

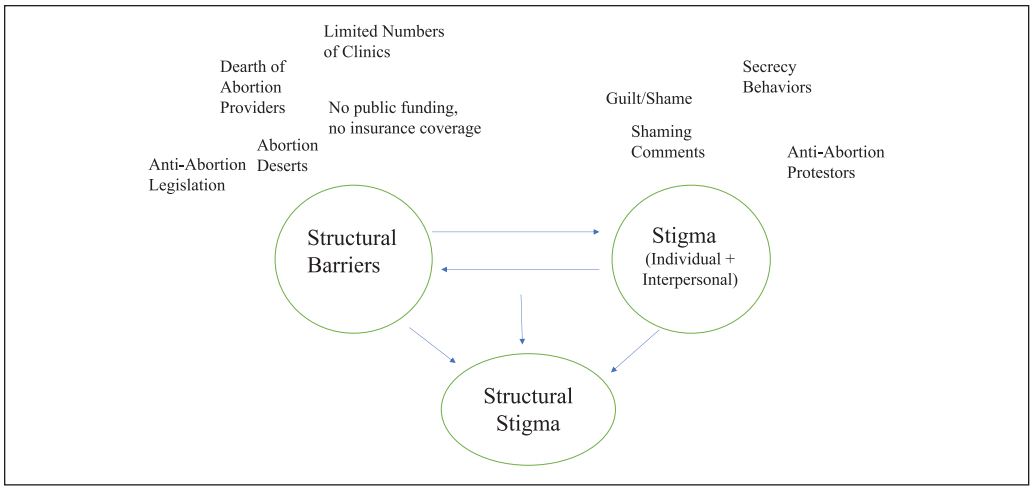

Figure 1. Structural Abortion Theoretical Model.

internalized beliefs, and interpersonal shame (see Figure 1). The findings may help direct future policy on expanding access to telehealth abortion, especially in the wake of the reversal of *Roe v. Wade*, which has and will continue to exacerbate long-standing inequities in abortion access.

Interview data point to a telehealth abortion model as a way of reducing structural abortion stigma that we define by modifying Hatzenbuehler's (2014) structural stigma framework. Structural abortion stigma is the product of cultural norms, societal-level conditions, and policies around abortion that constrain the opportunities, resources, and well-being of abortion patients. Due to geographic variation in abortion acceptance across the country, abortion stigma has been structurally codified via abortion deserts and states without abortion access—also referred to as spatial stigma (Kelaher et al. 2010). Abortion stigma has also been codified via policies that silo abortion care to freestanding abortion clinics where the presence of protestors has been normalized and via policies—including the Hyde Amendment—that render abortion financially unfeasible for many.

These various structural manifestations of stigma, in turn, exacerbate individual-level stigma. Being forced to surpass these various obstacles created by the structural marginalization of abortion care—particularly the need to travel—increases feelings of shame and exclusion and of being deviant or "abnormal" (Kimport and Rasidjan 2023). By continuing to explore the interplay between structures and the individual in the study of stigma, our findings build on a growing, relatively nascent body of work in sociology that can be applied to various stigmatized elements of health and health care—including mental health, sexually transmitted illness, and gender-affirming care for trans populations.

Our study indicates that telehealth abortion aids patients in managing the various cultural, societal, and policy-based manifestations of abortion stigma by circumnavigating the need to enter a physical clinic—where patients may encounter stigmatizing actors inside and outside of the clinic—and by reducing the barriers to care that we argue are the product of stigma. Most of the sample pointed to the ease and convenience of telehealth in seamlessly fitting the abortion in their schedule. This includes accommodating job schedules and child and elderly care, eliminating the need to travel, reducing the cost of the abortion itself, and reducing associated costs, such as lost wages, childcare, travel, and accommodations. This supports prior research on telehealth abortion as both a patient-centered model and a potent tool for reducing barriers to care, including by drastically reducing cost barriers (Endler et al. 2019; Kerestes et al. 2021; Raymond et al. 2019; Upadhyay, Koenig et al. 2024; Upadhyay, Schroeder et al. 2024).

As telehealth becomes increasingly part of U.S. health care models post-COVID-19, it is critical for sociologists to continue to theorize how this model disrupts long-standing social inequities. Moreover, it is long overdue for the field of sociology to seriously grapple with abortion as a site of theoretical exploration, interconnected as it is within the fields of health, gender, stigma, the family, and technology studies and perennially unresolved tensions

between structures and agency. This study therefore constitutes a key step in addressing the exclusion of abortion from mainstream sociological theorization while contributing key findings that could aid in paving the way for patient-centered health models both within abortion care and beyond.

ACKNOWLEDGMENTS

The authors appreciate contributions to data collection and management and other input on the California Home Abortion by Telehealth Study from Maricela Cervantes, Linda Shin, Kelly Song, and Lisa Peters. We thank Cindy Adam, Mark Adam, Kate Baron, Stephanie Bussmann, Leah Coplon, Lauren Dubey, Lindsay DuBois, Kiki Freedman, Gaby Izarra, Jamie Phifer, and Aisha Wagner for supporting data acquisition. We appreciate overall guidance from Elizabeth Raymond on classifying adverse events.

FUNDING

The author(s) disclosed receipt of the following financial support for the research, authorship, and/or publication of this article: This research was supported by the BaSe Family Fund, Erik E. and Edith H. Bergstrom Foundation, Isabel Allende Foundation, Jess Jacobs, Kahle/Austin Foundation, Lisa and Douglas Goldman Fund, Preston-Werner Ventures, and a Resource Allocation Program (RAP) Award from the UCSF National Center of Excellence in Women's Health. Ms. Koenig was funded in part by a training grant from the National Institute on Minority Health and Health Disparities of the National Institutes of Health under Award No. T32MD015070 for the duration of the study. The funders had no role in the study design, data collection, and analysis; the writing of the report; or the decision to submit the paper for publication.

AUTHOR BIOGRAPHIES

Andréa Becker, PhD, is an assistant professor of sociology at Hunter College, City University of New York. Dr. Becker is a medical sociologist with expertise in gender, reproduction, and feminist science and technology

studies. Her first book, *Get It out: On the Politics of Hysterectomy* (NYU Press), will be published July 2025.

Celina Doria, MSW, PhD, is an assistant professor at the University of Wisconsin-Madison Sandra Rosenbaum School of Social Work.

Leah R. Koenig, MSPH, is a data analyst with Advancing New Standards in Reproductive Health and a PhD candidate in epidemiology at the University of California, San Francisco. Her research focuses on examining the safety, effectiveness, patient experience, and health equity implications of novel methods of abortion care.

Jennifer Ko, MLIS, is a project director at University of California, San Francisco's Advancing New Standards in Reproductive Health for research projects that examine the safety, effectiveness, and acceptability of alternative models and tools for abortion care, including telehealth, with a focus on increasing equity and autonomy for health care in the United States.

Ushma Upadhyay, PhD, MPH, is a professor at the University of California, San Francisco in the Department of Obstetrics, Gynecology, & Reproductive Sciences and core faculty of Advancing New Standards in Reproductive Health. Dr. Upadhyay has expertise in abortion safety, abortion access in the United States, medication abortion, and state-level abortion restrictions, and she is the principal investigator of the California Home Abortion by Telehealth Study.

ABSTRACT

Objective To evaluate the efficacy and safety of home administration of buccal misoprostol after mifepristone for medical abortion up to 70 days' gestation in a general practice in Curaçao, where induced abortion is severely restricted by law.

Methods In a prospective study 330 women received 200 mg mifepristone and were instructed to take four tablets (800 μg) of misoprostol via the buccal route 24–36 h later, at home. One week later, follow-up took place.

Results The outcome could be evaluated in 307 of the 330 women. The efficacy of the mifepristone-buccal misoprostol procedure was 97.7% (300/307). In seven women vacuum aspirations for continuing pregnancy or incomplete abortion following treatment were required. Success rates at 64–70 days' gestation were the same as for gestations of less than 64 days duration. The main adverse effects were nausea and diarrhoea.

Conclusion Home administration of buccal misoprostol 24–36 h after mifepristone is a safe and effective method of medical abortion up to 70 days. It could be applied in a general practice in Curaçao, where induced abortion is legally restricted.

KEYWORDS Medical abortion, Mifepristone, Buccal misoprostol, Home abortion, Caribbean

INTRODUCTION

In Curaçao, a Caribbean island, part of the Kingdom of the Netherlands, induced abortion is rigorously restricted by law. Nevertheless, induced abortion on request of a woman is performed by a small number of general practitioners (GPs) and both the Health Inspectorate and the Public Prosecutor's office are

DOI: 10.3109/13625187.2011.555568

aware of that. The Public Prosecutor stipulated a tolerance policy in 1999 and the Inspectorate supervises correct compliance. In this tolerance policy the health personnel involved in abortion care is protected from prosecution and since 1999 GPs carrying out abortions have no longer been prosecuted. Women having an abortion are not protected, but none of them has been prosecuted because of an abortion since then. In our practice we provide medical abortion and although this is done clandestinely we can continue because of the tolerance policy. Induced abortion on medical indication can only be performed in the main (Roman Catholic) hospital after approval of the institution's ethical board. A change in law still seems far away because of the strong influence of the Roman Catholic Church and, for most policy makers, abortion is still a highly sensitive subject.

Because of the illegal nature of abortion, women may delay seeking assistance for abortion as well as seeking care in case of complications. During one year the 11 GPs carrying out abortions at the request of women registered their results. Compared to countries where induced abortion is legal, there were more complications (Boersma AA, Alberts JF, Meyboom-de Jong B, Kleiverda G. Termination of pregnancy in Curacao: Need for improvement of sexual education and reproductive healthcare. Unpublished.) In the Caribbean islands estimates of induced abortion are around 300,000 a year with a high hospitalisation rate for complications[1]. In most countries in the region induced abortion is prohibited. Since use of misoprostol for medical abortion in countries where induced abortion is illegal has increased, morbidity and mortality rates are declining[2].

Most studies on medical abortion are conducted in clinical settings in countries where abortion is legal. The combination of mifepristone and misoprostol is more effective and results in a higher rate of complete abortions (97–98%) than when either methotrexate and misoprostol (92–95%) or misoprostol alone (70–90%)[3] are used. Home abortion is preferred by most women[4,5]. In Curaçao, methotrexate was used in the past because mifepristone was not available[6].

To perform this study the import of mifepristone was allowed under stringent conditions of the Health Inspection. Women had to be informed about the fact that mifepristone was not registered and had to give written consent. A proper follow-up was also a condition.

Medical abortion at home is mostly reported to have been carried out at gestational ages of 63 days or less. Although there is evidence that medical abortion is safe up to 83 days – and even later – in clinical settings, hardly any studies have described medical abortion in the home situation at a gestational age exceeding 63 days[7–10].

In Curaçao, due to its illegal status, abortion on request is not available in a clinical setting. Therefore, it was decided to enroll women with pregnancies of a maximum of 70 days of amenorrhoea in our study of home treatment. We decided to use buccal misoprostol, as the bioavailability of the prostaglandin analogue in such cases is higher than after vaginal and oral administration[11]. In more advanced pregnancies, success rates of oral misoprostol diminish with increasing gestational age[12]. Buccal administration has the advantage that no residues can be found as with vaginal treatment. In countries with a restrictive abortion law this may be important.

We investigated whether in Curaçao, where induced abortion is legally restricted, medical abortion can safely be carried out in a general practice. Further, we assessed whether, to this end, home administration of buccal misoprostol after mifepristone is an effective and safe method of medical abortion up to 70 days' gestation.

METHODS

This study was conducted from 1 April 2009 until 1 April 2010. It involved women requesting induced abortion at a gestational age of up to 70 days, who presented in a general practice in an underprivileged neighbourhood in the old centre of Willemstad, the capital of Curaçao. The women concerned were patients registered at this general practice, had been referred by other GPs or were passers-by who had heard of the possibility of having a medical abortion in this practice. Most patients were of Afro-Caribbean origin. All were informed about the small risk of ongoing pregnancy and were strongly advised to proceed with a surgical procedure, if the medical abortion failed. Women received written information about the procedure, and written consent for medical treatment was obtained. The gestational age was confirmed by abdominal ultrasound; if there was no amniotic sac visible at a gestational age of less than 42 days, the pregnancy was confirmed by a urine test.

All women were offered 200 mg mifepristone orally at the first visit in the clinic and four tablets of 200 μg misoprostol for home administration 24–36 h later. Women were instructed to place two tablets of misoprostol (200 μg each) in each cheek for 30 min and then to swallow any remaining pill fragments with some water. Acetaminophen or ibuprofen was advised for pain relief. If bleeding did not occur within 48 hours, misoprostol was used again in the same dosage and via the same route. After an unsuccessful second attempt, an instrumental abortion was performed in the general practice. Follow-up consisted of either an abdominal ultrasound one week after termination of the pregnancy, or a telephone conversation after two weeks. On this occasion three questions were asked by the principal investigator: 'Did you have a bleeding of several days duration?', 'Did you lose the pregnancy?', and 'Do you feel that you are no longer pregnant anymore?'. The endpoints were effectiveness of treatment to achieve complete abortion, and safety. Treatment was considered to have failed if instrumental evacuation was needed because of ongoing pregnancy or incomplete abortion.

Approval for the study was obtained from the Medical Ethical Committee of Curaçao. The Fisher exact test was used to analyse categorical data and the Z-test was used to compare the proportions of two different groups. The level of statistical significance was defined as a p-value of <0.05.

RESULTS

A total of 331 women with first trimester pregnancies were treated. In one woman an ectopic pregnancy was detected after medical abortion was attempted; surgical removal was carried out. Of the remaining 330 women, 42 (13%) were registered in our practice, 182 (55%) were referred by other GPs, and 106 (32%) were passers-by.

The mean gestational age was 49 days (range 29–70 days). Most women (199; 60%) were 49 days pregnant or less, 105 (32%) were between 50 and 63 days, and 26 (8%) between 64 and 70 days of amenorrhoea.

At the time of the pregnancy, the mean age of the women was 26 years with a range of 14–45 years. Almost half of the patients (148) were between 21 and 30 years old, more than a quarter (92) was aged more than 30 years, and a quarter (87) was younger than 20 years. Of three women the age was unknown. Nearly one third (105; 32%) were nulliparous, 89 (27%) had one child, 82 (25%) had two children, and 54 (16%) had three or more children.

Follow-up was in most cases (237; 72%) with ultrasound and in 70 (21%) it consisted of a telephone conversation. If the answers to the three questions were positive the treatment was considered successful. Twenty-three women (7%) were lost to follow-up. The gestational ages in 13 of them were 49 days or less, in eight between 50 and 63 days, and in two between 64 and 70 days.

The available results show a success rate of 97.7% (300/307). Two women presented two days after the first visit with an ongoing pregnancy, and three with an incomplete abortion after one week (gestational age 41–59 days). After a second dose of 800 μg buccal misoprostol four of them had a complete abortion within 48 h. The fifth one, with an incomplete abortion, had a vacuum aspiration as had six other women, with ongoing pregnancy (2) or incomplete abortion (4) within two weeks after the first dose of misoprostol (gestational age 41–64 days). These six women chose vacuum aspiration after administration of mifepristone and one dose of misoprostol. Suction curettage rates for pregnancies between 50 and 63 days and between 64 and 70 days of amenorrhoea (4.2% and 3.8%, respectively) were not significantly higher than in those with a gestational age of 49 days or less. (1.1%) ($p=0.24$, Fisher Exact test) (Table 1). Nulliparity was not associated with a significantly greater risk of failure of abortion (Table 2). Of the five women with incomplete abortion who needed surgical intervention, two were admitted to the department of gynaecology with pain and heavy bleeding. The most frequently mentioned side effects were nausea and diarrhoea.

DISCUSSION

Induced abortion is still highly restricted by law in Curaçao. While mifepristone for medical abortion is used legally in most parts of Europe and in the United States, this compound is not registered in Curaçao. But with the assistance of the Health Inspectorate it was made available. This made medical abortion easier to perform compared to the method which had been applied during the previous ten years in Curaçao and which consisted in administering methotrexate intramuscularly, followed by intravaginal misoprostol

Table 1 Outcome, by gestational age, of medical abortions induced by oral administration of 200 mg mifepristone followed by 800 μg misoprostol via the buccal route

Duration of pregnancy	*Only one dose of misoprostol required*	*Second dose of misoprostol required*	*Suction curettage (after one or two treatments*)*	*Total*
≤49 days	182	2	2 (1.1%)	186
50–63 days	89	2	4 (4.2%)	95
64–70 days	25	0	1 (3.8%)	26
				307

*Six after administration of one dose of misoprostol, and one after two doses.

three to five days later. The success rate in the current study is higher. Moreover, in accordance with the literature, the women participating in this study found the ingestion of mifepristone followed by home administration of buccal misoprostol to be more convenient: not only were the results better, but also the expulsion of the products of conception (POCs) was faster and women had less complaints[6,13–15]. In addition, the procedure was also less time-consuming: women had to come back to the practice just once instead of three times with the methotrexate-vaginal misoprostol procedure.

In 2005 the first trial comparing buccal with vaginal misoprostol, after intake of mifepristone, was published[16]. Since then more publications have appeared and, in all, the results obtained with buccal misoprostol were similar to those observed after vaginal administration of that prostaglandin analogue and better than after its oral administration[12,13,17,18].

In our study only seven of the 307 women for whom complete data are available needed a vacuum aspiration. Two of these went to the Emergency Department and were admitted because of pain, but did not mention the previous medical abortion because of fear of retaliatory measures of the hospital staff due to the illegal status of abortion. A wait-and-see policy might have allowed for complete expulsion of the POCs and would have made the results even better.

Four of the five women who took a second dose of misoprostol had a complete abortion thereafter and only one woman had a vacuum aspiration. Results of repeat doses of misoprostol have not systematically been evaluated in the literature, because mifepristone combined with a *single* dose of (buccal) misoprostol is already highly effective. Therefore, the effectiveness of repeat doses of misoprostol after mifepristone is not established[19].

The introduction of mifepristone was allowed by the Health Inspection under binding conditions, among which was a mandatory follow-up. Women received explicit instructions and 72% returned for an ultrasound. The gestational age of the 23 women lost to follow-up did not differ notably from that of the other women. This makes the impact of the cases lost to follow-up small. Fourteen of these women were passers-by and nine had been referred by other GPs. All women registered at our general practice came back. Routine follow-up may be a burden for some women and its necessity has been questioned[20]. The main reasons for this control are to exclude continuing pregnancy, on the one hand, and ectopic pregnancy after early medical abortion when an intrauterine gestational sac had not been visualised on ultrasound prior to this, on the other hand.

The efficacy and safety of mifepristone-misoprostol regimens for medical abortion in clinical settings have

been proven for gestational ages of up to 91 days[8]. Different studies about home abortion show that safety and acceptability are high; most women value home abortion because it allows greater autonomy and privacy, and preserves personal integrity[9,21,22]. Home administration of misoprostol for medical abortion at a gestational age between 64 and 70 days has not been reported previously. Our findings indicate that buccal misoprostol remains equally effective up to and beyond 63 days' gestational age, while success rates of oral misoprostol diminish with increasing gestational age towards 63 days[12].

Its very low failure rate seems to make home administration of buccal misoprostol, after intake of mifepristone, suitable for medical abortion up to 70 days, in a general practice. When compared with literature data, our success rate was high[3,12,16,17,23,24]. In other studies, maternal age and parity have been cited as prognostic factors for failure of pregnancy termination with mifepristone and misoprostol[25–27]. In this series, this was not confirmed. The effect of more advanced gestational age was not apparent due to the small number of failures.

Home abortion is safe. We should be able to convince the Health Authorities of the lack of evidence for routine follow-up after this procedure. Instead women should be encouraged to contact qualified health personnel after a medical abortion *if* they feel a need for it or *if* there are symptoms suggestive of an ectopic pregnancy, an incomplete abortion or ongoing pregnancy. Legalisation of abortion is desirable in order to allow women to terminate their unwanted pregnancy in optimal circumstances and, for those with complications, to seek assistance openly.

The strength of this study is the high follow-up rate in a country where abortion is illegal. A weakness of this study is that the number of participants with gestational ages varying from 64 to 70 days was limited. Our findings reflect the effectiveness and the safety of mifepristone followed by home administration of buccal misoprostol up to 70 days' amenorrhoea in a general practice. Future research should address larger groups to confirm the efficacy and safety of home abortion up to 70 days' amenorrhoea.

In conclusion, home administration of buccal misoprostol 24–36 hours after oral mifepristone is a safe and effective method of medical abortion up to a gestational age of 70 days. The method was successfully applied in a general practice in Curaçao, where induced abortion is legally restricted.

Abstract

Objective: To test the effectiveness and acceptability of an outpatient medical abortion protocol with 200 mg mifepristone and 400 mcg sublingual misoprostol at 64–70 days' last menstrual period (LMP) and compare it to the already known efficacy of the 57–63 days' LMP gestational age range.

Study Design: We conducted a prospective, comparative open-label trial in six hospitals and clinics in Ukraine, Georgia, India and Tunisia. We enrolled 714 reproductive age women with pregnancies 57 to 70 days who presented requesting abortion. Medical abortions were managed with the current service delivery protocol (200 mg oral mifepristone followed in 24–48 h by 400 mcg sublingual misoprostol). Data on safety, efficacy and acceptability were collected. The main outcome measure was complete abortion without surgical intervention at any point.

Results: A total of 703 cases were analyzable for efficacy. Success rates did not differ significantly in the two groups [57–63-day group: 94·8%; 64–70-day group: 91.9%; Relative Risk (RR): 0.79 (0.61–1.04)]. Ongoing pregnancy rates also did not differ significantly (57–63 days: 1.8%; 64–70 days: 2.2%; RR: 1.10 (0.65–1.87)].

Conclusion: A medical abortion regimen of 200 mg mifepristone followed in 24–48 h by 400 mcg sublingual misoprostol is effective through 70 days' gestation and may be offered within existing outpatient abortion services.

Implications: A regimen of 200 mg mifepristone followed in 24–48 h by 400 mcg sublingual misoprostol is effective up to 70 days' LMP. The findings have important implications for expanding access to outpatient medical abortion services in settings where the cost of misoprostol is of concern or a two-pill misoprostol regimen is the standard of care.

1. Introduction

Mifepristone–misoprostol is used widely for early abortion and recommended for outpatient use through 63 days from the last menstrual period (LMP) [1–3]. Earlier studies demonstrated the effectiveness of medical abortion after 9 weeks' LMP, but most protocols required repeat dosing and inpatient care [4–10]. New evidence has shown that the most common outpatient protocol for early medical abortion in the United States (200 mg mifepristone followed by 800 mcg buccal misoprostol) is effective and acceptable for ending pregnancies 64–70 days from LMP and can be offered without altering existing outpatient services [11].

The first regimens of medical abortion introduced in most countries used 400 mcg oral misoprostol following mifepristone for medical abortion through 49 days' gestation [12,13]. Evidence has since shown that medical abortion is also safe and effective at increasing gestational ages, particularly using other in-the-mouth routes (buccal and sublingual) or with higher doses of misoprostol [1,14–18]. An alternative outpatient protocol of 200 mg mifepristone followed by 400 mcg sublingual misoprostol is used through 63 days' LMP [16,19] and is the standard of care in Tunisia, Georgia and Moldova, among other countries that have historically used two-pill misoprostol regimen since the method's introduction. The higher-peak misoprostol plasma concentration and greater bioavailability associated with sublingual administration allow for a lower dose of misoprostol when compared to buccal administration [20]. Although generally an inexpensive drug, the cost of misoprostol is subject to local market variability and may be difficult to access or expensive in some settings. In addition to a potentially reduced cost, lower doses of misoprostol are associated with fewer side effects [19,21,22]. Our study sought to estimate the efficacy and acceptability of a 400-mcg sublingual misoprostol regimen following 200 mg mifepristone through 70 days' LMP and to compare outcomes between women with pregnancies of 64–70 days' duration and women with pregnancies in the range of 57–63 days.

2. Materials and methods

This open-label prospective study was conducted between July 2009 and March 2012. Enrollment was planned at seven facilities in four countries: Zhordania Institute of Human Reproduction (Tbilisi, Georgia), Central District Maternity House (Odessa, Ukraine); Maternity Hospital No. 2 (Simferopol, Ukraine); Naval Nursing Home (Solapur, India); Government Medical College (Nagpur, India); La Rabta Maternity Hospital (Tunis, Tunisia); and Family Planning Center of Nabeul (Nabeul, Tunisia). One site was found to have an excessive amount of incomplete data and unanswerable queries on primary outcome data. Enrollment was discontinued, and none of the data from that site ($n=60$) was included in the analysis. The protocol was approved by the institutional review board at each facility. The study was registered with ClinicalTrials.gov, NCT00997347.

Women seeking abortion services were screened for eligibility and asked to participate in the study. Eligible women were 18 years or older, in good health and assessed to have a pregnancy greater than 56 days and less than 71 days from LMP based on the standard gestational age assessment practice at each site (ultrasound and/or clinical exam and history). Participants had to be willing and able to sign consent forms and agree to comply with the study procedures and visit schedule. All women gave informed consent to participate.

On day 1, women received 200 mg oral mifepristone and were given the option of administering 400 mcg sublingual misoprostol either in the clinic or at home 24–48 h later. Women were instructed to place two pills under the tongue for 30 min and swallow any remaining fragments. Each participant received analgesic medication and/or a prescription for analgesia, antidiarrheal and antiemetics as per individual clinic protocol. Women were also provided with a daily home study card to record bleeding days, time and date of misoprostol administration, and information on where to call with questions or concerns.

Women were asked to return to the clinic 7–14 days after mifepristone administration for follow-up to determine abortion outcomes. Outcome was determined by clinical assessment, including ultrasonography as needed. Women with an ongoing pregnancy were offered a surgical evacuation. Women with nonviable pregnancies (e.g., sac or other evidence of conception, but no growth in the gestation or cardiac activity on ultrasound) were given treatment options per the clinic's standard protocol including expectant management, an additional dose of misoprostol or a surgical evacuation. A short semistructured interview was conducted once the abortion was complete. Women were asked about the incidence and severity of side effects, and the acceptability of the overall process, side effects and bleeding. If a participant failed to return to the clinic, the assessment of abortion status and interview could be conducted via phone. If a woman failed to return or contact the clinic, study sites attempted to contact the woman three times before she was considered lost to follow-up.

The primary purpose of the trial was to assure that an outpatient medical abortion regimen could be used in gestations 64–70 days from LMP and achieve a success rate of at least 90%, which would characterize a clinically acceptable regimen. Three hundred thirty-four women per group were needed to detect a 5% or greater lower efficacy than the hypothesized 95% success rate in the 57–63 days group, based on previously published reports ($\alpha=0.05$, $1-\beta=0.8$, using a one-tailed test) and would allow us to estimate a success rate of 90% with a confidence interval (CI) of ±3.2% [13,18]. Data were analyzed using SPSS 15.0. An independent data and safety monitoring committee reviewed the interim results for safety and efficacy after 50% of the data were available.

The primary outcome was complete abortion without surgical intervention at any point, regardless of the number of misoprostol doses used. Secondary outcomes included side effects and days of heavy bleeding. Acceptability data will be presented in a separate publication. One tailed p<.05 was considered to indicate statistical significance. Fischer's exact test was used to determine differences in proportions and Student *t*-test to determine differences in means of continuous variables. The analysis of the primary outcome was intent to treat.

3. Results

A total of 714 women were enrolled: 389 women in the 57–63 days group and 325 women in the 64–70 days group. Gestational age was confirmed by ultrasound in approximately three-quarters of all cases [57–63 days: 72.2% (281/389); 64–70 days: 77.5% (252/325); p=.12]. Five women in the 57–63 day group and 4 women in the 64–70 day group were lost to follow-up. In the 57–63 day group, 8.2% of women (32/389) were followed up by phone compared to 6.7% of women in the later gestational age group (22/325). Two women in the 57–63 days group discontinued participation in the study on or before the follow-up visit. The final efficacy analysis included 703 women: 382 in the earlier gestational age group and 321 in the later gestational age group. The sociodemographic characteristics (mean age, parity, abortion history, level of education) of the two groups were similar (Table 1).

The success rate was 94.8% (or 362/382) in the 57–63 days group and 91.9% (or 295/321) in the 64–70 days group [Relative Risk (RR): 0.79 (0.61–1.04)] (Table 2). Two percent of women in each group received a surgical evacuation for an ongoing pregnancy [57–63 days: 1.8% (7/382); 64–70 days: 2.2% (7/321); RR: 1.10 (0.65–1.87)]. There was a significant difference between the two groups in rates of surgical evacuation for excessive or prolonged bleeding [57–63 days: 0.5% (2/382); 64–70 days: 2.5% (8/321); RR: 1.77 (1.29–2.44)].

Almost all women took the misoprostol according to protocol [57–63 days: 98.7% (384/389); 64–70 days: 97.5% (317/325)]. Most women elected to take the misoprostol at home [57–63 days: 78.9% (307/389); 64–70 days: 72.6% (236/325); p=.05]. Significantly more women in the later gestational group received one additional dose of 400 mcg sublingual misoprostol at the follow-up visit for management of bleeding or a retained sac [57–63 days: 5.7% (22/386); 64–70 days: 10.5% (34/325); p=.03].

Two women did not take the misoprostol at all (1 in 57–63 days group and 1 in the 64–70 days group) and failed to expel the ongoing pregnancy. Four women took misoprostol more than 48 h after mifepristone administration (i.e., 72–74 h after mifepristone administration). Of these, three women in the 64–70 days group had a successful medical abortion and one woman in the 57–63 days group underwent a surgical evacuation for a persistent nonviable sac.

Four women in the 64–70 days group used an alternate route of misoprostol administration. One woman administered the pills buccally and had a successful outcome. Three women administered the tablets orally. Two had a successful outcome, and one woman underwent a surgical evacuation and was hospitalized and received a blood transfusion as treatment for prolonged bleeding. A per-protocol analysis excluding cases who failed to administer the misoprostol or

[a] Excludes women lost to follow-up (57–63 days: 5; 64–70 days: 4) and women who withdrew from the study (57–63 days: 2).
[b] Includes 2 women who did not take misoprostol (57–63 days: 1; 64–70 days: 1) and 8 women who did not administer the misoprostol per protocol (57–63 days: 1; 64–70 days: 7).
[c] Substantial debris was subjectively defined and differed by local practice.

administered the misoprostol by an alternative route (buccal or oral) or more than 48 h after mifepristone yields slightly higher success rates, which were still not significantly different [57–63 days: 95.0% (361/380); 64–70 days: 92.7% (290/313); p=.21].

Three women in the study (including the protocol violation mentioned above) were hospitalized due to bleeding during the study period [57–63 days: 0.5% (2/382); 64–70 days: 0.3% (1/321); RR: 0.73 (0.15–3.62)]. One woman in the earlier gestational age group and one woman in the later gestational age group received a blood transfusion (p=1.000).

Ultrasound was performed at the follow-up visit in approximately two-thirds of cases [57–63 days: 61.1% (214/350); 64–70 days: 67.9% (197/290); p=.08]. Among women who returned to the clinic for follow-up, women in the later gestational age group were assessed as incomplete (i.e., persistent gestational sac or substantial debris as diagnosed by ultrasound) at the follow-up visit at a higher rate than women in the earlier gestational age group [57–63 days: 6.5% (21/350); 64–70 days: 9.7% (29/298); RR: 1.29 (1.00–1.66); p=.08]. Most women with incomplete expulsion were treated with additional misoprostol [57–63 days: 52.3% (11/21); 64–70 days: 75.9% (22/29); p=.13]. Of those women who received an additional dose of misoprostol, most went on to have a successful abortion [57–63 days: 90.9% (10/11); 64–70 days: 86.3% (19/22); p=.35].

Self-reported side effects experienced by women in both groups were similar. Over one-third of women in both groups reported no side effects [57–63 days: 38.2% (145/380); 64–70 days: 35.4% (111/314); RR: 1.07 (0.90–1.27)]. Reported rates of diarrhea, nausea, vomiting, chills, headache, dizziness and weakness were not significantly different in the two study groups (Table 3). Reports of fever were slightly fewer in the lower gestational age group [57–63 days: 9.2% (35/380); 64–70 days: 14.0% (44/314); RR: 0.79 (0.64–0.98)].

Median days of heavy bleeding	2	2	

[a] The 64–70 days group (*n*=313).

Data on bleeding were collected on a diary completed at home. Almost all women (93.2%, or 655/703) completed the diary. The median duration of all bleeding (i.e., spotting, moderate and heavy bleeding) was slightly longer in the later gestational age group (57–63 days: 10 median days; 64–70 days: 11 median days), although the mean difference in bleeding was not statistically significant (57–63 days: 9.8±3.0; 64–70 days: 10.2±3.0; p=.07). The mean difference in duration of heavy bleeding between the two groups approached significance (p=.05), with women in the 64–70 days group reporting slightly more days of heavy bleeding than their counterparts in the lower gestational age group (Table 3).

Approximately half of women in both groups used nonsteroidal anti-inflammatory drugs for pain management [57–63 days: 47.6% (182/382); 64–70 days: 53.6% (172/321); p=.13]. Rates of narcotic use were low and not significantly different between groups [57–63 days: 18.3% (70/382); 64–70 days: 17.8% (57/321); p=.92]. Mean days of any pain medication was not significantly different between the two study groups (57–63 days: 2.0 mean days; 64–70 days: 2.2 mean days; p=.35).

4. Discussion

Medical abortion with an outpatient regimen of 200 mg mifepristone followed 24–48 h later by 400 mcg sublingual misoprostol is effective in women 57 to 70 days from LMP. Our results are consistent with other studies of outpatient medical abortion regimens to 70 days' LMP [11,23]. Winikoff et al. [11] found a success rate of 92.8% (95% CI: 89–95) with a regimen of 200 mg mifepristone and 800 mcg buccal misoprostol in women with gestational ages 64–70 days from LMP. Rates of ongoing pregnancy in this group were also consistent across studies; the rate of ongoing pregnancy in this study (2.2%) was slightly lower than reported rate in the study of the 800 mcg buccal regimen (3.0%).

This study did show a statistically significant difference in the rate of surgical intervention for excessive/prolonged bleeding between the two study arms (0.5% in 57–63 days vs. 2.5% in 64–70 days). The rate of intervention in the higher gestational age group (2.5%) was also higher than the reported rate for a regimen of 200 mg following in 24–48 h by 800 mcg buccal misoprostol (1.0%, or 3/304) [11]. Most interventions for prolonged bleeding (8/10) occurred at two hospital study sites. The differences in rates of intervention for management of bleeding may reflect variations in provider practice for management of incomplete abortion. Still, women in the 64–70 days group may have also experienced slightly more bleeding. Women at the more advanced gestational age group did report experiencing more median days of bleeding (57–63 days: 10 median days; 64–70 days: 11 median days). The difference in mean duration of heavy bleeding between groups did approach significance

(57–63 days: 1.89 mean days; 64–70 days: 2.1 mean days; p=.05) but was similar to the rate reported for the 800 mcg buccal outpatient regimen (57–63 days: 2.5 mean days; 64–70 days: 2.3 mean days) [11].

Only fever was significantly more likely to be reported by women in the higher gestational age group. Relatively few women reported this side effect (57–63 days: 9.2%; 64–70 days: 14.0%). The difference, while statistically significant, may not be clinically relevant. The incidence of fever reported in this study is slightly lower than prior studies of this regimen (28.1% and 25.0%) [16,19]. Reports of chills (57–63 days: 17.3% and 64–70 days: 20.1%) are also lower than reports of chills/shivering from prior studies of 400- and 800-mcg regimens (38% and 52.9% of women reported experiencing chills/shivering up to 3 h after misoprostol administration, respectively) [21]. Fever and chills are commonly reported side effects associated with sublingual misoprostol administration, and the effect may be a result of the higher misoprostol plasma concentrations after sublingual administration [17,18].

This study was not powered to detect a difference in adverse events because these outcomes (e.g., hospitalization or need for transfusion) are rare. This study also suggests that such events occur infrequently with no evidence of a difference by gestational age. The study was conducted in sites where ultrasound is not used routinely for gestational age dating, but gestational age was confirmed by ultrasound in over three-quarters of cases in both groups. It is possible that some women could have been misclassified into study groups based on variability in woman's report of LMP or clinical assessment. Even so, the findings may help to reassure providers that medical abortion may be safely provided up to the 70 days' LMP without relying exclusively on ultrasonography for gestational age dating. Access to ultrasonography may be limited in many places where improved access to first trimester abortion services is greatly needed.

One limitation of the study is that the study was not blinded and two categories of failure (excessive bleeding and substantial debris in the uterus) are dependent upon subjective evaluation. As indicated above, interventions for excessive bleeding were primarily confined to two study sites. Rates of intervention for substantial debris in the uterus also varied with slightly higher rates in Tbilisi and Odessa (2.2% and 2.3%) compared to the sites in India and Tunisia (0–1%), where ultrasound use was less frequent.

In conclusion, the study findings show that a regimen of 200 mg mifepristone followed in 24–48 h by sublingual misoprostol is effective. The study results demonstrate that it is possible to expand access to outpatient regimens to 70 days' LMP using mifepristone plus a two-pill misoprostol regimen.

Randomized Trial of Very Early Medication Abortion

Karin Brandell, M.D., Tagrid Jar-Allah, M.D., John Reynolds-Wright, M.B., Ch.B., Ph.D., Helena Kopp Kallner, M.D., Ph.D., Helena Hognert, M.D., Ph.D., Frida Gyllenberg, M.D., Ph.D., Janina Kaislasuo, M.D., Ph.D., Anand Tamang, M.Phil., Heera Tuladhar, M.D., Clare Boerma, M.B., B.S., Karen Schimanski, M.H.Sc., Gillian Gibson, M.D., Mette Løkeland, M.D., Ph.D., Pia Teleman, M.D., Ph.D., Marie Bixo, M.D., Ph.D., Mette Mandrup Kjaer, M.D., Ervin Kallfa, M.D., Johan Bring, Ph.D., Oskari Heikinheimo, M.D., Ph.D., Sharon Cameron, M.D., and Kristina Gemzell-Danielsson, M.D., Ph.D., for the VEMA (Very Early Medication Abortion) Study Group*

ABSTRACT

BACKGROUND

Medication abortion, with a combination of mifepristone and misoprostol, is highly effective and safe. However, there is insufficient evidence on efficacy and safety at very early gestations before a pregnancy can be visualized with ultrasonography.

METHODS

We conducted a multicenter, noninferiority, randomized, controlled trial involving women requesting medication abortion at up to 42 days of gestation with an unconfirmed intrauterine pregnancy on ultrasound examination (visualized as an empty cavity or a sac-like structure without a yolk sac or embryonic pole). Participants were randomly assigned to either immediate start of abortion (early-start group) or standard-care treatment delayed until intrauterine pregnancy was confirmed (standard group). The primary outcome was complete abortion. The noninferiority margin was set at 3.0 percentage points for the absolute between-group difference.

RESULTS

In total, 1504 women were included at 26 sites in nine countries and were randomly assigned to the early-start group (754 participants) or the standard group (750 participants). In an intention-to-treat analysis, a complete abortion occurred in 676 of 710 participants (95.2%) in the early-start group and in 656 of 688 (95.3%) in the standard group; the absolute between-group difference was −0.1 percentage points (95% confidence interval, −2.4 to 2.1). Ectopic pregnancies occurred in 10 of 741 participants (1.3%) in the early-start group and in 6 of 724 (0.8%) in the standard group, with one rupture before diagnosis (early-start group). Serious adverse events occurred in 12 of 737 participants (1.6%) in the early-start group and in 5 of 718 (0.7%) in the standard group (P=0.10); the majority were uncomplicated hospitalizations for treatment of ectopic pregnancy or incomplete abortion.

CONCLUSIONS

Medication abortion before confirmed intrauterine pregnancy was noninferior to standard, delayed treatment with respect to complete abortion. (Funded by the Swedish Research Council and others; VEMA EudraCT number, 2018-003675-35; ClinicalTrials.gov number, NCT03989869.)

Medication abortion with a combination of mifepristone and misoprostol is a highly effective and safe method of first-trimester induced abortion.[1,2] As compared with procedural abortion, medication abortion has the advantage that the provision, treatment, and outcome assessment can be managed by the patient.[1] Although medication abortion is recommended by both national and international organizations, there is limited evidence regarding its efficacy when provided at very early gestations before a pregnancy can be visualized on ultrasound examination. Therefore, many clinical guidelines refrain from specific recommendations on clinical management for induced abortion before confirmed intrauterine pregnancy.[1,3-5]

A Quick Take is available at NEJM.org

Where medication abortion is available and barriers such as mandatory waiting times and provider referrals are removed, an increasing proportion of women present to abortion services even before an intrauterine pregnancy can be visualized with ultrasonography.[6-8] In services that routinely use ultrasonography before abortion, this scenario can lead to the labeling of a pregnancy as having an unknown location (positive pregnancy test but no ultrasonographic evidence of intrauterine pregnancy) or as being a probable intrauterine pregnancy (a sac-like intrauterine structure without a yolk sac or embryonic pole).[9] Providers may then delay treatment or recommend a diagnostic uterine aspiration owing to concerns that the pregnancy may be ectopic.[10,11] However, observational studies have shown that with assessment of human chorionic gonadotropin (hCG) levels before and after abortion, the time to diagnosis of pregnancy location does not increase (as compared with delaying abortion treatment until pregnancy location is confirmed).[5,12,13]

Evaluating provision of very early abortion is particularly important given recent legal changes in some U.S. states that limit access to abortion at gestations of more than 6 weeks.[14] A small number of observational studies of medication abortion performed before ultrasonographic confirmation of an intrauterine pregnancy suggest treatment efficacy ranging from 85 to 100%.[5,12,13,15-18] However, these studies differed in inclusion criteria for maximum gestational length, ultrasound criteria for unconfirmed intrauterine pregnancy, and definitions of failed abortion.[19] We conducted a multicenter, multinational, noninferiority, randomized, controlled trial to evaluate the efficacy and safety of early as compared with delayed start for women seeking medication abortion before confirmed intrauterine pregnancy.

Method

Trial Design

The VEMA (Very Early Medication Abortion) trial took place at 26 sites in nine countries (1 site in Austria, 1 in Australia, 2 in Denmark, 1 in Finland, 7 in Nepal, 1 in New Zealand, 1 in Norway, 2 in Scotland, and 10 in Sweden) from March 2019 through April 2023. The original protocol included 11 sites, but owing to slow recruitment, we added trial sites. The trial protocol (available with the full text of this article at NEJM.org) was approved by the Swedish Ethical Review Authority and local ethics committee at each trial site or in each country. (Trial sites are listed in the Supplementary Appendix, available at NEJM.org.) Participants were included after providing written informed consent. An external monitor and data and safety monitoring board were appointed. The data and safety monitoring plan is included in the Supplementary Appendix. Blinding with respect to trial-group assignments was not deemed to be feasible.

The trial funders did not have any involvement in or influence on the trial protocol or trial conduct. The first author wrote the first draft of the manuscript. The authors vouch for the completeness and accuracy of the data and for the fidelity of the trial to the protocol.

Trial Participants

Women seeking medication abortion with a maximum estimated gestational length of 42 days and an unconfirmed intrauterine pregnancy on vaginal ultrasound examination were screened for inclusion. We used the definition of an unconfirmed intrauterine pregnancy as either pregnancy of unknown location or probable intrauterine pregnancy.[9] For women with irregular menstrual cycles or an unknown date of the last menstrual period, enrollment was at the discretion of the local investigator. Women were eligible if they were 18 years of age or older, spoke English or a local language, and consented to participate after receiving written and oral information about the trial. Exclusion criteria were symptoms or signs of pathologic pregnancy (e.g.,

GBP-PET00129

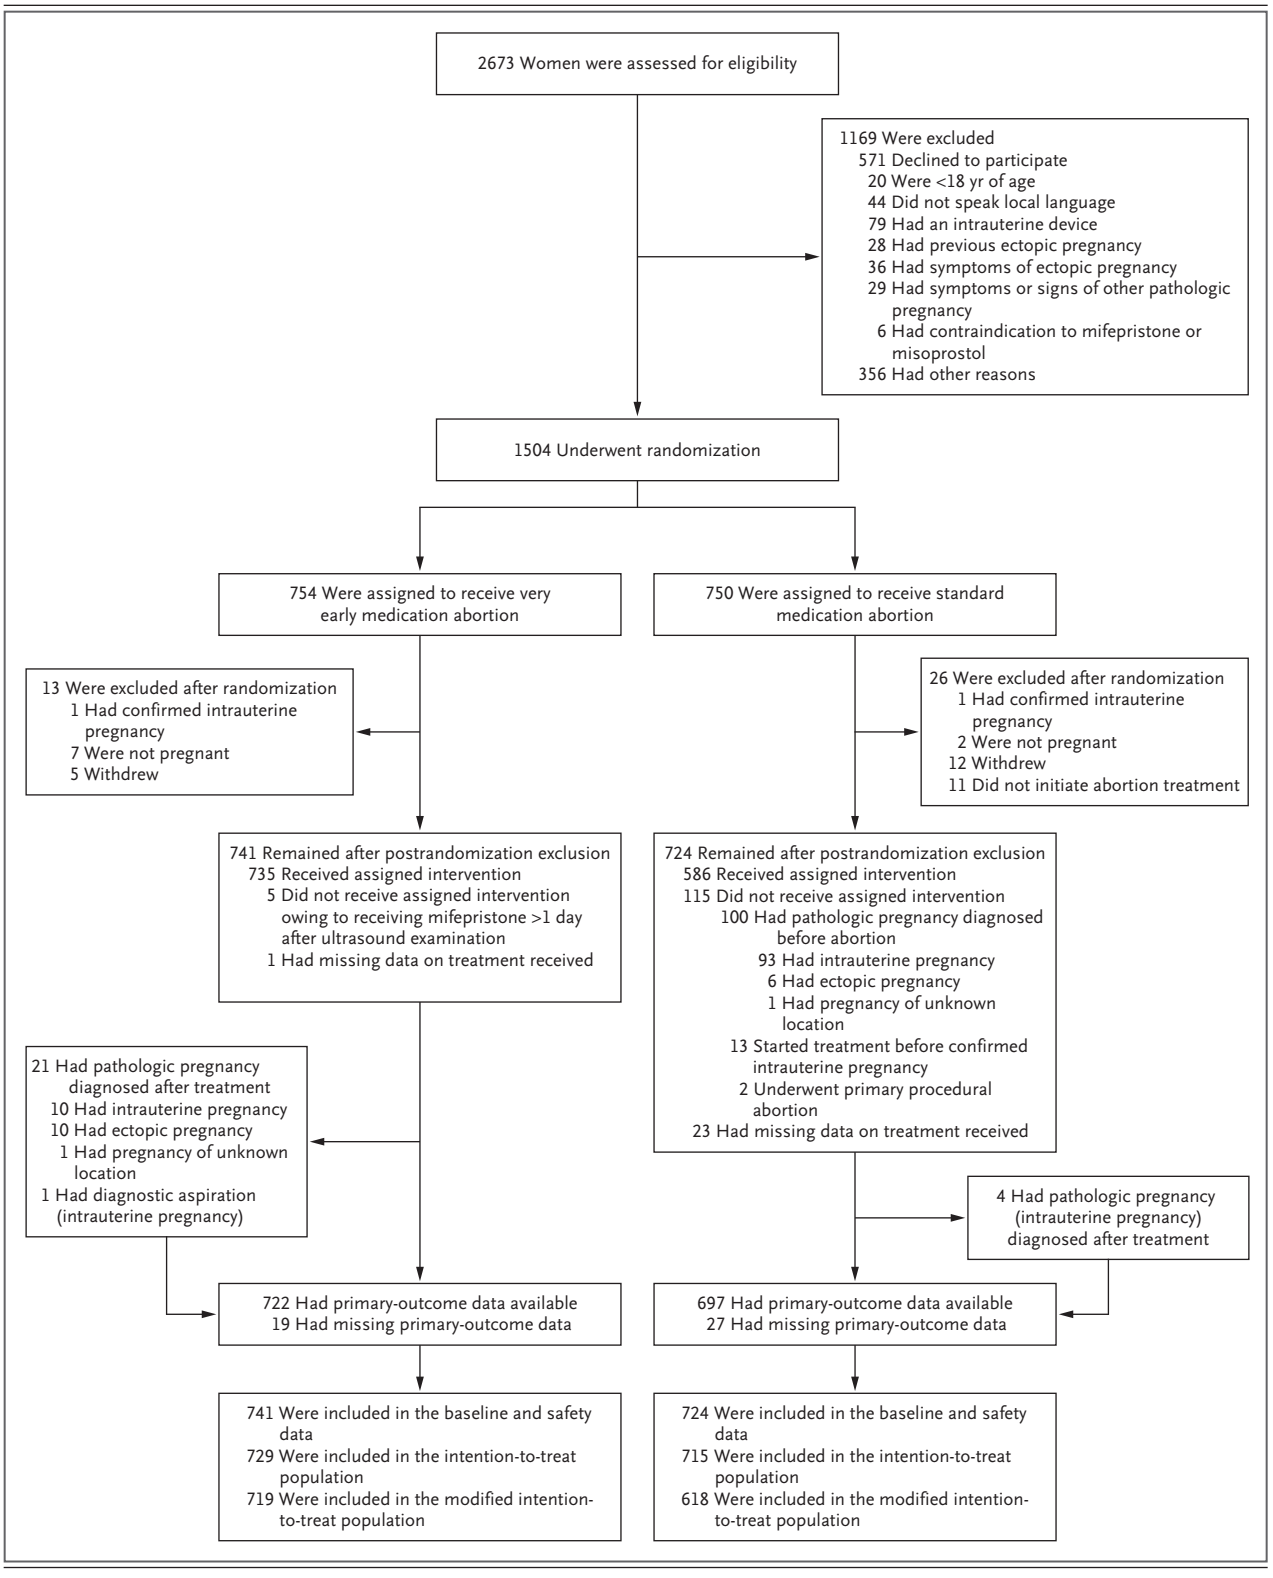
bleeding or unilateral abdominal pain), risk factors for ectopic pregnancy (previous ectopic pregnancy or the presence of an intrauterine device), or any contraindications to medication abortion (see the Supplementary Appendix). Baseline data on age, body-mass index, and previous and current pregnancy, as well as baseline ultrasound findings and hCG level, were collected for all the participants; data were not collected on race, ethnic group, and gender.

TRIAL PROCEDURES

Participants were randomly assigned, by means of block randomization with varying block size and stratification according to center, in a 1:1 ratio to receive either early treatment (early-start group) or delayed treatment (standard group). Participants in the early-start group initiated medication abortion on the day of or the day after trial inclusion. We delayed treatment for participants in the standard group until a repeat ultrasound examination on trial day 7 (with a window of ±2 days) visualized an intrauterine pregnancy. If an intrauterine pregnancy was still not confirmed, participants in the standard group had a third ultrasound evaluation at trial day 14 (with a window of ±2 days). If an intrauterine pregnancy could still not be confirmed, the participant was considered to have a pathologic pregnancy. Participants with a pathologic pregnancy that was diagnosed at any time during the trial were treated according to local clinical practice but followed for assessment of outcome and adverse events.

All the participants received the World Health Organization–recommended protocol for medication abortion: mifepristone at a dose of 200 mg orally, followed 24 to 48 hours later by misoprostol at a dose of 800 μg administered vaginally, sublingually, or buccally according to local standard practice.[1] An additional dose of misoprostol (400 μg) was administered if bleeding had not started within 3 hours (except in Australia).[4] Oral analgesia was offered according to local clinical routine with a combination of nonsteroidal antiinflammatory drugs and paracetamol with repeat doses or oral opioids (or both) if needed. The level of serum or plasma hCG was assessed at all preabortion visits for both groups (with the exception of Nepalese sites, where it was assessed only before intrauterine pregnancy had been confirmed). If the baseline hCG level was more than 5000 IU per liter, the participant was evaluated by a gynecologist for possible ectopic pregnancy before continuing in the trial.

Assessment of treatment outcome in the early-start group was by means of hCG measurements at mifepristone intake and on day 7. The treatment was deemed to be successful if a decrease of at least 80% was seen.[20] Additional clinical assessments were performed if there were signs or symptoms of complications or ongoing pregnancy. Assessment of treatment in the standard group was according to local clinical routine, including either blood or urine hCG levels (at home or in the clinic) or ultrasound examination.



All the participants were followed up at 4 weeks after abortion, by telephone or in person. If participants could not be reached for follow-up, medical records were retrieved and assessed.

OUTCOME MEASURES AND ADVERSE EVENTS

The primary outcome was complete abortion, with no ongoing intrauterine pregnancy and no need for surgical intervention for incomplete abortion within 30 days after treatment.[21] Adverse events were defined as complications related to the abortion treatment or trial conduct (e.g., pelvic infection, uterine perforation or other complications of surgery, side effects of mifepristone or misoprostol, and prolonged or heavy bleeding). Serious adverse events were defined as all conditions resulting in hospitalization (for ≥24 hours) or hemorrhage resulting in blood transfusion. Detailed data on all ectopic pregnancies were collected, including status at diagnosis (ruptured or unruptured) and type of treatment.

Secondary outcomes included incomplete abortion, additional medical treatment for incomplete abortion, infections treated with antibiotics, unscheduled telephone contacts, unscheduled visits, and acceptability measures including days with bleeding and maximum pain (assessed by means of a numerical rating scale, with scores ranging from 0 to 10 and a score of >7 classified as severe pain) as well as satisfaction with assigned treatment (assessed by means of the Likert scale, with scores ranging from 0 to 6 and a score of ≥5 classified as satisfied) and preferred and recommended treatment (early or standard treatment) (see the Supplementary Appendix). For data management, we used Research Electronic Data Capture (REDCap) software.[22]

Figure 1 (facing page). Enrollment, Randomization, Received Treatment, and Follow-up.

Among the women assessed for eligibility, exclusion data were missing from one site in Stockholm, and linear approximation was used for exclusion data from Helsinki before February 17, 2022. The intention-to-treat population included participants who started medication abortion, excluding those with ectopic pregnancy, primary procedural abortion, diagnostic aspiration, or a final diagnosis of pregnancy of unknown location. The modified intention-to-treat population included participants who started medication abortion, excluding those with a pathologic pregnancy, primary procedural abortion, or a final diagnosis of pregnancy of unknown location.

STATISTICAL ANALYSIS

We calculated that 1360 participants were needed to show noninferiority of early as compared with standard treatment with a power of 90%. The calculation was based on an estimated efficacy of 97% in both groups, on the basis of previous studies of very early medication abortion, and calculated by the construction of a two-sided 95% confidence interval for the difference in efficacy between the two groups.[5] The noninferiority margin was set at 3.0 percentage points, because this was deemed to be clinically relevant. Power calculation was done with the use of R software, version 3.3. To compensate for a 10% loss to follow-up (including participants with pathologic pregnancies diagnosed), we planned to include a total of 1500 participants.

The confidence interval for the primary-outcome analysis was constructed with the use of the proportion test for calculating the absolute between-group difference. According to our initial statistical analysis plan, a modified intention-to-treat analysis would include participants who started medication abortion and had a known outcome, excluding participants with pathologic pregnancies. We had anticipated a combined incidence of loss to follow-up and pathologic pregnancies of 10%. This calculation was exceeded in our standard group with 104 pathologic pregnancies (14.4%), as compared with 21 (2.8%) in the early-start group. To avoid selection bias, we opted to use a strict intention-to-treat approach that included participants with intrauterine pathologic pregnancies. Pathologic intrauterine pregnancies included early pregnancy loss and molar pregnancy, which can be treated with mifepristone or misoprostol (or both) or uterine aspiration in a fashion similar to induced abortion.[23,24] A modified intention-to-treat analysis and a per-protocol analysis were also performed as additional analyses of the primary outcome. Sensitivity analyses also included multivariate logistic regression with adjustment for country and ultrasound findings in the intention-to-treat population. According to our statistical analysis plan, adjustments were planned at the site level, but owing to the large number of sites (some of which had no failed abortions), we adjusted instead at the country level. Adjusted between-group differences were calculated as marginal means from a logistic-regression model.

The only prespecified subgroup analysis for the primary outcome was according to baseline ultrasound finding (pregnancy of unknown location or probable intrauterine pregnancy). Post hoc exploratory analyses included subgroups defined on the basis of baseline hCG level (≤1000, 1001 to 5000, or >5000 IU per liter) and gestational length in weeks according to the last menstrual period. All between-group differences for subgroup analyses were calculated as marginal means from a logistic-regression model that included interaction terms for the analyzed subgroup.

Secondary outcomes were analyzed in the modified intention-to-treat population. Risk ratios were calculated for binary outcomes. Confidence intervals around risk ratios for these outcomes were not adjusted for multiplicity and should not be used for hypothesis testing. For the main analysis of primary and secondary outcomes, the complete case analysis was used. As a sensitivity analysis, we imputed missing data using multiple imputation with chained equations.[25] All analyses were performed with the use of Stata software, version 17 (StataCorp).

RESULTS

PARTICIPANTS

In total, 2673 women were assessed for eligibility, of whom 1169 were excluded and 1504 were included in the trial (Fig. 1). We randomly assigned 754 participants to the early-start group

§ Data were missing for 103 participants in the early-start group and 96 participants in the standard group.
¶ Maximum pain was assessed by means of a numerical (integer) rating scale, with scores ranging from 0 to 10 and a score of more than 7 classified as severe pain.
‖ Satisfaction with treatment was assessed by means of a Likert scale, with scores ranging from 0 (dissatisfied) to 6 (very satisfied). Shown are participants with a score of 5 or 6.
** Shown is which treatment would be recommended to a friend.

early pregnancy losses and 1 molar pregnancy], 6 ectopic pregnancies, and 1 pregnancy of unknown location). Pathologic pregnancies that were diagnosed after treatment were followed for outcome and safety assessments. Primary-outcome data were not available for 19 participants in the early-start group and 27 in the standard group.

Baseline characteristics were similar in the two groups other than diagnosed pathologic pregnancies (Table 1 and Table S1 in the Supplementary Appendix). The demographic characteristics of the background population seeking induced abortion are shown in Table S2.

OUTCOMES

In an intention-to-treat analysis using complete data, the efficacy of medication abortion with respect to complete abortion was 95.2% (676 of 710 participants) in the early-start group and 95.3% (656 of 688 participants) in the standard group. The between-group difference was −0.1 percentage points (95% confidence interval [CI], −2.4 to 2.1), a finding consistent with noninferiority of early start to standard treatment (prespecified margin, 3.0 percentage points). Results were materially unchanged in analyses of the per-protocol population, the modified intention-

GBP-PET00135

to-treat population, and the intention-to-treat population with missing data imputed and in analyses adjusted for country and baseline ultrasound finding (Table 2 and Table S4).

Failed abortion included either ongoing pregnancy or surgical intervention for incomplete abortion; the reasons for failure differed between the two groups. The number of ongoing pregnancies was 21 (3.0%) in the early-start group and 1 (0.1%) in the standard group (risk ratio, 20.35; 95% CI, 2.74 to 150.87); surgical interventions for incomplete abortion were performed in 13 of 710 participants (1.8%) in the early-start group and in 31 of 688 (4.5%) in the standard group (risk ratio, 0.41; CI, 0.21 to 0.77) (Table 2).

Results of subgroup analyses, including subgroups stratified according to baseline ultrasound finding (pregnancy of unknown location or probable intrauterine pregnancy), hCG levels, and gestational length, are shown in Figure S1. These analyses were not adjusted for multiplicity, but they suggest a possible advantage of standard (over early) treatment for pregnancies of unknown location or with an hCG level of less than 1000 IU per liter, as compared with a possible advantage of early treatment for probable intrauterine pregnancy and when the hCG level was more than 5000 IU per liter.

Results of secondary-outcome analyses are shown in Table 3. In both groups, responses to questions about preference for future treatment and which treatment one would recommend to a friend favored early treatment.

There were 10 ectopic pregnancies (1.3%) in the early-start group and 6 (0.8%) in the standard group (Table 1), with one rupture occurring before diagnosis (early-start group). Clinical details are shown in Table S5. Serious adverse events were reported in 12 of 737 participants (1.6%) in the early-start group and in 5 of 718 (0.7%) in the standard group (P=0.10); most were uncomplicated hospitalizations (for ≥24 hours) for treatment of ectopic pregnancy or incomplete abortion (Table 4 and Table S6).

Table 4. Safety Outcomes.*

Event	Early Start (N=741)	Standard (N=724)	P Value

† Serious adverse events are not included and are presented separately.
‡ Details regarding serious adverse events are provided in Table S6 in the Supplementary Appendix.

DISCUSSION

In this large, multicenter, randomized, controlled trial involving women with a maximum estimated gestational length of 42 days, we found that early start of medication abortion before confirmed intrauterine pregnancy was noninferior to delayed treatment after confirmed intrauterine pregnancy with respect to completing abortion. Reasons for failed abortion differed between the two groups, with a higher incidence of surgical intervention for incomplete abortion after standard treatment and a higher incidence of ongoing pregnancy after early start.

Our results are consistent with findings from the largest observational study on very early medication abortion[5], which included 2643 patients and showed a similarly high incidence of complete abortion for treatment with and without confirmed intrauterine pregnancy. Yet more recent observational studies on medication abortion that were limited to pregnancy of unknown location showed a lower efficacy of early treatment than delayed treatment.[12,13] Our trial was not powered to detect noninferiority within this subgroup. However, subgroup analyses involving our large population with pregnancy of unknown location suggested the possibility of an advantage of

GBP-PET00136

delayed treatment in this subgroup (unlike in the subgroup with probable intrauterine pregnancy).

Findings for some secondary outcomes, such as postabortion infections, days with bleeding, satisfaction with assigned treatment, and preferred treatment, appeared to favor early start over standard treatment. However, the absence of adjustment for the multiplicity of testing precludes firm conclusions about these outcomes.

In this trial, as well as in previous observational studies, early diagnosis of an ectopic pregnancy was possible regardless of whether abortion treatment was started early or delayed.[5,12,13,18] Making this diagnosis requires adherence to follow-up with hCG assessment, ultrasonography, or both.

Limitations of our trial should be recognized. Women with pregnancy of unknown location and those with probable intrauterine pregnancy were included, and the trial was not designed to evaluate these groups separately. In addition, participants who received a diagnosis of a pathologic pregnancy were not followed for secondary outcomes such as bleeding, pain, and acceptability of assigned treatment. Because we had underestimated the prevalence and imbalance of diagnosed pathologic pregnancies between the groups, we have unbalanced groups for these analyses. Moreover, treatment outcome was assessed with the hCG level in the early-start group and according to local clinical practice in the standard group. In Nepal, the routine use of ultrasonography for participants in the standard group might have led to "unnecessary" uterine aspirations for this group. To control for this possibility and for other potential differences in clinical practice, we adjusted for country in our sensitivity analysis of the primary outcome and found consistent results.

Whereas participants in our trial were included on the basis of ultrasound findings, there has been a shift toward selective use of ultrasonography only for those at high risk for pathologic pregnancy or with uncertain gestational length.[1,4] Nevertheless, we consider our results to be relevant to women with early pregnancy regardless of whether an ultrasound examination was performed. In our trial, we determined success in the early-start group on the basis of the decrease in blood hCG levels over a period of 7 days. It would be of value to evaluate whether this could be determined with urine hCG levels or could be determined sooner, especially for settings where abortion is restricted after 6 weeks of gestation.[12,13,26] In addition, we did not include procedural abortion, which has shown potential to offer rapid diagnosis of pregnancy location and to be highly effective.[13] Finally, we did not collect data on race or ethnic group in our trial population and hence cannot address the generalizability of our findings according to these characteristics (Table S3).

The results of this large multicenter trial indicate the noninferiority of the early start of medication abortion before confirmed intrauterine pregnancy, as compared with the standard approach of delaying abortion until an intrauterine pregnancy is confirmed.

Abstract

Objective: To determine the outcome of early medical termination of pregnancy (TOP) among women who choose a "self assessment" follow up comprising a self-performed low sensitivity urine pregnancy test with instructions on signs/symptoms that mandate contacting the TOP service.
Study design: A retrospective review of computer databases of 1726 women choosing self-assessment after early medical TOP (<9 weeks) in the UK. The main outcome measures were (a) number of women choosing self-assessment, (b) contact rates with TOP service and (c) time to presentation with an ongoing pregnancy (failed TOP).
Results: Ninety-six percent of women having an early medical TOP and going home to expel the pregnancy chose self-assessment. Two percent of women made unscheduled visits to the TOP service. One hundred and eighty-eight women (11%) telephoned the service about concerns related to complications or the success of treatment. There were eight ongoing pregnancies (0.5%; 95% confidence interval 0.2–0.9%). Four were detected within 4 weeks of treatment; the remainder were not detected until one or more missed menses after the procedure.
Conclusions: Most women having an early medical TOP, who go home to expel the pregnancy, choose self-assessment. Relatively few women make unscheduled visits or telephone the TOP service. Most ongoing pregnancies are recognized at an early stage, although late presentation (as with all methods of follow up) does still occur.
Implications statement: If women are given clear instructions on how and when to conduct a urine pregnancy test and on signs/symptoms that mandate contacting the TOP service, then they can confirm the success of early medical TOP themselves. Late presentation due to failure to recognize an ongoing pregnancy is rare.

1. Introduction

It is estimated that one in three women will have a termination of pregnancy (TOP) at some point in their lives [1]. Increasingly in Great Britain, early TOP (up to 9 weeks gestation) is being conducted medically; 87% and 61% of those at less than 9 weeks gestation were conducted medically in Scotland and England/Wales, respectively, in 2013 [2,3]. The medical regimen at less than 9 weeks gestation usually consists of a single oral dose (200 mg) of mifepristone followed 24–48 h later by 800 mcg of misoprostol (usually administered vaginally) [4]. In most countries where early medical TOP is legal (e.g., USA, Sweden, France and Portugal), women are able to administer the second part of this treatment regimen (misoprostol) at home, and this has been shown to be safe and preferred by women [5]. In Great Britain, legal restrictions mandate that misoprostol must be administered on licensed premises, although women may then go home to expel the pregnancy [6,7]. This has sometimes been termed *early medical discharge*. With early medical

TOP, the risk of ongoing pregnancy is small—approximately 0.5–1% [4]. For women in whom expulsion of the pregnancy has not been confirmed by a clinician before, follow-up traditionally has involved a routine clinic visit for ultrasound. While ultrasound will reliably exclude an ongoing pregnancy, its use can lead to unnecessary medical or surgical intervention due to detection of blood clot or products of conception that are visible but not clinically important [8,9]. Reliance on ultrasound is also costly and requires highly skilled staff, and for some services, the volume of repeat appointments may limit the number of new referrals that can be seen. Observational studies report high loss to follow up when women are scheduled for a routine clinic follow-up, which is a waste of resources [6,10]. The most studied alternative method of follow up to exclude ongoing pregnancy is that of a telephone follow-up from the TOP provider combined with a self-performed pregnancy test conducted by the woman herself at home [11,12]. Although telephone follow-up has been shown to be an acceptable method of follow-up [11,12], a survey of women showed that more than half would have preferred no routine telephone call but rather simply to contact the service themselves if there was a problem [11].

The TOP service in Edinburgh, which is part of the National Health Service (NHS) Scotland and provides free treatment, introduced telephone follow as routine in 2011. However, by 2012, staff of the TOP service, reported that there were increasing requests from women not to receive a routine call, and that several attempts had to be made before most women were successfully contacted. Furthermore, staff reported that women had often forgotten to perform the pregnancy test on the day of the scheduled call necessitating a second call at a later date for results of the pregnancy test. In response to this in April 2012 the TOP service introduced "self assessment," permitting women having early medical TOP and going home to expel the pregnancy, to opt out of receiving this routine telephone call provided that they understood how to conduct and interpret the urinary pregnancy test and signs and symptoms that indicated the need to contact the TOP service. The quality improvement team for gynecology for the region approved the new service.

We wished to evaluate the self-assessment option in terms of (a) proportion of women choosing this, (b) contact rates with the TOP service and (c) time to presentation with an ongoing pregnancy (failed TOP).

2. Methods

2.1. Self-assessment

All women attending the TOP service in Edinburgh had an ultrasound to assess gestational age, and the medical TOP regimen used was 200 mg mifepristone followed 24–48 h later with 800-mcg misoprostol. From September 2012, clinics for women requesting a TOP were held both in a hospital outpatient clinic and a city centre community sexual and reproductive health (SRH) clinic, 3 mi away. The same clinical lead was responsible for both sites, and the same clinic protocols were used at both NHS sites. Women were provided with a low sensitivity pregnancy (LSUP) test (detection limit 1000 IU Human Chorionic Gonadotrophin) at the clinic visit for administration of misoprostol and were instructed by clinic staff on when and how to conduct the LSUP test (Baby Duo, Quadratech diagnostics, UK). This was supplemented with both written and pictorial instructions on how to perform and interpret the test together with and signs/symptoms that might indicate an ongoing pregnancy [13] and for which they should contact the service on the dedicated number provided. All women who chose to have self-assessment were required to sign a form stating that they wished to opt out of receiving a routine telephone call, that they accepted the responsibility for contacting the TOP service if the pregnancy test was positive or invalid or they were not certain of the result or that even if the LSUP test was negative that they should still contact the service if they had less than 4 days of bleeding, had persisting symptoms of pregnancy or if their next period failed to arrive by 1 month after treatment (Fig. 1). In this way, ongoing pregnancy should in theory be detected at the latest when the next menses following treatment were missed (after 4 weeks).

The TOP service also provided free ongoing contraceptive supplies (pills, patch, ring) to women to start on the day that they received misoprostol. Progestogen-only injectables and implants were also administered/inserted at this visit before the woman was discharged home. Women wishing intrauterine contraception (intrauterine device or system) were given an appointment for insertion at a later date at the SRH service [14].

A retrospective review of the TOP service databases was conducted for all women choosing self-assessment during the period of study. Demographics that are routinely recorded include reproductive history, deprivation category based upon Scottish postcodes [15], body mass index (BMI) and method of contraception supplied to women at discharge from the service. For all women, the regional hospital computerized database was also checked to determine if women made an unscheduled visit to either the hospital or SRH site with a complication of treatment within 3 months of TOP or to the maternity service with an ongoing pregnancy. The TOP service telephone call registers were also checked to determine if women made telephone contact and reason for this. The chair of the local ethics committee confirmed that formal ethical committee approval was not required for this retrospective database review.

2.2. Statistical analysis

Statistical analysis was conducted using International Business Machines (IBM) Statistical Package for Social Sciences (SPSS) software Version 18 (SPSS, Chicago, IL, USA). Descriptive statistics were performed for demographics, and groups were compared by chi-squared test of significance.

I understand that:
∞ I am accepting responsibility to perform a 'self assessment' to exclude the possibility of an ongoing pregnancy (1 in 100 risk of ongoing pregnancy)
∞ I will not receive the telephone call at 2 weeks
Signs that treatment may not have worked and that I still may be pregnant, are: ∞ **do not bleed within 24 hours of receiving misoprostol** ∞ **less than 4 days of bleeding** ∞ **still 'feel' pregnant at the end of one week or have symptoms of pregnancy such as sore breasts, sickness, tummy growing etc.** In such circumstances I should contact the clinic immediately, as I may require more treatment.
∞ Need to perform the urine pregnancy test that I have been given, 2 weeks after treatment
∞ The urine test must be performed using only my first morning urine
∞ If the pregnancy test is positive, or invalid, or I am not sure, that I should contact the clinic as soon as possible to arrange for an appointment, as I might still be pregnant
∞ If the pregnancy test is negative, that I could still be pregnant, if my next period does not come by one month after the treatment.
∞ If the treatment fails and I am still pregnant, that doctors cannot guarantee that the pregnancy will be healthy

Fig. 1. Details of the form that women sign if they choose self-assessment and wish to opt out of receiving a routine telephone call.

Ninety-five percent confidence intervals (CIs) for proportions and multiple logistic regression were conducted where appropriate. Statistical significance was taken as a p of <0.05.

3. Results

Between April 2012 and October 2013 (18 months), a total of 1791 women had an early medical TOP and chose to go home to expel the pregnancy. In 1726 cases (96%), the planned method of follow-up was self-assessment. All women from the SRH site opted for self-assessment, but 42 women (4%) attending the hospital chose to receive a routine telephone follow up (call from provider), and 23 women (2%) had a clinic visit with ultrasound arranged as routine follow-up.

3.1. Demographics

The demographics of women choosing self-assessment are shown in Table 1. The only difference between women assessed at hospital and SRH sites was that a statistically significantly higher percentage of women were at 6 weeks gestation or less at the SRH site (47% vs. 29% at SRH and hospital, respectively; $p<0.0001$(Table 1).

A total of 220 women (13%) made contact with the service after the TOP (Fig. 2). In 188 cases (11%), primary contact was by telephone, with only 32 women (2%) presenting to the hospital or SRH service with an unscheduled/emergency visit; mostly due to pain and/or heavy or persistent bleeding ($n=29$). Seven out of the 32 women who made an unscheduled visit required hospital admission for blood transfusion ($n=4$) and/or a surgical evacuation of the uterus ($n=3$) due to haemorrhage, and one woman required intravenous antibiotics for renal tract sepsis.

Of the 188 telephone calls, a clinic visit was subsequently scheduled for 120 women (7% of women having self-assessment). In 45 cases (2.6% of all women having self-assessment), the reason for the telephone call to the TOP service was a positive LSUP test ($n=17$) or invalid LSUP test result ($n=28$). In 43 cases, women called because they had less bleeding than expected (2% of women having self-assessment). A further 12 women (0.7% of total women having self-assessment) called due to concern about ongoing pregnancy symptoms ($n=7$) or because their next period after treatment had not arrived ($n=5$). In total therefore 100 women out of 1726 (6%), made a telephone call to the service on the basis of a self-assessment that indicated that they should contact the TOP service.

3.2. Detection of ongoing pregnancy

There were a total of 8 women in the self-assessment group (0.5%) with an ongoing pregnancy (95% CIs 0.2%–0.9%). Neither age, deprivation nor BMI affected the risk of ongoing pregnancy (results not shown). Of the ongoing pregnancies, the gestation at medical TOP had been 42 days or less ($n=2$), 43 to 49 days ($n=2$), 50 to 56 days ($n=1$) and 57 to 63 days ($n=3$). Two of the women telephoned the TOP service within 1 week of treatment to arrange a clinic review due to pain ($n=1$) and scant bleeding ($n=1$). An ultrasound confirmed the ongoing pregnancy, and both women proceeded to have a repeat medical TOP (both less than 9

Figures shown are number (%) except for age.
[a] Women should have been 16 years or older to be considered as an adult [12].
[b] Based upon Scottish post codes [15].
[c] p<0.0001 chi-squared.

weeks gestation). A further two women with ongoing pregnancies contacted the service between 2 and 4 weeks after treatment to arrange review due to scant bleeding/ongoing pregnancy symptoms (n=1) or a positive LSUP test (n=1). One woman chose to have a surgical TOP and the other a medical TOP (both less than 13 weeks gestation).

Two women contacted the service after missed menses, and the remaining two women presented only when they had missed two menses. In all four cases of delayed presentation, although bleeding post TOP lasted less than 4 days, this did not trigger contact with the TOP service. In two of the four cases presenting after 1 month, the LSUP test had been positive or invalid at 2 weeks but the other women reported that the LSUP test had been negative. All four women had a successful repeat TOP procedure performed either medically (n=2) or surgically (n=2) at between 12 and 22 weeks gestation.

Of the eight women with ongoing pregnancies, the method of contraception started post TOP was the combined oral contraceptive pill (n=3), injectable (n=1), progestogen-only pill (n=1) and no method (n=3). In one case, pregnancy symptoms and amenorrhoea were wrongly assumed to the due to progestogen-only injectable. In one case, the ongoing pregnancy was wrongly assumed to be a new intended pregnancy.

4. Discussion

This study showed that when given the option, most women who are planning to go home to expel a pregnancy following an early medical TOP choose not to receive a phone call from the TOP service. The proportion of women choosing this was considerably higher than the 50% or so that we had expected based upon our earlier survey [11], which may reflect changes in women's views about this over time, or provider's readiness to support women in this decision. Whatever the reasons, this does seem to suggest that most women feel comfortable with taking the responsibility for interpreting the result of LSUP test, in the knowledge that they can contact the TOP service directly should they have concern about the outcome of the test or about signs or symptoms. The study also showed that relatively few women (approximately 1 in 10) actually do make contact with the TOP service with a concern related to the procedure.

The study also confirmed the low rate of ongoing pregnancy with early medical TOP. Of course, compared to receiving a telephone call, self-assessment does place more responsibility on women to correctly interpret an LSUP test and to be sufficiently motivated to contact the TOP service should they have any suspicions that they might still be pregnant. Providers may therefore be concerned that ongoing pregnancies might be detected later. This may be particularly relevant in countries where midtrimester abortion is not legal or not available (in Great Britain the upper limit for abortion for nonmedical reasons is 24 weeks) [2]. However, our study provides some reassurance in this respect, since the delay between medical TOP and presentation at clinic with diagnosis of ongoing pregnancy did not appear to differ from previous reviews of ongoing pregnancy from our service when we scheduled a routine clinic visit with ultrasound [5] or had an active policy of telephone contact with women at 2 weeks [11,12]. Indeed, with a routine clinic visit for ultrasound to confirm success of TOP, we found that some women still presented late in the midtrimester for a repeat TOP or at childbirth [5,11,12]. Similar findings have been reported from a large retrospective review from the USA that showed that abandoning the clinic visit for routine follow up after surgical TOP does not affect the rate nor stage of detection of ongoing pregnancy [16]. A number of studies have also shown that even when women are concerned enough to call about a positive LSUP test and are scheduled for an urgent clinic review, many subsequently choose not to attend this [5,11,12]. Given that some ongoing pregnancies were in women who reported a negative LSUP test, this strengthens the need to remind women that no test is perfect and that scant bleeding, pregnancy symptoms or missed menses after treatment necessitate contact with the provider.

Although, it is important to start effective contraception immediately post TOP to prevent another unintended pregnancy, there is of course the potential that women with

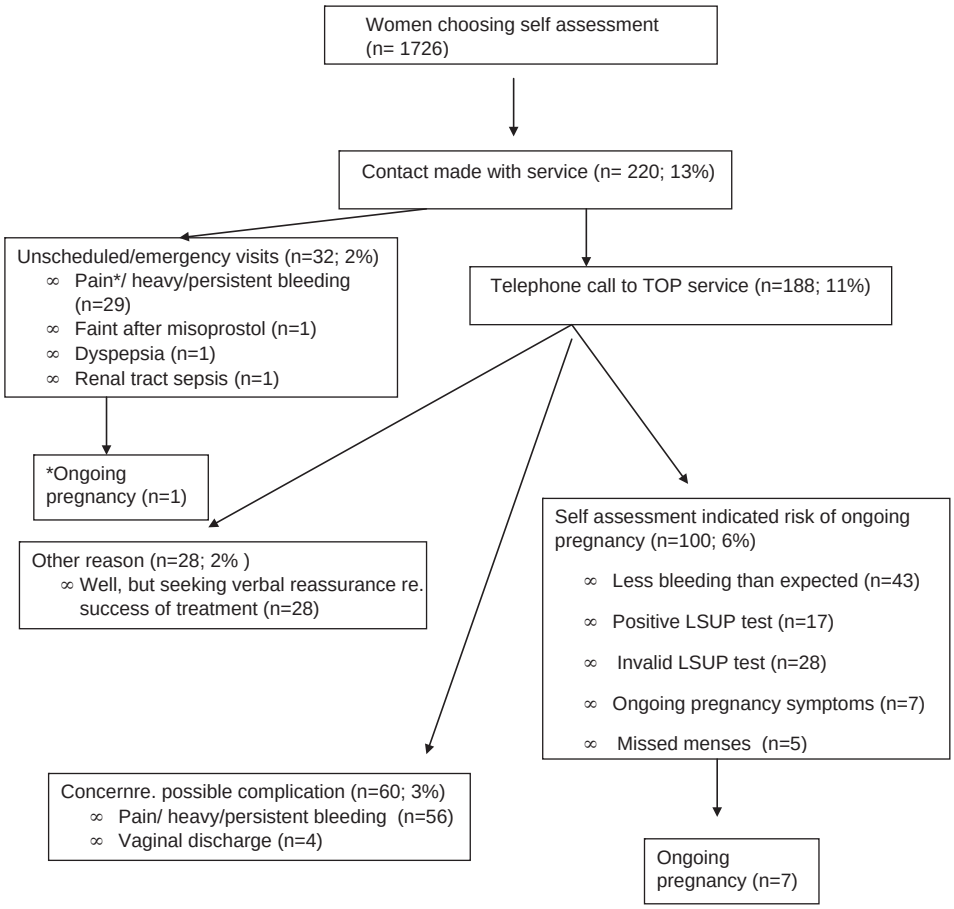

Fig. 2. Reasons for making contact with TOP service post abortion.

ongoing pregnancies might wrongly attribute paucity of bleeding or amenorhoea or pregnancy symptoms to the hormonal effect of the injectable or implant, and this was sadly a factor in one of our cases with ongoing pregnancy.

A strength of this study is that the data are from a large cohort of women having early medical TOP, the vast majority of whom have chosen self-assessment. We also went to considerable effort to search all available registers that could provide us with information of any unscheduled contact with the service related to the TOP. Furthermore, this is the only study to date to report a method of "follow up" that involves contact with a health care provider, only when initiated by the women themselves. Of course this study relates to a high income setting (Scotland), where all women have universal free access to health care. Furthermore, all women had to meet our criteria to be permitted to go home to pass the pregnancy, that is, adults with adult support at home and able to speak and understand English [12]. As such therefore, they represent a group of women who are already "selected" to be well-placed to be able to manage self-assessment and capable of contacting the TOP service with concerns. In addition, women attending our TOP service are provided with high-quality written [17] and pictorial information and can also access the same information in audiovisual format via the regional sexual health service Website.

A potential weakness of this study was that we were only able to verify ongoing pregnancies amongst women who presented in the same region. We believe it is unlikely that we will have missed other ongoing pregnancies, as we feel that women (or providers from other regions) would probably have contacted our service to complain or pursue litigation. However, we do accept that we cannot exclude the possibility that women may have been treated for an ongoing pregnancy in another region or another country.

There is good evidence that the pathway for women requesting an early medical TOP can be simplified. It has been shown that in uncomplicated cases, gestational age dating by ultrasound is not necessary [18]. Furthermore, both the assessment for medical TOP and the care can safely be delivered by midlevel providers [19,20]. It is also clear that most women can undergo the procedure just as safely at home as in a hospital setting [6]. We have previously shown that a clinic follow up is not routinely required and that in most cases this can be replaced with a self-performed pregnancy test with telephone support from a provider [11,12]. We now show that most women neither want nor need scheduled telephone contact from a provider.

This supports recent findings from a study in England that showed 84% of women randomized to clinic follow up with ultrasound after early medical TOP failed to attend [21]. Self assessment affords women greater control of their treatment and may minimize distress and costs to them, as a consequence of fewer visits to the service. In addition, it is possible that self-assessment could protect women from unnecessary intervention for ultrasonically visible but clinically unimportant retained products of conception that are commonly seen at a routine 2-week clinic visit [8,9]. For health care services, self-assessment is likely to result in reduced costs since the number of visits to the service is reduced. This will also free up clinical time for clinicians to see and treat more patients. Providers may worry that women may be more likely to make unscheduled visits to a TOP service if a clinic visit or telephone call is not scheduled; but our findings would negate this. Providers might also worry that women may not perform an LSUP test, perform it incorrectly or may try to seek litigation if a test is negative and they have an ongoing pregnancy. Whilst these are valid concerns, these risks can be minimized by careful counseling and documentation that the woman is taking responsibility for this assumed follow up and that any contact with the service is also documented. For women, it is important that they have easy access to specialist TOP advice and further assessment if required. In other areas of medicine there is a move away from routine follow-up visits after clinical procedures with emphasis being placed on advising patients how to reengage with a health care service if they require further care. This is generally viewed as a positive move in health service delivery and should encompass TOP care.

As clinicians, we should base treatment and care pathways on clinical evidence. The evidence now clearly shows that the pathway for women requesting an early medical TOP who are certain of their decision could consist of a single clinic visit. At this single visit all of the following could reasonably take place: counseling on TOP, administration of mifepristone with a supply of misoprostol for home use, instructions on when and how to conduct a pregnancy test, advice and contact numbers in case of emergency or if they require re-engagement with the TOP service, and provision of supplies of effective ongoing contraception.

Acknowledgments

We would like to thank the nursing staff of CHOICES, Chalmers sexual health service and Bruntsfield suite and reproductive health outpatients, Royal Infirmary of Edinburgh, for assistance with data collection.

U.S. FOOD & DRUG ADMINISTRATION

March 24, 2023

Evan Masingill
Chief Executive Officer
GenBioPro, Inc.
3651 Lindell Road
Suite D1041
Las Vegas, NV 89103

Mr. Masingill:

I write in acknowledgment of your March 1, 2023, letter addressed to the Commissioner of Food and Drugs, requesting "confirmation that any withdrawal of the approval of [GenBioPro, Inc.'s] abbreviated new drug application ('ANDA') for mifepristone—whether by court order or otherwise—will follow all applicable procedures afforded by law and regulation to GBP as the ANDA holder and that FDA will permit GBP to continue marketing and selling mifepristone until those procedures have been completed," including any applicable requirements of 21 U.S.C. § 355(e). Your letter has been referred to the Center for Drug Evaluation and Research for this response.

In their Complaint in *Alliance for Hippocratic Medicine v. FDA*, the Plaintiffs have asked the Court to issue "a preliminary and permanent injunction ordering Defendants to withdraw mifepristone . . . as [an] FDA-approved chemical abortion drug[]." According to the transcript of the March 15, 2023 hearing in this matter, the Plaintiffs have argued that "the Court, on its own accord, can order the FDA to withdraw or suspend the approval of the drug," rather than "order the FDA to begin a suspension or withdrawal" process under 21 U.S.C. § 355(e). Arg't Tr. at 145–46. The Court stated that it plans to "issue an order and opinion as soon as possible." *Id*. at 155. FDA will, of course, need to review the Court's opinion and order before determining what steps may be necessary to comply with it.

Sincerely,

Patrizia Cavazzoni

REVIEW

Open Access

Telemedicine for the provision of medication abortion to pregnant people at up to twelve weeks of pregnancy: a systematic literature review and meta-analysis

Leonardo Cely-Andrade[1*], Karen Cárdenas-Garzón[1], Luis Carlos Enríquez-Santander[1], Biani Saavedra-Avendano[2] and Guillermo Antonio Ortiz Avendaño[3]

Abstract

Background Telemedicine represents an important strategy to facilitate access to medication abortion (MAB) procedures, reduces distance barriers and expands coverage to underserved communities. The aim is evaluating the self-managed MAB (provided through telemedicine as the sole intervention or in comparison to in-person care) in pregnant people at up to 12 weeks of pregnancy.

Methods A literature search was conducted using electronic databases: MEDLINE, Embase, Cochrane (Central Register of Controlled Trials and Database of Systematic Reviews), LILACS, SciELO, and Google Scholar. The search was based on the Population, Intervention, Comparison, Outcome, and Study Design (PICOS) framework, and was not restricted to any years of publication, and studies could be published in English or Spanish. Study screening and selection, risk of bias assessment, and data extraction were performed by peer reviewers. Risk of bias was evaluated with RoB 2.0 and ROBIS-I. A narrative and descriptive synthesis of the results was conducted. Meta-analyses with random-effects models were performed using Review Manager version 5.4 to calculate pooled risk differences, along with their individual 95% confidence intervals. The rate of evidence certainty was based on GRADE recommendations.

Results 21 articles published between 2011 and 2022 met the inclusion criteria. Among them, 20 were observational studies, and 1 was a randomized clinical trial. Regarding the risk of bias, 5 studies had a serious risk, 15 had a moderate risk, and 1 had an undetermined risk. In terms of the type of intervention, 7 compared telemedicine to standard care. The meta-analysis of effectiveness revealed no statistically significant differences between the two modalities of care (RD = 0.01; 95%CI 0.00, 0.02). Our meta-analyses show that there were no significant differences in the occurrence of adverse events or in patient satisfaction when comparing the two methods of healthcare delivery.

Conclusion Telemedicine is an effective and viable alternative for MAB, similar to standard care. The occurrence of complications was low in both forms of healthcare delivery. Telemedicine services are an opportunity to expand access to safe abortion services.

Plain English summary

Globally, unsafe abortion causes 47,000 deaths and 5 million sexual and reproductive dysfunctions in young pregnant people due to complications of the procedure. This practice is related to barriers to accessing safe abortion services secondary to health system limitations and inequities in the distribution of resources.

Telemedicine has proven to be an efficient care alternative to reduce distancing gaps, decrease waiting time and rationalize the costs derived from the procedure. Consequently, several health systems in the world use this model with differences in treatment schemes, weeks of gestation, pregnancy confirmation methods and measurement of reported outcomes. For this reason, evaluating the effectiveness and safety of self-managed medication abortion (MAB) by telemedicine is a support for decision makers who consider implementing or expanding remote care services.

This systematic review integrated studies that evaluated MAB only by Telemedicine or in comparison with standard care on pregnant people with 12 weeks gestation or less. Available studies until January 2023 were chosen. Screening and selection of studies, data extraction, and risk of bias assessment were performed by expert reviewers. Aspects such as the effectiveness, safety, and satisfaction of the procedure, among other outcomes, were reviewed. A narrative and descriptive synthesis was carried out, as well as several meta-analyses of the differences in risks between Telemedicine and in-person care.

The meta-analysis of studies comparing telemedicine care with standard services reveals that the type of care provided does not affect the effectiveness and safety of MAB, nor does it affect user satisfaction, follow-up, or medication adherence.

Keywords Medication abortion, Telemedicine, Standard care, First trimester, Effectiveness, Adverse effects, Acceptability, Satisfaction, Systematic review, Meta-analysis

Introduction

Unsafe abortion poses significant challenges to pregnant people's health, public health, and the overall well-being of nations. Each year, approximately 47 000 pregnant people die and nearly 5 million experience sequelae or sexual and reproductive dysfunctions due to complications associated with this procedure [1, 2]. Unsafe abortion predominantly occurs among pregnant people aged 20 to 25 or those in vulnerable situations, such as migrants and those living in poverty, belonging to specific ethnic groups, or with low levels of education [3]. According to estimates, 90% of unsafe abortions occur in low- and middle-income countries, particularly in Africa, Southeast Asia, Latin America, and the Caribbean, where there is a higher burden of morbidity, mortality, and increased healthcare costs due to procedure-related complications [3, 4].

The political and legal landscape surrounding abortion plays a pivotal role in this regard, as, in countries with more favorable laws and well-funded healthcare systems, pregnant people have better access to safe abortion procedures. Conversely, in nations where abortion is either prohibited or restricted to specific circumstances, pregnant people seeking to terminate their pregnancies are compelled to undergo procedures performed by unqualified individuals or in unsanitary environments. This significantly heightens the risk of complications and fatal outcomes [1, 5].

To provide high-quality abortion services, it is crucial to establish a comprehensive political, legal, and healthcare framework that safeguards pregnant people's rights and considers their specific needs and social, economic, and cultural contexts [6, 7]. As a result, most countries have decriminalized abortion either entirely or under specific circumstances and have adapted their institutional guidelines to provide care to pregnant people seeking voluntary termination of pregnancy. However, universal access to sexual and reproductive health services remains a distant goal given the limitations within the healthcare system and social inequities, which turn a right into a privilege mostly accessible to pregnant people residing in urban areas with sufficient financial resources to afford such services [2, 4, 8, 9].

Safe abortion refers to the induced termination of pregnancy by healthcare professionals or qualified individuals using methods recommended by the World Health Organization (WHO), which are selected based on weeks' gestation [2]. For instance, a medication abortion (MAB) considered a safe option for pregnancies up to twelve weeks, involves orally administering a single 200-mg dose of mifepristone, followed by the use of misoprostol 24–48 h later. In some cases, additional doses of misoprostol are taken every 3–4 h. The concentrations and administration routes of misoprostol may vary depending on gestational weeks and user preference [1]. This treatment can be provided by healthcare

professionals or, if users have received sufficient information and counseling, it can be self-managed at home [10]. Consequently, the outpatient option somewhat liberates users from the structural limitations of healthcare services [11] and opens up possibilities for innovative care alternatives such as the use of Information and Communication Technologies (ICTs), including telemedicine services [11, 12].

As part of the broader concept of digital health or e-health, *telemedicine* is defined by the WHO as ""the practice of healthcare using interactive audio, visual, and data communications. This includes healthcare delivery, consultation, diagnosis, and treatment, as well as education and transfer of medical data"" [13]. This form of healthcare delivery has seen significant growth over the past 20 years, due to advancements in mobile technologies and the widespread availability of digital media, especially the internet [13–15]. Furthermore, the COVID-19 pandemic and the declaration of a public health emergency by the WHO in January 2020 led to a shift in healthcare delivery models due to mobility restrictions and lockdown measures. In response to these new and adverse public health conditions, remote care services were massively implemented worldwide, demonstrating their effectiveness in reducing geographical barriers, improving the quality and timeliness of care, optimizing costs for both patients and healthcare systems, and reducing healthcare disparities [11, 16–21].

One particular application of remote care is the provision of healthcare services during a MAB. Currently, several studies have shown that self-managed and telemedicine-guided MAB is a comparable alternative to in-person care in terms of effectiveness, safety, and patient satisfaction [10, 18, 20–34]. It also reduces the time required to access care and brings healthcare services to remote or underserved communities [35]. Yet, in order to promote the integration and appropriate use of these technologies, ongoing evaluation is necessary alongside the implementation and strengthening of these services [15, 16].

In most countries, the use of scientific evidence serves as the basis for prescribing interventions in healthcare services. Therefore, providing data on the effectiveness and safety of MAB provided through telemedicine is crucial for decision-makers to justify its implementation and widespread adoption. Moreover, given variations in treatment protocols, gestational weeks, methods of pregnancy confirmation, and outcome measurements reported in studies assessing MAB provided via telemedicine, it is important to consolidate the information through a Systematic Literature Review (SLR). Hence, the purpose of this study is to evaluate the effectiveness, safety, satisfaction, and acceptability of self-managed and telemedicine-guided MAB, either as the sole intervention or in comparison to standard or in-person care.

Materials and methods

For this SLR, we used Cochrane methods [36] and the PRISMA 2020 guidelines [37] as the reporting standard. The SLR protocol employed in this study can be accessed on PROSPERO (CRD42023416407).

Eligibility criteria

This SLR included studies that evaluated MAB provided through telemedicine as the sole intervention or in comparison with standard or in-person care. The research question was defined using the Population, Intervention, Comparison, Outcome, and Study Design (PICOS) framework [36].

Population

Pregnant people of childbearing age (aged 10–50 years) who used telemedicine services for MAB before or during the twelfth week of pregnancy, without restriction to any specific country or region.

Intervention

Telemedicine as a comprehensive model for self-managed MAB care. This involved the provision of healthcare services (in this case, MAB) through remote communication technologies.

Comparison

MAB through standard or in-person care.

Outcome

The primary outcomes assessed in this study were effectiveness of the procedure (successful completion of MAB without the need for additional medications and/or surgical intervention), safety (adverse effects/complications: death, surgical intervention, blood transfusion, hospitalization, antibiotic treatment, and emergency department visits), and user acceptability or satisfaction with the service. Other outcomes included follow-up (completion of all phases of MAB), user feelings regarding the procedure, emotional support provided to users, waiting time to treatment (in days), and adherence to prescribed regimens (compliance with correct dosage, administration route, and recommended intake times).

Study design

Experimental studies (Randomized Controlled Trials -RCTs-) and observational studies (cohort studies, case–control studies, and cross-sectional studies). To be eligible, studies had to be available as full publications, and pre-print publications were also considered. Publications

in English or Spanish were accepted, and there were no restrictions on the publication date. Excluded publications included abstracts, narrative reviews, expert consensus, study protocols, case studies or case series, comments, and letters to the editor.

Sources of information

A literature search was conducted in January 2023 using the following electronic databases: MEDLINE (via PubMed), Embase (via Elsevier), Cochrane Library (including the Cochrane Database of Systematic Reviews and the Cochrane Central Register of Controlled Trials), LILACS (via the Virtual Health Library), and SciELO. Additionally, Google Scholar was consulted as a source of gray literature, with the first ten pages of results being examined. To identify additional relevant research, the snowball search method was employed, checking the references of the included studies.

The search strategy was designed by two of the authors (KCG and LCES) and subsequently reviewed by the main author (JLCA). For the searches, key terms were chosen from the list of Medical Subject Headings (MeSH) and Health Sciences Descriptors (DeCS), and free terms based on opinions from subject-matter experts were used as well. The search strategies were tailored to each specific database, incorporating field identifiers, truncation, proximity operators, and Boolean operators as appropriate. Detailed information on the search terms and search strategies used for each database can be found in Appendix A.

Study selection

The study selection process consisted of two stages. In the first stage, the titles and abstracts of the retrieved papers were downloaded, duplicates were removed using Rayyan [38], and the papers were screened based on title and abstract. This initial screening was performed by two reviewers (KCG and LCES) in a double-blind peer review format. Disagreements were resolved through consensus, and if consensus could not be reached, a third reviewer (JLCA) was consulted.

In the second stage, the full text of the pre-selected studies was reviewed by the same two authors in a double-blind peer review format. Disagreements were resolved using the same methodology employed in the initial screening.

Data extraction

Data were extracted independently by two of the authors (KCG and LCES) using Excel®, and disagreements were resolved either between them or with the involvement of the main author (JLCA). The following details were documented: study title, first author, year of publication, country, study design, timeframe, objective, characteristics of the population (age group and diagnoses), number of participants (total and per group), intervention and comparison details (dose, frequency, duration), outcomes (measurement method and follow-up time), specific results for each outcome, and conclusion.

Risk of bias assessment

The risk of bias of the selected studies was assessed independently by two evaluators (KCG and LCES), and any disagreements were resolved through consensus between them. If disagreements persisted, a third evaluator (JLCA) was involved in the discussion.

To assess the risk of bias of the RCTs, Version 2 of the Cochrane risk-of-bias tool for randomized trials (RoB 2) [36] was used, and for the observational studies, the Risk of Bias In Non-randomized Studies—of Interventions (ROBINS-I) tool [39] was employed.

Data synthesis

A narrative and descriptive synthesis was conducted for each outcome. In studies that included a comparator, similar results were grouped together. For meta-analyses, Cochrane's Review Manager version 5.4 [40] was used to generate random-effects models and calculate pooled risk differences, along with their corresponding 95% Confidence Interval (CI) and p-values, which were then presented in a forest plot. Statistical heterogeneity was estimated using the I^2 statistic, where a value greater than 75% indicates significant heterogeneity. For the effectiveness outcome, two a-posteriori subgroup analyses were carried out: the first, according to gestational week (up to weeks 9, 10 and 12); and the second, according to the test used to determine the treatment results (self-assessment, blood test, ultrasound, or a combination of these methods). A Summary of Findings (SoF) table was elaborated to summarize the main results for each outcome (patients and studies, relative and absolute effects, certainty and observations), as well as an assessment of the quality of evidence rating based on GRADE recommendations [41] (rate evidence certainty as high, moderate, low or very low) using the GRADEpro tool [42].

Results

Data search

A total of 821 records were retrieved in the initial search, out of which 87 were duplicates. After reviewing the 734 remaining publications, only 21 met the eligibility criteria (Fig. 1).

Characteristics and risk of bias of the selected studies

Table 1 summarizes the characteristics of the 21 studies included in our review. Out of such studies published

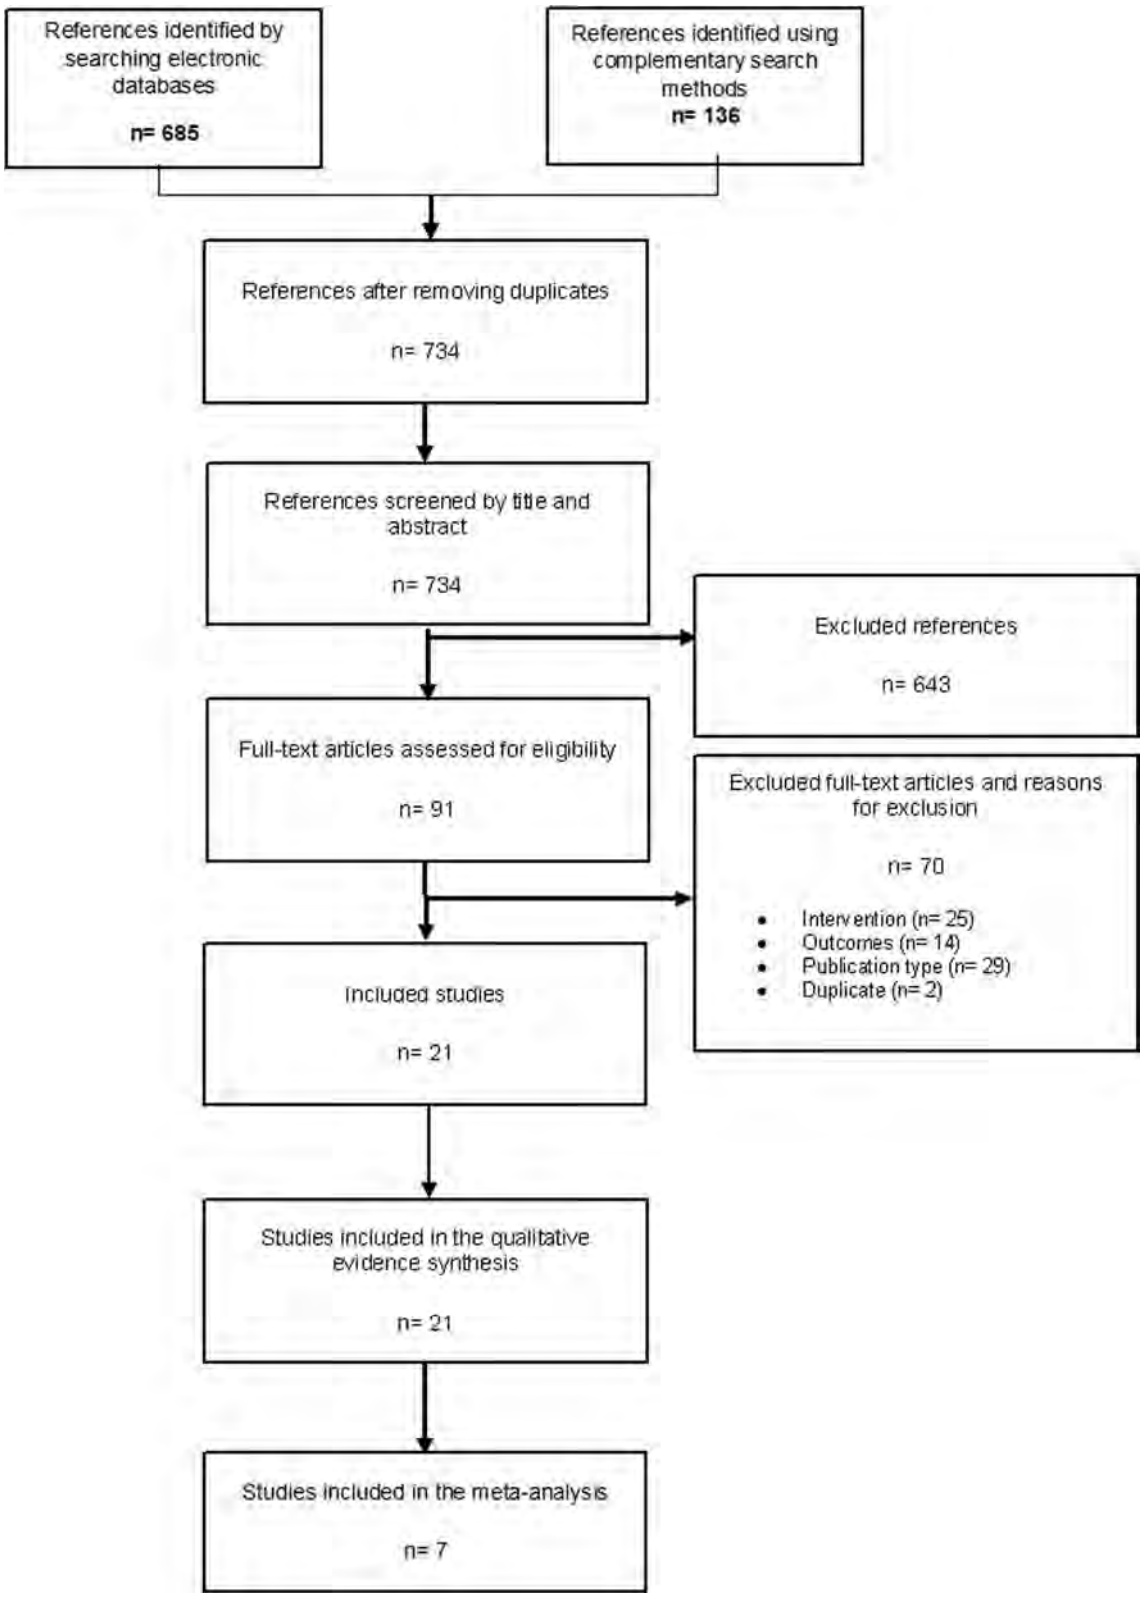

Fig. 1 PRISMA diagram: flow of search, screening, and selection of studies

between 2011 and 2022, 20 were cross-sectional [18, 20, 24, 26, 28–31, 33, 34, 43–52] and 1 was an RCT [32]. Regarding their geographical distribution, 7 (33.3%) originated from.

European countries, 6 (28.6%) from the United States (US), 3 (14.3%) from Latin America, 2 (9.5%) from Australia, 2 (9.5%) were multi-country studies, and 1 (4.8%) was from South Africa. The overall risk of bias was from low to serious in the cross-sectional studies, while the RCT exhibited a high risk of bias (Fig. 2).

Furthermore, 14 (66.7%) evaluated MAB provided through telemedicine as the sole intervention, and 7 (33.3%) compared it with standard care. In terms of gestational weeks, 9 studies (42.8%) included pregnant people at up to 9 weeks of pregnancy, 7 (33.3%) at up to 10 weeks, 3 (14.3%) at up to 12 weeks, and 2 (9.5%) beyond 12 weeks. 16 studies (76.2%) reported on the effectiveness of MAB, 16 (76.2%) examined the safety of the procedure, and 9 (42.8%) addressed user acceptability or satisfaction with the service. Other outcomes assessed in the studies included follow-up (n = 4; 19%), feelings regarding the procedure (n = 3; 14.3%), and average waiting time to treatment (n = 1; 4.8%).

Effectiveness

Sixteen studies evaluated the effectiveness of MAB, with ten exclusively evaluating telemedicine patients [18, 30, 31, 33, 34, 43, 45–48], and the remaining six comparing this outcome among telemedicine patients and standard patients [20, 26, 29, 32, 50, 52]. Treatment success was primarily confirmed through blood tests, followed by ultrasound. Only one study [20] used self-assessment to confirm termination of pregnancy.

In the studies that focused on telemedicine patients, the average effectiveness was 91.9%. All studies reported a standard regimen of 200 mg of orally, vaginally, or sublingually administered mifepristone, followed by an 800 µg dose of misoprostol after 24–48 h. Moreover, additional doses of misoprostol were administered after 3–4 h: six studies [18, 30, 34, 43, 46, 47] reported doses of up to 400 µg, three studies [31, 45, 48] reported doses of up to 800 µg, and one study [33] reported doses of up to 1600 µg. According to the results, increasing additional doses resulted in higher effectiveness rates (90.2%, 93.1%, and 98% respectively).

Six studies [26, 29, 32, 50, 52, 53] were conducted to compare the effectiveness of MAB between patients receiving telemedicine compared with standard care. 77,682 pregnant individuals made up the total sample size, with 43% using the telemedicine modality and 57% using standard care. A meta-analysis of the comparative effectiveness of the studies revealed no statistically significant differences between the two modalities of care (98.6% for telemedicine vs. 97.1% for standard care; RD = 0.01; 95% CI 0.00, 0.02).

Three of them [26, 32, 52] included pregnant people at up to nine weeks of pregnancy, two [20, 29] at up to ten weeks, and one [50] at up to twelve weeks. Moreover, one study [20] reported an additional 400-µg dose of misoprostol after 3–4 h, and two studies [26, 50] reported additional doses of up to 800 µg of misoprostol after the same time interval.

A subgroup analysis according to gestational age (Fig. 3) revealed that, in pregnancies of less than 12 weeks of gestation, there were 10 more successful cases in the standard care group than in the telemedicine group for every 1,000 MAB performed (RD = 0.01; 95% CI 0.01, 0.02). No statistically significant differences were observed among the subgroups of pregnancies under 9 and 10 weeks of gestation (RD = 0.01; 95% CI -0.00, 0.03 and RD = 0.01; 95% CI 0.00, 0.01, respectively).

Assessing effectiveness based on the method used to confirm successful abortion (Fig. 4), the meta-analysis revealed a slight advantage for standard care when either a blood test alone (RD = 0.02; 95%CI 0.01, 0.02) or informed clinical opinion (RD = 0.01; 95%CI 0.01, 0.02) were used, where for 1000 abortions performed, 20 or 10 cases of successful abortion were found in favour of standard care than in telemedicine, respectively. The certainty of the evidence for this outcome was low and moderate (supplementary Table 1).

In their study, Kohn et al. [50] demonstrated a higher rate of ongoing pregnancy in standard patients compared to telemedicine patients (1.8% vs. 0.5%.; OR = 0.23; 95%CI 0.14, 0.39).

Adverse effects

Mortality

Two cross-sectional studies investigated the mortality associated with MAB provided via telemedicine [50, 52]. Both studies employed a standard dose of 200 mg of mifepristone and 800 µg of misoprostol, with variations in the additional doses of misoprostol. One of the studies did not employ any additional dose [52], whereas the other used up to an additional 800-µg dose [50]. No deaths were reported during the follow-up period.

Surgical intervention

Thirteen studies included surgical intervention as an adverse effect of MAB, with nine reporting the incidence of this event for telemedicine patients only [18, 30, 31, 34, 43, 45–48] and the other four comparing this outcome between telemedicine patients and standard patients [20, 26, 50, 52].

In the studies that focused on telemedicine patients, the average percentage of surgical interventions was

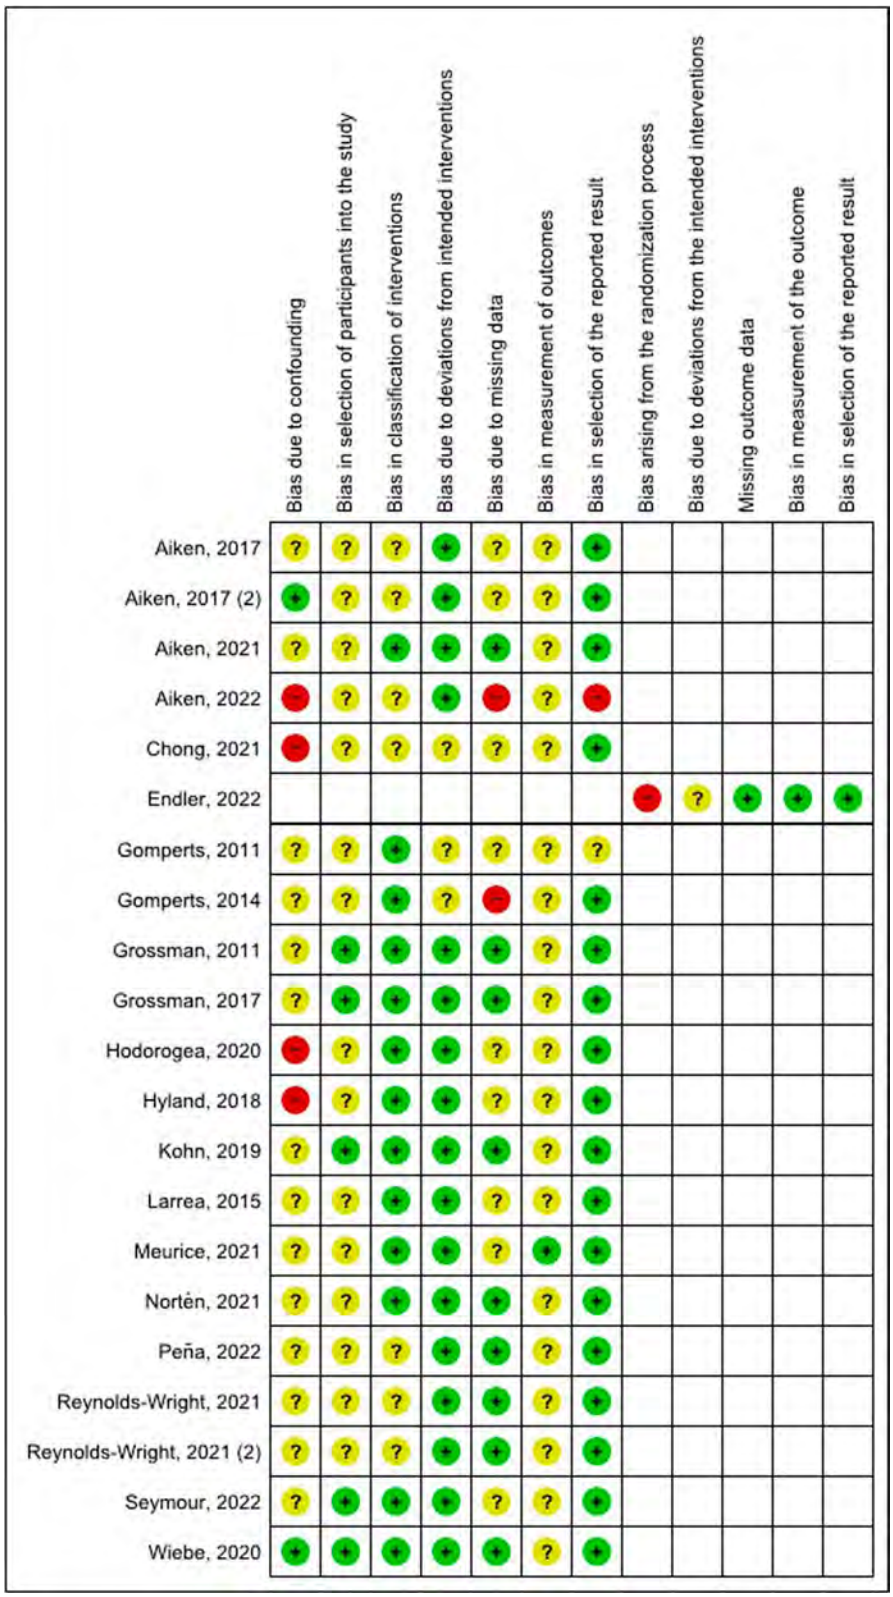

Fig. 2 Bias risk assessment of the included studies

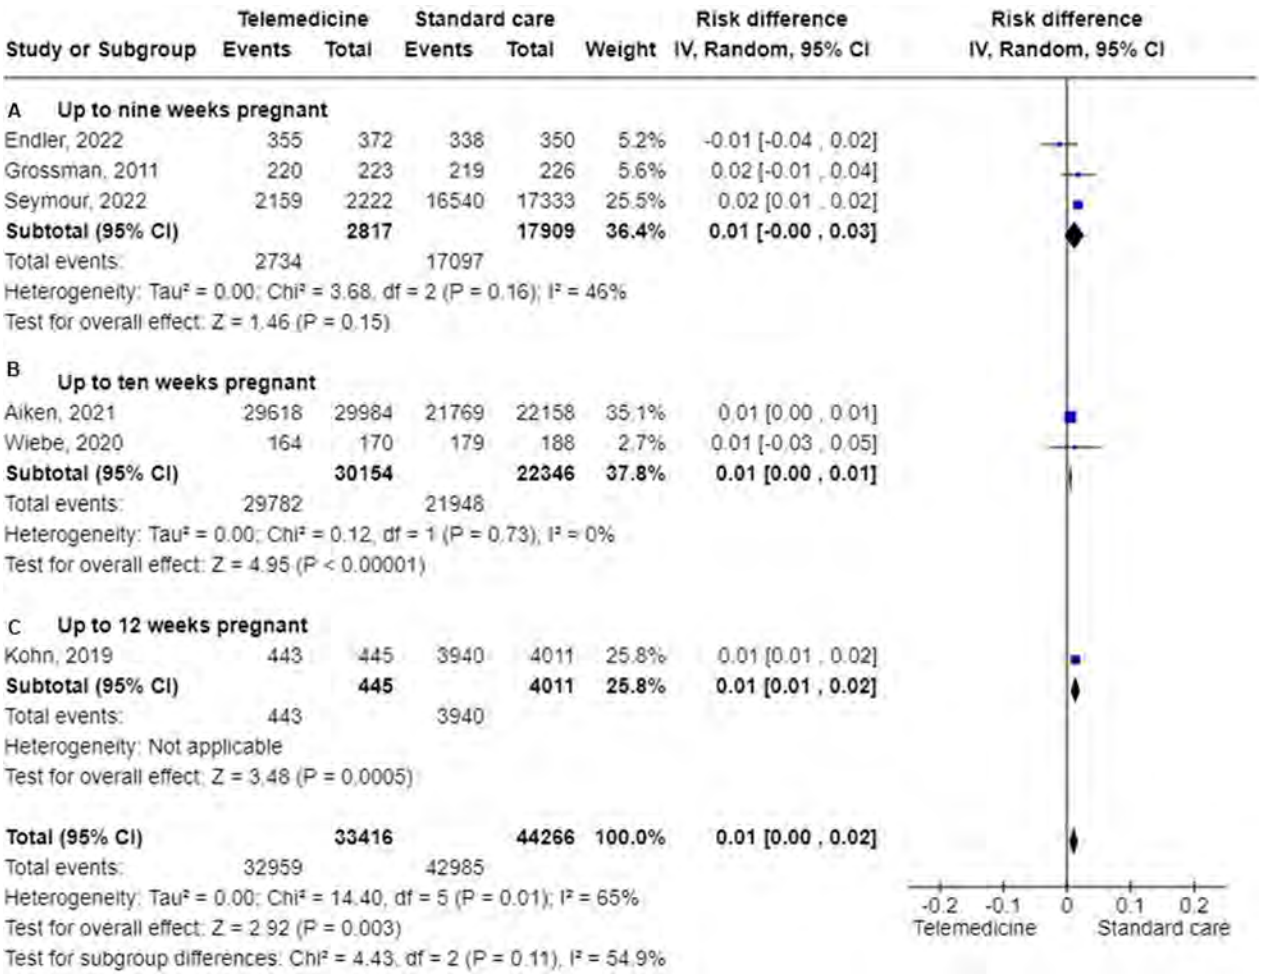

Fig. 3 Effectiveness of medication abortion via telemedicine compared to standard care by gestational week subgroups. **A**. Pregnant people up to 9 weeks pregnant, **B**. Pregnant people up to 10 weeks pregnant, **C** Pregnant people up to 12 weeks pregnant

8.1%. In all these studies, additional doses of misoprostol were administered. Six studies [18, 30, 34, 43, 46, 47] used additional doses of up to 400 μg [20], and the average percentage of surgical interventions was 10.4%. The other 3 studies [31, 45, 48] reported using additional doses of up to 800 μg, and the average percentage of surgical interventions was 3.6%.

In the four studies that compared the percentage of surgical interventions between telemedicine patients and standard patients, the treatment regimens varied in terms of the additional doses of misoprostol. One study did not employ any additional dose [52], another used a 400-μg dose [20], and two studies reported using 800 μg of misoprostol [26, 50]. Regarding gestational weeks, two studies included pregnant people up to nine weeks [20, 26], one up to ten weeks [52], and one up to twelve weeks [50]. The combined effect analysis did not reveal any differences between the two forms of healthcare delivery (RD = 0.00; 95%CI—0.00, 0.00; n = 78, 098; $I^2 = 94\%$) (Fig. 5). In the subgroup meta-analyses (based on gestational weeks), no differences were found in the occurrence of surgical interventions following MAB. The certainty of the evidence was very low (supplementary Table 1).

Blood transfusion

Eight studies examined the occurrence of blood transfusion events following MAB, with four exclusively focusing on telemedicine patients [18, 34, 43, 45] and the other four comparing this outcome among telemedicine patients and standard patients [26, 28, 32, 50]. Considering telemedicine patients alone, the incidence of this adverse effect was found to be approximately 0.5%.

Among the four studies that compared the occurrence of blood transfusion events between telemedicine patients and standard patients, one study used the standard dose of mifepristone and an initial dose of 800 μg of misoprostol without any additional doses

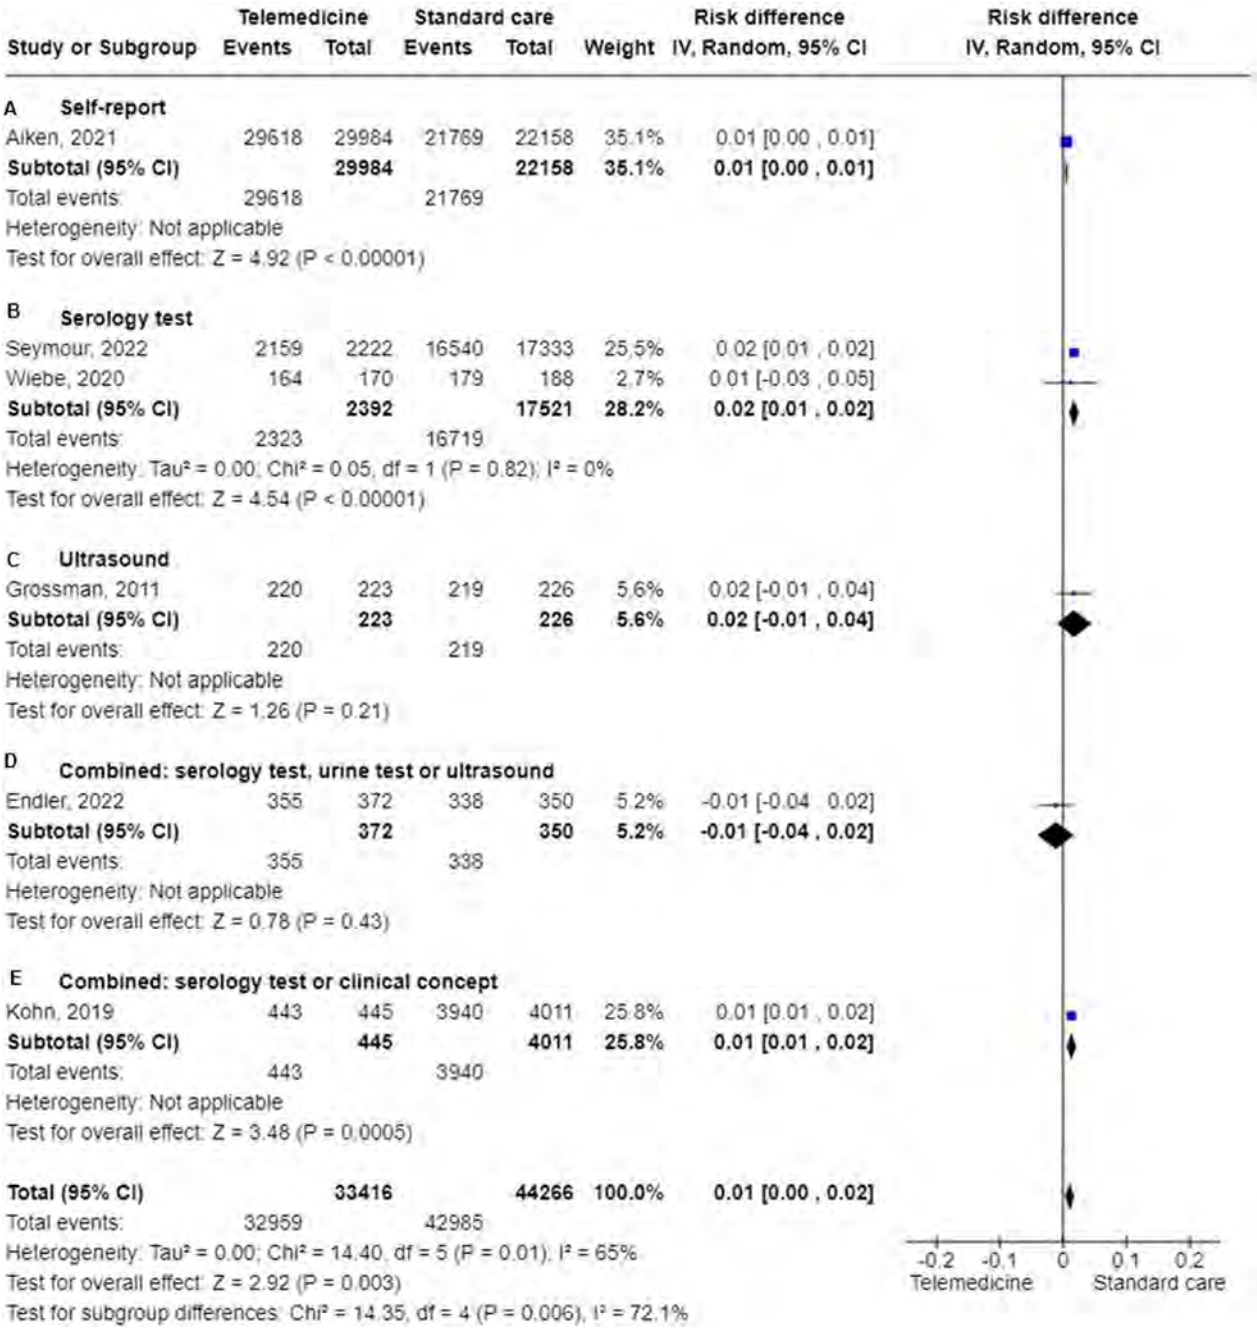

Fig. 4 Effectiveness of medication abortion via telemedicine compared to standard care by method of pregnancy confirmation. **A** Self-report, **B** Serology test, **C** Ultrasound, **D** Combined: serology test, urine test or ultrasound, **E** Combined: serology test or clinical concept

[32], while the other three studies employed an additional dose of 800 µg of misoprostol [26, 28, 50]. Three of the studies included pregnant people up to nine weeks [26, 28, 32], and one up to twelve weeks [50]. The combined effect analysis did not reveal any significant differences between the telemedicine and standard groups (RD = 0.00; 95%CI -0.00, 0.00; n = 26,307; $I^2 = 0\%$). In the subgroup meta-analyses (based on gestational weeks), no differences were found in the need for blood transfusions following MAB. The certainty of the evidence was low (supplementary Table 1).

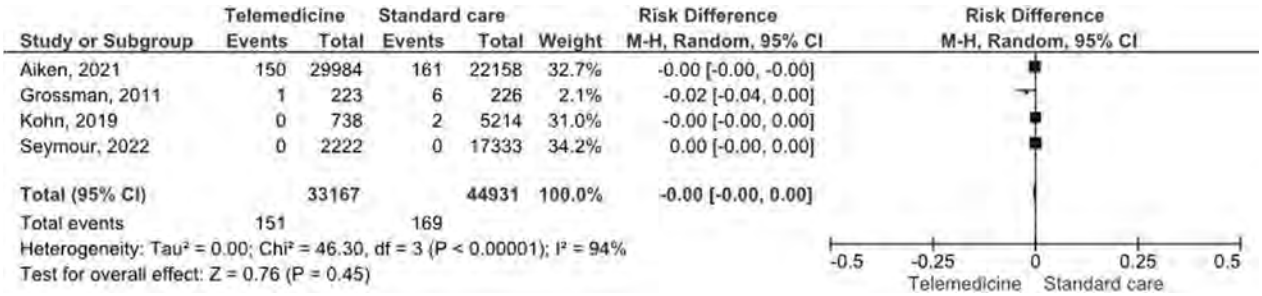

Fig. 5 Surgical intervention after medication abortion via telemedicine compared to standard care

Fig. 6 Hospitalization after medication abortion via telemedicine compared to standard care

Hospitalization

Six studies analyzed hospitalization cases following MAB, with three [31, 45, 49] exclusively focusing on telemedicine patients and the other three [28, 50, 52] comparing this outcome among telemedicine patients and standard patients.

In the three studies that solely considered telemedicine patients, the average occurrence of this event was 1.3%. In the other three comparative studies [28, 50, 52], no statistically significant differences were observed between the telemedicine group, which had an average hospitalization rate of 0.1%, and the standard care group, which had an average hospitalization rate of 0.2% (RD = 0.00, 95%CI -0.00, 0.00; n = 34,677; $I^2 = 58\%$) (Fig. 6). In the subgroup meta-analyses (based on gestational weeks), no differences were found in hospitalization rates following MAB. The certainty of the evidence was low (supplementary Table 1).

Antibiotic treatment

Five studies assessed the need for antibiotic treatment in patients with a clinical suspicion of infection following MAB. Three of such studies focused exclusively on telemedicine patients [30, 34, 43], revealing an average incidence of 4.1% for this outcome. In the other two studies [29, 52], the average incidence of antibiotic treatment in the telemedicine group was 0.4%, while it was 0.05% in the standard group (RD = 0.00; 95%CI -0.00, 0.01; n = 19,913; $I^2 = 0\%$). The certainty of the evidence was moderate (supplementary Table 1).

Emergency department visits

One cross-sectional study [45] examined the frequency of emergency department visits among pregnant people who used MAB services provided through telemedicine and reported a frequency of 7.8%. Another cross-sectional study [28] compared this outcome between telemedicine patients and standard patients. The frequency of emergency department visits in the telemedicine group was 0.1%, while it was 0.2% in the standard group. No significant risk difference was observed between the two groups of interest (n = 20,343; p = 0.3).

Acceptability/Satisfaction

Acceptability

Three observational studies [18, 24, 46] evaluated the acceptability of MAB provided via telemedicine, with an average acceptability rate of 93.2%.

Satisfaction

Three observational studies [45, 48, 51] analyzed user satisfaction with MAB provided via telemedicine, with an average satisfaction rate of 98.3%. One clinical trial [32] and one cross-sectional study [26] compared this outcome between two forms of healthcare delivery. According to their results, the average satisfaction rate among telemedicine users was 99.3%, while it was 98.2% among

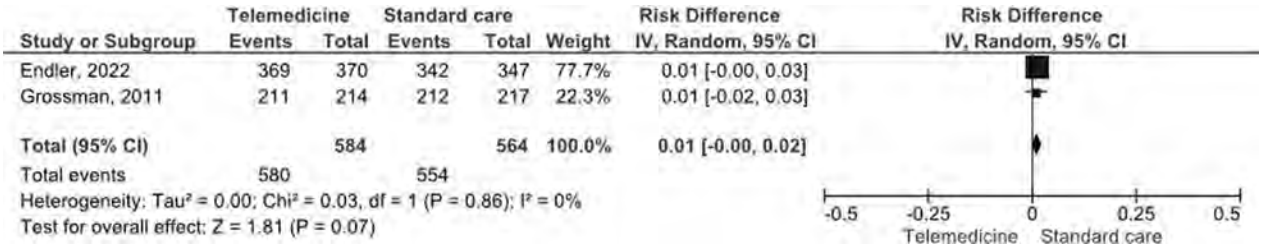

Fig. 7 Service satisfaction with medication abortion via telemedicine compared to standard care

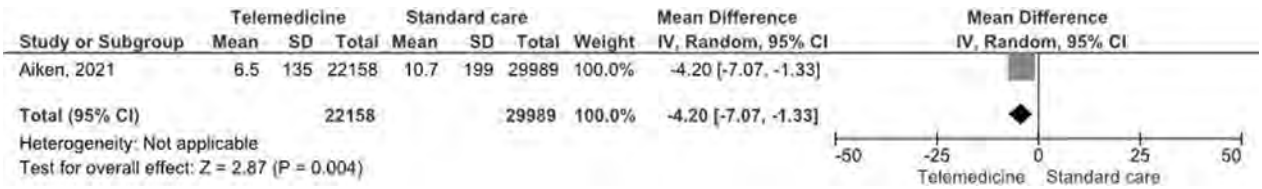

Fig. 8 Waiting time for delivery of medication abortion via telemedicine compared to standard care

standard users (RD = 0.01; 95%CI -0.02, 0.03; n = 1,134; $I^2 = 0\%$) (Fig. 7). The certainty of the evidence was low (supplementary Table 1).

Another noteworthy finding was the preference for telemedicine services. In a clinical trial [32], significant differences were observed in the proportion of pregnant people who preferred remote care, being higher in telemedicine care (97%) than in standard care (46%) (n = 717; $p < 0.001$).

Other outcomes

Successful follow-up

Two observational studies [31, 49] reported that, on average, 92% of patients who used telemedicine services for MAB had successful follow-up, typically occurring 45 days after taking the mifepristone dose.

Additionally, three cross-sectional studies [26, 29, 50] analyzed the follow-up rates after MAB, indicating that 77% and 70% of pregnant people using standard care group and telemedicine respectively, had successful follow-ups. The meta-analysis revealed no significant differences in lost to follow-up (RD = 0.05; 95%CI -0.18, 0.08; $I^2 = 95\%$), although it is evident that remote care exhibited higher rates of lost to follow-up. The certainty of the evidence was low (supplementary Table 1).

Waiting time to treatment

One prospective study [20] reported a reduction of 4.2 days in the waiting time to treatment for MAB via telemedicine when compared to standard care (Median Difference-MD = -4.2; 95%CI -7.07, -1.33; n = 52,147) (Fig. 8). The certainty of the evidence was low (supplementary Table 1).

Adherence to prescribed regimens

One clinical trial [32] evaluated adherence to abortion medication regimens. According to the results, the adherence rate was 94.7% in the telemedicine group and 96.1% in the standard care group, with no significant differences (n = 732; p = 0.89). The evaluation considered proper medication intake in terms of dosage, dose interval, route or manner of administration, and weeks' gestation limits.

Discussion

This SLR included twenty studies published between 2011 and 2022, half of them between 2021 and 2022. Nineteen studies have an observational design. Of these, seven present data collected during the COVID-19 global health crisis. One of the included studies is an RCT conducted between February 2020 and October 2021, which compares telemedicine abortion care with in-person services. Overall, the risk of bias for the cross-sectional studies ranged from low to severe, while the RCT had a high risk of bias. Taken together, this body of literature provides up-to-date evidence on indicators of success, safety, and acceptability in the use of telemedicine to expand the provision of abortion care in the first trimester of pregnancy.

Based on observational studies with no control group, a 91.1% effectiveness was identified. This is similar to what Ngo et al. [54] reported in an SLR published in

2011, which evaluated the same research question and reported an 86–97% effectiveness of home MAB.

The effectiveness found in this SLR increased when care protocols included additional doses of misoprostol to the basic drug regimen (200 mg of mifepristone and 800 µg of misoprostol).

The meta-analysis of studies comparing telemedicine with standard care services indicates that the effectiveness of MAB is not influenced by the type of care provided. The analysis of effectiveness by subgroups, including weeks' gestation and method of confirming treatment success, suggests that there are no significant interactions between the variables, as the estimated risk differences are minimal or negligible. Additionally, the results of the chi-square tests suggest that there is no statistically significant heterogeneity between the subgroups. It is important to note that, in forming the subgroups, the sample size was significantly reduced in some of them, which may affect the statistical power of the tests and, consequently, generate erroneous inferences.

Effectiveness decreases as the gestational limit increases; however, there were no statistically significant differences between telemedicine and in-person services for this variable. The effectiveness of MAB in pregnant people at 10-week gestation or less has been reported, with no differences between modalities of care [55]. In 2002, Ashok et al. [56] supported the effectiveness and safety of MAB between gestational weeks 10 and 13. However, in 2020, Schmidt-Hansen [55] proposed that more research is needed to support MAB in this period.

Effectiveness increased when doses of misoprostol were added to the basic drug regimen (200 mg of mifepristone plus 800 µg of misoprostol). A study on the use of abortion medications [57] identified that the use of 800 µg of misoprostol is more effective than 400 µg of misoprostol. Furthermore, it may increase the success of abortion if administered on the first day rather than on the third day, and there is no difference in its effectiveness if administered at home or in a clinic. In their study, Phupong et al. [58] concluded that the use of 600 µg and 1200 µg of misoprostol are equally effective, although the first dose reduces the occurrence of diarrhea as an adverse event. Another study that compared these two misoprostol regimens found a slightly greater effectiveness with the use of 1200 µg (66% with 600 µg and 70% with 1200 µg) and found no difference in the adverse effects produced [59]. The study recommended 800 µg of misoprostol for pregnant people under 10 weeks of gestation and 1000 to 1200 µg of misoprostol for pregnant people at 10–13 weeks of gestation. Another RCT [60] comparing these two doses of misoprostol found no difference in effectiveness between the two regimens given.

There are three methods that can be used for this: ultrasound, β-hCG levels in serum or urine. The most widely used for telemedicine services is the urine pregnancy test because it is easy to use at home. Studies support the use of this test [61, 62], although it should be considered that due to the detection threshold of β-hCG (< 50 mIU/mL), it may take a few weeks to become negative and thus interpret the result as a continuation of pregnancy, when it was actually a successful abortion. The other two tests (serum β-hCG and ultrasound) have been described as equally effective in measuring the outcome of abortion [63, 64].

Outcome on the need for surgery after MAB was measured both in observational studies without a comparison group and in those that compared the telemedicine care model with in-person services. As with the effectiveness indicator, surgical interventions interact with the additional doses of misoprostol added to the basic drug regimen. In this regard, the studies that added doses of misoprostol had a lower average prevalence of surgical interventions. In the meta-analysis of the comparative studies, no differences were found between the groups in the prevalence of postabortion surgery.

The safety of the telemedicine abortion procedure was documented in most of the included studies, with low rates of adverse events. No maternal deaths were reported. In observational studies without a comparison group, an average of 7.8%, 4.1%, 1.3%, and 0.5% of telemedicine patients attended the emergency department, required antibiotics, were hospitalized, or had a blood transfusion, respectively. However, there were no statistically significant differences in these indicators when comparing in-person services with telemedicine. The SLR by Ngo et al. [54] conducted in 2011 also found a low proportion of complications of MAB, finding that pain and vomiting were slightly longer lasting (0.3 days longer) among pregnant people who performed the procedure at home rather than in a medical facility.

In the meta-analysis, there were no differences in the proportion of pregnant people with follow-up after the abortion procedure, nor in adherence to treatment between the two modalities (telemedicine and in-person care). Nevertheless, the waiting time to receive abortion treatment was shorter among telemedicine patients.

The 2011 study by Grossman et al. went beyond establishing overall patient satisfaction, finding that initiating the abortion procedure as early as possible was a highly important factor [26]. This SLR found a significant difference in the waiting time for treatment initiation in favor of telemedicine. As in the satisfaction analysis, it is not possible to analyze this difference at all stages of the process. This result comes from an RCT conducted in a United States population [32], with a high risk of

bias, which may vary significantly in regions with fewer human, financial, and technological resources. The same study reports that telemedicine is the preferred modality. In fact, nearly half of the pregnant people who used in-person modality preferred telemedicine[32]. This result may be affected by situations of availability or timeliness of telemedicine care, thus showing that there is room for strengthening virtual care services to meet their demand.

In 2022, Endler et al. [32] reported that adherence to the recommended drug regimens in telemedicine and in-person care was 94.7% and 96.1%, respectively, with no statistically significant differences between the two groups. This result may indicate that the information provided by the counseling staff of both health care modalities is sufficient and understandable to the public at large.

The average acceptability of telemedicine from three non-comparative studies was greater than 90%. Systematic reviews [25, 65] as well as observational studies [66] report results in the same trend, but with ranges of 60–100% acceptability [25]. However, several of the studies were developed based on data from organizations that provide abortion care exclusively by remote consultation, such as Women on Web; therefore, it is not known whether users had access to other care alternatives to choose from in terms of convenience or cost. These results contrast with those obtained by Dagousset et al., who reported that 55% of the pregnant people accepted home treatment if the health institution gave them the option of choosing place for treatment [67].

Similar to the results reported by Ngo et al. in their 2011 SLR [54], satisfaction was 88.4% in the telemedicine care group and 85.4% in the in-person care group. Since satisfaction is an indicator of the quality perceived by patients, the values obtained may be explained by the effectiveness and safety of the procedure. It should be noted that both modalities of care include several stages that are not documented in all studies, such as the assessment of the means of communication, appointment scheduling, care provided by health professionals, delivery or acquisition of medication, instructions for the home abortion process, and other related issues, which may be the subject of evaluation in future research.

The results of this study and the contrast with the scientific evidence that supports interventions in sexual and reproductive health provide sufficient evidence to sustain the effectiveness and safety of MAB managed through the provision of in-person or remote health services.

However, there is no consensus on the conditions necessary for the implementation of telemedicine services that can be adapted to each context, including the description of technological, infrastructure, cultural, and social needs for the widespread use of this abortion modality. This method also requires proposing solutions when Internet connection difficulties arise, in addition to promoting training on information and communication technologies and the provision of equipment that adequately supports the service.

This SLR does not address the analysis of the potential impact of intermediate determinants such as educational level or social representations of abortion of those who access it and those who perform it and promote it as a sexual and reproductive health right, and how these elements may affect the outcomes assessed. This is illustrated in the study by Ennis et al. (2023), which concludes that existing stigma toward health workers who provide abortion services impacts service delivery in terms of quality and frequency [68]. Regarding the experience of individuals accessing abortion services, social support is a determining factor in the mental health of patients, as noted in the study by Hendrix et al. [69].

Patient safety is a major concern when providing telemedicine care. Health care providers must ensure that patients meet the established eligibility criteria for MAB and that they receive the necessary information to make informed decisions. In this regard, there is extensive literature showing the ability of pregnant people to establish their weeks' gestation from the date of last menstrual period [70–73]. Moreover, it is crucial to establish clear protocols for emergency care and appropriate referral in case of complications and adverse events.

Conclusions

Providing data of MAB provided through telemedicine is crucial for decision-makers to justify its implementation and widespread adoption. The published data support that MAB in the first-trimester abortion with telemedicine is an effective and safe alternative, similar to standard care. There were no differences between the care modalities in terms of other outcomes like user satisfaction, follow-up, and adherence; however, the telemedicine modality had a shorter waiting time for medication delivery.

Received 24 May 2011; revised 21 December 2011; accepted 21 December 2011

Abstract

Background: An 800-mcg dose of buccal misoprostol following mifepristone has been shown to be highly effective in terminating pregnancies through 63 days since the last menstrual period (LMP) (B. Winikoff, I.G. Dzuba, M.D. Creinin, et al., Two distinct oral routes of misoprostol in mifepristone medical abortion: a randomized controlled trial. *Obstet Gynecol* 2008; 112: 1303–1310). However, a two 200-mcg misoprostol pill option would simplify administration, and potentially reduce costs and increase women's satisfaction. This study compares a 400-mcg dose (Group I) to an 800-mcg dose (Group II) of buccal misoprostol.
Study Design: Eligible and consenting women requesting medical termination of early pregnancy (n=1122) were randomized and instructed to take misoprostol 36 to 48 h after taking 200 mg mifepristone. Follow-up visits occurred 12 to 15 days after mifepristone administration.
Results: Ninety-six percent of women in both groups had successful abortions. Women in Group I experienced significantly less vomiting and fever/chills than women in Group II. Ninety-six percent of women in both groups found the procedure very satisfactory or satisfactory.
Conclusions: Four hundred micrograms of buccal misoprostol is as effective as the standard 800-mcg dose in terminating pregnancies up to 63 days LMP and reduces side effects.

1. Introduction

Since the introduction of mifepristone+misoprostol medical abortion, much research has been conducted to improve the regimen to make it more accessible and acceptable to both women and providers. One area of research has focused on finding doses and routes of misoprostol administration that are effective through 63 days since the last menstrual period (LMP). An 800-mcg dose of vaginal misoprostol following mifepristone is highly effective through 63 days LMP and is recommended by the World Health Organization [1]; however, some women express discomfort with this route and prefer in-the-mouth routes of administration [2,3]. Misoprostol taken orally (swallowed) after mifepristone offers the easiest administration, but the efficacies of an oral regimen using a 400-mcg dose [4,5] or an 800-mcg dose [5–7] both decline with increasing gestational age to as low as 77% and 85%, respectively, in the ninth week after LMP.

Research has also looked at sublingual and buccal administration of misoprostol, in which the pills are held under the tongue or between the cheek and the gum until they dissolve. Initial studies with 800-mcg and 600-mcg doses of sublingual misoprostol after mifepristone found the regimens to be highly efficacious but also resulted in substantial levels of fever, chills, vomiting and diarrhea [8,9]. Subsequent studies suggest that the dose of misoprostol can be reduced to 400 mcg to minimize side effects, but still maintain a high success rate in the later gestational ages [10,11].

Clinical trials have shown an 800-mcg dose of buccal misoprostol after mifepristone to be highly effective through 56 and 63 days LMP [6,12]. A randomized controlled trial comparing 800 mcg oral to 800 mcg buccal misoprostol

doi:10.1016/j.contraception.2011.12.012

found that, in the ninth week LMP, the buccal regimen had a significantly higher success rate than the oral regimen (94.8% vs. 85.1%) and a significantly lower ongoing pregnancy rate (1.7% vs. 7.9%) [6]. Additionally, Planned Parenthood centers in the United States reported a 98% success rate with the buccal regimen in a 2006 audit in terminating pregnancies up to 59 days LMP [13].

Very little is known about the efficacy of a 400-mcg dose of buccal misoprostol after mifepristone; however, one study has been published that compared 400 mcg buccal misoprostol to 400 mcg sublingual misoprostol after mifepristone [14]. This study found comparable success rates between the two regimens (97.1% and 97.4%, respectively). Efficacy remained high at later gestational ages (100% and 94.6% among pregnancies 50–63 days LMP), although the sample size was small (38 and 37 women 50–63 days LMP). We were interested to see if, like misoprostol administered via the sublingual route, a reduced dose of buccal misoprostol after mifepristone would still be highly effective, yet reduce the side effects women experience. A two 200-mcg misoprostol pill option would simplify administration, substantially reduce the costs associated with the method in some settings and potentially increase women's satisfaction.

2. Materials and methods

The study was conducted from May 2007 to September 2009 at three clinics in Tbilisi, the Republic of Georgia [Zhordania Institute of Human Reproduction (ZIHR), Maternity House #2 and Maternity House #4), and at Hoc Mon Hospital, about 10 km outside Ho Chi Minh City, Vietnam. Two sites (ZIHR and Hoc Mon Hospital) had experience providing medical abortion prior to this study, while the other two sites were trained in medical abortion provision at the same time they were trained in the study procedures.

Women who presented for termination of pregnancy with gestations up to 63 days since LMP were recruited to participate in the study. Exclusion criteria included concurrent anticoagulant therapy, concurrent long-term corticosteroid therapy, adrenal insufficiency, inherited porphyria, suspicion of ectopic pregnancy, and known allergy to mifepristone or misoprostol. Gestational age was determined by ultrasound in 98% of cases; LMP and clinical examination were also used. Ethical committees at the ZIHR and Hoc Mon Hospital reviewed and approved the study protocol. All women gave their informed consent to participate in the study.

Women swallowed one 200-mg pill of mifepristone [in Georgia: Mirpharma or Pentcroft Pharma (Russia); in Vietnam: STADA (Vietnam)] at the clinic and were given the option of taking the misoprostol at the clinic or at home 36 to 48 h after taking mifepristone. After eligibility was confirmed, allocation to the 400-mcg or 800-mcg group was determined based on a random code generated in blocks of 10 by Gynuity Health Projects in New York, whose staff packed the pills and organized them in sequential, sealed envelopes. Randomization was stratified by study site. This study was double-blinded; women in the 400-mcg group received two 200-mcg misoprostol (U-miso; U-Liang Ltd, Taiwan) pills and two placebo pills, and women in the 800-mcg group received four 200-mcg misoprostol pills. The group

** $p \leq .001$.

assignments were maintained at the Gynuity office in New York and were not disclosed to the participants or the providers.

For those women who elected to take misoprostol at the clinic, providers stapled assigned envelopes to the women's study forms at the initial visit, and those pills were taken at the next (misoprostol) visit. Women were instructed to place the pills between the cheek and gums and to hold them there for 30 min, after which they should swallow any remaining fragments. In Georgia, women were given a prescription for paracetamol (500 mg) and advised to take it as needed; in Vietnam, all women were given four tablets of paracetamol (500 mg) and similarly advised. Women were asked to fill out patient diaries documenting the level of bleeding and any side effects that occurred in the 14 days following mifepristone administration. If women forgot to bring the diary with them to the follow-up visit, they were asked to complete at new diary at that time.

Follow-up visits were scheduled 12 to 15 days after the initial visit to determine abortion status. If the abortion was determined to be complete, women underwent an exit interview and were discharged from the study. Women with ongoing, viable pregnancies were offered a surgical completion. Women with incomplete abortions were offered the option of a surgical completion or waiting another week, with or without an additional dose of 800 mcg buccal misoprostol. If the abortion was still incomplete after the additional week, a surgical completion was recommended. Women could request a surgical completion at any time during the study.

Table 2
Treatment outcomes by study group and gestational age

	400 mcg	800 mcg	RR (95% CI)
Success (total)	96.4 (535/555)	96.4 (540/560)	1.00 (.98–1.02)
42 days or less	98.8 (164/166)	95.8 (159/166)	1.03 (.99–1.07)
43–49 days	97.2 (106/109)	96.2 (100/104)	1.01 (.96–1.06)
50–56 days	94.3* (182/193)	98.5* (201/204)	.96 (.92–.99)
57–63 days	95.4 (83/87)	93.0 (80/86)	1.03 (.95–1.10)

* $p<.05$, comparing 400-mcg and 800-mcg groups.

The study had two primary objectives: (1) to compare the efficacy of the two regimens, especially among women with gestations >49 days LMP, and (2) to compare the incidence of side effects of each regimen. We assumed that the 800-mcg buccal misoprostol regimen would be 95% effective, and therefore, 334 women per group were needed to detect a 5% lower efficacy with 400 mcg misoprostol (α=0.05, $1-\beta$=0.8, with a one-tailed test). An additional 10% was added to account for loss to follow-up, for a total sample size of 735. Initially, study enrollment occurred only at the three sites in the Republic of Georgia. An interim analysis of 383 women enrolled found too few women with gestational age >50 days LMP were being enrolled to permit comparison of efficacy at higher gestational ages once enrollment was complete.

Based on the interim analysis, we assumed that efficacy in the 800-mcg group would be 93% for gestational ages 50–63 days LMP, requiring a sample of 303 women in each study arm to detect a 6% lower efficacy with 400 mcg (α=0.05, $1-\beta$=0.8). Adding 5% to account for loss to follow-up, we sought a final sample of 640 women in this gestational age range. In Vietnam, enrollment was limited to women presenting at 50–63 days LMP. We stopped the study when 1115 women had been enrolled and followed up, including 570 women in the 50–63-day gestational age group, when efficacy in both groups substantially exceeded that hypothesized based on interim review.

Table 3
Reasons for failure by study group and gestational age

	400 mcg	800 mcg	RR (95% CI)

[a] Treatment group was force entered into the model as the initial term; all other variables were entered with PIN=0.05, POUT=0.10.
[b] Compared with ≤42 days.
[c] Compared with primary school.

Data were entered in Georgia and Vietnam, merged in New York and analyzed using SPSS 14.0 (SPSS Inc., Chicago, IL, USA) and EpiInfo™ Version 3.4.3 (Centers for Disease Control, Atlanta, GA, USA). The χ^2 with Fisher's Exact Test was used as appropriate for independent nominal data, and independent *t* tests were used for continuous variables. Statistical significance was defined as a p value of <.05. Hierarchical logistic regression analyses were conducted to adjust for possible confounders and the effects of including women solely with later gestation abortions in Vietnam, with forced entry of the term for treatment group and using both forced entry and, separately, the backwards stepwise Wald method with probability of score statistic for variable entry (PIN)=0.05 and probability of the Wald statistic to remove a variable (POUT)=0.10 for all covariates (age, gestational age, country, completion of high school, completion of university, marital status, parity, and number of previous abortions). Success was defined as a complete abortion using mifepristone and misoprostol without any surgical intervention. In the few cases where the woman did not return for follow-up, telephone follow-up was deemed acceptable to determine the abortion outcome. Per-protocol analysis was used since there was only one woman who did not follow the protocol (she took mifepristone but not misoprostol). The analyses excluded six women who were lost to follow-up and one woman who did not take misoprostol (Fig. 1). Data on adverse effects were stratified by country to illustrate cultural differences in experiencing and reporting of these symptoms.

3. Results

One thousand one hundred twenty-two women were enrolled in the study, of which 559 were randomized to the 400-mcg buccal group of misoprostol and 563 to the 800-mcg buccal group. Three women did not return to the clinic for follow-up but confirmed by phone that they received surgery elsewhere (Fig. 1). There were no statistically significant differences between the two study arms with respect to mean age, education, marital status, gravidity and parity, abortion history and gestational age (Table 1). In general, participants in this suburban area of Vietnam

** p<.01, comparing 400-mcg and 800-mcg groups.

tended to be less educated, less likely to have had a previous abortion and more likely to be married than women in Georgia.

Ninety-five percent of Georgian participants decided to take the misoprostol at home, whereas only two women in Vietnam availed themselves of this option. Ultrasound use at the follow-up visit varied widely by site, ranging from 37% at Maternity House #4 to 90% at Hoc Mon Hospital. Eighty-four women had incomplete abortions at follow-up, and 83 decided to wait an additional week (47 taking an additional dose of misoprostol/oxytocin and 36 opting for expectant management). Ninety-two percent of women who took additional misoprostol and 78% of women using expectant management had complete abortions at the extended follow-up visit [relative risk (RR)=1.18, 95% confidence interval (CI) 0.97–1.43].

Overall, the efficacy of the two regimens was identical, with 96.4% of women having a successful abortion in each arm (Table 2). The two regimens maintained a high success rate at the later gestational ages as well, with 95.4% of the 400-mcg group and 93.0% of the 800-mcg group successfully aborting in the ninth week of gestation.

The ongoing pregnancy rate was slightly, but not significantly, higher in the 400-mcg study arm than the 800-mcg study arm (1.4% vs. 0.9%, RR 1.61, 95% CI .53–4.9) (Table 3). However, the ongoing pregnancy rate was the same in both arms in the ninth week of gestation (2.3%). No significant differences were seen in the rates of incomplete abortion, heavy or prolonged bleeding, or provider preference/patient request. Adjustment for covariates including country did not influence the difference in rates of success [fully adjusted model odds ratio (OR)=1.03, 95% CI 0.55–1.94; unadjusted model OR=1.01, 95% CI 0.54–1.90] (Table 4).

Since side effects are experienced and reported differently in different cultures, Georgia and Vietnam data are reported separately as well as in aggregate (Table 5). In general, Georgian women tended to report side effects at a higher rate than Vietnamese women. In Georgia, women in the 800-mcg group were significantly more likely than women in the 400-mcg group to report experiencing nausea (48% vs. 42%, RR=.88, 95% CI 0.75–1.02), vomiting (22% vs. 16%, RR=.72, 95% CI 0.54–0.95) and fever/chills (41% vs. 31%, RR=.75, 95% CI 0.63–0.91). In Vietnam, the only significant difference in the side effects reported actually occurred in the opposite direction, with 33% of women in the 400-mcg group and 22% of women in the 800-mcg group reporting dizziness (RR=1.49, 95% CI 0.97–2.31). No serious adverse events occurred.

Nearly all women reported feeling very satisfied or satisfied with their abortions, regardless of study group allocation (Table 6). Women in the 800-mcg group were slightly less likely than women in the 400-mcg group to say that buccal administration of misoprostol was very acceptable or acceptable (88% vs. 92%, RR=1.05, 95% CI 1.01–1.09). Ninety-six percent of women in both groups would choose to have a medical abortion in the future should the need arise, and 98% would recommend the method to a friend.

4. Discussion

This study demonstrates that both 400-mcg and 800-mcg doses of buccal misoprostol after 200 mg mifepristone are highly effective at terminating pregnancy through 63 days LMP. Our results on the performance of the 800-mcg buccal regimen are consistent with the only previous study in the literature that looked at buccal misoprostol through 63 days LMP with an interval of at least 24 h between mifepristone and misoprostol [6]. The high success rate of the 400-mcg buccal regimen, even at later gestational ages, corroborates a study conducted in Moldova by Raghavan et al. [14] that found a 97% success rate overall, with no decline in efficacy at gestations 50 to 63 days LMP.

Halving the dose of misoprostol resulted in significantly fewer reports of vomiting and fever or chills in the Georgia sites, but not in the Vietnam site. Women in Georgia reported fewer side effects with the 400-mcg misoprostol regimen and found buccal administration of misoprostol to

Table 6
Women's satisfaction with the procedure

	400 mcg (*n*=551)	800 mcg (*n*=555)	RR (95% CI)
Satisfied with procedure	95.6 (527)	96.2 (534)	.99 (.97–1.02)
Buccal administration acceptable*	92.0 (507)	87.9 (488)	1.05 (1.01–1.09)
Side effects acceptable	86.0 (474)	84.7 (470)	1.02 (.97–1.07)
Pain medication adequate			
Yes[a]	72.1 (397)	76.2 (423)	.99 (.95–1.03)
No	6.4 (35)	5.9 (33)	1.12 (.71–1.77)
Did not take pain medication	21.6 (119)	17.8 (99)	1.21 (.95–1.54)
If in need of another abortion, would choose:

Medical	96.2 (530)	96.2 (534)	1.00 (.98–1.02)
No preference	2.4 (13)	2.3 (13)	1.01 (.47–2.15)
Would recommend method to friend	98.4 (542)	97.8 (543)	1.01 (.99–1.02)

[a] Excluded 'did not take medication' to compare treatments.

* p<.05, comparing 400-mcg and 800-mcg groups.

be slightly more acceptable than women in the 800-mcg arm, despite the fact that both groups were instructed to hold four pills in their cheeks.

This study has very few limitations. As the study was double-blinded, the effects of provider bias should be minimal. Abortion outcomes were confirmed for nearly all participants, as less than 1% of women were lost to follow-up. However, we are limited in the trend analyses we can conduct on success rates by gestational age due to the uneven distribution of patients in the two countries. Also, because the study was powered to detect differences in efficacy between the two arms at later gestational ages, it was perhaps overpowered to detect differences in other outcomes, such as side effects. Thus, a six-percentage point difference in reporting of nausea in Georgia is statistically significant, but perhaps less important in clinical terms.

The findings of our research indicate that a regimen of 400 mcg buccal misoprostol after mifepristone is as safe and effective as a regimen of 800 mcg buccal misoprostol and results in fewer side effects. While 800 mcg vaginal misoprostol and 800 mcg buccal misoprostol remain excellent options for abortion through 63 days LMP, 400 mcg buccal misoprostol is highly efficacious as well. Clinicians interested in a two-pill in-the-mouth misoprostol regimen for ease of administration, decreased cost and increased acceptability may consider this method.

ABSTRACT

Objective: To present updated evidence on the safety, efficacy and acceptability of a direct-to-patient telemedicine abortion service and describe how the service functioned during the COVID-19 pandemic.
Study Design: We offered the study at 10 sites that provided the service in 13 states and Washington DC. Interested individuals obtained any needed preabortion tests locally and had a videoconference with a study clinician. Sites sent study packages containing mifepristone and misoprostol by mail and had remote follow-up consultations within one month by telephone (or by online survey, if the participant could not be reached) to evaluate abortion completeness. The analysis was descriptive.
Results: We mailed 1390 packages between May 2016 and September 2020. Of the 83% (1157/1390) of abortions for which we obtained outcome information, 95% (1103/1157) were completed without a procedure. Participants made 70 unplanned visits to emergency rooms or urgent care centers for reasons related to the abortion (6%), and 10 serious adverse events occurred, including 5 transfusions (0.4%). Enrollment increased substantially with the onset of COVID-19. Although a screening ultrasound was required, sites determined in 52% (346/669) of abortions that occurred during COVID that those participants should not get the test to protect their health. Use of urine pregnancy test to confirm abortion completion increased from 67% (144/214) in the 6 months prior to COVID to 90% (602/669) in the 6 months during COVID. Nearly all satisfaction questionnaires (99%, 1013/1022) recorded that participants were satisfied with the service.
Conclusions: This direct-to-patient telemedicine service was safe, effective, and acceptable, and supports the claim that there is no medical reason for mifepristone to be dispensed in clinics as required by the Food and Drug Administration. In some cases, participants did not need to visit any facilities to obtain the service, which was critical to protecting patient safety during the COVID-19 pandemic.
Implications: Medical abortion using telemedicine and mail is effective and can be safely provided without a pretreatment ultrasound. This method of service delivery has the potential to greatly improve access to abortion care in the United States.

Introduction

Telemedicine abortion is a broad term that describes the use of telecommunications (phone, videoconference, texting, email) to provide one or more aspects of abortion care such as counseling, eligibility assessment, medication provision, guidance through the process, and follow-up assessment. These services may be provided as part of or independent from the formal healthcare system and may involve some degree of in-person contact for parts of the process.

A substantial body of literature from around the globe provides evidence that telemedicine models of abortion provision are highly acceptable to clients and providers, and success rates and safety outcomes are similar to those reported for in-person care [1–6]. Furthermore, a growing amount of data from the United States suggests that telemedicine allows people to obtain abortions at an earlier gestational age, improves access to care for rural patients, and may be associated with decreases in time to schedule an appointment and distance traveled [7,8].

Having the option to receive abortion care via telemedicine is critical, as accessing in-person care has become increasingly challenging in certain regions of the country. In 2017, 95% and 94% of counties in the Midwest and the South, respectively, did not have a facility that provided abortion care [9]. Individuals who can get to a clinic find an increasingly hostile environment outside; the National Abortion Federation's 2019 annual report on violence and disruption statistics documented 3387 incidents of obstructing facilities (up from 3038 in 2018), and 123,228 incidents of picketing (up from 99,409 in 2018) [10].

The COVID-19 pandemic has exacerbated barriers to accessing abortion care by hindering people's ability to pay for the service (due to loss of income) and limiting mobility because of childcare needs, stay-at-home orders, and the imperative to limit in-person interactions [11,12]. To mitigate some of these effects, many abortion providers have modified their clinical protocols and incorporated telemedicine to varying degrees [13]. Experts have advocated for adoption of "no-test medication abortion," which, by not mandating screening ultrasound, blood tests, or follow-up tests unless clinically warranted, would allow the treatment to be provided without an in-person encounter [14].

The TelAbortion Project is a direct-to-patient service model whereby participating clinics counsel and screen patients remotely, and then send mifepristone and misoprostol by mail to those who are eligible. Because of restrictions on mifepristone imposed by the Food and Drug Administration (FDA) under the drug's Risk Evaluation and Mitigation Strategy (REMS), we implemented TelAbortion as a research study conducted under an Investigational New Drug (IND) application. Specifically, the REMS for mifepristone states that the drug must be dispensed to patients only in clinics, medical offices, and hospitals, which is commonly interpreted as prohibiting the mailing of the medication. Results from the first 32 months of the project (May 2016–December 2018) in which 248 packages were sent found that the service was safe, effective, efficient and satisfactory [6]. The objective of this analysis is to present data on safety, efficacy and acceptability collected from May 2016 through September 2020 (inclusive of the previously published data), during which time the study expanded dramatically both geographically and in sample size, and describe how the service functioned amidst the numerous challenges imposed by the COVID-19 pandemic.

Methods

In the reporting period, the study was implemented at 10 institutions (4 independent clinics, 4 Planned Parenthood affiliates, and 2 academic medical centers) that provided the TelAbortion service in 13 states (CO, GA, HI, IA, IL, MD, ME, MN, MT, NM, NY, OR, WA) and Washington, DC. Five sites provided the service in states where they were not physically located because their clinicians were licensed there. One site stopped recruitment in 2017 due to slow enrollment. Sites were added on a rolling basis, with the newest site beginning enrollment in May 2020. Before adding each state to our study, we confirmed that it had no laws that prohibited the service, although some state laws constrained or complicated the way the service was offered.

Patients interested in receiving a TelAbortion underwent a prescreening process by phone that reviewed basic eligibility requirements and explained the study procedures. Those who wished to proceed obtained any necessary tests at laboratories or radiology offices and had evaluations with a study clinician via videoconference during which the clinician confirmed eligibility, obtained consent electronically, and agreed on a plan for evaluating abortion outcome using ultrasound, serum hCG tests, or urine pregnancy test (UPT). Individuals were required to obtain a pre-abortion ultrasound or pelvic exam, and were deemed eligible for TelAbortion if the study clinician determined that the patient would be able to receive and take the mifepristone at $\leq$70 days of gestation and had no suspicion that the pregnancy was ectopic or nonviable (See the prior paper for a full description of procedures and eligibility requirements [6].).

Sites sent participants packages containing one tablet of mifepristone 200 mg and eight tablets of misoprostol 200 mcg (one site prescribed the misoprostol instead), an instruction sheet, and a UPT if indicated. Sites advised participants to take mifepristone followed by misoprostol 800 mcg within 48 hours either vaginally or buccally, as per standard clinic practice, and to take the other 800 mcg of misoprostol if no bleeding occurred within 24 hours after the first dose. In the event of any problems, sites instructed participants to call, recommended they seek in-person care if indicated, and followed up with them until the resolution of the problem. Following standard practice at the site, study clinicians evaluated abortion outcome using patient history, ultrasound, serum HCG tests before and after mifepristone ingestion, pelvic examination, and/or urine pregnancy testing. At sites that offered more than one method, the participant and clinician agreed on which method to use. Within a month after mailing each study package, sites conducted follow-up contacts to review any test results, assess abortion outcome, and inquire about any adverse events or unplanned visits. Once the abortion was complete, sites conducted a short, structured satisfaction questionnaire by telephone.

The study team made some modifications to study procedures over time. For the first 127 participants, the study paid for care and medications provided directly by sites. We offered participant compensation of $50 until late 2018, when we stopped to better mirror standard provision of abortion care and obtain more accurate data on acceptability and satisfaction (245 participants in our sample were offered compensation). Other changes included a switch from paper data forms to a secure browser-based electronic data capture application in early 2019. If a participant was

Table 1
Characteristics of TelAbortion study participants who were sent a medical abortion package: n (%) or median (range)[a]

	N = 1356
Age	
15–24 years	346 (25.5)
25–34 years	735 (54.2)
35–47 years	275 (20.3)
Highest level of education completed	
Less than HS	65/1305 (5.0)
HS/GED	357/1305 (27.4)
More than HS	883/1305 (67.7)
Number of previous pregnancies	
0	344 (25.4)
1	291 (21.5)
≥ 2	721 (53.2)
Number of previous medical abortions	
0	1086/1348 (80.6)
1	210/1348 (15.6)
≥2	52/1348 (3.9)
Gestational age at prescreen[b]	
18–35 days	280 (20.6)
36–63 days	1053 (77.7)
64–68 days	23 (1.7)
Median (range)	42 (18-68)
Distance of residence from provider (Continental US)[c]	
1–9.9 mi	80/1075 (7.4)
10–49.9 mi	347/1075 (32.3)
50–99.9 mi	169/1075 (15.7)
100–149.9 mi	92/1075 (8.6)
≥ 150 mi	387/1075 (36.0)
Hawaiian island of residence	
Oahu	55/281 (19.6)
Other island	226/281 (80.4)
Race/ethnicity (more than 1 category allowed)[c]	
White	750/1073 (69.9)
Black	163/1073 (15.2)
Hispanic	87/1073 (8.1)
Asian/Pacific Islander	93/1073 (8.7)
Native American	42/1073 (3.9)
Multi-racial, not specified	8/1073 (0.7)
Classification of participant's current address[c]	
Urban	826/1031 (80.1)
Rural	205/1031 (19.9)
Payment method for care provided by site (more than 1 method allowed)[d]	
Private/public insurance	470/1228 (38.3)
Self-pay	899/1228 (73.2)
Abortion fund	175/1228 (14.3)
Actual/planned payment method for pre-abortion tests obtained elsewhere (more than 1 method allowed)[d]	
Private/public insurance	606/919 (65.9)
Self-pay	332/919 (36.1)
Abortion fund	26/919 (2.8)
None; did not have any preabortion tests	327

[a] Does not include 32 second abortions and 2 third abortions during the study period. For participants with multiple abortions, we included only the first.
[b] Using clinician's estimate of gestational age at time package sent and then backdated.
[c] Question not asked in first version of study forms.
[d] Does not include 127 participants who had study site services paid for by study.

Table 2
Abortion outcomes[a] and unplanned encounters, n (%)

	N = 1390
Neither medication taken, or medications taken after miscarriage diagnosis	47 (3.4)
Lost to follow-up	186 (13.4)
Known abortion outcome	1157 (83.2)
Abortion outcome at last contact	n = 1157
Complete abortion without surgical intervention	1103 (95.3)
Surgical intervention	47 (4.1)
Reason: ongoing pregnancy	14 (1.2)
Ongoing pregnancy; carrying to term or unknown[b]	7 (0.6)
Method used in outcome assessment among complete abortions with no surgical intervention	n = 1103
Facility-based test (ultrasound, serum HCG, and/or pelvic exam)[c]	396 (35.9)
No facility-based test	707 (64.1)
Urine pregnancy test (UPT)[d]	647 (58.7)
Patient history only	60 (5.4)
Abortion-related unplanned encounters[e]	n=1173
Emergency room (ER)/urgent care	70 (6.0)
Other outpatient visit	92 (7.8)
Serious Adverse Events	10 (0.9)
Hospitalization	8 (0.7)
Transfusion[f]	5 (0.4)

[a] Includes multiple abortions by same individual.
[b] Includes one abortion where participant threw up mifepristone after 10 minutes and then decided to continue pregnancy.
[c] Outcomes assessed with facility-based tests may also have utilized UPTs and/or patient history.
[d] In 3 cases, the UPT result(s) were positive and the diagnosis of complete abortion was made by patient history only.
[e] Denominator includes abortions with known outcome or any unplanned encounters that occurred after study consent was signed. Does not include encounters for lab tests, anti-D immunoglobulin, or contraception alone. Includes 1 hospitalization, 4 ER visits, and 12 other outpatient encounters that occurred prior to taking (or deciding not to take) mifepristone. Abortions may be included in more than one category.
[f] Two of the transfusions occurred in an ER and are not included in Hospitalization.

Table 3
Acceptability of TelAbortion to study participants at exit interview, among those with known abortion outcome: n (%)[a]

Satisfaction with the service	n = 1022
Very satisfactory	869 (85.0)
Satisfactory	144 (14.1)
Unsatisfactory/Very unsatisfactory	9 (0.9)
Satisfaction with speaking to provider remotely	n = 891
Very satisfactory	763 (85.6)
Satisfactory	123 (13.8)
Unsatisfactory/Very unsatisfactory	5 (0.6)
Experience getting pre-abortion tests[b]	n = 693
Easy or very easy	594 (85.7)
Difficult or very difficult	99 (14.3)
Future preference	n = 886
TelAbortion	754 (85.1)
In-person abortion	56 (6.3)
No preference	76 (8.6)
Would recommend TelAbortion to a friend	n = 892
Yes	863 (96.7)
No	9 (1.0)
Maybe	20 (2.2)

[a] Includes multiple abortions by same individual.
[b] Does not include abortions where no pre-abortion tests were planned.

lost to follow-up and outcome and/or satisfaction data had not been collected, the sites sent via email a link to an online survey for the participant to complete. As new practice guidelines became available, sites could make corresponding changes in care for their TelAbortion patients (as permitted within the constraints of the study protocol); these included forgoing Rh typing or prophylaxis with anti-D immunoglobulin for participants under a certain gestational age and advising participants to take a second dose of misoprostol routinely in the 9th and/or 10th week of gestation [15].

Here we present descriptive analyses of our service delivery data. For data on participant characteristics (Table 1) our unit of analysis was the individual so that participants who had multiple abortions were not counted more than once. For abortion outcome, unplanned encounters, and satisfaction data (Tables 2 and 3), we utilized the abortion as the unit of analysis as we did not want to undercount any of these outcomes. We defined an adverse event as serious if it was fatal, life-threatening or resulted in hospitalization, transfusion, or significant disability. An unplanned clinical encounter was any visit to a clinician after the study package was mailed, except visits to obtain anti-D immunoglobulin, con-

traception, or routine ultrasound or lab tests to evaluate abortion outcome in the absence of concerning symptoms. The study team evaluated the reason for each unplanned encounter to determine whether or not it was abortion-related. We used 3/13/20 as the start date of the COVID crisis as that was the date the federal government declared COVID-19 to be a "national emergency" [16].

Advarra Institutional Review Board, the University of Hawaii's Office of Research Compliance Human Studies Program, and Oregon Health and Science University's Institutional Review Board approved the protocol. We registered the study on clinicaltrials.gov (NCT02513043).

Results

Partnering sites sent 1390 packages to 1356 participants who were prescreened between May 11, 2016 and September 11, 2020. Thirty participants received 2 abortions and 2 received 3 abortions during the reporting period. Of the 1356 individuals who received a package, 26% were under 25 years of age, and 14 were minors (Table 1). Participants tended to contact the clinics early in the first trimester; 47% were less than 42 days gestation at the time of the prescreening. In the continental U.S., 60% of participants lived 50 miles or more from their study site, and 36% lived 150 miles or farther. Thirty participants had their packages mailed to a state that was not their state of residence. While only 38% used insurance to pay for care provided by the study site (e.g., counseling, abortion medications), 66% used insurance to pay for preabortion tests.

In 47 instances (3%), neither abortion medication was taken, or the medications were taken after a diagnosis of miscarriage (Table 2). The median gestational age on the day of mifepristone ingestion was 53 days gestation (range 29–76). In eleven abortions (1% of those with outcome information), the participant took mifepristone past 70 days of gestation. Of the 76 times (7%) a participant reported taking more than 800mcg of misoprostol from the study package, 20 did so due to gestational age, as advised by the site during counseling. In 42 instances, participants took another 800 mcg of misoprostol because of little or no bleeding, or due to concerns that they did not pass the pregnancy.

We obtained abortion outcome information on 83% of abortions (1157/1390) and satisfaction data after 74% of abortions (1022/1390). Fourteen percent of the satisfaction questionnaires (141/1022) were completed via the online survey. Of the 1157 abortions with outcome information, 95% were complete abortions without a procedure (Table 2). Twenty-one abortions (1.8%) resulted in ongoing pregnancy. The majority of complete abortions were confirmed using a method that did not require a visit to a facility; 59% relied on UPTs, and 5% depended on patient history alone.

There were seventy unplanned visits (6%) to emergency rooms or urgent care centers for reasons related to the abortion (Table 2). Ten serious adverse events (SAEs) occurred, including five transfusions (0.4%). We determined that none of the SAEs was attributable to the telemedicine delivery of the service (e.g., they would not have been avoided if the participants had had in-person screening or picked their pills up in person).

When the COVID-19 national emergency was declared, we worked with our study sites to adapt to new challenges. The FDA required that our protocol retain the screening ultrasound requirement, but on a case-by-case basis, and following broader FDA guidance on conduct of clinical trials during the pandemic [17], sites evaluated whether forgoing the ultrasound was necessary to protect patient and provider health and safety (e.g., if the patient's locale was under stay-at-home orders, or a patient was quarantining because of COVID exposure or infection). Overall, 52% (346/669) of abortions during COVID occurred without a screening ultrasound, though this proportion varied widely by site (0%–83%). No ectopic pregnancies were reported among those who received a package during the entire analysis period (pre- and during COVID).

Prior to COVID, we had already started encouraging sites to preferentially offer UPT follow-up to confirm abortion outcome because participants were reporting that getting testing at facilities was burdensome. Comparing the 6 months prior to COVID to the period during COVID, selection of UPT as a follow-up method increased from 67% (144/214) to 90% (602/669). While some sites were already doing UPT follow-up for nearly all participants in the pre-COVID period, four study sites that had rarely used UPT for follow-up before COVID reported substantial increases during the COVID period (Fig. 1).

Enrollment increased dramatically in the months after March 2020; compared to January and February 2020, monthly enrollment more than tripled in April, May, and June of the same year (Fig. 2), Months with high enrollment were also months in which large percentages of abortions occurred without screening ultrasounds, and also in which new states were added to the project.

Over the entire reporting period, participants were overwhelmingly satisfied with the service, and with speaking to their providers remotely (Table 3). Despite some difficulty obtaining preabortion tests reported by 14% of the sample, 85% would choose TelAbortion again, and nearly all would recommend the service to a friend.

Discussion

With a larger, more geographically diverse sample, these data confirm our earlier findings that the TelAbortion service is safe, feasible, effective, and acceptable. Mifepristone can safely be dispensed by mail, and the REMS requirement that mifepristone must be dispensed in person, instead of enhancing patient safety as it purports to do, could have the exact opposite effect, particularly during a pandemic. Our abortion success rate of 95% is comparable to rates in the literature for in-person care [18]. A substantial proportion of our participants lived significant distances from their providers (and in Hawaii, most lived on different islands), underscoring the potential of direct-to-patient services to improve access to care. Preabortion ultrasounds are usually unnecessary for safe and effective medication abortion [1,14,19,20], and we found during COVID that sites sometimes actually felt it necessary to omit the ultrasound to protect a participant's health. The finding that a higher proportion of participants used insurance to pay for preabortion tests than the abortion medications and counseling (66% vs 38%) suggests that the TelAbortion service model could lower costs for some patients. This may be true especially in states where insurance will not cover the cost of abortion but may cover the cost of tests (as there is nothing to link the tests to subsequent abortion care).

We were interested to see that only 7% of participants took a second dose of misoprostol. In light of the recent misoprostol shortage that began in September 2020 [21] (J. Price, personal communication, 2/26/21), and adhering to the general principle of conservation of resources, rather than send out a second dose to all patients as standard practice, services might consider only sending it to patients above a certain gestational age (e.g., above 64 days or 71 days depending on clinic protocols), and calling in additional doses to pharmacies as needed.

A small but noteworthy number of patients (n = 30) obtained a TelAbortion in a state other than their state of residence. As the practice of medicine occurs where the patient is physically, crossing a state border can allow a patient to access care in an environment with fewer restrictions. In these instances, participants crossed the border for their video conference and then sites mailed packages to courier or post office locations, or to friends or family

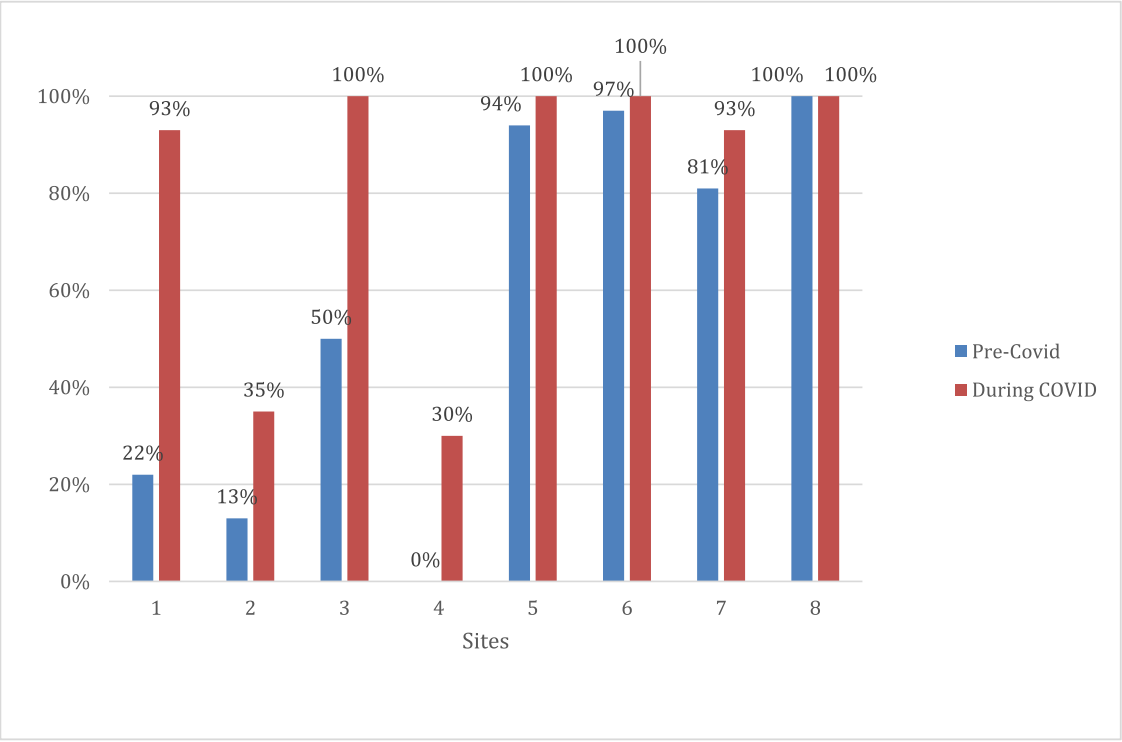

Fig. 1. Percentage of abortions with urine pregnancy test selected as follow-up method before COVID and during COVID, by site.[a,b]
[a]'Pre-COVID' period defined as 9/13/19–3/12/20; 'During COVID' period defined as 3/13/20–9/11/20.
[b]Does not include 1 site that did not enroll patients in the defined periods, and 1 site that did not enroll patients in the pre-COVID period (and enrolled 14 participants in the during COVID period).

members, who held the package until the participant picked it up. While this still required participants to travel, this approach may have enabled them to travel shorter distances than they would have had to in order to get to the nearest in-person appointment, and it allowed some to bypass home-state restrictions on abortions such as in-person counseling or waiting period laws. Some sites actively conducted outreach to metropolitan areas with restricted access to abortion care that were located near a border with a project state. Since 19 states prohibit the use of telemedicine for medication abortion within their borders, this may be a strategy to explore further to increase access in more restrictive states [22].

When the first surge of COVID-19 occurred in the spring, enrollment in the service soared, likely due to greater challenges in accessing in-person care, the ability for some participants to obtain the service without having to get an ultrasound (which meant they could do the entire process from home), and the addition of new states to the project. This spike in enrollment at a time when barriers to abortion care were limiting access elsewhere emphasizes the critical value of our service delivery method. Changes in practice during COVID varied widely by site, and reflected a number of factors including provider preference, institutional policies, and the provider's perception of the degree to which obtaining tests increased a patient's risk of infection or the patient's risk of infecting others.

Our data have some limitations. While we were able to improve on the follow-up rate of 77% from our first analysis (possibly due to the adoption of the online exit survey), we did not have outcome data on 13% of participants. As such, our estimates of medical abortion failure or complications may be underestimated or overestimated. As this analysis was descriptive, we are limited in the associations we can make between various aspects of the service and outcomes.

Compared to people obtaining abortions in the United States, our study population had a higher proportion of people who were older, more educated, and more likely to identify as white [23]. Telemedicine innovations need to prioritize the most disadvantaged populations so that they are not left behind. Future innovations in our project should focus on addressing this issue.

When we started the TelAbortion Project in 2016, it was the first service in the United States in which people could obtain an abortion legally without an in-person visit to an abortion provider. After a federal district court issued an injunction in July 2020 blocking the FDA from enforcing the rule that patients must pick up the abortion medication in person from their provider, several new online services launched. These promising efforts were recently threatened by a Supreme Court decision in January 2021 that reinstated the prior harmful policy. We believe our data disprove the notion that medication abortion pills must be dispensed in-person, and that direct-to-patient services that mail the pills to patients are safe, effective and feasible, even without a screening ultrasound.

Aligning mifepristone regulation with evidence: driving policy change using 15 years of excellent safety data

Kelly Cleland*, Nicole Smith

Office of Population Research, Princeton University

Received 7 June 2015; revised 15 June 2015; accepted 16 June 2015

Mifepristone was approved for sale in the United States 15 years ago this month. Use of mifepristone has steadily increased since its introduction; medical abortions now account for approximately 36% of the 1.1 million induced abortions that occur in the United States each year [1,2]. As clinical experience and research with mifepristone have expanded, the gold standard for medical abortion care has evolved beyond the protocol indicated in the FDA-approved label. Currently, the most common evidence-based protocols involve 200 mg mifepristone and 800 mcg misoprostol, and allow for use up to at least 63 days of gestation; these regimens are recommended by the World Health Organization [3], the American College of Obstetricians and Gynecologists and the Society of Family Planning [4] and the Planned Parenthood Federation of America [5]. The experiences of the hundreds of thousands of women who have had medical abortions using these protocols provide strong reassurance that mifepristone is extraordinarily safe; recent studies that include more than 423,000 women undergoing medical abortion with evidence-based regimens demonstrate that serious adverse outcomes are exceedingly rare [5–13].

Most complications associated with medical abortion are minor and include (but are not limited to) bleeding, cramping, fever and chills [9,13]. The outcomes of greatest clinical concern are heavy bleeding requiring transfusion, serious infection resulting in hospital admission, ongoing pregnancy, undiagnosed ectopic pregnancy and death attributable to the medical abortion regimen. In one large study [5], 0.10% (238/233,805) of patients presented to the emergency department for treatment following medical abortion; another recent study found that that, in the majority of cases, when women sought care in emergency departments following medical abortion, the complications were typically minor and expected [13]. Rates of hospital admission due to any medical-abortion-related complications are extremely low, with reports ranging from 0.04% (6/13,373) to 0.3% (119/45,528) [5,11,12]. Bleeding is an expected consequence of medical abortion, and it is only in the most extreme of circumstances that women require transfusion to replace excessive blood loss. Recent studies report that blood transfusion was required in 0.03% (4/13,373) to 0.14% (16/11,319) of medical abortion patients [5,7,8,11,12]. Serious infection requiring hospitalization following medical abortion is also rare; recent estimates range from 0.01% (2/13,373) to 0.23% (26/11,319) [5,7,12,13]. Infection is more prevalent when misoprostol is administered through a vaginal, rather than an oral or buccal, route [14]. Five deaths have been attributed to septic shock associated with serious bacterial infections after using misoprostol vaginally [15,16], prompting the Planned Parenthood Federation of America to adopt new guidelines in 2006 that include buccal administration of misoprostol.

Ongoing pregnancy does not pose health risks to the woman per se but is important to monitor because surgical intervention may be required to complete the abortion and because misoprostol can be teratogenic [17,18]. However, medical abortion using mifepristone and misoprostol is highly effective, with recent studies reporting very low rates of ongoing pregnancy ranging from 0.13% (70/13,373) to 1.1% (499/45,528) [5,11–13].

Ectopic pregnancy is a serious, but rare, event; ectopic pregnancies make up 1.3% to 2.0% of pregnancies in the United States [19,20]. Half of the pregnancies in the United States are unintended [21], and therefore, many women may not even be aware that they are pregnant, which could delay diagnosis of an ectopic pregnancy. However, women seeking abortion services, by definition, know that they are pregnant and may therefore be more likely to receive an early diagnosis of ectopic pregnancy. Furthermore, some studies show that rates of ectopic pregnancy are substantially lower among women seeking abortion services compared with overall rates in the general population [4,22,23].

Updated evidence-based regimens for medical abortion have increased options and lowered costs for women seeking abortion, all while maintaining an excellent safety profile. Research and practice in medical abortion continue to evolve, creating the potential to expand the medical option to even more women seeking abortion services. New studies demonstrate safe and effective use of mifepristone for medical abortion up to 70 days of gestation [24–26]. In addition, a growing body of research supports the safety of moving medical abortion away from clinic-centered models of care, allowing women to use mifepristone and misoprostol in the privacy and comfort of their home and to use technologies such as semiquantitative pregnancy tests to assess whether clinic follow-up is needed [27–29].

The current FDA-approved label for mifepristone limits its use to 49 days of gestation and indicates a 600-mg dose of mifepristone. In addition, mifepristone is not available in pharmacies; unlike other medications for which a doctor writes a prescription that the patient fills at a pharmacy, the prescriber's agreement specifies that mifepristone can be dispensed only in medical offices, clinics and hospitals. Furthermore, the FDA-approved label for mifepristone requires that patients make three office visits to receive the medications and complete extensive follow-up [30,31]. Although the safety and efficacy of updated evidence-based regimens for medical abortion are clear, some states require that providers follow the original FDA-approved protocol for medical abortion [32]. Requiring adherence to the FDA label does not serve the best interests of women; rather, it restricts the population of eligible women because of gestational age limits, directs women to take three times more mifepristone than evidence has shown to be necessary and requires that they make repeat visits to the clinic, demanding that increasing numbers of women travel great distances to receive services [33]. An extensive and rigorous literature supports the safety of both the current evidence-based regimens as well as innovative expanded protocols, providing a strong foundation for improving access to medical abortion by aligning the mifepristone label with the evidence.

Abstract

Objective—To analyze rates of significant adverse events and outcomes in women having a medical abortion at Planned Parenthood health centers in 2009 and 2010, and to identify changes in the rates of adverse events and outcomes between the 2 years.

Methods—In this database review we analyzed data from Planned Parenthood affiliates that provided medical abortion in 2009 and 2010, almost exclusively using an evidence-based buccal misoprostol regimen. We evaluated the incidence of six clinically significant adverse events (hospital admission, blood transfusion, emergency room treatment, intravenous antibiotics administration, infection, and death) and two significant outcomes (ongoing pregnancy and ectopic pregnancy diagnosed after medical abortion treatment was initiated). We calculated an overall rate as well as rates for each event and identified changes between the 2 years.

Results—Amongst 233,805 medical abortions provided in 2009 and 2010, significant adverse events or outcomes were reported in 1,530 cases (0.65%). There was no statistically significant difference in overall rates between years. The most common significant outcome was ongoing intrauterine pregnancy (0.50%); significant adverse events occurred in 0.16% of cases. One patient death occurred due to an undiagnosed ectopic pregnancy. Only rates for emergency room treatment and blood transfusion differed by year, and were slightly higher in 2010.

Conclusion—Review of this large dataset reinforces the safety of the evidence-based medical abortion regimen.

INTRODUCTION

First-trimester abortion with medications rather than surgery is widely used throughout the world, primarily utilizing a combination of mifepristone and misoprostol. Extensive experience with medical abortion has proven it to be highly effective and safe (1–6). As with surgical abortion, complications with medical abortion are relatively infrequent. The low probability of clinically significant adverse events and outcomes and varying protocols make it difficult to estimate these rates without a very large patient population.

Planned Parenthood is a large, multi-site provider of women's healthcare whose health centers have offered medical abortion as an option since 2001(6). Most Planned Parenthood affiliates (accredited by the Planned Parenthood Federation of America (PPFA)) operate several health centers; some health centers within one affiliate may offer medical abortion services while others may not. At Planned Parenthood health centers that offer medical abortion, this option is available up to and including 63 days of gestation (assuming that state regulations do not restrict providers to the FDA-approved regimen).

All Planned Parenthood affiliates are required to follow the PPFA Manual of Medical Standards and Guidelines as a condition of accreditation. The 2009 and 2010 guidelines outlined three acceptable medical abortion regimens using mifepristone and misoprostol (Table 1) including the FDA-approved regimen and two evidence-based regimens. All three regimens required that patients start a course of antibiotics the day they took mifepristone and that a follow-up appointment be scheduled within two weeks of mifepristone (PPFA Manual of Medical Standards and Guidelines, 2009 and 2010). PPFA internal data from affiliate surveys indicate that at least 99% of the medical abortions performed during 2009 and 2010 followed the evidence-based buccal regimen.

PPFA has a centralized reporting mechanism for significant adverse events and outcomes after medical abortion, which allows a large number of patient outcomes to be assessed through routine reporting. The primary objective of this study was to analyze rates of significant adverse events and outcomes in women having a medical abortion at Planned Parenthood health centers in 2009 and 2010. We also sought to identify changes in the rates of adverse events and outcomes between the 2 years, overall and separately for each event or outcome.

METHODS

Data Collection

This analysis includes data obtained from Planned Parenthood affiliates that provided medical abortion from January 1, 2009 through December 31, 2010. The total number of medical and surgical abortions provided by Planned Parenthood affiliates is collected by the PPFA national office via quarterly and annual summary reports. Abortion in the first trimester is defined as occurring through the 12th week of pregnancy. This study was approved by Allendale Investigational Review Board.

Planned Parenthood health center staff are trained in accurate and complete reporting of significant adverse events and outcomes after medical abortion, and such reporting is centralized through the PPFA national office. Since 2005, the PPFA accreditation process has included auditing to verify that significant adverse events and outcomes related to the use of mifepristone for medical abortion are reported as required. In accordance with the Mifeprex® (mifepristone) prescribing information, PPFA reports all significant adverse events and outcomes to Danco Laboratories, the U.S. distributor of mifepristone, which in turn reports them to the U.S. Food and Drug Administration (FDA).

NIH-PA Author Manuscript

NIH-PA Author Manuscript

NIH-PA Author Manuscript

Planned Parenthood health center staff collect information about significant adverse events and outcomes after medical abortion from different sources including routine follow-up visits, reports from clinicians providing care at hospital inpatient units or emergency rooms, or voluntary reports by patients. The 2009 and 2010 PPFA Manual of Medical Standards and Guidelines included requirements to emphasize the importance of the follow-up visit to all patients, and staff members were required to make three attempts (two in writing) to reach patients who did not return for follow-up. Despite substantial effort to follow up with patients, complete information on the proportion of women who did not return for follow-up as well as any complications they may have experienced is not available.

Study procedures

During the study period, protocols for providing medical abortion and reporting significant adverse events and outcomes remained consistent, with the exception that beginning in July 2010, affiliates had the ability to submit reports via a secure web-based system in addition to submitting reports via fax. We analyzed reports of significant adverse events and outcomes after medical abortion, and rates were evaluated for both years together, as well as individually for 2009 and 2010. We excluded 2010 data from one affiliate (that had reported only two cases of adverse events or outcomes) which as of September 2010 was no longer a member of PPFA. Because delays in reporting adverse events and outcomes are common, we could not be certain that all adverse events and outcomes that may have occurred at this affiliate during the first nine months of 2010 had been adequately reported.

Per the Danco Laboratories Mifepristone Prescriber's Agreement "adverse events, such as hospitalization, blood transfusion, ongoing pregnancy, or other major complications after the use of Mifeprex® and misoprostol must be reported to Danco Laboratories"(7). In this report, we evaluate six clinically significant adverse events (hospital admission, blood transfusion, emergency room [ER] treatment, intravenous antibiotics administration, infection requiring treatment with IV antibiotics or admission to the hospital, and death) and two significant outcomes (ongoing intrauterine pregnancy and ectopic pregnancy diagnosed after medical abortion treatment was initiated) after medical abortion. In this analysis, blood transfusion is binary (whether or not blood products were administered) because not all reports included the specific components or amount.

The PPFA Manual of Medical Standards and Guidelines defined ongoing pregnancy as "a living, viable pregnancy that is growing. For example, the ultrasound shows a fetal pole with cardiac activity or a gestational sac that has grown appropriately since mifepristone was given" (PPFA Manual of Medical Standards and Guidelines, 2009 and 2010). The PPFA Manual of Medical Standards and Guidelines permitted use of a repeat dose of misoprostol when the initial follow-up evaluation demonstrated an ongoing pregnancy up to and including 63 days gestation. In this analysis, if a repeat dose of misoprostol was successful, the case was not included as an ongoing pregnancy.

Categories of significant adverse events and outcomes are not mutually exclusive; in some cases, one problem could be counted as more than one event or outcome. For example, if a patient with a serious infection was admitted to the hospital and treated with intravenous antibiotics, this case would be counted in each of the three outcome categories.

Statistical analysis

We calculated 95% exact binomial confidence intervals for rates, and used Fisher's Exact Test to test the statistical significance of differences in proportions. Two-sided p-values of less than 0.05 were considered to be indication of statistical significance. All calculations were performed using StataSE 11 (College Station, TX).

NIH-PA Author Manuscript

NIH-PA Author Manuscript

NIH-PA Author Manuscript

RESULTS

As of December 31, 2010, PPFA included 85 independent affiliates operating 810 health centers in 49 states and the District of Columbia; 39% (324) of health centers provided abortion care, and nearly all of these (97.8%, 317) offered medical abortion. In 2009, 314,772 first-trimester abortions were provided by PPFA affiliates, 35% of which were medical abortions. In 2010, medical abortion comprised 38% of the 320,991 first-trimester abortions. Overall, in 2009 and 2010, medical abortion comprised 37% of all first-trimester abortions provided by Planned Parenthood health centers.

Amongst the 233,805 medical abortions provided at Planned Parenthood health centers in 2009 and 2010, significant adverse events or outcomes were reported in 1,530 (0.65%) cases. There was no statistically significant difference in overall rates between years (p=0.29). Rates for each significant adverse event and outcome are shown in Table 2. A clinically significant adverse event occurred in 0.16% of cases; this rate did not differ by year. A clinically significant outcome occurred in 0.5% of cases (with no difference by year). Of importance is the rarity of an undiagnosed ectopic pregnancy, which occurred at a rate of 0.7 per 10,000 medical abortions. The most common significant adverse event or outcome after medical abortion during the study period, ongoing intrauterine pregnancy, was reported in 0.50% of cases for both years combined. Among 1,158 ongoing intrauterine pregnancies, 1,095 (94.6%) were known to be terminated surgically, and 63 (5.4%) were either lost to follow-up or patients indicated that they would continue or were considering continuing the pregnancy.

The only adverse event rates that differed in statistical significance in bivariate models between 2009 and 2010 were ER treatment (0.07%, n=87 *versus* 0.12%, n=151, respectively, p=0.001) and blood transfusion (0.04%, n=42 *versus* 0.06%, n=72, respectively, p=0.024). There was one death, due to an undiagnosed ectopic pregnancy, for a mortality rate of 0.4/100,000 over the two year study period.

DISCUSSION

As the largest provider of abortion care in the United States, PPFA is in a unique position to provide reliable, large-scale data on the efficacy and safety of abortion procedures. The data presented here reinforce the infrequency of clinically significant adverse events and outcomes after medical abortion. The vast majority (99.34%) of medical abortions provided at Planned Parenthood health centers in 2009 and 2010 were completed with no known complications. Clinically significant adverse outcomes were rare, occurring at a rate of 16 per 10,000 medical abortions. The most common significant adverse event or outcome reported was ongoing intrauterine pregnancy, occurring in 0.5% of all medical abortion procedures.

Ongoing pregnancy is reportable to Danco Laboratories per the Mifepristone Prescriber's Agreement. Since it is the efficacy metric for medical abortion, data on ongoing intrauterine pregnancy should be reported and reviewed. However, ongoing intrauterine pregnancy is not a complication that is related to the safety of medical abortion the same way serious infection or blood transfusion are. The risk associated with ongoing pregnancy is tied to the potential teratogenicity of misoprostol (8,9). Continuing pregnancy is of clinical significance only if it is unrecognized through follow-up and the patient does not have a surgical abortion.

Although we present data for ongoing pregnancy rates, we are unable to assess an overall "failure rate" for the two year reporting period. Treatment failure encompasses all reasons for a D&C, including incomplete abortion. While incomplete abortion managed outside the

NIH-PA Author Manuscript

NIH-PA Author Manuscript

NIH-PA Author Manuscript

Planned Parenthood health center is reportable when it is tied to an adverse event (i.e. treatment in the ER or hospital), incomplete abortion managed at the health center is not. Therefore, we have data only on rates of surgical evacuation for ongoing pregnancy.

Ectopic pregnancy diagnosed after medical abortion treatment was initiated was extremely rare with a rate even lower than the likelihood of maternal death during delivery (10) Our study includes only ectopic pregnancies that were diagnosed after the medical abortion regimen had begun, not those diagnosed during the initial screening process. One death occurred during the study period due to an undiagnosed ectopic pregnancy.

The overall rate for all clinically significant adverse events and outcomes combined did not differ between 2009 and 2010; nor did the rate for most of these events differ by year. Exceptions were ER treatment and blood transfusion, both of which were higher in 2010 than in 2009. Because each health center has different local resources available, and patients may travel from more rural areas to some health centers, ER treatment may be related to where the original service was provided. Patients who drove for several hours to a health center to obtain care might be more likely to need ER treatment for a complication because of less access to a health center for any urgent issue. We do not have any data regarding locale of patients to compare whether ER treatment or blood transfusion is related to distance from home to the health center.

The findings in this paper are of timely significance as some states in the United States have passed or are considering legislation to restrict mifepristone and misoprostol use to the FDA-approved regimen. The largest U.S. trial of mifepristone and misoprostol using the FDA-approved regimen through 49 days gestation showed an ongoing pregnancy rate of 1% amongst 827 women (11). The 92% efficacy rate of the FDA-approved regimen (11,12) is lower than the 96% efficacy rate for the evidence-based regimen using buccal misoprostol through 63 days gestation (13). This current large database analysis reinforces the low ongoing pregnancy rate when using one 200 mg mifepristone tablet and buccal misoprostol.

Potential limitations to this analysis should be considered. The data analyzed in this paper are those reported to or received by PPFA; we cannot exclude the possibility that some clinically significant adverse events or outcomes were not included. Some patients may have experienced a significant adverse event or outcome but did not follow-up after their medical abortion. Additionally, despite intensive efforts at training affiliate and national office staff in procedures for reporting significant adverse events and outcomes, there remains the potential for human error and omission in the reporting process. Additionally, because experiencing, treating, and reporting an adverse event is subjective, an event may not always reflect the severity of the condition, but rather the concern of the patient. Similarly, treatments with blood products and intravenous antibiotics for the same condition may vary substantially among physicians or institutions.

The last potential limitation to consider is the lack of information available about women who did not experience a significant adverse event or outcome. Detailed information about patient age and gestational age (but no other demographic information) is collected through the PPFA reporting system only for those women with significant adverse events or outcomes after medical abortion. Therefore, we are unable to analyze rates of significant adverse events and outcomes based on patient age, gestational age or other demographic variables, or to identify the exact regimens used in the 232,275 medical abortions with no reported complications. Despite these potential limitations, the findings in this study confirm that evidence-based medical abortion is highly effective and extremely safe.

The FDA allows and encourages off-label use of registered products when existing medical evidence supports such use (14). The data presented in this paper contribute to existing

NIH-PA Author Manuscript

NIH-PA Author Manuscript

NIH-PA Author Manuscript

information in the medical literature; all of this evidence, taken together, does not support legislation restricting providers to use of the FDA-approved regimen. Every woman deserves factual medical information whenever she is faced with a decision of whether or not to terminate her pregnancy (15). Mandating the FDA-approved regimen, without a scientific basis, does not protect patients from unsafe abortion; it only limits access to safe and effective medical abortion for women desiring a pregnancy termination. This review of PPFA's medical abortion data confirms the safety and efficacy of medical abortion, and should be taken into consideration both by clinicians and legislators when considering policy and protocols related to abortion.

Table 1

Medical Abortion Regimens Provided at Planned Parenthood Health Centers in 2009 and 2010*

Regimen†	Gestational Limit (up to and including)	Mifepristone	Misoprostol	
			Days after Mifepristone	Dosage
FDA-approved	49 days	3 200-mg tablets, orally, in office	Two days (only if needed)	2 200 mcg tablets, orally, in office
Evidence-based, oral misoprostol	49 days	1 200-mg tablet, orally, in office	One day	4 200 mcg tablets (split into two doses over two hours), orally, at home
Evidence-based, buccal misoprostol	63 days	1 200-mg tablet, orally, in office	One or two days	4 200 mcg tablets, bucally, at home

*Follow-up appointment scheduled within 2 weeks of mifepristone ingestion for all regimens.

†All medical abortion regimens required that patients start a course of antibiotics on the day mifepristone was administered. Patients received doxycycline 100 mg orally twice a day for 7 days; if a patient was allergic to doxycycline, acceptable alternatives included azithromycin 1 gram orally, erythromycin base 500 mg orally four times a day for 7 days; erythromycin ethylsuccinate 800 mg PO four times a day for 7 days; ofloxacin 300 mg twice a day for 7 days or levofloxacin 500 mg PO once a day for 7 days).

Mifepristone and Misoprostol Administered Simultaneously Versus 24 Hours Apart for Abortion

A Randomized Controlled Trial

*Mitchell D. Creinin, MD, Courtney A. Schreiber, MD, MPH, Paula Bednarek, MD, MPH, Hanna Lintu, MD, MPH, Marie-Soleil Wagner, MD, MS, and Leslie A. Meyn, MS, for the Medical Abortion at the Same Time (MAST) Study Trial Group**

OBJECTIVE: Mifepristone and oral misoprostol are typically used for medical abortion in women up to 49 days of gestation, with a 36- to 48-hour interval between the medications. Alternative routes of misoprostol administration allow for use beyond 49 days of gestation. We designed this randomized, noninferiority trial to compare the efficacy, adverse effects, and acceptability of misoprostol 800 mcg vaginally administered simultaneously with, or 24 hours after, mifepristone 200 mg orally for abortion in women up to 63 days of gestation.

METHODS: The 1,128 participants swallowed mifepristone 200 mg and were then randomized to self-administer misoprostol intravaginally immediately in the office (group 1) or 24 hours later at home (group 2). Subjects returned for an evaluation, including transvaginal ultrasonography, 7±1 days after initiating treatment. Women who had not aborted were offered a second dose of misoprostol and returned for another evaluation in approximately 1 week. A phone contact was also attempted approximately 5 weeks after treatment. Treatment was considered a failure if a suction aspiration was performed for any indication.

RESULTS: The complete abortion rate for group 1 (95.1%, 95% confidence interval [CI] 93.0–96.8%) was statistically noninferior to that for group 2 (96.9%, 95% CI 95.1–98.2%) (P=.003). The abortion rates between groups did not significantly differ by gestational age. Adverse effects were mostly similar, although nausea, diarrhea, and warmth or chills were significantly more common in group 1.

CONCLUSION: Mifepristone 200 mg and misoprostol 800 mcg vaginally used simultaneously is as effective for abortion as compared with regimens using a 24-hour dosing interval.

Medical abortion techniques have evolved over the past 2 decades based on scientific advances. The original mifepristone and misoprostol regimens included 600 mg of oral mifepristone, followed 36–48 hours later by 400 mcg of oral misoprostol in women up to 49 days of gestation. Large, prospective, randomized trials support equal efficacy with regimens using a lower dose of mifepristone (200 mg).[1–3] Addi-

tionally, alternative methods of administration of misoprostol, including vaginal,[4–6] buccal,[7] and sublingual,[8,9] allow for use of the medications for gestations beyond 49 days of gestation.

Over the past 5 years, multiple studies have focused on the time interval between medications. Regimens with oral misoprostol are not very effective when the time interval decreases below the recommended 36–48 hours.[10] Buccal regimens appear effective with dosing intervals as little as 24 hours in women up to 56 days of gestation.[7] The largest trials include vaginal misoprostol, with which efficacy is maintained in women up to 63 days of gestation when the time interval is as little as 6–8 hours.[11] Decreasing the time interval allows most women to complete a medical abortion in less than 1 day. Additionally, because approximately 50% of women have vaginal bleeding during the 48-hour interval between mifepristone and misoprostol administration with the standard regimen,[10,12,13] administering the drugs on the same day would decrease undesirable adverse effects like bleeding.

The natural progression in the evaluation of the effect of time between mifepristone and vaginal misoprostol administration is simultaneous administration of the agents. Such studies appear scientifically rational based on available pharmacokinetic and clinical data. Vaginal administration appears to act as a depot of misoprostol acid.[14] Typically, cramping begins approximately 2 hours and bleeding about 3 to 3½ hours after misoprostol placement.[11,15,16] Significant serum levels of misoprostol acid are still present 4 hours after administration based on the pharmacokinetic profile,[14] thereby rationalizing simultaneous application.

Pilot trials were performed with the primary objective of evaluating 24-hour expulsion rates after simultaneous administration of mifepristone 200 mg and vaginal misoprostol 800 mcg.[17,18] These trials included 120 women, with 40 women in each of the gestational age ranges of 49 days or less, 50–56, and 57–63 days of gestation. The expulsion rates of 90%, 88%, and 85%, respectively, were similar to those seen in regimens with intervals of 6–8 hours,[15,16] demonstrating the potential efficacy of these drugs for medical abortion when administered simultaneously. We performed this prospective, randomized, multicenter trial to compare the efficacy, adverse effects, and acceptability of misoprostol 800 mcg vaginally administered simultaneously with, or 24 hours after, mifepristone 200 mg orally in women up to 63 days of gestation. This study is designed as a noninferiority trial, with efficacy as the primary outcome variable.

MATERIALS AND METHODS

The study was conducted at four centers: the University of Pittsburgh, Oregon Health and Science University, Northwestern University, and the University of Southern California. The study was reviewed and approved by the institutional review boards of the respective institutions and by the U.S. Food and Drug Administration (FDA). The University of Pittsburgh served as the sponsoring institution; all protocol changes were submitted and approved by the University of Pittsburgh Institutional Review Board before submission to other institutions. All participants provided written consent before participation in the study.

We enrolled 1,128 healthy women who were requesting an elective abortion, had an intrauterine pregnancy at 63 days of gestation or less on the day of mifepristone administration as confirmed by vaginal ultrasonography, were willing to comply with the visit schedule, were willing to have a surgical abortion if indicated, and had access to a telephone. Potential subjects were excluded if they had any contraindication to mifepristone, including chronic systemic corticosteroid administration or adrenal disease; had any contraindications to misoprostol, including glaucoma, mitral stenosis, sickle cell anemia, poorly controlled seizure disorder, or known allergy to prostaglandin; had a hemoglobin level less than 10 g/dL; had cardiovascular disease, including angina, valvular disease, arrhythmia, or cardiac failure; had a known coagulopathy or were receiving treatment with anticoagulants; had a pregnancy with an intrauterine device in utero; had an ultrasound examination that demonstrated any evidence of an early pregnancy failure; had active cervicitis on examination; were breastfeeding; or had previously participated in the trial.

After obtaining informed consent, a medical history was reviewed, hemoglobin and blood type were obtained, and pelvic and transvaginal ultrasound examinations performed. Only women with a visible intrauterine gestational sac were eligible. Mean sac diameter ([length+width+depth]/3) was used to determine estimated gestational age (EGA) when an embryonic pole was absent using the formula: mean sac diameter (EGA [days]=mean sac diameter [mm]+30).[19] For gestations with an embryonic pole, the formula embryonic pole (EGA [days]=embryonic pole [mm]+42) was used.[20] Last menstrual period (LMP) was used to determine EGA if the LMP was within 3 days of the ultrasound EGA, but the ultra-

Copyright© American College of Obstetricians and Gynecologists

GBP-PET00195

sound estimate was used if it differed by 4 days or more from the EGA by LMP.

At the University of Pittsburgh, subjects returned for enrollment at least 24 hours after signing informed consent as required by the Pennsylvania Abortion Control Act. At all other sites, screening and enrollment occurred at the same visit. Once entry criteria were confirmed, each woman was counseled further about the correct method of inserting the misoprostol. She then swallowed mifepristone 200 mg, after which the randomization envelope was opened by the research staff. Women randomized to immediate insertion (group 1) went into an examination room in the office and inserted 4 tablets of misoprostol 200 mcg as high up as possible into the vagina within 15 minutes of swallowing the mifepristone. Those women randomized to routine insertion (group 2) were given the misoprostol tablets to take home with instructions to insert the misoprostol tablets 23–25 hours after taking the mifepristone. Group assignment was performed in a randomized fashion using sequentially numbered opaque envelopes containing a card with computer-generated assignment information and prepared for each center by the Data Coordinating Center. Randomization was stratified by center with equal frequency to the two treatment arms. Random allocations were performed in a permuted block design with varying block sizes as described by Pocock.[21]

Rh-immune globulin 50 mcg intramuscularly was administered to all subjects who were Rh-negative. Subjects were given written instructions regarding pain medication use and bleeding parameters. Women were advised to contact the research office if vaginal bleeding exceeded two soaked sanitary pads per hour for 2 consecutive hours. Participants were given a prescription for or supply of 20 tablets of codeine phosphate (30 mg), oxycodone (5 mg), acetaminophen with codeine (300 mg/30 mg) (with instructions not to take more than 13 tablets in a 24-hour period), or acetaminophen with hydrocodone (500 mg/5 mg) (with instructions not to take more than 8 tablets in a 24-hour period). Subjects were instructed to use ibuprofen or acetaminophen initially and to use the prescribed narcotic only if necessary. Subjects were asked to maintain a daily diary of medication use and adverse effects throughout the study. At each follow-up visit, the diary was reviewed and data collected regarding bleeding, cramping, other adverse effects, and medication use since the prior visit. An investigator was available 24 hours a day in the case of emergency and to answer subjects' questions.

Participants were scheduled to return for a follow-up examination 7 (±1) days after taking mifepristone, during which transvaginal ultrasonography was performed. Women who had not expelled the gestational sac were offered a repeat dose of misoprostol and scheduled to return. Subjects who missed the first follow-up visit and were not seen again until 12 or more days after receiving the mifepristone could not receive a second dose of misoprostol.

All women had a follow-up contact scheduled at 14 (±2) days after mifepristone administration. Those women who had expelled the pregnancy received a phone call from the researchers, and those who had not expelled the gestational sac returned for a visit that included transvaginal ultrasonography. Subjects who had not aborted by the second follow-up and had a viable gestation were offered a surgical abortion. Women with a nonviable persistent gestation at the second follow-up were offered a surgical abortion or scheduled to return again in another 3 weeks. If the abortion had not been completed by this final follow-up visit, subjects were offered a surgical abortion or weekly follow-up. Suction aspiration was also performed at any time if it was clinically necessary because of uterine hemorrhage or incomplete abortion, or at the subject's request.

Five weeks after initiating the study, we attempted to contact by telephone all women who had expelled the gestational sac by the first or second follow-up visit to review if there have been any problems since the abortion. The procedure was considered successful if the abortion occurred without requiring a suction aspiration. Neither the study staff, investigators, or participants were blinded to treatment group, as is common in medical abortion trials.[11]

Immediately before enrollment, women completed a questionnaire regarding their prior experience with abortion and a visual analog scale (VAS)[22,23] measuring the amount of pain and bleeding they anticipated. At each participant's final follow-up visit, she was questioned about her satisfaction with this medical abortion regimen and completed a VAS measuring the amount of perceived bleeding and pain experienced during the abortion process and her preference for medical or surgical abortion if she needed an abortion again in the future. On a 100-mm line, with 0 equaling no bleeding and 100 equaling heavy bleeding, subjects were asked to mark the amount of bleeding they experienced. In a similar fashion, level of pain was recorded, with 0 equaling no pain and 100 representing severe pain. Likewise, preference for abortion method was recorded, with 0

Copyright© American College of Obstetricians and Gynecologists

GBP-PET00196

equaling medical abortion and 100 representing surgical abortion.

On-site monitoring was performed by staff from the Data Coordinating Center at a minimum of every 4 weeks or upon request of the Principal Investigator. The monitor reviewed the center's documents to ensure appropriate institutional review board approval and communication as well as accurate and appropriate reporting of source data.

Sample size was estimated to demonstrate noninferiority of the study treatment (simultaneous administration) to standard treatment (24-hour interval). The complete abortion rate in the standard care group (group 2) was set at 97%.[11] Using a one-sided, two-group test of equivalence, 552 subjects per group were required to demonstrate equivalence within a 3% observed difference (upper 95% confidence interval of 5%).[24] This sample size was statistically able to establish noninferiority with the same 3% observed difference, with an efficacy in the standard group as high as 100% and as low as 95%. To allow for 2% of subjects to not have documentation of a final outcome, the total sample size was increased to 1,128 women. Because individual adverse effects in medical abortion regimens using these agents typically occur at a rate exceeding 10%,[11,13,15,16,25] this sample size had 80% power to detect at least a 60% difference in the rates of adverse effects between the two treatment groups. For adverse effects occurring at rates of 20%, this study had 80% power to detect at least a 45% difference between the two groups.

Baseline demographic data were compared according to treatment group using Student *t* test, Fisher exact test, χ^2 test, or χ^2 test for linear trend, where appropriate, to assess for clinically significant differences. An intent-to-treat analysis was performed to include all women with adequate follow-up defined as having at least one follow-up visit, more than one phone contact beyond 7 days after using the medications with a history by phone consistent with expulsion, or by review of outside records that confirmed expulsion.

The primary objective of this study was to compare complete abortion rates in women who received mifepristone followed by vaginal misoprostol within 15 minutes (experimental group) and 24 hours later (standard care group) using a one-sided equivalence test of proportions, with an equivalence limit of 5%. The null hypothesis for the test of equivalence is that two treatments are not equivalent. Rejecting the null hypothesis, indicated in this study by $P \leq .05$, implies that the two treatments are equivalent.[24] Interim analyses based on the complete abortion rate (both overall and stratified by gestational age) were conducted when 360 women and 720 women (approximately 33% and 66% of the study population, respectively) completed their follow-up visits. This interim analysis reduced the alpha for the final analysis to 0.0472 according to the O'Brien and Fleming method.[26]

Secondary outcomes included evaluation of the efficacy of mifepristone and one dose of misoprostol, adverse effects, bleeding, and acceptability data. Gestational age efficacy (overall, within group, and after mifepristone and a single dose of misoprostol) and the rate of adverse effects by gestational age were evaluated using the χ^2 for linear trend. Efficacy within groups by study site was evaluated using the χ^2 test. The rate of adverse effects (nausea, vomiting, and pain medication use), bleeding, and acceptability, as measured by positive or negative answers, between the two abortion regimens was compared using Fisher exact test. The length of bleeding after treatment, and the pre- and posttreatment VAS assessments were compared between treatment groups using the Mann-Whitney *U* test because these data did not appear to be normally distributed when their frequency distributions were graphically displayed. For analyses of adverse effects, bleeding, and acceptability data, two-tailed *P* values less than .05 were considered statistically significant.

RESULTS

Between April 2004 and May 2006, 1,128 subjects were enrolled (Fig. 1). Both groups were similar in demographic characteristics (Table 1). The gestational age was set by LMP and confirmed by ultrasonography in 49% and 45% of women in groups 1 and 2, respectively. The remaining women had their gestational ages adjusted by the ultrasound examination.

A final outcome was established for 1,100 women, with 26 (2.3%) women lost to follow-up (Fig. 1). A small number of women (19, 1.7%) had follow-up consisting only of multiple phone contacts or by review of medical records subsequent to the occurrence of the medical abortion; all of these women had histories consistent with expulsion and no signs of a continuing pregnancy. The median times of misoprostol administration in groups 1 and 2 were 5 minutes and 24 hours after mifepristone, respectively. All subjects in group 1 (0.2%) except for one used the misoprostol within 15 minutes of the mifepristone; the one outlier used her dose at 24 minutes. In group 2, four (0.7%) women did not use the misoprostol at the correct time, defined as more than 15 minutes outside of the assigned time interval. These four women used

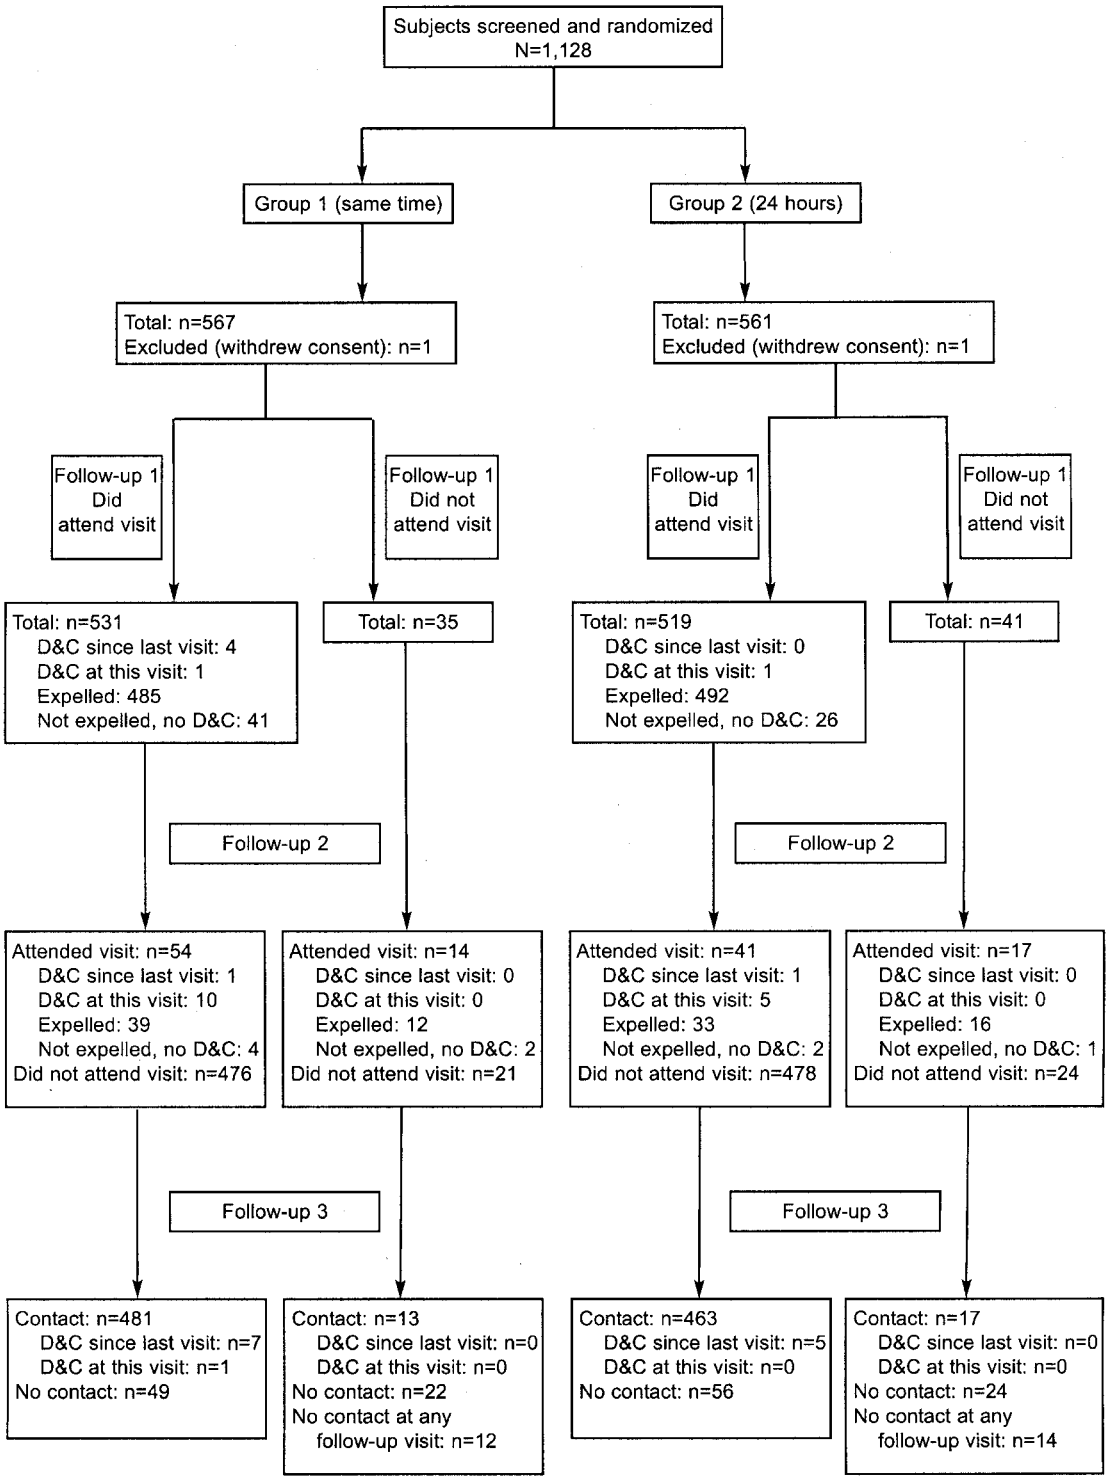

Fig. 1. Flow of study participants. Group 1: mifepristone 200 mg orally followed within 15 minutes by misoprostol 800 mcg vaginally. Group 2: mifepristone 200 mg orally followed by misoprostol 800 mcg vaginally 23–25 hours later. Follow-up 1: scheduled visit 7 (±1) days after mifepristone. Follow-up 2: scheduled visit 14 (±2) days after mifepristone. Follow-up 3: scheduled visit (if patient had not expelled pregnancy by follow-up 2 and pregnancy was nonviable) or scheduled phone call 5 weeks after mifepristone. Two subjects in group 1 and five subjects in groups 2 had dilation and curettage (D&C) after the final scheduled follow-up contact. One subject in group 1 received additional misoprostol at the day 35 visit and was considered a treatment failure.

* P=.04. All other variables P>.05 by Fisher exact test, χ^2 test, χ^2 test for linear trend, or Student t test, where appropriate.

the misoprostol at 21.45 hours, 22.75 hours, 25.33 hours, and 44.75 hours. Additionally, one subject in group 2 swallowed her misoprostol; she was at 57 days of gestation and failed treatment but was included in the analysis.

The efficacy of treatment in women with simultaneous administration was noninferior to that in women who administered the medications 24 hours apart (Table 2) (P=.003). If the women who were lost to follow-up were included as treatment failures, the outcomes were still equivalent (data not shown). However, the success rates with mifepristone followed by a single dose of misoprostol were different (Table 2) (91% versus 94%, respectively, P=.1 for noninferiority). There was no trend for decreasing success overall or with mifepristone and a single dose

Table 2. Complete Abortion Rate With Mifepristone 200 mg Followed by Misoprostol 800 mcg Vaginally*

	Study Treatment (Interval 0–15 min)	Standard Treatment (Interval 23–25 h)	P†
Overall (d)	95.1 (93.0–96.8) (n=554)	96.9 (95.1–98.2) (n=546)	.003
49 or less	95.5 (92.3–97.6) (n=266)	98.3 (95.6–99.5) (n=229)	.08
50–56	94.3 (89.5–97.4) (n=159)	95.3 (91.0–98.0) (n=172)	.051
57–63	95.3 (90.2–98.3) (n=129)	96.6 (92.1–98.9) (n=145)	.06
With single dose misoprostol (d)	91.0 (88.3–93.2) (n=554)	94.0 (91.6–95.8) (n=546)	.1

of misoprostol with increasing gestational age within study groups ($P>.3$ for all comparisons). There was also no difference for overall efficacy within study groups by study site (data not shown).

Treatment failures in groups 1 and 2 included viable pregnancy at the second follow-up visit (four women and one woman, respectively), persistent nonviable pregnancy at the second follow-up visit (seven and four women, respectively), persistent nonviable pregnancy at the third follow-up visit (two women and 1 woman, respectively), incomplete abortion (12 and 11 women, respectively), and subject request (two and no women, respectively).

Cramping began after a median of 2.5 hours (range 0 to 143 hours) and 1.7 hours (range –24 to 115 hours) after misoprostol administration in groups 1 and 2, respectively ($P<.001$). Bleeding began after a median of 3.7 hours (range 0 to 74 hours) and 2.0 hours (range –23 to 24 hours), respectively ($P<.001$). Pad count data were available for 549 (99.1%) and 544 (99.6%) women in groups 1 and 2, respectively. For these women, 31.5% and 36.8% reported that the heaviest amount of bleeding they experienced was soaking at least two pads in 1 hour ($P=.07$). There was also no difference in the number of women who reported that the heaviest amount of bleeding exceeded two pads in 1 hour (9.7% versus 10.1%, $P=.8$). Bleeding and spotting duration was not different between groups, lasting a median of 10 and 15 days, respectively, for women in group 1, and 10 and 14 days, respectively, for women in group 2 (Table 3).

Adverse effects are presented in Table 4. Women in group 1 had statistically significantly higher rates of nausea, diarrhea, and warmth or chills after misoprostol administration. Bleeding, cramping, and acceptability information are presented in Table 3. Complete pre- and posttreatment VAS assessments were available for 533 (96%) and 527 (97%) women in groups 1 and 2, respectively. The median level of pain reported on the post-questionnaire was 64 mm and 62 mm, respectively. The indicated level of pain was 3 mm higher in group 1 and 2 mm lower in group 2 than that anticipated on pretreatment VAS assessment in both groups. The findings were similar for bleeding, with a median posttreatment severity of bleeding of 63 mm and 64 mm for groups 1 and 2, respectively, and the differences as compared with pretreatment estimation of bleeding, 8 mm and 7 mm lower, respectively.

Serious adverse events occurred in 17 (1.5%) women. Four women (0.4%) received a transfusion, all in group 2, with gestational ages at initiation of treatment of 50, 51, 57, and 63 days. One subject in group 1 had a heterotopic pregnancy and had surgery for the tubal gestation after a successful medical abortion. Two other women had hospitalizations for events unrelated to the medical abortion. In addition to these serious events, 10 women (0.9%), five in each group, were diagnosed with acute pelvic infection after the medical abortion but were treated as outpatients. One of these infections (in group 2) occurred after a suction aspiration for an incomplete abortion.

Bleeding	6	100	100	.2

Data are expressed as percentages.
All subjects received mifepristone 200 mg and misoprostol 800 mcg vaginally. Women receiving standard treatment inserted the misoprostol 23–25 hours after mifepristone; those receiving study treatment inserted the misoprostol within 15 minutes of mifepristone administration.
* Comparing adverse effects after misoprostol treatment.

DISCUSSION

We have demonstrated that simultaneous administration of mifepristone and vaginal misoprostol is at least as effective as administration of the medications 24 hours apart. The sample size was calculated to evaluate noninferiority for the overall study sample and was not large enough to determine noninferiority at each gestational age range. However, even with smaller samples within each gestational age range, the abortion rates within each gestational age range were almost noninferior, with *P* values of .051 to .08 (Table 2), suggesting that larger trials would likely demonstrate equivalence. The point difference between the two treatment groups was 3%, the value declared a priori for noninferiority of the overall complete abortion rates. Given that the standard treatment group had a single-dose efficacy below 95%, the sample was not large enough to demonstrate this 3% difference to be noninferior.

The complete abortion rates[4,11,27] and adverse effect rates[11] in the standard treatment groups were similar to those previously published for this regimen, inferring external validity. In a prior trial comparing dosing intervals of 6–8 hours and 23–25 hours, women in the shorter interval group experienced fewer adverse effects and were less likely to experience significant bleeding.[11] Further shortening the interval to simultaneous dosing does not appear to create these same benefits in relation to adverse effects or bleeding. It is possible that the lack of a decrease is, in reality, the result of women experiencing adverse effects from both the mifepristone and misoprostol when administered simultaneously. Importantly, the differences, albeit statistically significant, are relatively small and are not likely to have clinical relevance as evidenced by the high and equal satisfaction in both treatment groups.

When this study was initiated, the "evidence-based" use of vaginal misoprostol was very common in the United States. In December 2005, Fischer et al[28] reported four deaths in the United States from *Clostridium sordellii* infection in women who had received mifepristone and vaginal misoprostol. A fifth infectious death, related to *C perfringens*, was reported at a Centers for Disease Control and Prevention meeting in May 2006.[29] One theory about infection and medical abortion is that mifepristone causes immunosuppression[30]; however, more widespread and serious infections would be occurring with more common organisms. In our current study, mild infection was diagnosed in less than 1% of subjects, a rate that is too low to support the idea of significant immunosuppression. Another theory is that use of the misoprostol vaginally increases the likelihood of infection with rare organisms. Such a finding would obviate the importance of this study. Additional recent reports have linked *C sordellii* infection to the deaths of eight women who recently had delivered infants either vaginally or by caesarean, two women who had miscarriages, and one woman who was infected during her menstrual period.[29] Obviously, neither mifepristone nor vaginal misoprostol was routinely used in these cases. For now, the evidence does not allow any inference as to whether the use of vaginal misoprostol as opposed to other routes impacts this risk. It is unclear if these rare infectious deaths with medical abortion are a direct effect of the medications used or a result of the process of medical abortion caused by the medications.

We, as providers and policy makers, may not be able to globally categorize how women assess risks and benefits of pregnancy options, and it is likely that such decisions are complex and personal. If there really is an increased risk of death with medical as compared with early surgical abortion, that difference

Copyright© American College of Obstetricians and Gynecologists
GBP-PET00201

is likely 1 per 100,000 with medical abortion[31] and 1 per million with early surgical abortion.[32] For perspective, the mortality risk with a term delivery is 1 per 10,000.[33] The risk of death is small regardless of pregnancy outcome, but the experience of each process for the woman is vastly different. The current study shows that women can use regimens with vaginal misoprostol without any time delay between medications with efficacy that is similar to those with a delay. Studies with a 6–8 hour interval demonstrate fewer adverse effects than those with a 24-hour interval. For women, what is the relative value of all of these differences? Would women prefer a vaginal route with fewer adverse effects or the ability to have their abortion completed sooner? Are changes in mortality from very, very rare to very, very, very rare more relevant to a woman than significant decreases in adverse effects or timing issues? These are questions we need to understand better to provide the best options for women.

Correspondence: M Endler, Division of Obstetrics and Gynaecology, Department of Womens' and Children's Health, Karolinska Institutet, Tomtebodagatan 18A, 117 77 Stockholm, Sweden. Email: margit.endler@ki.se

Accepted 4 November 2018. Published Online 28 December 2018.

Objective To assess the safety and acceptability of abortion through telemedicine at $>9^{+0}$ weeks of gestation.

Design Cohort study.

Setting Poland.

Population Six hundred and fifteen women who requested and underwent a abortion through telemedicine from 1 June to 31 December 2016.

Methods Risks of adverse outcomes were calculated as adjusted odds ratios (aORs) with 95% confidence intervals (95% CIs) by unconditional logistic regression according to gestational age at abortion: ≤9 or >9 weeks of gestation.

Main outcome measures Self-reported clinical visits for complaints related to the abortion within 0–1 days of the treatment, heavy bleeding, pain or bleeding more than expected, and low satisfaction.

Results Among women undergoing a abortion at ≤9 or >9 weeks of gestation, 3.3 versus 11.7% went to hospital with concerns within 0–1 days of the termination (aOR 3.82, 95% CI 1.90–7.69). Among women undergoing a abortion from 11^{+1} to 14^{+2} weeks of gestation, the rate was 22.5% (aOR 9.20, 95% CI 3.58–23.60). Among women undergoing a abortion at ≤9 or >9 weeks of gestation, the rate of heavy bleeding was 6.8 versus 10.1% (aOR 1.65, 95% CI 0.90–3.04), the rate of low satisfaction was 2.4 versus 1.6% (aOR 0.69, 95% CI 0.14–3.36), the rate of bleeding more than expected was 45.6 versus 57.8% (aOR 1.26, 95% CI 0.78–2.02), and the rate of pain more than expected was 35.6 versus 38.8% (aOR 1.11, 95% CI 0.71–1.71).

Conclusions Medical abortion through telemedicine at >9 weeks of gestation is associated with a higher risk of same-day or day-after clinical visits for concerns related to the procedure, and this risk increases with gestational age. Self-reported rates of heavy bleeding, low satisfaction, or unmet expectations with medical abortion do not increase with gestational age.

Keywords Medical abortion, post-abortion care, safe and unsafe abortion, telemedicine.

Tweetable abstract A cohort study shows that abortion through telemedicine at >9 weeks of gestation is associated with more hospital visits but not with increased bleeding.

Introduction

Twenty-five million unsafe abortion and 43 000 termination-related maternal deaths are estimated to occur each year, predominantly in countries with restrictive abortion laws.[1,2] To investigate alternative options for providing abortion care is a stated research priority by the World Health Organization (WHO), in an effort to expand global access to safe abortion.[3]

Today, telemedicine abortion services bridge the lack of access to safe abortion in many countries. The abortion law in Poland is estimated to prohibit the termination of unwanted pregnancies in 97% of cases, allowing the procedure only in case of severe danger to the life of the woman or fetus, or if the pregnancy results from a criminal act, such as rape or incest.[4,5] Conscientious objection is constitutionally sanctioned, and the Polish parliament is now considering further restrictions to the legal access of abortion.[6] Many

© 2018 Royal College of Obstetricians and Gynaecologists

women in Poland wanting an abortion use the telemedicine service Women on Web (WoW), which provides online consultation and guidance and abortion medication by post.[7]

The gestational age limit for outpatient (at-home) self-administration of Misoprostol recommended by the WHO is 9 weeks of gestation, and this limit is adhered to in many countries.[8] The Food and Drug Administration (FDA) in the USA increased this limit to 10 weeks of gestation in 2016.[9] Home medical abortion and post-abortion evaluation up to 9 weeks of gestation, through regular (non-telemedicine) abortion clinics, have been shown to be non-inferior to in-hospital abortion, and are well tolerated.[10–12] Several studies have also indicated that medical abortion through telemedicine, up to 9 weeks of gestation, is safe and well tolerated in settings with an established healthcare infrastructure.[13–15] Outcomes after abortion through telemedicine after 9 weeks of gestation are, however, much less documented in published research.

The aim of this study was thus to assess whether medical abortion through telemedicine performed after 9 weeks of gestation is comparable, in terms of safety and acceptability for women, with abortion performed at or before 9 weeks of gestation.

Methods

We performed a retrospective cohort study investigating self-reported adverse outcomes among all women having requested a abortion through the telemedicine service WoW in Poland from 1 June to 31 December 2016. We included all women who were approved for home abortion with Mifepristone and Misoprostol, who received the medication by post, who confirmed taking the medication, and who provided follow-up through the online questionnaire or by email communication.

Women access the WoW telemedicine service and make a request for a abortion through the website www.womenonweb.org. They fill in an online questionnaire, where they self-report their obstetric history and gestational age, which is assessed by a physician at WoW. Routinely the gestational age limit to be eligible for a abortion through the service is 70 days of gestation at consultation. If no contraindications to home abortion exist, medical abortion treatment according to WHO recommendations (200 mg of mifepristone orally followed by 800 + 400 + 400 micrograms of the prostaglandin misoprostol to be administered sublingually, 1–2 days later) are sent by post to the woman's requested address.[8] If a woman is approaching 9 weeks of gestation, an additional four misoprostol tablets (200 μg each) are sent. The service and medication are donated for free if women are unable to make a donation. Online 24-hour support is available to women during and after the abortion by helpdesk staff trained in guidance for abortion. Five weeks after the medication is sent, the service sends a follow-up evaluation form by email including questions about symptoms during and after the abortion, complications of the abortion, in-hospital interventions, and experience of the abortion. Answers in the follow-up form are categorical. Women specify whether they took their medication 'less than 1 week after the package arrived' or 'more than 1 week after the package arrived'. If they went to hospital they specify 'yes, because I wanted to have an ultrasound like I was advised' or 'yes, because I had complaints and was worried I might have a complication'. If they had complaints they may specify: 'I was bleeding more than 2 maxi pads each hour for more than 2 hours' or 'I had pain that continued several days after the abortion and did not go away'. WoW send two follow-up evaluation form reminders in the case of non-response. Many women who do not fill in the questionnaire still confirm taking the medication and provide follow-up information through direct email communication.

Comparison groups

We compared women with a gestational age at abortion intake of abortion medication above 63 days of gestation, corresponding to 9 weeks of gestation (exposed group), with women at a gestational age at or below 63 days of gestation ($\leq$9 weeks of gestation, non-exposed group). We calculated the gestational age at intake of abortion medication by summing the gestational days according to the last menstrual period (LMP) reported in the online consultation, days until delivery of the medication, and the number of days until the woman took the medication. If a woman reported taking the medication within 1 week of delivery, we registered the gestational age at intake as that corresponding to the day of delivery. If a woman reported taking the medication later than 1 week after delivery, we registered the gestational age at intake as that corresponding to 7 days after delivery. If the woman specified her intake date through email, we registered the gestational days at intake corresponding to that date, otherwise we registered the gestational day corresponding to the day of delivery. In a subanalysis of the association between gestational age and emergency hospital visits, we stratified gestational age in the higher gestational age group into the span from 9^{+1} to 11^{+0} weeks of gestation and from 11^{+1} to 14^{+2} weeks of gestation.

Outcomes

The primary outcomes related to safety were heavy bleeding and a hospital or clinic visit for a concern related to the abortion within 0–1 days of the termination. Both these outcomes aimed to identify acute complaints related to the abortion. The outcome of heavy bleeding was registered if a woman reported in the follow-up evaluation form that 'I was bleeding more than 2 maxi pads each hour for more than 2 hours' during the abortion, or if she reported in her

© 2018 Royal College of Obstetricians and Gynaecologists

email communication heavy bleeding requiring a clinical assessment at any moment during the process of abortion.

The outcome 'clinical visit for a complaint within 0–1 days of the abortion' was registered if a woman reported, either in the follow-up evaluation form or in email communication, a hospital or clinic visit on the same day or on the day after taking the misoprostol, and also reported one of the following outcomes in the evaluation form: that she visited a hospital 'because I had concerns that I might have a complication', that she had heavy bleeding as defined above, or that she had pain 'that continued several days after the abortion and did not go away'. We stipulated that most clinical visits occurring in the immediate days following the termination would take place because of acute complaints related to the abortion (i.e. that most women would not seek medical attention immediately, unless they had symptoms that they believed required clinical attention). We added the presence of a suspected complication, heavy bleeding, and/or pain to this outcome in order to exclude the few anticipated cases where women went to a clinic within this time frame without symptoms.

The primary outcomes related to acceptability were unmet expectations for the experience of abortion and low satisfaction with the procedure. Unmet expectations in relation to pain were defined as an answer of 'more than expected' or 'much more than expected' to the question 'How much pain did you have?' Unmet expectations in relation to bleeding were defined as an answer of 'no, it was more than expected' or 'no, it was much more than expected' to the question 'Was the bleeding after taking the medication as expected?' Dissatisfaction with the abortion procedure was defined as an answer of 'no, I was dissatisfied' or 'no, I was very dissatisfied' to the question 'Was medical abortion an appropriate method for you?'

Secondary outcomes were surgical evacuation after abortion (dilatation and curettage or vacuum aspiration), and any medical intervention after the abortion in the form of surgical evacuation, blood or fluid transfusion, additional misoprostol treatment, or antibiotic treatment.

Confounding factors

Confounding factors adjusted for in the regression analysis were the woman's age at consultation and payment of a donation for the clinical service, which was used as proxy for financial status. Age and financial status may influence both the gestational age at which a woman requests a abortion and her self-reported symptoms and experience of the termination process.[16]

Data relating to exposures, outcomes, and confounding variables were recorded from the WoW pre-abortion consultation form, post-abortion follow-up evaluation form, and in email communication recorded in the patient records. If no answer was provided or an unintelligible answer was provided in relation to the outcomes, the variable was registered as missing. In the case of contradictory responses relating to the outcomes of whether, when, and why a women visited hospital after the abortion, an assessment was made of the written communication to the clinic or extra comments were made in the free-text portion of the questionnaire, to see if the correct answer could be ascertained.

Core outcomes sets, patient involvement, and study funding

Core outcome sets for medical abortion are yet to be formulated, so our study outcomes adhere to the overall aim of assessing the safety, effectiveness, and acceptability of medical abortion.[17] The study question was formulated based on the clinical demands of the telemedicine service, but the study did not have any direct public or patient involvement. It was funded by grants from the Swedish Research Council and the Karolinska Institutet.

Statistical analysis

Medians and ranges for non-normally distributed data and rates and associated risks were calculated group-wise for each gestational age group. Comparisons of medians between groups were performed using an independent-samples median test for non-normally distributed data. Odds ratios were calculated using unconditional regression analysis. The null hypothesis was rejected where $P < 0.05$. Statistical analysis was carried out using IBM SPSS Statistics for Windows, Version 23.0. (IBM Corp., Armonk, New York, NY, USA). The sample size was established in order to be able to show, with 80% power and a 95% confidence level, a doubling in the rate of our primary safety outcomes after abortion at ≤9 or >9 weeks of gestation, and with an expected baseline incidence of heavy bleeding and clinical visits for complaints related to the procedure within 0–1 days of 5% for abortion performed ≤9 weeks of gestation, and with a presumed loss to follow-up of 30%.

In order to address the uncertainty in the data regarding gestational age at intake of medication, we performed a sensitivity analysis where gestational age was increased by 7 days for all participants. This analysis allowed for the fact that women who reported taking the medicine 'within 1 week' of delivery of the medication could have taken the tablets after 7 days (and not at the day of delivery, as assumed in our main analysis), and that women who reported their intake 'after 1 week' could have taken the tablets 2 weeks after delivery (i.e. 7 days later than what is assumed in our main analysis).

Results

During the study period, 1220 women in Poland requested a medical abortion through WoW. All were approved for

© 2018 Royal College of Obstetricians and Gynaecologists

medical abortion and sent medication. The medication was not used by 166 women (13.6%). Intake was unconfirmed for 427 (35%) women who provided no follow-up information and were defined as lost to follow-up (LTFU). Twelve women confirmed intake through communication with the service but provided no follow-up with regards to the primary outcomes of interest. The main analysis consisted of 615 women who confirmed their intake and provided information for one or more of our primary outcomes, either in the follow-up evaluation (n = 419) or through email communication (n = 196). A study flowchart specifying the reasons for non-intake is shown in Figure 1.

The median age at first consultation for women who performed a abortion was 28 years (range 16–56 years) and 26 years (range 16–45 years) among women at ≤9 or >9 weeks of gestation, respectively (P = 0.13). The median gestational age at first consultation was 37 days of gestation (range 13–53 days of gestation) and 49 days of gestation (range 23–79 days of gestation) for women at ≤9 or >9 weeks of gestation, respectively (P < 0.001). At the time of intake of medication, 25.7% were at ≤7 weeks of gestation, 43.7% were between 7^{+1} and 9^{+0} weeks of gestation, 24.1% were between 9^{+1} and 11^{+0} weeks of gestation, and 6.5% were between 11^{+1} and 14^{+2} weeks of gestation. Among women at ≤9 or >9 weeks of gestation, 2.1 and 4.8%, respectively, did not make a donation to the clinic (OR 2.34, 95% CI 0.91–5.98). Background variables are summarised in Table 1.

Three women at ≤9 weeks of gestation (0.7%) and two women at >9 weeks of gestation (1.1%) had a viable or suspected viable pregnancy after the intake of medication (OR 1.57, 95% CI 0.26–9.52). Rates and associated risks of continuing pregnancy, symptoms during the abortion, medical interventions, and reason and timing of clinical visits during or after the abortion are presented in Table S1.

Fourteen out of 427 women at ≤9 weeks of gestation (3.3%) and 22 out of 188 women at >9 weeks of gestation (11.7%) went to hospital or clinic on the first or second day of the abortion for concerns related to the termination (aOR 3.82, 95% CI 1.90–7.69). In a stratified analysis this correlated to 8.8% of women between 9^{+1} and 11^{+0} weeks of gestation (aOR 2.76, 95% CI 3.94–23.57) and 22.5% of women between 11^{+1} and 14^{+2} weeks of gestation (aOR 9.20, 95% CI 3.58–23.60). The incidence of self-reported heavy bleeding at any point during the termination process was 6.8% among women at ≤9 weeks of gestation and 10.1% among women at >9 weeks of gestation (aOR 1.65, 95% CI 0.90–3.04). Among these women, none at ≤9 weeks of gestation and one at >9 weeks of gestation received a blood transfusion. One woman at >9 weeks of gestation received a blood transfusion but reported no heavy bleeding.

Extra medical treatment in the form of either surgical evacuation, antibiotic or misoprostol treatment, fluid or blood transfusion at any moment after the abortion was reported by 18.3 and 29.0% of women at ≤9 and >9 weeks of gestation respectively (aOR 1.84, 95% CI 1.13–3.00). The incidence of surgical evacuation alone was 12.5% among women at ≤9 weeks of gestation and 22.6% among women at >9 weeks of gestation (aOR 2.04, 95% CI 1.18–3.32). Forty-eight out of the 65 women (73.8%) who underwent surgical evacuation reported no heavy bleeding after the abortion, and 39 (60%) reported neither heavy nor prolonged bleeding.

Incidence rates and associated risks for primary and secondary outcomes related to safety and acceptability are presented in Tables 2 and 3.

Low or very low satisfaction with the procedure was reported by 2.4% of women at ≤9 weeks of gestation and by 1.6% of women at >9 weeks of gestation (aOR 0.69, 95% CI 0.14–3.36). Among women at ≤9 weeks of gestation and >9 weeks of gestation, 45.6 and 57.8%, respectively, reported that the blood loss was more than expected (aOR 1.26, 95% CI 0.78–2.02), and 35.6 and 38.8%, respectively, reported the pain to be more than expected (aOR 1.11, 95% CI 0.71–1.71). Incidence rates and associated risks for outcomes related to patient acceptability are presented in Table 2.

Women LTFU were of similar median age at first consultation (29 versus 27 years, P = 0.08), median gestational age at first consultation (40 versus 39 years, P = 0.61), and median gestational age at delivery of medication (57 versus 56 days, P = 0.37), compared with women who confirmed their intake of medication. They were, however, more likely to have been at >9 weeks of gestation at first consultation (OR 1.34, 95% CI 1.02–1.74), and were more likely not to have paid the service fee (OR 2.54, 95% CI 1.44–4.49). The sensitivity analysis of women LTFU is available in Table S2.

In the sensitivity analysis where we assumed the intake of abortion medication 1 week later than the assumed intake in the main analysis, 135 women were re-categorized from ≤9 to >9 weeks of gestation. Among women at ≤9 or >9 weeks of gestation in this analysis, 5.8 and 9.6%, respectively, reported heavy bleeding (aOR 1.80, 95% CI 0.95–3.43), and 1.4 and 9.9%, respectively, reported clinical visits for complaints within 0–1 days (aOR 3.91, 95% CI 1.65–9.25). Sensitivity analysis addressing the uncertainty of gestational age is available in Table S3.

Discussion

Main findings

In this study, medical abortion through telemedicine at >9 weeks of gestation compared with ≤9 weeks of gestation

© 2018 Royal College of Obstetricians and Gynaecologists

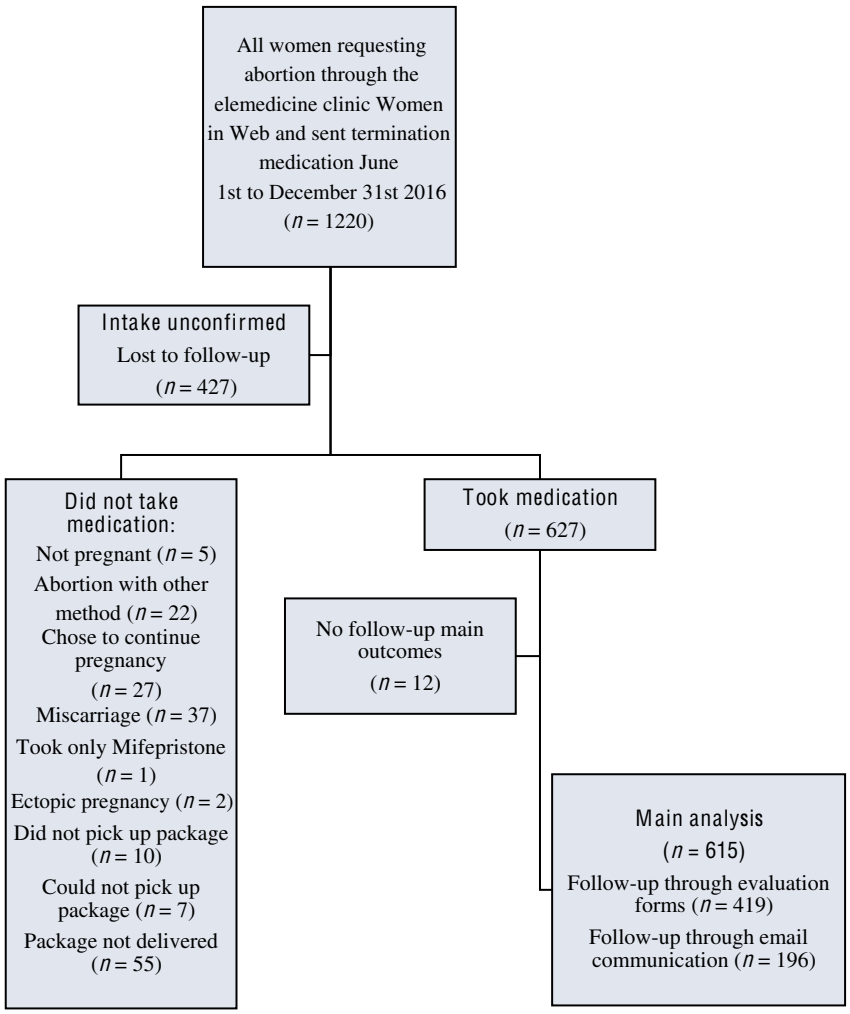

Figure 1. Flowchart of the inclusion of women to the study based on 1220 women requesting a abortion through telemedicine and sent termination medication from 1 June to 31 December 2016.

was associated with an increased rate of immediate clinical visits for concerns related to the termination procedure, and this rate increased with increasing gestational age. The rate of reported heavy bleeding was not increased but both the rate of surgical evacuation and the rate of other medical treatments during or after the abortion were increased among women at >9 weeks of gestation. Satisfaction levels and rates of met expectations were similar across gestational age groups.

Strengths and limitations

Women reported the timing of the abortion as either within or after a week of receiving their medication, and this was assumed to correspond to intake on the day of medication delivery or 1 week after delivery, respectively, so the gestational age at abortion in this study is the minimum gestational age at which the abortion could have been initiated. Theoretically, gestational age-specific adverse outcomes may therefore be overestimated and some women in the lower gestational group may be misclassified, which might underestimate the relative differences between groups. In the sensitivity analysis addressing this bias, however, the risks and significance level of heavy bleeding and hospital visits within 0–1 days for a complaint, associated with a gestational age of >9 weeks, were similar to those seen in the main analysis. The LTFU rate was high but was in line with previous studies on abortion, and was lower than other studies on abortion through telemedicine.[15,18–20] Women LTFU were more likely to be at >9 weeks of gestation at consultation and were more likely not to have made a donation to the clinic. Overall this may indicate lower financial means but also a lower likelihood of actual intake. The LTFU rate was slightly higher (35%) than what we had stipulated for our power calculation (30%), so it is possible that a larger sample would have shown significant differences in some outcomes. Symptoms were self-reported,

which may not be representative of a clinical assessment. Data were extracted from standardised evaluation forms, however. The outcome data extracted from email communication was restricted to reported hospital visits for specific symptoms. The level or direction of subjectivity is therefore not expected to vary between groups, making relative comparisons valid.

The data upon which this study is based represent a patient population outside the formal health sector, for which there is otherwise little access to quantitative data. The data were collected prospectively, which reduces the risk of investigator bias.

Interpretation

In this study women at >9 weeks of gestation had an almost four-fold increased risk of clinical visits within 0–1 days of the abortion for a concern related to the termination, compared with women at ≤9 weeks of gestation. The rate of these immediate clinical visits increased with increasing gestational age, and increased nine-fold at >11 weeks of gestation compared with ≤9 weeks of gestation. The rate of heavy bleeding, strong and prolonged pain during the abortion, experiencing pain or bleeding more than expected, symptoms that may be expected to account for most emergency consultations, were however not significantly increased among women at >9 weeks of gestation. Some studies on abortion indicate that both blood loss and pain during medical abortion increase with gestational age at abortion up to 9 weeks of gestation,[21] even to the extent that it affects the acceptability to women,[22] but other studies have not supported this.[23,24] Although it is not possible to assess the clinical validity of the woman's decision to seek hospital care, it can be assumed that she herself found that her symptoms warranted assessment. It is possible that women at >9 weeks of gestation went to the hospital more readily because they assumed that their gestational age put them at higher risk of complications and wanted to pre-empt these. Although the categorical survey data show that there was no greater reporting of heavy bleeding amongst women at >9 weeks of gestation, it is possible that women at >9 weeks of gestation were more likely to have symptoms towards the extremes of heavy bleeding and pain, which mandated hospital assessment. Another possible explanation is that more women at >9 weeks of gestation, particularly those approaching 12 weeks of gestation, would have needed additional doses of misoprostol in order to complete the abortion at home. WoW routinely send four extra misoprostol tablets if a woman is at >9 weeks of gestation (i.e. 800 + 400 + 400 micrograms of misoprostol), but the service cannot always predict who will be at this gestational age at the time of the abortion. It may take into consideration whether additional online support might benefit women at higher gestational ages. Women in both gestational age groups reported a high rate of unexpected pain, which indicates that the information about what symptoms to expect during the abortion, as well as specific recommendations for pain relief, may need to be amended in the clinical guidance information provided.

[i]Vacuum aspiration or dilatation and curettage after abortion.
[j]Antibiotic or misoprostol treatment, fluid or blood transfusion, vacuum aspiration, or dilatation and curettage.

Despite an increased rate of clinical visits within the first 2 days, the satisfaction rate with the abortion procedure was 95.2% among women at >9 weeks of gestation, compared with 97.9% among women at ≤9 weeks of gestation. The high satisfaction rates suggest that it is unlikely that women in either gestational group experienced their physical or mental health to be in jeopardy.

Women at >9 weeks of gestation had a higher risk of medical treatment or interventions during or after the abortion, mainly with an increased rate of surgical evacuation. The increasing rate of surgical evacuation with gestational age at abortion is supported by previous studies.[15,20,25] Complete abortion without intervention has, however, been estimated to occur in 94.5–97.0% of medical abortion in the first trimester, which means that the rate of surgical evacuation in both gestational groups was higher than the expected.[26–30] Most women in this study who underwent surgical evacuation reported neither heavy nor prolonged bleeding. The rates of surgical evacuation found are in line with previous studies on telemedicine abortion in Poland, but are higher than reported in a recent study on telemedicine abortion in Australia.[18,19,31] It is possible

therefore that the high rates found in this and in previous studies reflect either clinical practice in the assessment of 'miscarriage' in Poland or existing financial incentives to performing surgical procedures, rather than clinical indications. This is supported by the comparatively low rate of post-abortion additional misoprostol treatment, which is an efficient and non-invasive treatment for incomplete abortion.[32] The rate of continuing pregnancy was similar between groups and is in line with previous studies.[33] A larger sample size would be expected to show an increasing rate of continuing pregnancy with increasing gestational age at abortion.

Our results are probably generalizable to study populations in similar socio-economic settings. A lack of access to safe abortion continues to be a major health impediment for women globally as a result of questions of legality, stigma, or infrastructural constraints.[1,2,34] Establishing whether medical abortion through telemedicine can be performed at gestational ages of >9 weeks, without risking safety and acceptability standards, is a step towards expanding this alternative model of abortion care to women who are otherwise at high risk of the consequences of unsafe abortion.

Conclusion

Medical abortion through telemedicine at >9 weeks of gestation is associated with a higher rate of clinical visits for complaints related to the termination procedure in the immediate days following the abortion, compared with abortion at ≤9 weeks of gestation. It is associated with an increased risk of post-abortion treatment and intervention, but not with a lower rate of satisfaction or unmet expectations. Abortion through telemedicine seems to be safe and acceptable to women at >9 weeks of gestation, but may necessitate adjustments to misoprostol doses, online information, and support.

Disclosure of interests

RG is the founder and current director of Women on Web, the source for the participant data in the study. Otherwise, all authors report no support from any organisation for the submitted work, no financial relationships with any organisations that might have an interest in the submitted work in the previous 3 years, and no other relationships or activities that could appear to have influenced the submitted work. Completed disclosure of interests form available to view online as supporting information.

Contribution to authorship

RG had the original idea for the study. ME designed the study, performed the main analysis, wrote the first and final draft of the manuscript, and is the guarantor for the article. LB contributed substantially to the literature review and data analysis. RG and KGD contributed to the study design and interpretation of the results. KGD, RG, and LB contributed to manuscript revision.

Details of ethics approval

Women gave permission in their initial consultation for their anonymised data to be used for statistical and research purposes. Ethical permission for the study was granted through a broad ethics approval for studies on WoW data granted by the Local Ethics Committee at Karolinska Institutet, Stockholm, Sweden, on 27 January 2010 (dnr 2009/2072-31/2).

Telemedicine: are we still falling short?

A Lavelanet

Department of Reproductive Health and Research and UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), World Health Organization, Geneva, Switzerland

Linked article This is a mini commentary on M Endler et al., pp. 609–618 in this issue. To view this article visit https://doi.org/10.1111/1471-0528.15553

Published Online 8 February 2019.

Telemedicine has transformed the way in which healthcare services are delivered. Telemedicine can connect multiple remote sites, reducing both direct and indirect costs for individuals, and serving as an asset for burdened or under-resourced health systems. Through telemedicine, inequities related to the geographical distribution of medical services are reduced, thereby improving access to communities that are traditionally underserved (World Health Organization. Telemedicine: opportunities and developments in Member States: report on the second global survey on eHealth, 2009). These benefits are magnified for abortion services, where access can be more difficult because of stigma and fear of persecution, especially in restricted settings.

Endler et al. assess the safety and acceptability of medical abortion provided through telemedicine beyond 9 weeks of gestation (Endler et al. *BJOG* 2019;126:609–18). The work of Endler et al. is important, especially as telemedicine for later gestational ages is being employed. Their results confirm what other studies show: abortion the late first trimester is safe (Kapp et al. *Contraception* 2018;https://doi.org/10.1016/j.contraception.2018.11.002).

Some of the author's conclusions warrant further discussion, however. Women with pregnancies of 9 weeks of gestation or longer have a higher rate of hospital visits for concerns related to the abortion, leading to an increased risk of post-abortion treatment and intervention. Women still find the procedure acceptable, which includes satisfaction with the procedure and whether expectations related to the experience are met. The authors correctly highlight that acceptability is about so much more than whether medical abortion is the right choice of method, but greater discussion could have been afforded to the acceptability of telemedicine itself and how telemedicine can better facilitate managing women's expectations as they go through the process of abortion. The authors state that information about what symptoms to expect during the abortion, at least in relation to pain and specific recommendations for pain relief, may need to be overseen in the clinical guidance information provided. This acknowledgment by the authors highlights that medical abortion provided through telemedicine is perhaps still falling short on managing women's expectations.

Dawson et al. (*BMC Health Serv Res* 2016;16:612) include acceptability as an important component of accessing comprehensive abortion services. Questions as to whether the information, explanation, and services provided accommodate social norms and values, and whether women find self-management easy to use, are important to assess. A qualitative evidence synthesis review by Wainwright et al, including research from legal and legally restricted contexts, demonstrates that women self-managing their abortion appreciate counselling that prepares them for variability in personal experiences. Women need pragmatic information related to managing expulsion at home (Wainwright et al. *Reproductive Health Matters* 2016;24:155–67). Increased opportunities for partners to be involved (where desired) are seen as a benefit to alleviate partner concerns related to pain or bleeding (Wainwright et al. *Reproductive Health Matters* 2016;24:155–67). Yet, although access to such counselling improved confidence and acceptability, anxieties related to managing complications persist.

Thus, as Endler et al. note, additional information and support may be needed by women, but it appears that greater guidance is still needed to those providing abortion services through telemedicine on how best to do this. Time and resources should be directed into collecting data related to how well we are responding to the needs of these women in order to maximise the benefits of telemedicine.

Founded in 1976, the **Ethics and Public Policy Center** is Washington, D.C.'s premier institute working to apply the riches of the Jewish and Christian traditions to contemporary questions of law, culture, and politics, in pursuit of America's continued civic and cultural renewal.

In pursuit of our mission, we work closely with Americans at all tiers of society, advising policymakers and religious leaders alike, engaging the courts and the education system, and working closely with parents and other culture-makers to apply the truth in daily life. We equip Americans who cherish our founding ideals and our nation's rich Jewish and Christian heritage to think through the ethical, political, and cultural questions facing them in the twenty-first century, and find the help they need to live those truths out.

We are focused on the following priorities:

Pushing back against the extreme progressive agenda while building a consensus for conservatives.

Shaping the future of Jewish and Christian public witness for all who seek to lead full lives as faithful believers and engaged citizens.

Developing a humane conservatism and advancing economic policies that serve working families rather than

elites and Big Tech oligarchs.

Supporting culture makers and assisting families in living out their faith in their homes and in the public square.

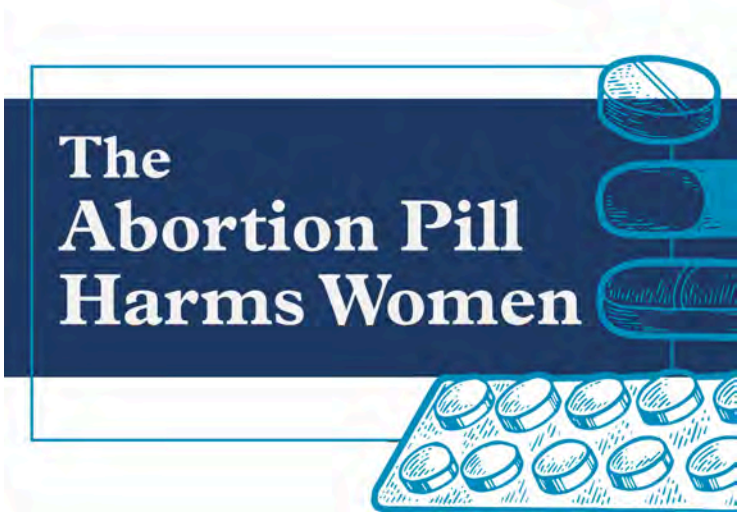
Life and Family Initiative

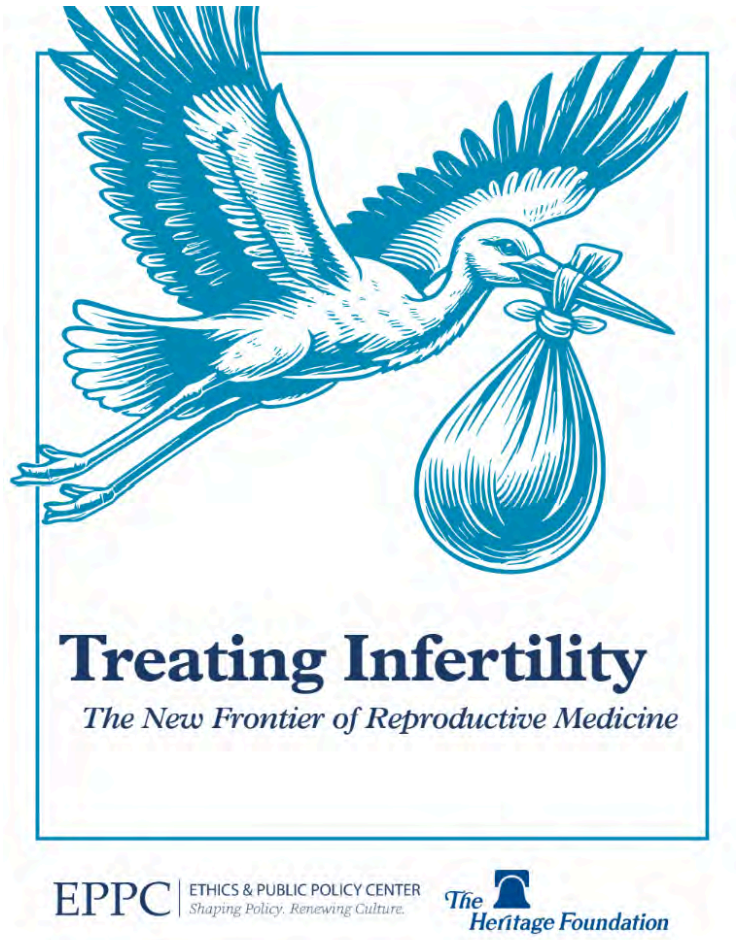


EPPC is committed both to ensuring the equal protection of unborn children in the law and to providing concrete support to families by advancing a pro-life, pro-family agenda that takes our duties in justice to the unborn and to families seriously.

Recognizing the duties of care owed by parents to their dependent children, and the rights those duties engender, we seek to order society toward the full flourishing of human beings by properly protecting both. A full account of reproductive justice must embrace the inherent dignity and value of each human being by giving pregnant women and caregiving families the societal support they deserve and require. It must also ask of expectant mothers that they offer their developing unborn children due care, and of fathers that they take up their shared duties of care toward both mother and child. And it must prevent abortionists from performing acts of lethal violence to vulnerable and dependent human beings.

EPPC's Life and Family Initiative brings together the longstanding pro-life efforts of many EPPC scholars—including Mary FioRito, Erika Bachiochi, Patrick T. Brown, Alexandra DeSanctis, and Nathanael Blake —and coordinates with our existing programs on HHS Accountability, Bioethics and American Democracy, The Constitution, the Courts, and the Culture, Catholic Studies, and Evangelicals in Civic Life to create an integrated, holistic response addressing both the necessary protections for unborn children and the necessary support for pregnant mothers and their families.

The Life and Family Initiative works nationwide to advance pro-life policies that protect unborn children by restricting abortion at the state and federal levels, via legislation, regulation, and litigation. We continue to advance cultural remedies and propose robust public policies that support families and offer necessary aid to women facing unexpected pregnancies. The Initiative builds on the heroic and critical work that maternity homes, pregnancy resource centers, and countless volunteers have carried out for more than fifty years. Strong families and communities are essential building blocks of a healthy society, and economic policy must keep that point front and center.



Building an authentic culture of life will require an energetic agenda to support mothers and children, to more fully engage fathers, and to call upon society at large to promote justice and the common good.

LIFE AND FAMILY INITIATIVE

5 Things to Know About In Vitro Fertilization (IVF)

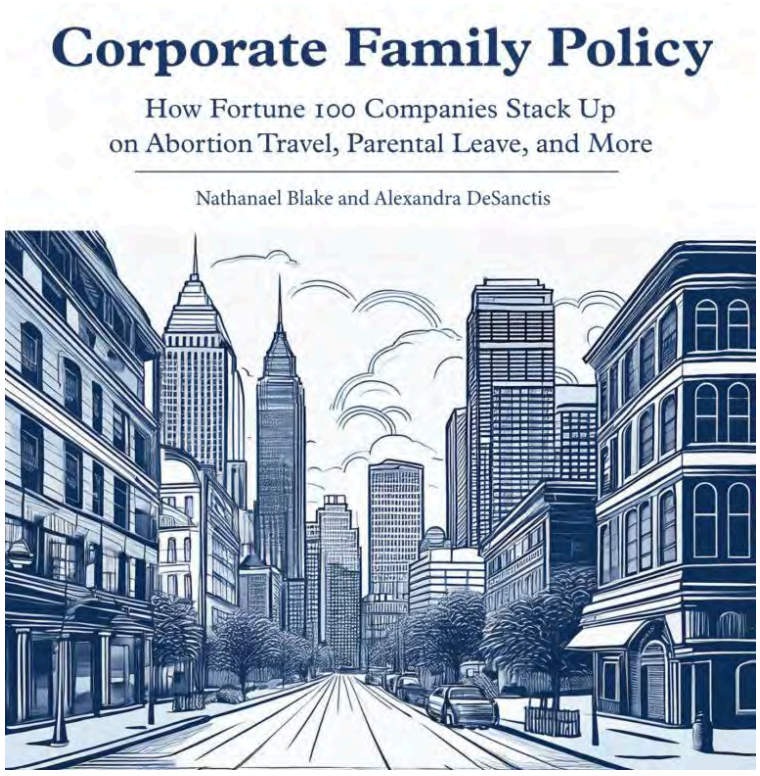
Patrick Brown, Ethics and Public Policy Center

ETHICS AND PUBLIC POLICY CENTER
Shaping Policy. Renewing Culture.

1 *Myth: Expanding public funding for IVF will boost birth rates*
Fact: Virtually no nation that has publicly subsidized IVF has seen a subsequent increase in birth rates
Countries like Japan, Hungary, and Australia have implemented public IVF funding, yet their overall fertility rates have continued to decline. This is partly because IVF gives some couples a false sense of security, leading them to delay trying to get pregnant, yet IVF success falls rapidly after age 35. The main exception is Israel, which compliments IVF funding with a broadly pro-family culture and generous spending on child benefits.

2 *Myth: Expanding public funding for IVF is uncontroversial*
Fact: The U.S.' light-touch regulations around assisted reproduction raises questions about patient safety and bioethics concerns
The U.S. has some of the fewest restrictions around IVF in the world; the last major regulation was passed in 1992, and most nations require much higher standards of patient care from fertility clinics. Additionally, the U.S. permits practices, such as eugenic embryo screening and sex selection, which raise serious concerns and are impermissible in many other countries.

3 *Myth: Expanding public funding for IVF is inexpensive*
Fact: Depending on the way it's implemented, expanding public subsidy for IVF could lead to higher health care costs or raise federal expenditures
The average cost of an IVF cycle is around $15,000, and many need more than one cycle to successfully become pregnant. If insurers are required to cover this cost without co-payments for all who want it, it will lead to a perceptible increase in health insurance premiums for workers and families. If the federal government were to assume those costs, the fiscal impact would be at least $80 billion over a ten-year budget window.



4 *Myth: Expanding public funding for IVF is the best way to help couples with infertility*
Fact: Many couples have higher success with restorative reproductive health approaches, such as those championed by the MAHA movement
Many couples struggling with infertility achieve better outcomes through restorative reproductive medicine, such as NaProTechnology or hormonal therapies. This fits the Make America Healthy Again agenda, which emphasizes holistic solutions and long-term well-being over high-intervention treatments. And while the IRS does currently limit tax-deductibility of IVF expenses to married couples, many fertility clinics apply the concept of "social infertility" to provide IVF services to single parents or third-parties.

5 *Myth: Expanding public funding for IVF is a political winner*
Fact: While polls do show helping couples face fertility is broadly popular, most polls do not put that top-line support in context
Polls tend to show broad support for IVF in theory, but few have polled the question against a backdrop of ethical concerns or higher costs. Polling for public benefits often falls when voters are informed about the impact it will have on their cost of living. Additionally, despite the attempts to attack President Trump over the politics of reproduction into an albatross in 2024, very few polls suggest his discussion of IVF costs were a top issue for many voters.

Protecting the Unborn:
A Scholars' Statement of Pro-Life Principle and Political Prudence

Lawmakers around the nation are deciding how to respond to the reversal of *Roe v. Wade*. As pro-life scholars, we believe that a truly just society would meet the myriad needs of pregnant women while legally protecting their unborn children at every stage.

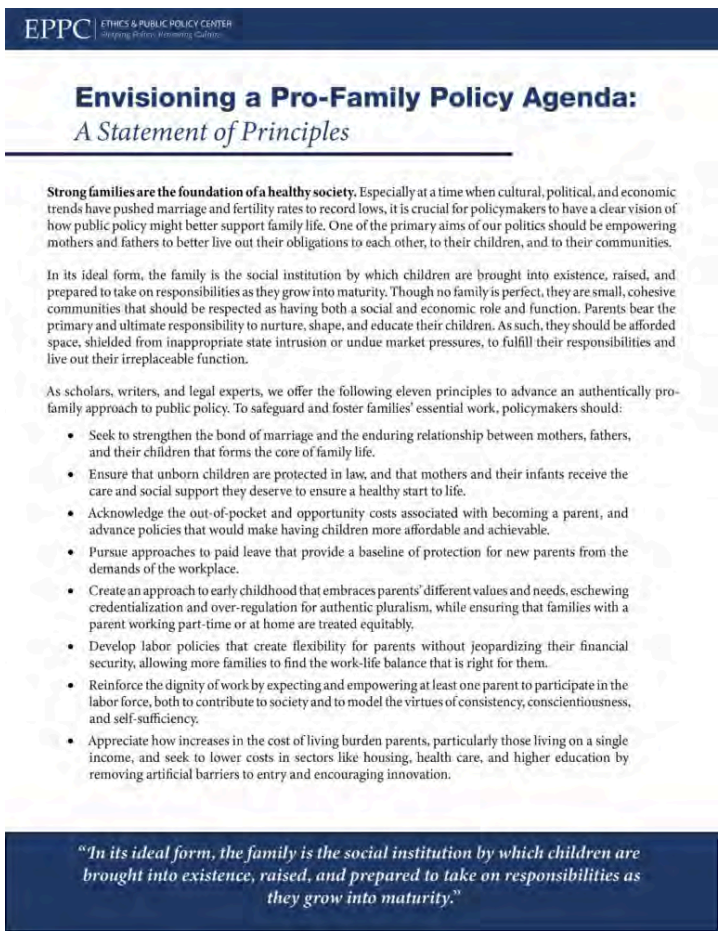
We write to advance two propositions, the first of pro-life principle, the second of political prudence. First, the principle: Just as justice requires us to protect all unborn children, so too does it require us to protect access to life-affirming medical treatment for pregnant women facing grave medical complications. This is part of the pro-life ideal, not an exception to it. Ensuring access to such treatments is morally right and consistent with giving both mothers and unborn children the same protections accorded to others.

Second, the prudential: While children at all stages of development ought to enjoy the law's protections, political realities may make it impossible to achieve this fully and immediately in many jurisdictions. When that is so, enacting the most pro-life law realistically possible is justified. We should not allow the perfect to be the enemy of the good where the perfect is not currently feasible, but a law better than the legal status quo is achievable. Even as citizens and lawmakers may accept less-than-ideal laws on abortion, we must always make clear that the ultimate goal toward which we steadily work is to protect every human being in law and life.

I. A Statement of Principle: Enforcing the Child's Right to Life While Honoring the Mother's

Every human being, born or unborn, is the bearer of profound, inherent, and equal worth and dignity. From the moment of a human being's conception, he or she is morally entitled to legal protection from unjust lethal violence. This includes protection from acts in which the developing child's death is not sought for its own sake but seems necessary to bring about some other goal—for instance, to avoid parenting the child in very difficult circumstances. In these cases, the child's death is sadly the chosen means. If the child somehow survives, the procedure will have failed to achieve its end. And choosing an innocent human being's death as a means (*or* end) is unjust.

It is also possible to cause death as a foreseeable though unintended effect of pursuing a goal that is not in any way advanced by the victim's death. All innocent human beings have a right to protection against being killed even as an expected side effect of actions taken *for any but the weightiest reasons*. But when such reasons are present, accepting death as a side effect may be permissible—consistent with the right to life and just to all concerned.



Sometimes an unborn child's death falls in this category. It may be the side effect of treatment to save the mother from a grave medical complication—for example, removal of her cancerous uterus. Because the child's death is not a means to an end, every reasonable effort is made to preserve his or her life if possible, and the procedure is performed in a way that aims to treat his or her body with respect. If the child is not viable, then his or her death is expected, but still is not a means, as it contributes nothing to the mother's survival. (What saves her is, for instance, removal of the cancerous uterus, not the child's subsequent death.) And given the stakes, accepting the child's death is not unjust.

"We believe that a truly just society would meet the myriad needs of pregnant women while legally protecting their unborn children at every stage."

Protecting the Unborn: A Scholars' Statement of Pro-Life Principle and Political Prudence

"Protecting the Unborn: A Scholars' Statement of Pro-Life Principle and Political Prudence," signed by EPPC's Ryan T. Anderson, Erika Bachiochi, Alexandra DeSanctis, Aaron Kheriaty, Carl R. Trueman, Ed Whelan, and George Weigel with a coalition of leading intellectuals, articulates an ethically sound foundation for pro-life efforts and offers guidance for political leaders in prudent decision-making in the post-*Roe* political landscape.

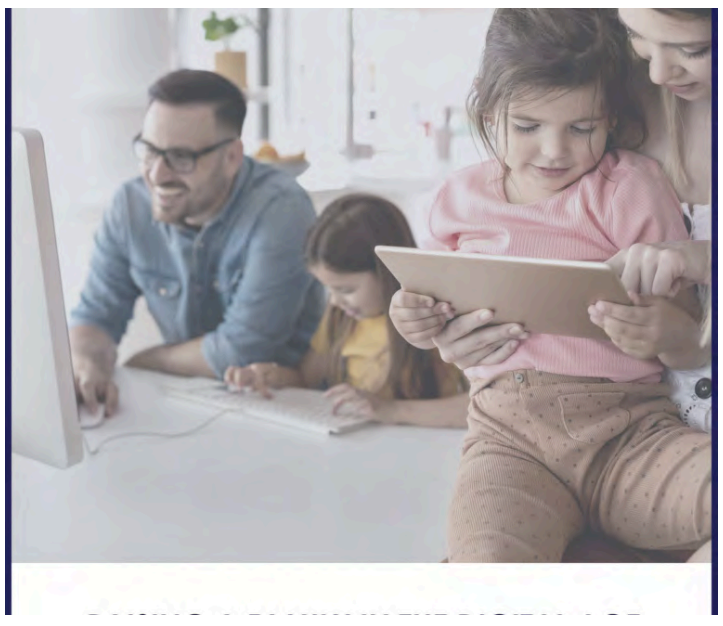
Envisioning a Pro-Family Policy Agenda:
A Statement of Principles

Strong families are the foundation of a healthy society. Especially at a time when cultural, political, and economic trends have pushed marriage and fertility rates to record lows, it is crucial for policymakers to have a clear vision of how public policy might better support family life. One of the primary aims of our politics should be empowering mothers and fathers to better live out their obligations to each other, to their children, and to their communities.

In its ideal form, the family is the social institution by which children are brought into existence, raised, and prepared to take on responsibilities as they grow into maturity. Though no family is perfect, they are small, cohesive communities that should be respected as having both a social and economic role and function. Parents bear the primary and ultimate responsibility to nurture, shape, and educate their children. As such, they should be afforded space, shielded from inappropriate state intrusion or undue market pressures, to fulfill their responsibilities and live out their irreplaceable function.

As scholars, writers, and legal experts, we offer the following eleven principles to advance an authentically pro-family approach to public policy. To safeguard and foster families' essential work, policymakers should:



- Seek to strengthen the bond of marriage and the enduring relationship between mothers, fathers, and their children that forms the core of family life.
- Ensure that unborn children are protected in law, and that mothers and their infants receive the care and social support they deserve to ensure a healthy start to life.
- Acknowledge the out-of-pocket and opportunity costs associated with becoming a parent, and advance policies that would make having children more affordable and achievable.
- Pursue approaches to paid leave that provide a baseline of protection for new parents from the demands of the workplace.
- Create an approach to early childhood that embraces parents' different values and needs, eschewing credentialization and over-regulation for authentic pluralism, while ensuring that families with a parent working part-time or at home are treated equitably.
- Develop labor policies that create flexibility for parents without jeopardizing their financial security, allowing more families to find the work-life balance that is right for them.
- Reinforce the dignity of work by expecting and empowering at least one parent to participate in the labor force, both to contribute to society and to model the virtues of consistency, conscientiousness, and self-sufficiency.
- Appreciate how increases in the cost of living burden parents, particularly those living on a single income, and seek to lower costs in sectors like housing, health care, and higher education by removing artificial barriers to entry and encouraging innovation.

"In its ideal form, the family is the social institution by which children are brought into existence, raised, and prepared to take on responsibilities as they grow into maturity."

Verifying the effectiveness of medical abortion; ultrasound versus hCG testing

Christian Fiala[a,b], Peter Safar[a], Marc Bygdeman[b], Kristina Gemzell-Danielsson[b,*]

[a]Department of Obstetrics and Gynecology, General Public Hospital, Wiener Ring 3-5, 2100 Korneuburg, Austria
[b]Department of Woman and Child Health, Division of Obstetrics and Gynecology, Karolinska Hospital/Institute, S-17176 Stockholm, Sweden

Received 23 August 2002; received in revised form 9 December 2002; accepted 12 December 2002

Abstract

Objectives: The combination of mifepristone and misoprostol is an established method for termination of pregnancy. However, there is no general agreement about how best to evaluate the treatment outcome.

Study design: In 217 women with an unwanted pregnancy below 49 days of amenorrhoea, ultrasound examination and serum hCG test were performed before treatment and at follow-up.

Results: Treatment was successful in 98.2%. At follow-up their hCG dropped to a mean of 3% (S.D. 3) of initial levels and the endometrium measured a mean of 10 mm (S.D. 4). Interpretation of endometrium was difficult in some cases because of inhomogeneous structure. Using hCG was reliable in 98.5% of successful abortions. For ultrasound the corresponding figure was 89.8% for the cases with a confirmed intrauterine pregnancy before treatment but only 66% if all pregnancies were included.

Conclusion: Measuring serum hCG before treatment and at follow-up is more effective than ultrasound to confirm a successful medically induced abortion in early pregnancy.

Keywords: Medical abortion; Mifepristone; hCG; Ultrasound; Verification of expulsion

1. Introduction

Treatment with a combination of mifepristone (Mifegyne®, Exelgyn, France) and the prostaglandin analogue, misoprostol (Cytotec®, Searle AG, USA), both administered orally, has been shown to be a safe, effective method for termination of early pregnancy [1–7]. Medical abortion with mifepristone and misoprostol is licensed for use in about 30 countries including most of Europe, USA, Russia and China.

The method is highly effective up to 49 days of amenorrhoea. The estimation of duration of pregnancy before treatment is therefore of importance and is in most cases based on medical history, gynaecological examination and an ultrasound examination. For the evaluation of the outcome of treatment, complete abortion, incomplete abortion, missed abortion or continuing pregnancy various methods are used. Beside clinical events and a gynaecological examination either measurement of serum hCG or an ultrasound examination is performed at a follow-up visit 1–3 weeks following start of treatment [8,9].

The aim of the present study was to compare the usefulness of hCG measurement and ultrasound examination before and after medical abortion in determining the outcome of treatment.

2. Material and methods

Two-hundred and seventeen women with an unwanted pregnancy up to 49 days of amenorrhoea, requesting medical abortion, were treated between 26 April and 10 November 1999. The treatment was performed on an outpatient basis at a general public hospital in Austria. A vaginal ultrasound (Toshiba Powervision 6000, vaginal probe 7.5 MHz) was performed to confirm pregnancy gestation in all women. A crown-rump length (CRL) of 10 mm was used as upper limit for treatment, consistent with 49 days amenorrhoea [10,11]. Furthermore serum hCG levels were determined in all women. All patients gave an informed consent for the abortion.

doi:10.1016/S0301-2115(03)00012-5

The patients received 600 mg mifepristone orally at the hospital. They returned 48 h later to take 400 μg misoprostol orally once or twice. A second dose of 400 μg misoprostol orally after 3 h was given, according to routine, if bleeding had not started at that time or if bleeding was less than on the first day of menstruation [1].

The first follow-up to assess the treatment outcome was performed on day 6–18. The ultrasound examination and hCG testing was repeated at this time. If there was a continuing pregnancy, vacuum aspiration was performed. Surgical intervention was also performed if there was heavy bleeding or if requested by the patient. If it was unclear whether the woman had aborted completely a further follow-up visit was scheduled. The treatment was regarded as successful only if no surgical treatment was necessary up to the first menstruation.

Women who wanted combined oral contraceptives (OC) were advised to start on day 3 (day 1 being the day of mifepristone treatment). If there was suspected retention or heavy bleeding at follow-up, women on OC were asked to stop taking the pill after the fourteenth tablet.

The hCG levels at follow-up are given as the percentage of the value before the treatment and presented as mean and (S.D.). Measurements of endometrial thickness are given in mm and presented as mean and (S.D.).

3. Results

All patients completed the treatment and returned for follow-up.

The distribution of the gestational age of the pregnancies before treatment based on the ultrasound findings is shown in Table 1.

The hCG levels ranged from as low as 28 in the earliest up to 190,750 mU/ml in the most advanced pregnancy. The correlation between ultrasound findings and the hCG levels before treatment is shown in Table 2. Examples of ultrasound images of the endometrium are shown in Figs. 1–6.

A second dose of misoprostol was given to 28 women (12.9%) who had not started to bleed or had a minimal bleeding within 3 h following the first dose. One hundred and eight (49.7%) women obtained OC on day 3 following start of treatment.

Table 1
Ultrasound findings before treatment, $n = 217$

No gestational sac	6 (2.7%)	(see patient 1, Fig. 1)
Gestational sac but no yolk sac or foetal pole	44 (20.3%)	(see patient 2, Fig. 2)
Gestational sac with yolk sac but no foetus or CRL <2 mm	105 (48.4%)	(see patient 3, Fig. 3)
CRL >2 mm	62 (28.6%)	(see patient 4, Fig. 4)

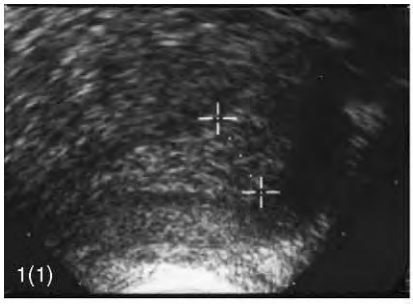
CRL: crown-rump length.

Table 2
Correlation between ultrasound findings and serum hCG level before treatment

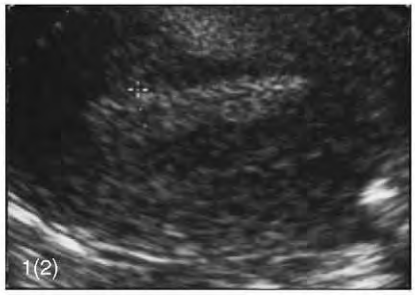
No gestational sac	28–1,752 mU/ml, (median 558 mU/ml)
Gestational sac, no yolk sac	802–54,443 mU/ml, (median 4.072 mU/ml)
Yolk sac	2,700–107,400 mU/ml, (median 17.295 mU/ml)
CRL >2 mm	22,900–190,750 mU/ml, (median 63.600 mU/ml)

CRL: crown-rump length.

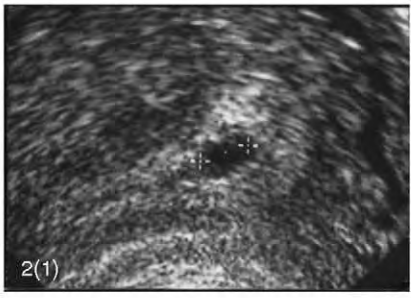
Treatment was successful without the need for surgical intervention in 98.2% of cases. A total of four vacuum aspirations had to be performed; two for continuing pregnancy and two for haemorrhage.



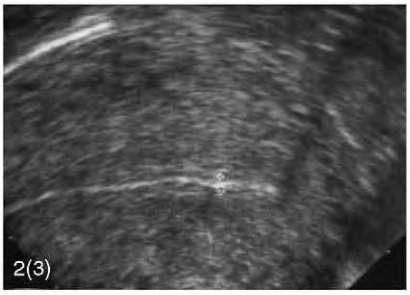
The hCG levels dropped to a mean of 3% (S.D. 3) of the value before treatment, ranging from 1 to 44% of the initial value in the cases of successful abortion (Fig. 7). The hCG value was above 17%, range 27–44%, in only three cases. Expulsion was confirmed by ultrasound in all of them, without the need for further follow-up. The two women with a continuing pregnancy had elevated hCG levels, 159% on day 10 and 7900% on day 8, respectively. Two patients were found to have a missed abortion. In each a gestational sac was seen on ultrasound which failed to grow from treatment to the time of the first follow-up at days 8 and 9 respectively. The drop in hCG was 91% in one and 3%, in the other woman. At a second follow-up visit, 8 and 15 days later respectively, both subjects had expelled the gestational sac without further treatment.



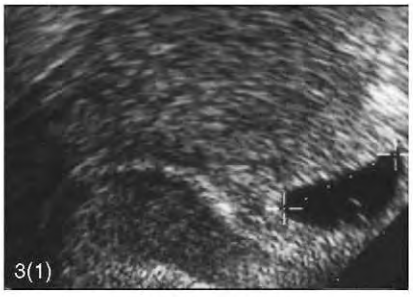
When 20% of the initial hCG value was used as cut-off, a positive predictive value for successful expulsion of 0.995 was obtained (Table 3).



If the reduction of the hCG level is less than 80%, the negative predictive value is 0.5 and further evaluation using ultrasound examination and repeated hCG measurements are needed to confirm the outcome of treatment.



The date of follow-up had been scheduled between day 6–18 according to the preferences of the patients. Due to the wide variation between treatment and follow-up, any cut off value of the hCG level has to be interpreted with caution. Nevertheless we found the cut-of at 20% valid, as all cases with complete abortion and early follow-up were far below this value.



Verification of successful abortion by ultrasound was possible only for the cases where the initial ultrasound examination had shown the presence of an intrauterine pregnancy (yolk sac or CRL). This was the case in 167 women (77%). Endometrium at follow-up measured 10 mm (mean, S.D. 4) in cases of successful abortion, ranging from 1 to 24 mm (Fig. 8). The content of the uterine cavity was inhomogeneous in some cases, making interpretation difficult (see Figs. 3 and 5). Complete abortion could not be verified at first follow-up (performed on days 7–12) by ultrasound alone in 17 of these cases (10.2%) due to the inhomogeneous picture. A further follow-up was scheduled in these cases (Fig. 5).

Figs. 1–6. Examples of patients with various duration of pregnancies up to 49 days counted from last menstrual period (LMP). Ultrasound images of the endometrium and S-hCG levels before and after treatment with 600 mg mifegyne (day 1) followed by 0.4 mg of misoprostol orally, 48 h later (day 3).

(1) Day 1 S-hCG 269 mU/ml. Day 9 S-hCG 20 mU/ml.
(2) Day 1 gestational sac 5 mm. S-hCG 862 mU/ml. Day 3 expelled gestational sac. Day 7 thin endometrium. S-hCG 7 mU/ml.
(3) Day 3 expelled gestational sac. Day 7 endometrium 12 mm. S-hCG 837 mU/ml.
(4) Day 1 CRL 1/4 10 mm. S-hCG 83439 mU/ml. Day 8 endometrium 8 mm. S-hCG 312 mU/ml.
(5) Day 1 CRL 1/4 6 mm. S-hCG 104 900 mU/ml. Started OC on Day 3. Day 10 endometrium 20 mm. S-hCG 16 841 mU/ml. Day 21 withdrawal bleeding. Day 28 S-hCG 100 mU/ml.
(6) Day 1 gestational sac and yolk sac. S-hCG 11947 mU/ml. Started OC on Day 3. Day 9 ultrasound image consistent with a missed abortion. S-hCG 10819 mU/ml. Day 18 withdrawal bleeding (stopped OC on day 16). Day 19 endometrium 8 mm. S-hCG 718 mU/ml.

4. Discussion

Treatment with 600 mg mifepristone and 0.4 mg misoprostol orally followed 3 h later by a second dose of 0.4 mg misoprostol if the woman had not started to bleed was found to be a highly effective method to terminate pregnancy in women with a duration of amenorrhoea up to 49 days. Out of the 217 women treated, 213 aborted without surgical intervention giving an overall success rate of 98.2%. Vacuum aspiration was performed in four women due to continuing pregnancy (two women) or heavy bleeding (two women). The outcome corresponds well with previous results using the same treatment [1].

The success of treatment is dependant on gestational age. If the duration of amenorrhoea is more than 49 days the efficacy of mifepristone and oral misoprostol is less effective [12]. The duration of pregnancy can usually be determined by menstrual history and a gynaecological examination. However, in some subjects these parameters are not sufficient and an ultrasound examination can be of considerable value.

There is no general agreement on how to verify the outcome of medical abortion. Some centres use ultrasound before administration of mifepristone and at follow-up, others rely on serum hCG levels or use a less sensitive urine pregnancy test (500 mU/ml) at follow-up. Whether ultrasound examination or serum hCG measurement is more suitable depends on several factors (Table 4). Ultrasound is not reliable in very early pregnancy before the yolk sac is visible. It could be useful to exclude a persisting extra uterine pregnancy after treatment but not in all cases. On the other hand it gives an immediate result in most cases and is inexpensive where available. Also, it can sometimes be of great relief for women in early pregnancy to see for herself that no foetal heart rate can be demonstrated.

The use of ultrasound to determine the outcome of medical abortion and possible need for surgical intervention clearly requires knowledge of the ultrasound finding following medical abortion. In the present study follow-up was performed according to the wish of the patient between days 6 and 18. Ultrasound at follow-up was sometimes difficult to interpret. The endometrium was often thick and sometimes inhomogeneous resembling an incomplete abortion (Figs. 3 and 5). It might be difficult to abstain from surgical intervention in such cases. However, no negative consequences were observed whilst waiting for the next menstrual bleeding to occur. Thus, the need for curettage in cases with missed abortion or a thick endometrium at follow-up could be reduced by refraining from immediate surgical intervention. An increasing hCG level at follow-up on the other hand, indicates a need for surgical intervention.

Table 4
Comparing ultrasound and hCG measurement to verify the effectiveness of the treatment

Advantages	Disadvantages
Ultrasound	
Usually done before starting the treatment	No reliable result in very early pregnancy
Easy to perform	Sometimes difficult to interpret at follow-up
Immediate result	
Great relief for the woman when there is no foetal structure visible	Vaginal ultrasound necessary
hCG	
Always a definite result	Not possible to exclude a gestational age >49 days LMP
Easy to perform	Some time needed to obtain the result

To measure serum hCG levels is especially helpful in early pregnancy. Measuring hCG is also reliable in detecting a persistent pregnancy or incomplete expulsion, even when extra uterine. Successful expulsions were consistent with a marked decline in hCG value at follow-up. Using 20% of the initial value as cut-off at follow-up gave a high sensitivity. It allowed correct diagnosis in 98.5% of the patients with successful expulsion. Only one patient with missed abortion at follow-up discovered by ultrasound had a marked decrease of hCG. She expelled the gestational sac with time without complications. There is probably a high frequency of spontaneous expulsion until or during the next menstruation in such cases. Measuring hCG can easily be done in most places and might be more convenient for the woman than an ultrasound examination. Furthermore there is no need to have it performed in the same institution that provided the medical abortion.

Even following medical abortion an ovulation could occur before the first menstruation. It is therefore of importance to provide the woman with an effective contraceptive method immediately after treatment. It has previously been demonstrated that OC can be given immediately after treatment without influencing outcome or bleeding [13].

In conclusion, hCG levels are a safe and effective way to verify complete abortion following medical treatment. Performing hCG is recommended especially in very early pregnancy. It's advantage over ultrasound is less pronounced at a later gestational age, as soon as an intrauterine pregnancy can be diagnosed by ultrasound. Plasma hCG level at follow-up compared to the initial value gave a reliable result in 98.5% of successful abortions, when using 20% of the initial value as cut-of. In contrast the reliability of ultrasound examination in diagnosing successful expulsion was 89.8% in the cases with a prior diagnosis of an intrauterine pregnancy. Ultrasound at follow-up showed a thick endometrium in many cases, sometimes with an inhomogeneous structure even when the abortion was complete. The ultrasound findings might be difficult to interpret and may lead to unnecessary surgical interventions. Conservative management i.e. waiting for the menstruation or an withdrawal bleeding proved to be safe. Surgical intervention was performed only in cases of continuous evolving pregnancy or

heavy bleeding. Thus if ultrasound is used alone to verify outcome of treatment, caution should be made to avoid unnecessary interventions.

Acknowledgements

The authors thank Dr. Danica Zunic and Leila Akinyemi for taking excellent care of the patients and for helping in data collection. The General Public Hospital has been highly supportive in introducing medical abortion into the German speaking area. *Funding*: this study has been funded by the General Public Hospital Korneuburg, Austria and the Swedish Medical Research Council (0855).

Telehealth vs In-Clinic Medication Abortion Services

Anna E. Fiastro, MPH, MEM, PhD; Zihan Zheng, MS; Molly R. Ruben, MPH; Jessica Gipson, PhD, MPH; Emily M. Godfrey, MD, MPH

Introduction

Abortion is a common health care service, yet federal and state regulations continue to restrict care options, with disproportionate impacts on underserved communities.[1-3] Due to limited in-clinic access throughout the country, telehealth medication abortion services (tele-MAB), including online consultations and medications delivered directly to patients, can make abortion care more convenient and accessible.[4]

Other areas of health care have documented disparities in telehealth access, although less is known about tele-MAB services.[5] We sought to understand differences in patient characteristics

between those using telehealth vs in-clinic for medication abortion care and to explore the role of tele-MAB in serving diverse patient populations.

Methods

This cross-sectional study follows the STROBE reporting guideline[6] and was approved by the University of Washington and University of California, Los Angeles institutional review boards with exemption from informed consent because data were deidentified in accordance with 45 CFR § 46. We analyzed electronic medical record data from tele-MAB and tele-MAB–eligible patients who received in-clinic medication abortion services at Cedar River Clinics, a reproductive health care clinic in Washington State, between April 23, 2020, and January 31, 2022 (eFigure in Supplement 1). A sensitivity analysis was completed excluding in-clinic patients with missing information on tele-MAB eligibility (208 patients [17%]). Using bivariable and multivariable logistic regressions, we examined associations of patient characteristics (eTable in Supplement 1) with odds of receiving

GBP-PET00229

tele-MAB vs in-clinic services. We used 2-sided tests with an α criterion of .05, using Stata IC statistical software version 16.1 (StataCorp). Data analysis was conducted from September to December 2022.

Results

Of the 1241 patients (mean [range] age, 30 [13-52] years) included in the study, 858 individuals (69%) received in-clinic appointments for medication abortion services and 383 (31%) received tele-MAB services (**Table 1**). In the unadjusted analysis, number of living children and payment type were not different between tele-MAB and in-clinic patients. In the adjusted model, individuals who lived further from a clinic and had at least 1 prior abortion were more likely to receive tele-MAB (**Table 2**). Compared with White individuals, patients who self-reported as multiracial or other race were also more likely to receive tele-MAB, whereas Black individuals were more likely to be seen in-clinic. Younger individuals, non-English speakers, and those with at least 1 health condition were also less likely to receive tele-MAB vs in-clinic services. The association of gestational duration (GD) with appointment type was not significant in the multivariable model but was significant in the sensitivity analysis, with those at 57 to 70 days GD more likely to choose tele-MAB than those at 43 to 56 days (adjusted odds ratio, 1.75; 95% CI, 1.06-2.89). The sensitivity analysis found all other associations to be robust.

Discussion

Our findings suggest that tele-MAB facilitates abortion care access for those further from brick-and-mortar abortion facilities and, thus, may mitigate the impacts of travel logistics and costs. Additionally, tele-MAB may better meet the needs of those with prior abortion experience, perhaps due to greater familiarity with the abortion process. Further research is needed to better understand patients who identified as multiracial or other race and how identity, including prior experiences of racism in health care settings, may impact patient preference for tele-MAB services. Additional research is also needed to determine whether those at later GD are more likely to choose tele-MAB, perhaps anticipating initiation of their termination.

Our findings also suggest some groups with limited access to abortion care (ie, younger individuals, those with limited English proficiency, and those with health conditions) are less likely to use tele-MAB services. Efforts to educate patients about telehealth procedures and improve availability of language support are needed to make tele-MAB feasible for diverse populations. Limitations of this study are that findings may not be generalizable to asynchronous or less-integrated telemedicine models, or other care settings.

Patients face many barriers to accessing abortion care, and tele-MAB services facilitate more convenient and timely care. Tele-MAB services reach some communities traditionally underserved by clinic-based services, addressing some disparities in receipt of care. As access to abortion care continues to be restricted in the US, innovative models of care delivery are needed to accommodate the sustained demand for services and to meet the needs of diverse patient populations.

Trends in Maternal Mortality and Severe Maternal Morbidity During Delivery-Related Hospitalizations in the United States, 2008 to 2021

Dorothy A. Fink, MD; Deborah Kilday, MSN; Zhun Cao, PhD; Kelly Larson, BS; Adrienne Smith, PhD, MS, CHES; Craig Lipkin, MS; Raymond Perigard, BS; Richelle Marshall, BAA; Taryn Deirmenjian, BS, BBA; Ashley Finke, MS, MPH; Drew Tatum, MS; Ning Rosenthal, MD, PhD, MPH

Abstract

IMPORTANCE Maternal mortality and severe maternal morbidity (SMM) are important focus areas in public health. Further understanding trends, health disparities, and risk factors for these adverse outcomes is vital to public health decision-making.

OBJECTIVE To describe trends and risk factors for delivery-related maternal deaths and SMM in the United States.

DESIGN, SETTING, AND PARTICIPANTS This is a retrospective cross-sectional study using data from a large, geographically diverse, all-payer hospital administrative database. Hospital discharges from January 2008 to December 2021 with any Medicare Severity Diagnosis Related Group, *International Classification of Diseases, Ninth Revision, Clinical Modification*, or *International Classification of Diseases, Tenth Revision, Clinical Modification* delivery diagnosis or procedure code were included. Data analysis took place from February 2021 to March 2023.

EXPOSURES Year, quarter (Q), age, race and ethnicity, delivery method.

MAIN OUTCOMES AND MEASURES Maternal mortality, SMM during delivery-related hospitalization.

RESULTS Overall, 11 628 438 unique hospital discharges were analyzed, with a mean (SD) age of 28 (6) years. There were 437 579 (3.8%) Asian, 92 547 (0.8%) American Indian, 1 640 355 (14.1%) Black, 1 762 392 (15.2%) Hispanic, 83 189 (0.7%) Pacific Islander, and 6 194 139 (53.3%) White patients. Regression-adjusted maternal mortality per 100 000 discharges declined from 10.6 deaths in Q1 2008 to 4.6 deaths in Q4 2021. Mortality was significantly higher among patients with advanced maternal age (eg, age 35-44 years vs 25-34 years: adjusted odds ratio [aOR], 1.49; 95% CI, 1.22-1.84). Other significant risk factors for mortality included cesarean delivery, comorbid conditions, complications, and COVID-19 diagnosis (eg, cesarean delivery: aOR, 2.28; 95% CI, 1.87-2.79). The prevalence of any SMM increased from 146.8 per 10 000 discharges in Q1 of 2008 to 179.8 per 10 000 discharges in Q4 of 2021. SMM risk factors included age 24 years or younger or age 35 years or older, belonging to a racial or ethnic minority group, cesarean delivery, Medicaid insurance, and having 1 or more comorbidities (eg, age 10-19 years: aOR, 1.39; 95% CI, 1.36-1.42).

CONCLUSIONS AND RELEVANCE This cross-sectional study found that delivery-related mortality in US hospitals decreased for all racial and ethnic groups, age groups, and modes of delivery during 2008 to 2021, likely demonstrating the impact of national strategies focused on improving maternal quality of care provided during delivery-related hospitalizations. SMM prevalence increased for all patients, with higher rates for racial and ethnic minority patients of any age. Advanced maternal age,

(continued)

Key Points

Question What were trends of and risk factors associated with maternal mortality and severe maternal morbidity (SMM) among women giving birth in US hospitals during 2008 to 2021?

Findings In this cross-sectional study of more than 11.6 million delivery-related hospitalizations, regression-adjusted in-hospital maternal delivery-related mortality per 100 000 discharges declined from 10.6 to 4.6, while the prevalence of SMM per 10 000 discharges increased from 146.8 to 179.8 during 2008 to 2021. Differences were found across racial and ethnic groups, age, mode of delivery, and comorbidities for mortality and SMM.

Meaning In this study, in-hospital maternal mortality improved between 2008 and 2021 despite increases in SMM prevalence and presence of comorbidities for the overall population.

Abstract (continued)

racial or ethnic minority group status, cesarean delivery, and comorbidities were associated with higher odds of mortality and SMM.

JAMA Network Open. 2023;6(6):e2317641. doi:10.1001/jamanetworkopen.2023.17641

Introduction

Complications from pregnancy and childbirth are leading contributors to mortality and severe morbidities, resulting in significant burden on pregnant patients and their babies. Among developed countries, the United States has the highest maternal mortality ratio.[1] In 2019, there were 3 747 540 births in the United States, with an estimated birth rate of 11.4 per 1000 population.[2] According to US Pregnancy Mortality Surveillance System (PMSS) data, the pregnancy-related mortality ratio in the United States had increased since 1987 from 7.2 deaths per 100 000 live births to 17.3 deaths per 100 000 live births in 2017, although the trend slowed substantially after 2008.[3]

Maternal mortality has been described as the "tip of the iceberg" and maternal morbidity as a larger problem, "the base."[4] For every individual who dies as a result of their pregnancy, it is estimated that 20 or 30 more experience significant lifelong complications that affect their health and well-being.[5,6] Severe maternal morbidity (SMM), which the US Centers for Disease Control and Prevention (CDC) defines as "unexpected outcomes of labor and delivery that result in significant short- or long-term consequences to a woman's health,"[1] has steadily increased in the United States in recent years and is estimated to affect more than 50 000 patients annually.

Causes of maternal deaths and SMM at the time of delivery are multifactorial and are not well documented.[7] Measuring specific outcomes occurring during delivery and hospitalization could improve understanding of how to predict, manage, and mitigate maternal outcomes. In addition, enhanced understanding of the causes of delivery-related death and SMM can inform potential strategies to improve overall maternal health outcomes in the United States. This study aimed to provide evidence to enhance understanding of patterns, trends, and risk factors associated with delivery-related deaths and SMM in US hospitals using a large maternal sample in the hospital setting.

Methods

Study Design

This retrospective cross-sectional study was conducted to examine trends associated with delivery-related maternal in-hospital mortality and SMM between January 2008 and December 2021, using data from the Premier PINC AI Healthcare Database (PHD). All data were statistically deidentified and adherent to the Health Insurance Portability and Accountability Act. Based on US Title 45 Code of Federal Regulations, Part 46, this study was exempted from institutional review board approval and informed consent. The study followed the Strengthening the Reporting of Observational Studies in Epidemiology (STROBE) reporting guideline.

Data Source

The PHD is a large, all-payer (including Medicaid), geographically diverse administrative database comprising more than 1200 US hospitals and health systems.[8] This database represents approximately 25% of all US inpatient admissions. All data were validated at both facility and patient levels. The CDC, the National Institute of Health, and academic and industry researchers have used PHD data for studies in a variety of disease areas.[9-15]

Study Population

This study reviewed inpatient hospitalizations between January 1, 2008, and December 31, 2021, with any Medicare Severity Diagnosis Related Group (MS-DRG) or *International Classification of Diseases, Ninth Revision, Clinical Modification* (*ICD-9-CM*) diagnosis or procedure codes (on or before September 30, 2015) or *International Classification of Diseases and Related Health Problems, Tenth Revision, Clinical Modification* (*ICD-10-CM*) codes (on or after October 1, 2015) indicating delivery (eTable 1 in Supplement 1). Hospitalizations for patients younger than 10 years at time of admission and those with evidence of abortive outcomes were excluded from the study. The index date was defined as the discharge date for the qualifying hospitalization. Missing data for categorical variables were included in the other or unknown group. Only a small percentage of patients had missing data, which should not have affected the trend analysis.

Study Variables

SMM

Complications or procedures indicative of SMMs were examined during the delivery-related hospitalization; these included acute myocardial infarction, acute kidney failure, amniotic fluid embolism, aneurysm, cardiac arrest or ventricular fibrillation, cardioversion, disseminated intravascular coagulation, eclampsia, heart failure or arrest during procedure, puerperal cerebrovascular disorders, acute heart failure or pulmonary edema, severe anesthesia complications, sepsis, shock, sickle cell anemia with crisis, air and thrombotic embolism, blood transfusion, hysterectomy, temporary tracheostomy, and ventilation. The diagnosis and procedure codes to identify the complications are listed in eTable 2 in Supplement 1. The presence of any SMM was used as a measure for the adverse event occurring during delivery. Morbidities were reported as number of patients with each SMM or any SMM of interest per 10 000 eligible discharges.

In-Hospital Delivery-Related Mortality

Death was defined as having delivery-related hospitalization discharge status as deceased. In-hospital mortality was reported as the number of patients who died during index hospitalization per 100 000 eligible discharges.

Patient, Hospital, and Visit Characteristics

Patient characteristics included age (10-19, 20-24, 25-34, 35-44, ≥45 years), race and ethnicity (categorized as American Indian, Asian, Black, Hispanic, Pacific Islander, White, and other or unknown), and primary insurance payer. The other or unknown category captures all patients who selected other category for race, had missing data for race or ethnicity, or had a hospital-reported race that could not be matched to the standard race categories used in this article. Race and ethnicity were reported by the hospital. For the purposes of this study, we defined racial or ethnic minority patients as those with race or ethnicity classifications other than White. Hospital characteristics included population served (urban, rural), teaching status, US census divisions (ie, Middle Atlantic, Mountain, East North Central, East South Central, New England, Pacific, South Atlantic, West North Central, and West South Central), and hospital size (1-299, 300-499, and ≥500 beds). Visit information, such as index year, quarter (Q), admission type (elective, emergency, urgent, or trauma center), and an indicator for pre–*ICD-10-CM* or post–*ICD-10-CM* coding system change on October 1, 2015, were also examined.

Clinical Characteristics

The individual conditions in the Maternal Comorbidity Index (MCI)[16] were assessed as potential risk factors of maternal mortality or morbidity, including pulmonary hypertension, placenta previa, sickle cell disease, gestational hypertension, mild or unspecified preeclampsia, severe preeclampsia, chronic kidney disease, preexisting hypertension, chronic ischemic heart disease, congenital heart disease, systemic lupus erythematosus, HIV, multiple gestation, substance use disorder, alcohol

GBP-PET00235
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 06/19/2023

abuse, tobacco use, cardiac valvular disease, chronic congestive heart failure, asthma, preexisting diabetes, gestational diabetes, obesity, cystic fibrosis, and previous cesarean delivery (eTable 3 in Supplement 1). The type of delivery (vaginal, cesarean) and COVID-19 status were also examined.

All SMMs were included as covariates for the mortality analysis. Because of overlap across comorbid conditions, certain SMMs were grouped together. Per CDC recommendations, cardiac conditions (including acute myocardial infarction, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery or procedure, and pulmonary edema or acute heart failure) were grouped into 1 binary variable called cardiovascular complications for multivariable modeling. Acute respiratory conditions (including acute respiratory distress syndrome, temporary tracheostomy, and ventilation) were grouped into a binary variable called respiratory complications.[17] Hemorrhage and blood transfusion were combined into bleeding complications with 3 categories: no bleeding, hemorrhage with no blood transfusion, and blood transfusion. Eclampsia, severe preeclampsia without eclampsia, mild or unspecified preeclampsia without eclampsia, or severe preeclampsia, and no preeclampsia or eclampsia were grouped into one 4-level covariate.

Statistical Analysis

Descriptive analysis was performed to assess the distribution of demographics and hospital and clinical characteristics for each year. Categorical variables were expressed as counts and percentages. Owing to space limitations, we only included specific descriptive results for 2008, 2014 (ie, the year before the *ICD-9-CM* to *ICD-10-CM* coding change), 2016 (ie, the year after the *ICD-9-CM* to *ICD-10-CM* coding change), 2019 (ie, the year before the COVID-19 pandemic), 2020, and 2021 (ie, years during the COVID-19 pandemic), rather than for all years in this study.

Two separate multivariable logistic regression models were created to assess the independent associations of potential risk factors with delivery-related maternal mortality and SMM, adjusting for confounders. For both models, patient demographics, hospital and visit characteristics, and MCI conditions were included as covariates. In the mortality regression, the SMM complications were added to the model to account for disease conditions that happened during the delivery-related hospitalization before the occurrence of mortality. In addition, a logistic regression of mortality without SMMs as covariates was performed as a sensitivity analysis. Backward selection with $P < .05$ was used to select final models, with the exception that patient age, race and ethnicity, delivery type, and study year and Q were kept in the model regardless of *P* values. For the mortality model, SMM conditions that were closely related to each other were combined. Combined variables included bleeding complications, cardiovascular complications, respiratory complications, and an eclampsia or preeclampsia category. In the regression of SMM, eclampsia was 1 component of the SMM outcome, while the preeclampsia conditions were used as separate covariates in the model.

Adjusted mortality and SMM rates for the overall study population were calculated using recycled prediction methods[16,18] based on estimates from the regressions. Adjusted mortality and SMM rates were also reported by age group, race and ethnicity, and type of delivery, based on additional regression models that included interaction terms between year and the variable of interest.

All analyses were conducted using Python Scikit-Learn package version 0.22.1 (Python Software Foundation). Analysis of the data took place from February 2021 through March 2023. *P* values were 2-sided, and statistical significance was set at $P < .05$.

Results

Patient Characteristics

Among the 11 628 438 eligible discharges related to delivery, more than half (6 498 217 [55.9%]) were among patients aged 25 to 34 years, 1 885 571 (16.2%) were among patients aged 35 years or older, and 759 301 (6.5%) were among patients aged 10 to 19 years. There were 437 579 (3.8%) Asian patients, 92 547 (0.8%) American Indian patients, 1 640 355 (14.1%) Black patients, 1 762 392

GBP-PET00236
Downloaded from jamanetwork.com by Arnold & Porter Kaye Scholer, LLP user on 06/19/2023

(15.2%) Hispanic patients, 83 189 (0.7%) Pacific Islander patients, and 6 194 139 (53.3%) White patients. Medicaid was identified as the primary payer for 4 958 174 discharges (42.6%). The census region distribution reflected the geographic distribution of the PHD patient population. Approximately one-third of the sample underwent cesarean delivery. The proportion of discharges in younger age groups decreased while the proportion in older age groups increased over the study period. The distribution of race and ethnicity, primary payer type, census region, and delivery type did not differ significantly across years (**Table 1**).

Maternal Comorbid Conditions

As shown in Table 1, obesity (91.0 per 1000 discharges), gestational diabetes (74.3 per 1000 discharges), and tobacco use (58.2 per 1000 discharges) were the most common comorbidities, followed by gestational hypertension, asthma, preeclampsia, preexisting hypertension, and substance use disorder. Compared with the prevalence in 2008, higher prevalence of sickle cell disease, gestational hypertension, severe preeclampsia, preexisting hypertension, substance use disorder, asthma, gestational diabetes, obesity, and hemorrhage were observed in 2021 (Table 1).

Prevalence and Trend of SMMs

The unadjusted prevalence of any SMM was estimated to be 163.3 per 10 000 discharges for the overall sample from 2008 to 2021, with higher prevalence observed in 2021 (206.1 per 10 000 discharges) compared with 2008 (135.2 per 10 000 discharges). Blood transfusion was the most common SMM observed, with a prevalence of 108.4 per 10 000 discharges. Other relatively common SMMs included disseminated intravascular coagulation (24.7 per 10 000 discharges), hysterectomy (11.0 per 10 000 discharges), acute respiratory distress syndrome (9.8 per 10 000 discharges), acute kidney failure (9.7 per 10 000 discharges), sepsis (7.4 per 10 000 discharges), eclampsia (7.2 per 10 000 discharges), shock (6.1 per 10 000 discharges), and acute heart failure or pulmonary edema (5.6 per 10 000 discharges). Prevalence of acute kidney failure, acute respiratory distress syndrome, sepsis, shock, mechanical ventilation, blood transfusion, and hysterectomy were higher in 2021 than in 2008 (Table 1).

As seen in **Figure 1**A, the adjusted prevalence of any SMM increased from Q1 2008 (146.8 per 10 000 discharges) to Q4 2021 (179.8 per 10 000 discharges). The increasing trend was observed in all age groups with the greatest change observed in patients aged 45 years or older and those aged 10 to 19 years (Figure 1B). Consistent increasing trend was also observed in all racial and ethnic groups, with the biggest increase observed among Pacific Islander patients (from 132.0 per 10 000 discharges in Q1 2008 to 298.8 per 10 000 discharges in Q4 2021), American Indian patients (from 156.5 per 10 000 discharges in Q1 2008 to 245.0 per 10 000 discharges in Q4 2021), and Asian patients (from 133.4 per 10 000 discharges in Q1 2008 to 238.2 per 10 000 discharges in Q4 2021) (Figure 1C). A significant increase in adjusted SMM prevalence was observed in patients undergoing cesarean delivery (from 252.4 per 10 000 discharges in Q1 of 2008 to 312.1 per 10 000 discharges in Q4 of 2021), and a similarly increasing trend was seen in patients with vaginal delivery (from 84.4 per 10 000 discharges in Q1 of 2008 to 108.4 per 10 000 discharges in Q4 of 2021) (Figure 1D).

Unadjusted and Adjusted Trend of In-Hospital Delivery-Related Mortality

As shown in **Figure 2**A, a downward trend was observed for in-hospital mortality among deliveries after adjusting for changes in patient demographic, visit, hospital, and clinical characteristics. From Q1 of 2008 to Q4 of 2021, the adjusted in-hospital mortality decreased from 10.6 per 100 000 discharges to 4.6 per 100 000 discharges. Each subsequent year after 2008 had an 11% decrease in odds of death compared with the previous year (adjusted odds ratio [aOR], 0.89; 95% CI, 0.87-0.92) (**Table 2**). There was an increase in mortality from Q2 of 2020 through Q4 of 2021 that may be associated with the COVID-19 pandemic. However, after controlling for COVID-19 diagnosis, the adjusted trend decreased consistently across the full study period. The downward trend for in-hospital mortality was observed in all age groups, with the biggest decrease occurring in patients

Abbreviations: *ICD-9-CM*, *International Classification of Diseases, Ninth Revision, Clinical Modification*; *ICD-10-CM*, *International Statistical Classification of Diseases, Tenth Revision, Clinical Modification*; NE, not entered in final model; OR, odds ratio; SMM, severe maternal morbidity.

[a] Overall, 728 deaths among 11 628 380 inpatient hospitalizations were included in the analysis; 58 patients reported by hospitals with in-hospital mortality followed by readmission were excluded from the regression of mortality. Additional covariates included in the regression of mortality are described in the Statistical Analysis section.

[b] A logistic regression of mortality without SMMs as covariates was performed as a sensitivity analysis.

[c] A total of 189 908 discharges with SMM (of 11 628 438 inpatient hospitalizations) were included in the analysis. Additional covariates included in the regression of severe maternal morbidity are described in the Statistical Analysis section.

[d] Respiratory complications included acute respiratory distress syndrome, temporary tracheostomy and ventilation as defined by the US Centers for Disease Control and Prevention.

[e] Cardiovascular complications included any of the following severe maternal morbidities: acute myocardial infarction, cardiac arrest or ventricular fibrillation, conversion of cardiac rhythm, heart failure or arrest during surgery or procedure, and pulmonary edema or acute heart failure as defined by the US Centers for Disease Control and Prevention.

aged 45 years or older (Figure 2B). A decreasing trend for in-hospital mortality was observed in all racial and ethnic groups. In particular, the greatest decrease in adjusted mortality was observed for American Indian patients: from 34.8 per 100 000 discharges in Q1 of 2008 to 2.7 per 100 000 discharges in Q4 of 2021 (Figure 2C; the 95% CI for mortality among American Indian patients is

GBP-PET00244

provided in eTable 4 in Supplement 1). In-hospital mortality consistently decreased during the study period for patients with cesarean delivery (from 12.6 per 100 000 discharges in Q1 of 2008 to 5.2 per 100 000 discharges in Q4 of 2021) and also for patients with vaginal delivery (from 6.6 per 100 000 discharges in Q1 of 2008 to 3.0 per 100 000 discharges in Q4 of 2021) (Figure 2D).

Risk Factors for In-Hospital Mortality and SMM

Compared with patients aged 25 to 34 years, those between 35 and 44 years had higher odds of dying during the index hospitalization (aOR, 1.49; 95% CI, 1.22-1.84). Although the association between race and mortality was not statistically significant in the regression in which SMMs were included as covariates, a sensitivity analysis showed that American Indian (aOR, 1.93, 95% CI, 1.10-3.39), Black (aOR, 1.78; 95% CI, 1.47-2.15), and Asian patients (aOR, 1.61, 95% CI, 1.11-2.34) had increased risk of death compared with White patients, suggesting that the racial disparity was partly attributable to the difference in the SMM rates across racial and ethnic groups. The mortality of Pacific Islander patients and Hispanic patients was not statistically significantly different from White patients in the sensitivity analysis. Patients with cesarean delivery had 2-fold higher odds of death than those with vaginal delivery (aOR, 2.28; 95% CI, 1.87-2.79). Patients with a COVID-19 diagnosis had a 13-fold increased odds of mortality compared with those without COVID-19 (aOR, 13.31; 95% CI, 8.95-19.79). Among comorbidity and acute complications assessed, cardiac complications, cystic fibrosis, aneurysm, trauma, and puerperal cerebrovascular disorder were among the risk factors associated with death during delivery-related hospitalization (Table 2).

As seen in Table 2, after adjusting for other risk factors and compared with patients aged 25 to 34 years, both patients younger than 24 years (eg, age 10-19 years: aOR, 1.39; 95% CI, 1.36-1.42) and older than 35 years (eg, age ≥45 years: aOR, 1.76; 95% CI, 1.65-1.88) had increased odds of SMM. All minority racial and ethnic groups were associated with increased odds of experiencing any SMM (Pacific Islander: aOR, 1.53; 95% CI, 1.45-1.61; American Indian: aOR, 1.41; 95% CI, 1.35-1.48; Black: aOR, 1.39; 95% CI, 1.38-1.41; Asian: aOR, 1.33; 95% CI, 1.30-1.36; Hispanic: aOR, 1.22; 95% CI, 1.20-1.24). Cesarean delivery (aOR, 3.00; 95% CI, 2.97- 3.03) and COVID-19 diagnosis (aOR, 4.44; 95% CI, 4.23-4.66) were also associated with substantially higher adjusted odds of SMM. Among all the chronic comorbidities assessed, placenta previa (aOR, 6.32; 95% CI, 6.17-6.47), chronic kidney disease (aOR, 5.21; 95% CI, 4.99-5.44), severe preeclampsia (aOR, 4.55; 95% CI, 4.48-4.62), cardiac valvular disease (aOR, 3.50; 95% CI, 3.32-3.69), chronic ischemic heart disease (aOR, 3.92; 95% CI, 3.50-4.39), and sickle cell disease (aOR, 2.93; 95% CI, 2.82-3.05) were associated with the highest odds of experiencing SMM (Table 2).

Discussion

This cross-sectional study examined rates of delivery-related in-hospital maternal mortality and SMM in a large national inpatient database. In this sample encompassing more than 11 million inpatient discharges, delivery-related in-hospital mortality was found to decrease significantly over a period of 14 years. The adjusted mortality per 100 000 discharges decreased by more than 50% from Q1 of 2008 to Q4 of 2021, likely demonstrating the impact of national strategies focused on improving the maternal quality of care provided by the hospitals during delivery-related hospitalizations. In contrast, the rates of overall SMM increased over time for the overall population, which may be attributable to preexisting conditions and the increasing trend in the age of delivering patients in the past decade. The increasing trend of adjusted SMM rates was seen in all racial and ethnic minority groups and was most prominent in Asian, American Indian, and Pacific Islander patients. The fact that many of the comorbid conditions are risk factors for mortality and SMM indicates that it is essential to consider comorbid conditions when assessing SMM and mortality and that better management of patients' comorbid conditions during pregnancy may help reduce SMM occurrence and ultimately decrease mortality risk. Further improvement in patient outcomes could be achieved if patients with known risk factors could access improved care during pregnancy and during hospital delivery.

Delivery-related in-hospital maternal mortality in this study was lower than that reported in PMSS data, which defined pregnancy-related death as death during pregnancy or within 1 year of the end of pregnancy, from a cause related to pregnancy or its management.[3] PMSS data showed an increasing trend in pregnancy-related mortality during 1987 to 2017, which differs from our findings. A plausible explanation for these differences is that the timeframe for assessing mortality was substantially different between our study and the PMSS. Our study focused on mortality during delivery-related hospitalizations, which was associated with the change in quality of care for all patients in a hospital setting. In contrast, the PMSS estimates cover the entire pregnancy and postpartum period, which are associated with the overall burden of deaths among pregnant patients. Because a proportion of pregnancy-related deaths occur during delivery hospitalization, the differences between our findings and the PMSS estimates reinforced the importance of examining mortality separately for different stages of pregnancy and postpartum.

The study found that mortality risk was associated with several factors, including advanced maternal age, Medicaid as primary insurance, cesarean delivery, comorbid conditions, and severe complications during delivery. Similarly, a maternal age younger than 19 years or older than 35 years; being Asian, American Indian, Black, Hispanic, Pacific Islander; cesarean delivery; Medicaid enrollment; and maternal comorbid conditions were associated with higher risk of developing SMM during delivery. The racial and ethnic differences observed in delivery-related maternal mortality seem to be at least partly attributable to the racial and ethnic variation observed in SMM based on the main and sensitivity analyses of this study. Therefore, further research and understanding on the causes of both mortality and SMM, including the impact of comorbidities on maternal outcomes, is needed. Additionally, developing a national hospital measure to more clearly identify and reduce SMMs will likely have a beneficial impact on improving national quality strategies aimed at improving maternal health outcomes in the United States.

Limitations

The study has limitations. The PHD is a hospital administrative database and does not include as much clinical details as electronic health records. Identifying clinical conditions and procedures relied on the accuracy of hospital-reported diagnosis and procedure codes. Coding errors may lead to misclassification of variables. The definition of mortality was based on in-hospital death during the visit for delivery, without accounting for death before delivery admission or after discharge.

Maternal comorbid conditions were defined based on diagnosis during the visit for delivery. Conditions occurring before admission may not have been captured. Since the study spanned 14 years, there were changes in how hospitals collected and reported race and ethnicity. Hispanic was reported as a race category before 2011, while ethnicity was listed as a separate field in the patient admission form in later years. Hispanic race or ethnicity as defined in this study included patients who reported Hispanic as their race before 2011 and those who reported Hispanic as their ethnicity in 2012 and later, regardless of their reported race.

Conclusions

This large national study found a decreasing trend of in-hospital delivery-related maternal mortality during 2008 to 2021, regardless of racial or ethnic group, age, or mode of delivery, likely demonstrating the impact of national and local strategies focused on improving the maternal quality of care provided by hospitals during delivery-related hospitalizations. Risk factors for in-hospital delivery-related mortality included cesarean delivery, COVID-19 diagnosis, and comorbidities and acute complications. Analysis indicated that American Indian, Black, and Asian patients had a statistically significant increased risk of death compared with White patients only when not controlling for SMMs, suggesting that the racial difference in mortality could be at least partly attributable to the differences in SMM rates across racial groups (analysis of Pacific Islander and Hispanic patients were not statistically significant).

From 2008 to 2021, there was an increasing trend of SMM rates, and chronic comorbid conditions were associated with higher rates. SMMs are known risk factors of maternal deaths and impose substantial social and economic burdens. Notably, disparities in both mortality and SMM remained across age, delivery mode, and racial and ethnic groups. These characteristics should be considered when designing maternal care quality improvement programs. As current national strategies increasingly focus on improving delivery-related maternal outcomes among high-risk groups, including racial and ethnic minority groups, it will become important to evaluate the effectiveness of these strategies in reducing occurrences of maternal mortality and SMM.

Received 24 June 2014; revised 7 January 2015; accepted 7 January 2015

Abstract

Objective: The aim of this study was to report on the safety and efficacy of an evidence-based medical abortion regimen utilizing 200 mg of mifepristone orally followed by home use of 800 mcg misoprostol buccally 24–48 h later through 63 days estimated gestational age.

Study design: We analyzed outcomes in women presenting for medical abortion between April 1, 2006, and May 31, 2011, using an evidence-based alternative to the United States Food and Drug Administration (FDA)-approved regimen. Cases were identified for this descriptive study from our electronic practice management (EPM) database, and our electronic database on adverse events was queried for information on efficacy and safety. The primary outcome was successful abortion. Logistic regression was used to identify predictors of successful abortion.

Results: Among the 13,373 women who completed follow-up, efficacy of the regimen was 97.7%. Efficacy was highest at 29 to 35 days (98.8%) and 36 to 42 days (98.8%) of gestation and lowest at 57 to 63 days (95.5%). The odds of needing aspiration for any reason were greatest at higher gestational ages. Rates of infection requiring hospitalization and rates of transfusion were 0.01 and 0.03%, respectively.

Conclusions: An evidence-based regimen of 200 mg of mifepristone orally followed by home use of 800 mcg of buccal misoprostol 24–48 h later is safe and effective through 63 days estimated gestational age. Further, the need for aspiration for any reason was low, and hospitalization was rare.

Implications: This study reinforces the safety and efficacy of the evidence-based regimen for medical abortion (200 mg mifepristone orally followed by home use of 800 mcg of misoprostol buccally 24–48 h later) through 63 days estimated gestational age, and contributes to the existing evidence against restrictions requiring use of the FDA-approved regimen.

Keywords: Medical abortion; Mifepristone; First-trimester abortion; Evidence-based regimen; Buccal misoprostol; Efficacy

1. Introduction

The United States Food and Drug Administration (FDA) approved the use of mifepristone and misoprostol for pregnancy termination in 2000. The regimen, labeled for use through 49 days estimated gestational age, required a minimum of three visits to the healthcare provider. Six hundred milligrams of mifepristone was taken orally at Visit 1, followed in 2 days by misoprostol 400 mcg, also taken orally. A third follow-up visit was required in 14 days to ensure that the abortion was complete. The efficacy of this regimen ranged from 92 to 97% [1–3]. Publications soon followed providing an evidence base for alterations to the regimen. Alterations included a lower dose of mifepristone, different routes of administration of misoprostol, variations in the timing of misoprostol administration, home use of misoprostol, and increasing the gestational age limit for the regimen [4–11]. A recent publication confirmed the low rate of significant adverse events with use of the evidence-based regimen [11].

In 2008, a prospective study was published describing the use of 200 mg of mifepristone followed in 24 to 36 h by 800 mcg of buccal misoprostol for pregnancy termination to 63

days of gestation with a success rate for the regimen of 96.2% [8]. Despite the growing literature supporting evidence-based provision of medical abortion, some providers are required by law to limit the provision of medical abortion to that regimen, which was FDA-approved more than a decade ago [12]. The goal of the current study was to assess, in a much larger cohort of patients, the safety and efficacy of an evidence-based medical abortion regimen utilizing 200 mg of mifepristone orally followed by home use of 800 mcg of misoprostol buccally 24–48 h later through 63 days estimated gestational age.

2. Materials and methods

2.1. Medical abortion protocols and monitoring

Our large network of urban healthcare centers includes 19 health centers providing approximately 15,000 abortions per year, of which about 30% are medical abortions. Demographic information, treatment dates, and diagnostic codes for all patients were retrieved using the electronic practice management (EPM) billing system. Some clinical information was retrieved from an electronic medical records (EMR) system, which was gradually implemented across all study sites between 2008 and 2010. All patients undergo an ultrasound examination for pregnancy dating prior to abortion. The clinician administering the medication abortion performed and interpreted the ultrasound. All clinicians had undergone the same standardized training and were monitored regularly to ensure accuracy and to maintain consistency. Ultrasound machines using a Hadlock scale calculated gestational age in days; herein, we analyze and report gestational age in 7-day increments (e.g., 22 to 28 days). Since April 2006, our medical abortion regimen has consisted of 200 mg of mifepristone taken orally at the health center followed by 800 mcg of buccal misoprostol used by the patient at home 24 to 48 h later. Medical protocols during the study period allowed for repeat doses of misoprostol for patients who had an incomplete medical abortion. Data on which patients received a repeat dose are not available from the EPM system, but only in the EMR system; therefore, for patients seen at sites that had not yet implemented EMR at the time of treatment, information on whether a repeat dose of misoprostol was given is not available. For the first 3 years of the study period, the upper gestational age limit for this regimen was 56 days. In February 2009, based on newly published data, the upper limit was increased to 63 days [8]. All patients were scheduled to return in 7 to 14 days for a postabortion evaluation. Beginning in 2007, all patients also received routine antibiotic coverage beginning on the day of the mifepristone administration. The standard antibiotic regimen was a 7-day course of doxycycline (100 mg twice a day), with an alternative regimen of one dose of azithromycin (1 g) for cases in which doxycycline was contraindicated.

Our EPM database contains information on all patients undergoing medical abortion, including patient demographics and the ultrasound-determined gestational age. We also maintain a separate electronic database of adverse events including ongoing pregnancy, aspiration for symptoms and/or retained products of conception, infection requiring hospitalization, and hemorrhage requiring transfusion.

2.2. Statistical methods

Bivariate and multivariate logistic regression were used to assess predictors of successful medical abortion. Covariates available in our data set were poverty level, race/ethnicity, gestational age, and patient age; other patient-level data were not available. Results were considered statistically significant at $p < .05$. Statistical analysis was performed using Stata/SE 11.2 (College Station, TX).

The primary outcome of interest was successful abortion. A successful abortion was defined as expulsion of the pregnancy without the need for aspiration. Patients who required aspiration for an ongoing pregnancy or symptoms such as pain or bleeding were considered to have had unsuccessful medical abortions. We queried our adverse events database to identify continuing pregnancies (those pregnancies with documented fetal growth or cardiac activity seen at the follow-up), all cases of aspiration, and hospitalization for either infection or transfusion. We cross-checked this against the list of postprocedure visits in our EPM system in order to ensure that all cases had been identified.

Institutional review board (IRB) approval was obtained from the Ethical and Independent Review Service of Independence, MO, and an exemption for analysis of the existing data was granted by the Princeton University IRB.

3. Results

3.1. Sample description

For this descriptive study, we queried our EPM database and identified 15,890 patients who had a medical abortion between April 1, 2006, and May 31, 2011. During the period under review, medical abortions were provided at 14 different clinic sites belonging to our network in one urban area, all using the same evidence-based protocol. There were 2470 (15.5%) patients who failed to return for a follow-up visit and were excluded from analysis. An additional 20 patients were excluded from the analysis due to missing data on gestational age, and a further 27 patients were excluded because they did not complete the medical abortion (these patients either changed their mind and chose a surgical abortion, were ineligible for a medical abortion because they were beyond the 63-day gestational limit, or began the regimen but did not take all of the medications). This left 13,373 patients for analysis.

Demographic characteristics of the 13,373 women who had a medical abortion between April 1, 2006, and May 31, 2011, and who returned for follow-up are shown in Table 1. Half of the women were between the ages of 18 and 24, and small proportions were under the age of 18 (4.5%) or 40 or

older (2.2%). Nearly half of women identified as Hispanic or Latino, and 72% reported an income at or below the poverty line. The most frequent gestational age in our data set was 43 to 49 days (36.0%), and the least frequent was 22 to 28 days (4.1%).

3.2. Frequency and predictors of successful abortion

Termination of pregnancy with 200 mg of oral mifepristone followed by 800 mcg of buccal misoprostol 24–48 h later was successful among 97.7% of women who completed follow-up. Only 307 (2.3%) of the 13,373 women included in this study underwent aspiration for any reason. Specifically, 70 (0.5%) women had a continuing pregnancy, and 237 (1.8%) women required aspiration for reasons other than continuing pregnancy, most commonly due to reported symptoms of pain and/or bleeding. Data on the need for a repeat dose of misoprostol were available from a subset of women from clinics in which the EMR system was used, which included 7335 women (54.8% of the total sample). Of these 7335 women, 87 (1.2%) received a repeat dose of misoprostol.

Table 2 shows the proportion of patients requiring aspiration for ongoing pregnancy or for symptoms, such as heavy bleeding, by gestational age. The proportion with ongoing pregnancy ranged from 0.15% for those at 36 to 42 days of gestation to 1.63% at 57 to 63 days of gestation. Compared with the reference category (43 to 49 days), odds of ongoing pregnancy were greater for those at the highest gestational age. The proportion of women treated with aspiration for symptoms, not ongoing pregnancy, ranged from 0.65 to 2.49%. The incidence of hospitalization for infection or hemorrhage requiring transfusion was very low (Table 3). In total, six women required hospitalization for any reason (two women were hospitalized for infection, and four were hospitalized for transfusion), and incidence was at or below 0.1% among all gestational ages.

In a multivariate logistic regression model (Table 4), poverty level and race/ethnicity were not significant predictors of successful abortion. Certain categories of gestational age were significantly associated with success; compared with the reference category (43 to 49 days), those at 36 to 42 days of gestation had greater odds of success, whereas those at 50 to 56 days and 57 to 63 days had lower odds of success. Compared with the reference category (18 to 24), those in the middle three age groups had significantly lower odds of success, but differences for those in the youngest (17 and under) and highest (40 and older) age groups were not significant.

3.3. Loss to follow-up

A comparison of patients who completed follow-up and those who were lost to follow-up is presented in Table 5. Compared with patients at 43 to 49 days of gestation, patients at higher gestational ages were more likely to be lost to follow-up. For patients with incomes at or below the Federal Poverty Level (FPL), the odds of being lost to follow-up were greater than those above FPL. Odds of being lost to follow-up were greater for those younger than 18 (compared with those 18 to 24) and lower for those aged 40 and older.

4. Discussion

4.1. General implications

This study demonstrates that the evidence-based regimen for medical abortion (mifepristone 200 mg orally followed by home use of misoprostol 800 mcg buccally 24–48 h later) is highly effective through 63 days estimated gestational age, with an overall success rate of 97.7%. This is higher than the efficacy rates reported in two pivotal trials used in submission for FDA approval of mifepristone,[1,2] yet utilizes one-third the dose of mifepristone (200 mg rather than 600 mg) and buccal administration and home use of misoprostol rather than oral administration in the clinic. Repeat dosing of misoprostol was administered in only 1.2% of patients for whom this information is available, and given the way in which the EMR system was implemented across study sites, we can assume that this rate would be representative of the entire sample. Although efficacy is lower at later gestational ages, even in the 57- to 63-day range, this evidence-based regimen was still more effective than rates reported in the FDA-approved regimen, which sets the upper gestational age limit at 49 days. Furthermore, the rates of unsuccessful abortion in this study are lower than the rates reported in the two trials that were initially submitted to the FDA for approval of mifepristone.

* This column includes 29 cases wherein reason for aspiration is unknown.

This study adds to the growing literature supporting provision of medical abortion using evidence-based regimens, and supports the conclusion that legislative efforts to restrict medical abortion to the FDA regimen are based on political goals to restrict abortion services, not efficacy or patient safety.

4.2. Limitations

Our study has some limitations. It is retrospective in nature and relies on the accuracy of our EPM database. However, review of our EPM system has shown a high degree of accuracy when compared with patient records [13]. In addition, we are not a closed system, and it is possible and even likely that some patients who experienced complications did not return to us for care. However, since many patients need to pay for aftercare obtained outside our system, but not within our system, it is more likely than not that the patients who did not return for follow-up did so because they did not feel that they needed follow-up, rather than that they were experiencing a complication. In that case, excluding them from our analysis would have tended to overestimate, rather than underestimate, the need for aspiration in our population. We based our analysis of efficacy only on those patients who did return for a follow-up visit, so we cannot exclude the possibility of additional visits or treatment elsewhere.

Loss to follow-up is common in studies of medical abortion, as many patients may determine on their own that their abortion is complete and that follow-up is not needed. The rate of loss to follow-up in this study (15.5%) is lower than loss to follow-up found in other clinical medical abortion studies, which report loss of follow-up of 18 to 45% [14–17]. We found that loss to follow-up was significantly more common among those at higher gestational ages; given that odds of success are lower among those with more advanced pregnancies, it is possible that this study underestimates the true odds of unsuccessful abortion. Loss to follow-up was significantly higher among the youngest age group and lower among the oldest age group, but as these age categories were unrelated to whether the abortion was successful, we do not believe that these differences would systematically bias our results.

OR, odds ratio; CI, confidence interval.
[a] OR represents odds of being lost to follow-up.

48–72 h later is safe and effective through 63 days estimated gestational age. Further, need for aspiration for any reason was low, the chance of needing aspiration increased with gestational age at the time of medical abortion, and the frequency of hospitalization was rare. This study reinforces the safety and efficacy of the evidence-based regimen for medical abortion, and contributes to the evidence against restrictions that require use of the FDA-approved regimen.

Abstract

OBJECTIVE: To explore patient perspectives regarding patient–clinician communication during telemedicine medication abortion compared to traditional, facility-based, in-clinic visits.

METHODS: We conducted semi-structured interviews with participants who received either live, face-to-face telemedicine or in-clinic medication abortion from a large, reproductive healthcare facility in Washington State. Using Miller's conceptual framework for patient-doctor communication in telemedicine settings, we developed questions exploring participants' experiences of the medication abortion consultation, including the clinician's verbal and non-verbal interpersonal approach and communication of relevant medical information, and the setting where care was received. We used inductive-deductive constant comparative analysis to identify major themes. We summarize patient perspectives using patient–clinician communication terms outlined in Dennis' quality abortion care indicator list.

RESULTS: Thirty participants completed interviews (aged 20–38 years), 20 of whom had medication abortion by telemedicine and 10 who received in-clinic services. Participants receiving telemedicine abortion services reported high-quality patient–clinician communication, which came from their freedom to choose their consultation location and feeling more relaxed during clinical encounters. In contrast, most in-clinic participants portrayed their consultations as lengthy, chaotic, and lacking comfort. In all other domains, both telemedicine and in-clinic participants reported similar levels of interpersonal connection to their clinicians. Both groups appreciated medical information about how to take the abortion pills and relied heavily on clinic-based printed materials and independent online resources to answer questions during the at-home termination process. Both telemedicine and in-clinic participant groups were highly satisfied with their care.

CONCLUSION: Patient-centered communication skills used by clinicians during facility-based, in-clinic care translated well to the telemedicine setting. However, we found that patients receiving medication abortion through telemedicine favorably ranked their patient–clinician communication overall as compared to those in traditional, in-clinic settings. In this way, telemedicine abortion appears to be a beneficial patient-centered approach to this critical reproductive health service.

Précis:

Telemedicine appears to be a beneficial patient-centered approach to critically needed first-trimester abortion services.

Today, medication abortion makes up more than half of all abortions occurring in the United States (U.S.).[1] Abortion by telemedicine became more prevalent during the COVID-19 Public Health Emergency (PHE) when the U.S. Food and Drug Administration (FDA) temporarily, and then permanently suspended the mifepristone in-clinic dispensing requirement.[2] Requests for direct-to-patient telemedicine medication abortion services, in which patients choose where they receive care are expected to increase following the 2022 U.S. Supreme Court case Dobbs decision.[3,4]

Despite its growing use, data regarding best practices for patient-clinician communication when providing abortion care through telehealth are lacking. Patient-clinician communication is considered a critical element of patient-centered care, and has been associated with valuable health system outcomes, including increased patient trust, improved treatment adherence, overall positive patient experience, improved healthcare efficiency, and lower cost.[5–7]

For abortion care, however, patient-clinician communication considerations are unique because of both stigma and the systemic access issues that often compromise the ability for care to be patient-centered.[8] Unlike other aspects of reproductive health care, patients often obtain abortion care from someone other than their usual clinician, further compromising comfort and trust.[9–11] By interviewing participants who received direct-to-patient telemedicine medication abortion services, we explored the setting and how clinicians' interpersonal and communication behaviors affected the patient experience of patient–clinician communication compared to traditional, in-clinic medication abortion care.

METHODS

We conducted a cross-sectional, in-depth, semi-structured interview study of patients who had recently received an in-clinic or telemedicine medication abortion. This study received institutional review board (IRB) approval by the University of Washington (UW) Human Subjects Division (ID: STUDY00013954) and is reported using the Consolidated Criteria for Reporting Qualitative Research (COREQ) guidelines.[12]

The team consists of a Principal Investigator (PI) who is a Complex Family Planning Fellowship-trained physician with master-level training in qualitative research (EMG), a PhD candidate in public health with experience working in abortion policy and qualitative research (AEF), a medical anthropologist and a master's level qualitative methods consultant (EAJ), a research coordinator with a masters of public health in maternal/child health (MRR), a medical student (EVY) and a family physician who provides abortion care with research expertise in implementation science (IMB). Throughout the study period, we enlisted a Community Advisory Board that represented Latina, young adult, and rural communities, two abortion advocacy organizations and a staff member from the clinic where we recruited participants.

We used Miller's conceptual framework for the evaluation of patient-clinician communication in telemedicine settings (Fig. 1).[13] We chose this model because it incorporates core components of patient-centered communication that have been widely quoted in the literature. The Miller framework also includes a category with factors related to the medium (e.g., telemedicine) used for the patient–clinician encounter, a key aspect we sought to evaluate among our participants.

This study used convenience sampling of all patients who had been given the option to receive medication abortion either by telemedicine or in-clinic from a Washington State independent, high-volume reproductive healthcare clinic organization, Cedar River Clinics (CRC). CRC is certified by several networks, including the National Abortion Federation. CRC began offering telemedicine medication abortion services using live, face-to-face video conferencing software in April 2020, in addition to continuing traditional in-person, clinic appointments. Telemedicine appointments require a known last menstrual period within 7 days, regular periods, no symptoms or risk factors for ectopic pregnancy and verbal confirmation of a positive pregnancy test, without requiring an ultrasound exam for gestational dating. Washington State permits nurse practitioners to provide medication abortion services, thus participants' clinical encounters involved either a physician or nurse practitioner.

To be eligible, participants had to speak and understand English, be at least 18 years old, had either telemedicine or in-clinic medication abortion in the prior month, and agree to an audio-recorded interview. Because we were most interested in evaluating patient–clinician communication with novel telehealth abortion, we purposively enrolled more telemedicine than in-clinic participants. To recruit participants, CRC staff asked every eligible patient to indicate their interest in being contacted by the UW study team when they signed their consent for abortion services. On a weekly basis, CRC staff provided contact information of

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

interested patients to the research coordinator, who then attempted to contact each interested participant up to three times by email, text, or call over a two-week period. Contacted participants completed an eligibility survey in a secure REDCap database,[14] provided informed consent and scheduled an interview using an online calendar platform or by phone. Each participant received a $50 electronic gift card by email following their interview.

The qualitative methods consultant conducted semi-structured, in-depth interviews using HIPAA-compliant conferencing software at a time and place of the participant's choosing between September 2021-January 2022.

The research team developed the interview guide based on Miller's conceptual framework. Questions included the decision about the medication abortion service type (telemedicine vs. in-clinic), scheduling and attending their appointment, the clinician encounter, the setting where the encounter occurred, satisfaction with the care and clinical outcomes. Prior to initiating the interview, the qualitative methods consultant provided a brief description of the study team and assured participants their information would not be reported back to CRC. Each interview ranged between 35–60 minutes, was audio-recorded and transcribed. The interviewer recorded field notes after each interview, reflecting on data collection, personal biases, and patterns. No interviews were repeated. After the research team completed all the interviews, CRC provided the team with requested participant characteristic information (Table 1). Although an imperfect measure, we chose to list race/ethnicity as a proxy of shared lived experience to highlight the voices that informed this study.[15]

We used descriptive statistics to report participant characteristics. We used inductive-deductive constant comparative analysis to identify major themes and summarize patient perspectives consistent with Miller's conceptual model.[16] The analysts (EAJ and AEF) both coded the first ten interviews, meeting regularly to discuss coding discrepancies until they agreed on the codebook. After that point, they coded independently. The analysts created memos as they coded to track and synthesize thematic discussion and generate consensus. We defined data saturation as the point at which no relevant new themes related to the areas of focus were identified.[17] The analysts presented iterative summaries of the interviews to the larger research team and the community advisory board during the study's data collection and analysis phases. Dedoose software (version 9.0.62) was used to organize and manage the data . To increase the applicability of our findings to the abortion care setting specifically, we summarize patient perspectives using patient–clinician communication terms used in Dennis' quality abortion care indicator list (Fig 1).[18]

RESULTS

Of 42 patients who enrolled and scheduled interviews, our final study sample consisted of 30 individuals; 20 who received telemedicine and 10 who received in-clinic services (see Fig 2). Table 1 lists the selected sociodemographic characteristics of the study population. Twenty-three participants received their care from nurse practitioners and seven from physicians.

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

We identified four separate domains of patient-clinician communication. Within these domains, we identified 8 relevant categories and 17 factors representing the perceptions of patients who received either telemedicine or in-clinic care. Domains, categories, factors, and illustrative quotations are listed in Table 2. Based on our findings, we summarize best practices for patient–clinician communication for medication abortion services (Box 1).

Domain 1: Medical Consultation Settings

Factors related to the medical consultation setting includes: (1) geographic accessibility of the appointment with the clinician, (2) efficiency of services and (3) perception of space where care was received in terms of privacy and comfort, all of which affected participants' attitudes about the consultation visit. Factors related to telemedicine consultation settings contrasted considerably with in-clinic (Table 2, Domain 1).

Participants who received telemedicine reported feeling like the care was accessible and efficient. They appreciated choosing where their medical consultation occurred. Examples of telemedicine consultation settings included one's own bedroom, a friend's home, or their car. Participants chose these spaces because they were quiet, familiar, convenient, away from kids or workplaces, providing a more controlled and relaxed consultation compared to the in-clinic setting. Many emphasized that telemedicine allowed them to talk more freely and openly, and feel more confident about the privacy of their abortion decision. For example, one participant shared, "I definitely felt at greater ease doing a telemedicine appointment when it came to going over the information…just because I was more comfortable in my own environment versus having to go to a doctor's office" (Participant 15, Telemedicine).

In contrast, participants described in-clinic visits as less accessible, inefficient, chaotic, and lacking privacy. Many struggled with transportation, traveling several hours to get to and from the clinic and expressed concern about potentially encountering someone they might know at the clinic. Compared to the shorter time spent with telemedicine, in-clinic appointments required a full day off work, with many describing having to wait for 4–6 hours, being moved to different waiting rooms and seeing multiple clinicians. In-clinic participants reported the setting as confusing, redundant and inefficient, with "lots of shuffling around." One participant shared feeling indifferent about the in-clinic setting, and thus did not connect with their clinician, stating: "I really didn't care who I spoke with. Honestly, I just wanted to get out…Get it done." (Participant 23, In-clinic). Many in-clinic participants expressed frustration about perceived COVID-19 restrictions of not being allowed to bring snacks, a support person, or their children, which would have made them more comfortable.

Domain 2: Patient–Clinician Interactions and Decision Making

This domain includes factors related to patient screening, how patients are treated by clinicians and staff, and respect for patients' ability to make decisions about their care. We did not detect major differences within this domain between participants who received their care through telemedicine versus in-clinic (Table 2, Domain 2).

Participants were given thoughtful, thorough and complete answers from their clinicians and felt respected and heard. Participants described emotionally empathetic, attentive,

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

and non-judgmental interactions facilitated by clinicians with strong interpersonal skills. Telemedicine and in-clinic patients valued clinicians who personally customized the medical information to meet participant needs, concerns, and histories. A few participants preferred encounters that were brief and direct. In those instances, clinicians pivoted to that communication preference: “The doctor had a very straight to the point, matter-of-fact tone, and for me personally, that was helpful” (Participant 01, Telemedicine).

Domain 3: Clinician information provision, Postabortion Contraceptive Care, and Technical Competence

Within this domain, we compare factors related to participants receiving complete information about the medication abortion process and post-abortion contraceptive care, where to call if questions or complications arise, and quality of pain management. We did not detect differences within this domain between participants who received their care through telemedicine versus in-clinic (Table 2, Domain 3).

Most participants valued highly clinicians’ thorough explanation of the medication abortion process and symptom management. They appreciated when clinicians clearly and chronologically walked through the steps of medication abortion, including how to take the pills, when to expect symptoms to begin and end, and how to manage typical and atypical symptoms. They valued realistic, detailed information about how much blood to expect, especially compared to what is “normal,” intensity and length of pain, frequency of vomiting or diarrhea, and when symptoms typically subside. Most participants also appreciated clinicians’ suggestions regarding how to set up a supportive environment, such as requesting time off work, reassigning childcare responsibilities, and identifying a support person. Participants overwhelmingly applauded knowing about the clinic’s 24/7 nurse hotline for abortion-related questions, although few utilized it. “I didn’t feel as if I needed to (call) because I went online and I found my answers pretty easily…and everything seemed to be fine” (Participant 01, Telemedicine).

Many patients reported appreciating that the visit was not just about the abortion itself but included information about post-abortion contraceptive options: “We spent the bulk of the time talking about birth control…I said I wasn’t super worried about the abortion. I was more worried about birth control options because that’s something that I have struggled to figure out” (Participant 37, In-clinic). Participants expressed clinicians who took “extra” time to set up a contraceptive plan helped them feel confident that they would not need to pursue future abortions.

Clinicians seemed to lack technical competence related to adequate pain control, regardless of service type. Telemedicine and in-clinic participants equally made a point to mention the pain control recommendation given by clinicians was something they would have changed about their service. Participants appreciated hearing their options to treat the pain and cramping associated with pregnancy expulsion, such as heating pads, massage and over-the-counter medications and some conveyed adequate pain control. Nonetheless, a number of participants in both groups wished they had better access to pain relief (Table 2, Domain 3).

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

Domain 4: Outcomes Related to Patient Knowledge and Attitudes

Health outcomes include participants' feeling like they understood the information provided, overall satisfaction, and having trust and confidence in the clinicians (Table 2, Domain 4).

Participants in both groups reported they had sufficient and accurate information that allowed them to comply with the medication regimen. They also reported the ability to recall clinician-shared information to manage symptoms at home and remain autonomous throughout their abortion. When asked if they felt prepared regarding pill taking and abortion side effects, most participants felt their clinicians provided sufficient levels of detail and they were, in turn, able to describe those details during the interviews, while others used clinic handouts or conducted web-searches. Regardless, some telemedicine and in-clinic participants reported being unprepared for amount and duration of vaginal bleeding and pelvic pain.

Overall, telemedicine and in-clinic participants shared high levels of satisfaction of care. Telemedicine participants overwhelmingly reported being satisfied with their abortion visit, many stating that they would pursue it again or recommend it. In-clinic participants, on the other hand, reported that patients should have the option to decide between telemedicine and in-clinic services, with about half stating "next time" they would choose telemedicine. Both telemedicine and in-clinic participants also shared similar attitudes about trusting the clinic to provide high-quality abortion care. Feelings of trust were especially evident with a telemedicine participant who became stressed about waiting online for her clinician who was running 30 minutes behind schedule but had not been notified by the clinic about this delay. Despite feeling uncertain, the participant's attitude toward the clinic as a place to trust made her satisfied about this particular encounter: "What stuck out to me [as I was waiting for the clinician] is that I felt really confident…like everything was going to be fine and that they were really there to support my choice…" (Participant 32, Telemedicine).

DISCUSSION

Our results show that both telemedicine and in-clinic participants felt respected, heard, understood, and valued by their clinician who provides abortion. The ability to choose the consultation location allowed telemedicine participants to feel like their encounter was more controlled and relaxed, while most in-clinic participants portrayed it as lengthy, chaotic, and lacking comfort. Because this study occurred when COVID-19 infection was still widespread, we surmise that many of the in-clinic participant experiences were due to unpredictable staff absences and social distancing requirements limiting clinic capacity. These in-clinic constraints ultimately compromised overall patient-clinician communication.

Both telemedicine and in-clinic participants had less favorable views about the clinic's pain control regimen, with several expressing they felt unprepared for the pain associated with medication abortion. This is unsurprising given the limited high-quality evidence regarding adequate pain management during medication abortion.[19] While participants stated they knew about the 24/7 nurse line, for reasons we did not thoroughly explore, participants who felt unprepared about the pain asserted they wish they had more pain medications at the moment of their abortion. This suggests that even if they had phoned the 24/7 line, they

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

would have had to wait for a prescription to be called into a pharmacy for pick up, which may not have met their needs. Future studies should define patient characteristics associated with the need for additional pain medication to better inform clinic protocols.

Patient satisfaction with telemedicine over in-clinic care is consistent with other telemedicine abortion studies.[20,] Similar to other comparative telehealth and in-clinic studies, our telehealth participants appreciated reduced appointment times.[21,22] In contrast to a prior qualitative study in which some telemedicine participants stated they felt reduced personal interactions with their clinician than if they had seen them in-clinic, we detected no such difference.[23] This present study found that many of the patient–clinician interactions were consistent with behaviors and attributes associated with patient-centered communication. In essence, we showed that patient-centered communication qualities traditionally provided in the in-person abortion care setting can readily be translated to live, face-to-face video telemedicine.

The present study has several strengths. Based on our recruitment methods, each participant had had a medication abortion within the prior month. We also sampled to saturation and enrolled a relatively diverse participant population. Nonetheless, our study was limited by a convenience sample of participants who sought medication abortion within a single healthcare entity in Washington State, when the nation and state were still under a COVID-19 PHE. Thus, our findings may not be generalizable to all abortion care settings or to a time-period when the nation/state is not under a PHE. Our study evaluated participants who had live, face-to-face video telemedicine abortion care, which may not be applicable to asynchronous, online abortion care. Although we chose a conceptual framework that includes core components of patient-centered communication, we recognize it is a multifaceted construct, making it difficult to succinctly measure.[6,24,25] Ideally, patient–clinician communication is evaluated more comprehensively, using combinations of direct observations of clinical encounters or with standardized patients, validated survey measures that patients complete after the clinician encounter, post-visit patient interviews, and peer-colleague assessments.[6] Given the stigmatizing nature of abortion services, direct observations between clinicians and patients proved infeasible. Additionally, while there is a growing interest to develop and validate a person-centered abortion scale, such a scale has not been implemented for patients receiving abortion services through telemedicine.[26]

In conclusion, telemedicine is a beneficial patient-centered approach to critically needed first-trimester abortion services. To be patient-centered clinics should provide telemedicine abortion in the setting of the patient's choice and apply principles of patient-centered communication, including clinicians being non-judgmental, demonstrating respect and trust, tailoring to meet patients' needs, and explaining medication abortion processes and post-abortion contraceptive care as understood by patients. Clinics should also provide printed information with instructions about abortion pill use and where to call for questions and emergencies.

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

Box 1: Best practices for patient–physician communication for medication abortion encounters based on 30 in-depth interviews at a single healthcare facility

Patient–physician interactions:

- First minutes of the visit, create a non-judgmental, supportive, safe communication space
- Customize visits to meet patients' emotional/social needs. Some patients require straightforward facts and others need more emotional support
- Listen, pause
- Allow time/space for the patient to ask questions
- Express trust, validation and empowerment toward the fact this is the patient's decision to make
- Use check-back, have the patient summarize what was discussed

Provide the patient necessary information:

- Obtain baseline knowledge of what the patient knows and doesn't know about medication abortion
- Create awareness around the fact that most patients have already done extensive research
- Many patients already had an abortion, so consider asking about that first and tailor the visit accordingly
- Co-create a plan, order of events and ensure the patient knows what to expect in terms of passing the pregnancy at home
- Communicate first, yet flexible timing of events and symptoms [example, "Typical bleeding occurs between x # of days and y # of days but can also happen between z # of days and a # of days. If it is beyond a #, call the clinic."]
- Ensure the patient understands the details of taking the pills
- Ensure the patient has all the supplies potentially needed, especially for pain relief
- Post-abortion care is important- discuss birth control information and future fertility with the patient

Support:

- Ensure the patient knows how to get their questions answered
- Ensure the patient has social/emotional support in place
- Ensure the patient has a support person present at home during the procedure
- Reinforce that even though this is a home-based service, adequate time off work and childcare is needed
- High pain levels often necessitate last-minute medication or supplies so ensure someone can run to the pharmacy if needed

Setting:

- If telemedicine:
  - Send patients clear instructions about what programs to download before the telemedicine appointment and how to log onto the appointment
- If in-clinic:
  - Send patients clear directions that include how to find the clinic and get into the clinic Consider instructions with pictures
  - Communicate to patients what to expect inside the clinic (wait times, # of rooms/flow of visit, # of providers they will see)

Table 2:

Representative quotations, comparing telemedicine and in-clinic medication abortion care

Category	Factor	Telemedicine	In-clinic
Domain 1: Service geographic accessibility, efficiency of services, perception of space where care is received			
Setting	Geographic accessibility	"I wanted telehealth appointments because I live very rural. And I live on a farm and so access to services is really hard to get here and the community that my farm is near [a town that] is against all kinds of access to services like [abortion care]." (Participant 32, Telemedicine)	"Since I had to drive [more than 60 miles] to the clinic, [the in-clinic visit] …was like a whole day I spent doing that to take that first pill. Which if I had done it online and if I could take the pill at home, then I could have still gone about my day regularly and not wasted a day." (Participant 26, In-clinic)
Setting	Efficiency of services	"I liked the flexibility of doing things virtually, so I was able to just do it while I was at work. I didn't have to take time off because I [have to be at work during] the time that clinics are open." (Participant 08, Telemedicine)	"[While at the clinic I felt] like cattle herding, go in, get it done, go out and go to the next room. She didn't really say anything to me or walk me through anything, which I would have liked. But then [when you do get explained things], it felt redundant because you already get a big packet of paperwork while you're waiting… everyone is just reiterating the same thing, walking through the exact same thing. From Google I read it, I read it in the packet, I get told in the rooms and with the doctor, they tell me the same thing. So it kind of was redundant." (Participant 11, In-clinic) "Everybody was kind. Ultrasound tech was wonderful. And then I met the [clinician]. She was strained, I could see. She kept telling me, "I know it's you, I have not forgotten about you." And every time she passed by, she gave me some reassurance and very thorough, made sure I understood all the instructions. I just think it was just the waiting in between, that it could have been better." (Participant 09, In-clinic)
Setting	Privacy	"The doctor did tell me we were in a secure location, there wasn't anybody else around that had to deal with the appointment or anything. So I felt completely comfortable continuing on with the appointment via telemedicine." (Participant 15, Telemedicine)	"In the waiting room and there were 12 other women…And I was in that waiting room, I think for about half an hour. And then someone else came and brought me into an office type room. So there was the main meeting room, the ultrasound room, the second waiting room, and now I'm in an office room." (Participant 10, In-clinic)
Setting	Perception of space where care received	"I took the call on my lunch break from work… I was comfortable at a friend's apartment using her room…It was ideal for me…If it was in person, I would've been more emotional. I'm glad that I was in a safe place that if I needed anything, my friends were there…I felt very secure…Also I could be close to home versus traveling across the state to have this appointment…I would've had to get time off work. I didn't want to get in trouble with work. A video call made it way better." (Participant 03, Telemedicine)	"[The clinic space could have had] a more human touch to it. Like, hey, maybe there is like a vending machine or just something to distract yourself a little bit. Like they had a TV, but it wasn't on and it's just you get kind of antsy waiting there of course…just maybe a little cozier or something to put you at ease a bit more." (Participant 30, In-clinic) "The building was kind of set back away from the road. And there were two ladies with signs, right by the sidewalk, by the road. So I was in my car and I was just turning. But yeah, I saw a couple of protestors as I was leaving." (Participant 40, In-clinic)
Domain 2: Client-clinician interactions, decision making			
Client-clinician interactions	Respectful care	"[For the clinician] time seemed like it wasn't a concern. It wasn't like, 'Oh, I only have 15 minutes. Do you have any other concerns?' It was more making sure I felt comfortable, giving me that reassurance, going over the procedure, asking me if I had any questions." (Participant, 22, Telemedicine)	"I felt more heard than I ever have by any [clinician] ever prior talking to [Clinician Name] about birth control options....She gave me exactly what I asked for, which was a three month trial. And said I could come back for the rest of the year if I decide I like it." (Participant 37, In-clinic)
Client-clinician interactions	Positive interactions, promote an atmosphere of trust	"…I felt really comfortable with the doctor. He introduced himself, asked me about myself, told me about the process that he was going to go through…He was really knowledgeable, but also intentionally answered my questions in an accessible way. His whole demeanor was really	"She gave me time to ask questions and was reassuring that [abortion is a] pretty common thing, and it's not super scary…Her demeanor was supportive and she humored me with whatever I had to say. She behaved like a friendly mother… She gave you space and was not being overly scientific. I don't

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

Category	Factor	Telemedicine	In-clinic
		calm and personable…He wasn't trying to hurry me along to get to his next appointment. And whenever I'd ask a question, he'd wait a second, he'd say something positive to indicate he had heard my question, and then he would think for a second and then he would answer thoughtfully." (Participant 08, Telemedicine)	mind that in any other kind of medical interaction, but I think [abortion] needs a little bit more air to breathe and a little bit more human touch." (Participant 30, In-clinic) "… when I was with the doctor, she was making sure, 'Are you comfortable with this? Are you understanding this?' Not just speaking at me, she was definitely checking in repeatedly, 'Are you getting this? Is this what you want?' So that was nice." (Participant 11, In-clinic)
Client-clinician interactions	Promote patient's dignity	"…hearing from another woman [the clinician] that they understand why I am thinking about this option [was important], 'I totally understand why you're feeling [an abortion] might be necessary, you have a 3 ½ month old baby,'…she was very relaxed, knowledgeable, and she communicated really well, so it helped make my decision." (Participant 35, Telemedicine)	"[The clinician] had a social worker feel to her…we were both seated and [she had good] eye contact…she let me vent…I think every woman that makes it there might have some emotional baggage, so just being able to listen to that." (Participant 9, In-clinic)
Client-clinician interactions	Tailored care	"… I'd already [had a medical abortion] once before, so I knew what I was doing....but I [still] needed more information because ..from the time that I took the first pill to when I take the second dose, the timeframe had changed. That was confusing to me… but I was rest assured because I knew I was getting [printed] information with the medication." (Participant 42, Telemedicine)	"The [clinician] got me in and out. She was like, 'I know you've been here all day…I can go through everything. Or, since you've said you've [had an abortion] before, you can tell me if you don't need me to go through this or if you want me to go through it again.' I told her I honestly just want to leave. So [she honored that]. She just sped through the things that she absolutely needed to tell me." (Participant 23, In-clinic)
Decision-making	Interactions absent of bias or coercion, trusting patient to make informed decision	"[The clinician] started off the call by saying, 'This is a no judgment zone. We just want to make sure it's your decision and you're not being influenced by anybody. And as long as it's what's best for you, then that would be the right decision.'…That gave me the reassurance that I need to know that I'm making the best decision…it's a huge weight lifted off my shoulders." (Participant 22, Telemedicine)	"She asked me how I'm doing, and if anyone pressuring me to come and do it..she reassured me....she asked, 'Why are you here?' And I told her, 'It's just not the right timing. I have a life to build. I can always have kids later'…I appreciated that a lot." (Participant 27, In-clinic) "[The clinician] definitely asked when I was going to take the second [set of] pills, just so that she could have note of it and if I had a day that would be best. Since I did have work on the weekend, I wanted to take it as soon as possible so I could be back to kind of normal as soon as possible…I kind of had my mind made up already, so when she asked I kind of had my answers ready that I knew, regardless of if she had any opinion on it." (Participant 11, In-clinic)
Domain 3: Clinician information provision, assessing support system, technical competence			
Information provision	Explanation of abortion process	"She was very thorough with the health information…the information was actually quite overwhelming…there was a really long list of different symptoms that may arise from the pill, the whole process of taking the pill… Even if I were to go to the clinic, there is not really any way around that." (Participant 04, Telemedicine) "[The clinician] told me, 'This is how often you will be needing to change your padding.' And I asked, 'What's a lot? Because I have a heavy period…And then he asked me to describe my level of flow. And he said, 'No, it would be a lot heavier than that…'He was really specific in when I should be concerned and when I shouldn't be concerned. And the description that he gave was really accurate to my experience." (Participant 08, Telemedicine)	"…[the clinician] talked through the abortion pill procedure…about what would happen in my body, things to expect before going ahead…I took the first one, and we talked through when to take the next one, and again, what to expect. She was really thorough.... I appreciated that she read the materials with me, instead of handing me some things to read later. I have a copy so that I could look back on it, but really explaining what things mean, taking time to make sure that I understand what's going to happen." (Participant 37, In-clinic) "[The clinician] highlighted specific things, the big takeaways from the [written instructions], so that was nice." (Participant 11, In-clinic) "[The clinician] reminded me, you're going to want to take it easy and you're going to expect the bleeding, and the size of the blood clots, how long I could be bleeding for…There was certainly a lot of bleeding, but I was prepared for that…he also told me that I would feel like I kind of like flu like symptoms, so I knew I was going to feel crummy…" (Participant 41, In-clinic)
Information provision	Information about possible complications	"[The clinician] did tell me that they have 24-hour telephone support, so if I had any concerns or needed anything…that made me feel more	"[The clinic staff] let me know that there was going to be a 24-hour service line, I could call if I needed any help or if I had any questions or if I was worried

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

Category	Factor	Telemedicine	In-clinic
	and how to obtain appropriate care	comfortable, and it made me feel a lot better about their organization, just knowing that they have people that care enough to be on call 24 hours a day in case you would need something. Because it's something you don't want to just call like a friend or a regular doctor to ask about because a lot of people have varying opinions on abortion." (Participant 16, Telemedicine) "I definitely felt if there were more serious medical problems, then I could reach out to the clinic, but no [I did not need to call them], all of the symptoms that she said would happen, happened, and I was prepared for that…" (Participant 04, Telemedicine)	about something." (Participant 12, In-clinic) "[It was particularly helpful they said] to call them if there's any excessive bleeding over the four to six hour period…. there's also a 24-hour support line, if something is out of the ordinary or if there's excessive bleeding, I felt comfortable that I could call them and ask any questions." (Participant 26, In-clinic)
Information provision	Post-abortion contraceptive care information	"[The clinician] told me that she would send to the pharmacy Plan B just in case I do need it for the future…Not only did she care about the right now, she was trying to make sure I was good for future." (Participant 22, Telemedicine)	"[The clinician] gave me some plan Bs, which was really helpful." (Participant 27, In-clinic)
Support	Patient support systems	"[The clinician] asked if I had a support system and she was very concerned about who was going to be my care person. Which I thought was cool because it wasn't brought up to me in my first two visits at [an outside clinic]. And I thought looking back that was something that would've been extremely important… I had a lot of blood loss with my first [medication abortion] and it scared me to death and I didn't have anybody for helping me… [at this clinic], you have to have a care person. And I think that's absolutely how it should be." (Participant 07, Telemedicine)	"[The clinician] did say to have a support person, have someone to take care for your child [during the 4–5 hours of pain when passing the pregnancy]" (Participant 09, In-clinic).
Technical competence	Appropriate pain management	"I think what really helped is the tip that [the clinician] gave for while that process [of passing the pregnancy] was happening, to have a heating pad for the discomfort, because that helped more than anything. I didn't want to feel nauseous of having more pain medicine, so using the heat pad really, really eased everything." (Participant 02, Telemedicine) "The only thing that I would complain about is pain. I mean, [the clinician] had Naproxen sent to me, but …Naproxen…just wasn't what I needed because of how bad the pain was. And like me crying on the toilet because I'm in so much pain and basically screaming, yelling out because of the pain, it shouldn't be that bad." (Participant 29, Telemedicine).	"They gave me a tracking form to track my symptoms and track when I took the medication, so that was nice. Really easy process. I do remember there was one scary part on one of the forms that I filled out. It said that this might be the most pain that you've ever experienced in your whole life… I've birthed two children…it wasn't really painful at all." (Participant 40, In-clinic) "It was horrible pain, and Naproxen didn't do anything. I also took Tylenol…[The clinician] told us we could use a hot water bag…But the amount of cramping and the bleeding, it's just really hard to manage at home…" (Participant 09, In-clinic).
Domain 4: Outcome indicators: Patient knowledge and attitudes			
Client knowledge	Understand information given during clinic visit	"… Another nice thing is they send you a brochure with the medication. It was a quick, easy reference to answer common questions. I'm like, 'Oh, is this normal when I was taking it?' I could reference that pamphlet and that was super nice." (Participant 03, Telemedicine)	"[the clinical staff] gave me a lot of papers to read and I found those really, really good and all the kind of statistics and information and the things that could potentially go wrong. I thought that was really helpful and I felt comfortable because only recently I've heard at about the abortion pill." (Participant 26, In-clinic)
Client attitudes	Patient satisfaction	"I really felt cared for and even respected of how to take care of myself." (Participant 02, Telemedicine)	"[The clinician] was…easily the best doctor's appointment I have ever had. If I had to rank the experience, it would be a 10 out of 10 despite the wait." (Participant 37, In-clinic)
Client attitudes	Level of clinical competency	"I did end up bleeding a bunch and it was crazy. I was grateful that I was aware enough to say, '[The clinician] said to call this number on this paper.' [My husband called it and the nurse explained] to massage my stomach and it will help stop the bleeding and he did that and it worked." (Participant 25, Telemedicine)	"I didn't have anything happen [with the first pill], no cramping, no bleeding from that. 24 hours later almost exactly I dissolved the pills in my mouth. After the 30 minutes I swallowed them, and then probably 15 minutes later I threw everything up and I had to Google because I was like, 'Oh my god, did I just mess this whole thing up?' But I googled it and it basically was like, 'Yeah, it's fine as long as you

Author Manuscript Author Manuscript Author Manuscript Author Manuscript

Category	Factor	Telemedicine	In-clinic
			let it dissolve for 30 minutes.' So I was like, 'Well, hopefully that still works.' That was the only thing that I was like, 'They didn't tell me I could throw up then.'" (Participant 11, In-clinic) "Honestly the process seems kind of simple…. if it was super complicated, I'm sure [the clinician] probably could have dumbed it down, but you know, you just really put the pills in your mouth and let them sit there and whatever." (Participant 23, In-clinic)

doi: 10.5694/mja12.10297

Abstract

Objective: To describe the use of mifepristone in combination with buccal misoprostol in women undergoing an early medical abortion (EMA) in Australia.

Design, setting and participants: Retrospective, observational study of 13 345 EMAs (gestational age ⩽ 63 days) conducted at 15 Marie Stopes International Australia clinics between 1 September 2009 and 31 August 2011.

Intervention: Oral mifepristone 200 mg, administered at the clinic, followed 24–48 hours later by buccal misoprostol 800 µg, self-administered at home.

Main outcome measure: Failure rate (proportion of women with an incomplete abortion requiring surgical aspiration or a continuing pregnancy).

Results: Pregnancy termination follow-up information was available for 83.4% (11 155/13 376) of EMAs. From the patient demographic database, the EMA failure rate was 3.5% (465/13 345). Of these, most (382; 2.9% of total) were incomplete abortions requiring surgical aspiration, and 83 (0.6% of total) were continuing pregnancies. Haemorrhage (16; 0.1%) and known or suspected infection (25; 0.2%) were infrequent. One woman, who did not seek follow-up despite signs of infection, died from sepsis (< 0.01%). In 6755 EMAs with clinic follow-up from April 2010 to August 2011, 6381 women participated in a survey. Most reported medium or heavy bleeding and moderate or severe pain/cramps; most also reported that bleeding, pain/cramps and their overall experience were as expected or better than expected.

Conclusions: Mifepristone, with buccal misoprostol self-administered at home, for EMA up to 63 days of gestation had a low failure rate, was well accepted, and provided an effective treatment option with a favourable safety profile for women seeking an abortion in Australia.

The antiprogesterone mifepristone combined with a prostaglandin analogue (misoprostol or gemeprost) is effective for terminating early pregnancy and has a favourable safety profile.[1] Early medical abortion (EMA) regimens using 200 mg oral mifepristone and misoprostol have been endorsed by the Royal College of Obstetricians and Gynaecologists (RCOG) as an effective and appropriate method of terminating early pregnancy.[2] Randomised controlled trials have shown that mifepristone 200 mg followed 24–48 hours later by misoprostol is as effective as surgical abortion in gestations up to 63 days, with complete abortion generally occurring in 93%–98% of cases, incomplete abortion in 1.1%–4.2%, and ongoing pregnancy in 0.2%–2.7%.[3-10]

Since its first registration in France in 1988, mifepristone has been registered in around 50 countries and is on the World Health Organization list of essential medicines.[11] Mifepristone is currently an unapproved medicine in Australia, but can be accessed under the Authorised Prescriber provisions of the *Therapeutic Goods Act 1989*.[12] Results for Authorised Prescriber use of mifepristone in Australia[12-14] have been similar to those reported for other countries.[1]

The not-for-profit, non-governmental organisation Marie Stopes International Australia (MSIA) started Authorised Prescriber use of mifepristone–buccal misoprostol for EMA in Australia in 2009. This article describes outcomes from the use of this regimen in 13 345 EMAs.

Methods

Study information

This retrospective multicentre observational study was conducted at 15 MSIA clinics in New South Wales, Victoria, Queensland, Western Australia and the Australian Capital Territory. Women undergoing a medical abortion between 1 September 2009 and 31 August 2011 were retrospectively identified and data were collected from their patient records. The study was conducted in accordance with the Declaration of Helsinki. All women provided written informed consent for treatment. The Authorised Prescriber protocol and, retrospectively, publication of the data were approved by the Queensland Clinical Trials Network Human Research Ethics Committee. The study was retrospectively registered in the Australian New Zealand Clinical Trials Registry (ACTRN12611001051932).

Eligibility criteria

Women eligible for EMA had gestations of up to 63 days, as confirmed by ultrasound, and met the relevant state or territory's legal requirements for pregnancy termination.

Exclusion criteria included known or suspected ectopic pregnancy; concomitant administration of anticoagulants or corticosteroids; adrenal failure, inherited porphyria or haemorrhagic disorder; allergy to mifepristone and/or misoprostol; intrauterine device in situ; and pelvic infection. Unless they declined, women were screened for *Chlamydia trachomatis* and, based on a risk assessment, screened for other sexually transmitted infections. Women were not excluded based on their proximity to emergency medical care.

Treatment regimen

The mifepristone–buccal misoprostol regimen selected was based on the peer-reviewed literature, extensive experience of Marie Stopes International with mifepristone in the United Kingdom, and MSIA's 2-year experience using methotrexate–buccal misoprostol for medical abortion to 49 days of gestation. Mifepristone 200 mg (Linepharma) was administered orally at the clinic, followed 24–48 hours later by buccal misoprostol 800 µg (Pfizer), self-administered at home. Buccal administration involved placing four 200 µg tablets between

Editorial p 257

GBP-PET00272

the cheek and gum for at least 30 minutes; any undissolved residue was then swallowed. If women had no bleeding within 24 hours of misoprostol administration, they were instructed to contact the clinic and return, preferably within the next 24 hours, for a second dose of misoprostol 800 µg. Women were informed of the signs and symptoms of possible complications (including infection) and what to do if complications occurred. Women were strongly encouraged to have a support person present throughout the process and to attend a mandatory clinic visit about 2 weeks after their initial treatment to confirm pregnancy termination and exclude complications. All women had access to an MSIA-funded, Melbourne-based, 24-hour after-care, nurse telephone service; women with issues of concern were referred to an MSIA clinic or their local medical services. Prophylactic antibiotics were not routinely prescribed except for women considered at high risk of infection. Oral analgesics (paracetamol with codeine or ibuprofen with or without codeine) were recommended. Rhesus status was determined and rhesus D-negative women were administered rhesus D immunoglobulin (250 IU) at the time of mifepristone administration.

Assessments

Information on EMA outcomes and complications was collected, including incomplete abortion requiring surgical aspiration; ongoing pregnancy; bleeding; and infection. Pregnancy termination was confirmed using a combination of ultrasound, urine pregnancy test, serum β-human chorionic gonadotropin levels, patient history, and symptoms. At the follow-up visit, women were asked to complete a seven-item questionnaire on pain, bleeding and their overall experience; however, not all women completed the questionnaire or all questions. Questionnaire responses from April 2010 to August 2011 were analysed (the questionnaire was expanded in April 2010; data before this date were excluded).

Data collection and analysis

Patient demographic, follow-up and complications data were collected in three separate databases, with slight variances in the total numbers of EMAs. Patient disposition was summarised using frequency counts for the number of women undergoing an EMA, the number of EMAs conducted, and the proportion of women with a follow-up visit. Demographic variables were summarised using descriptive statistics, including mean, standard deviation and range for continuous variables, and frequencies and percentages for categorical variables. The number and type of complications were summarised using frequency counts and proportions. The failure rate was defined as the proportion of women with a treatment outcome of incomplete abortion requiring surgical aspiration or of continuing pregnancy. Statistical analyses were conducted using TIBCO Spotfire S+, version 8.2 (TIBCO Software Inc).

Results

Demographics

Between 1 September 2009 and 31 August 2011, 13 345 EMAs were conducted at 15 MSIA clinics using the mifepristone–buccal misoprostol regimen (Box 1). Of the 12 968 women who had an EMA, 362 women (2.8%) had more than one EMA (Box 1). The mean age of the women was 28.4 years (SD, 6.8 years) (Box 1) and the mean length of gestation was 6.3 weeks (SD, 0.9 weeks) (Box 2).

Follow-up

For most EMAs (11 155/13 376, 83.4%; Box 3), follow-up information was obtained, primarily via a clinic visit, to confirm pregnancy termination. During the study, an extra 31 EMAs were recorded in the follow-up database (13 376) than in the patient demographics database (13 345; 0.2% variance). This discrepancy may be related to duplication of patient records in the follow-up database and carryover of follow-up records from a previously used treatment protocol for EMA.

Complications and failure rate

The overall complication rate was low (519/13 345, 3.9%; Box 4). The EMA failure rate was 3.5% (465). Incomplete abortion requiring surgical aspiration occurred in 382 (2.9%) cases and continuing pregnancy in 83 (0.6%) cases. There were 16 cases of haemorrhage (0.1%). There were four cases (0.03%) of known and 21 cases (0.2%) of suspected infection, including one death from sepsis (< 0.01%). This woman suffered fever and flu-like symptoms about 6 days after taking mifepristone, but unfortunately did not seek medical advice, despite urging from family members. She died 9 days after taking mifepristone. Group A streptococcus (*Streptococcus pyogenes*) was identified from a vaginal swab and blood culture.

1 Demographic data for women undergoing early medical abortion (EMA) with mifepristone–buccal misoprostol

Characteristic	
Age, years	
Mean (SD)	28.4 (6.75)
Range	14–49

ACT = Australian Capital Territory. NSW = New South Wales. Qld = Queensland. Vic = Victoria. WA = Western Australia. * During the study, an extra 31 EMAs were recorded in the follow-up database (13 376) than in the patient demographics database (13 345; 0.2% variance). This discrepancy may be related to duplication of patient records in the follow-up database and carryover of follow-up records from a previously used treatment protocol for EMA. † Follow-up contact was made via a clinic visit or a telephone call. The use of different databases for recording those who had any follow-up (11 155/13 376; clinic or phone) and those who specifically had a clinic visit (8955/13 345) precludes a precise breakdown of the type of follow-up contact (clinic or phone). As 8955 women were known to have a clinic-based follow-up, about 2175 women may have had a phone-based follow-up (ie, assuming 83.4% of 13 345 patients had any type of follow-up). ◆

Feedback on the EMA method

From April 2010 to August 2011, 10 093 EMAs were conducted. In 6755 of these EMAs, women attended follow-up and were asked to complete a seven-item questionnaire; if a woman had more than one EMA, she was asked to fill out a questionnaire for each EMA. Responses were available from 6381 women. Almost all of the women reported medium or heavy bleeding (5914/6330, 93.4%) and the majority reported moderate or severe pain/cramps (5001/6381, 78.4%) (Box 5, A and B). Most women said the bleeding (5226/6233, 83.8%), pain/cramps (4829/6340, 76.2%), and overall experience (5660/6265, 90.3%) were as expected or better than expected (Box 5, C–E). Most women reported that they would choose the EMA method again (4939/6335, 78.0%) and would recommend it to a friend (4770/5196, 91.8%) (Box 5, F and G).

4 Reported complications for women undergoing early medical abortion (EMA) with mifepristone–buccal misoprostol

	No. of complications*
Total no. of EMAs	13 345
Complications†	519 (3.89%)
Type of complication†	
Incomplete abortion requiring surgical aspiration	382 (2.86%)
Continuing pregnancy‡	83 (0.62%)
Haemorrhage with transfusion	11 (0.08%)
Haemorrhage without transfusion	5 (0.04%)
Suspected infection	21 (0.16%)
Known infection§	4 (0.03%)
Pain requiring hospital treatment	5 (0.04%)
Surgical procedure chosen before misoprostol administration	2 (0.01%)
Drug reaction to misoprostol	2 (0.01%)
Death§	1 (< 0.01%)
Other (not specified)	3 (0.02%)

* Figures represent number of complications, except that relating to total number of EMAs. † Proportion of complications calculated based on the total number of EMAs (13 345), not the number of EMAs with follow-up data (11 155); the number and type of complications could not be calculated for EMAs without follow-up data. ‡ 82 of the 83 women had surgical intervention; one woman chose to continue the pregnancy and delivered a healthy baby. § One woman died from sepsis as a result of group A Streptococcal (*Streptococcus pyogenes*) infection. ◆

Discussion

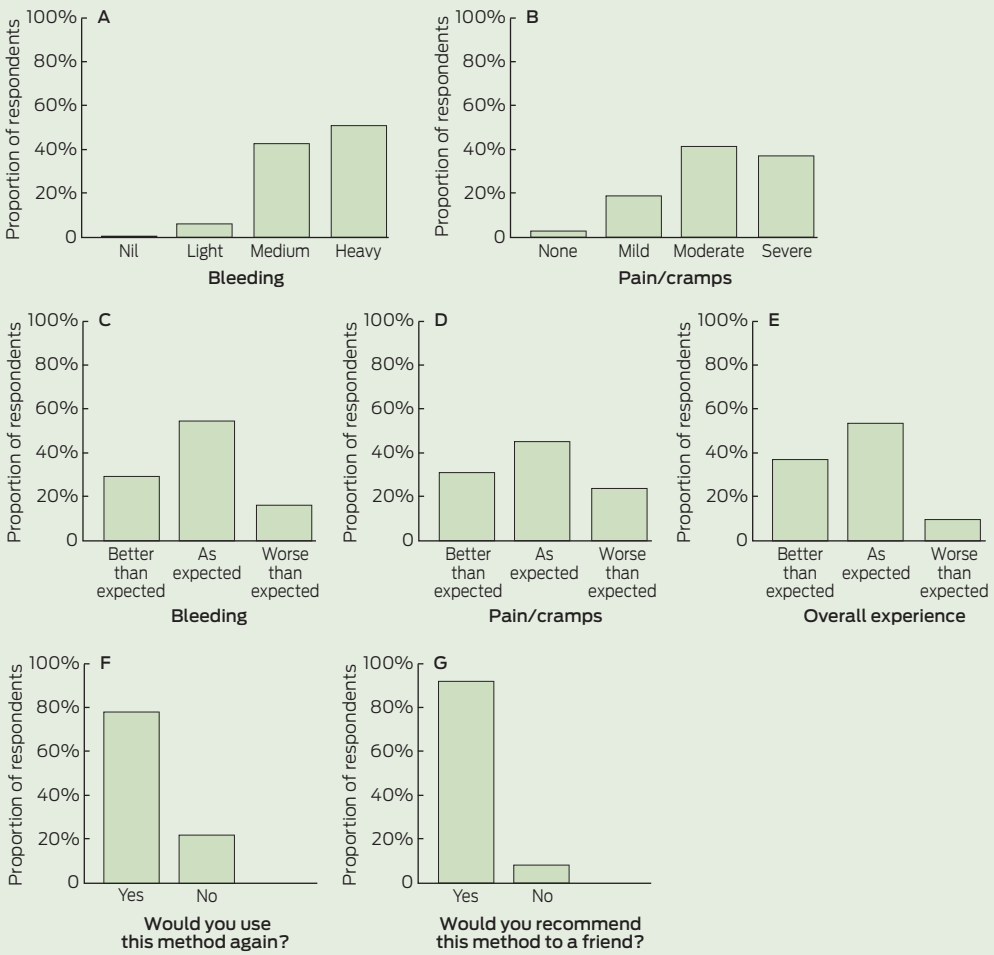
This is the first large-scale Australian study of mifepristone for EMA up to 63 days of gestation. Clinic-administered mifepristone (200 mg) in combination with home-administered buccal misoprostol (800 µg) was associated with a low failure rate, low rates of haemorrhage and infection, and was well tolerated.

The low failure rate (3.5%) with mifepristone in our study was similar to that reported for mifepristone in randomised controlled trials (failure rates, 2%–7%)[3-10] and in other Australian Authorised Prescriber Schemes (failure rates, 2.9%–5.6%).[13,14] Notably, the rate of surgical intervention for incomplete abortion declined from 4.3% during the first 3-month period of our study to 1.6%–2.6% during subsequent 3-month periods. We propose that as clinic staff gained experience with the EMA method, they felt more comfortable with expectant management rather than proceeding directly to surgical intervention.

In our study, there were four cases of known infection reported (0.03%), including one death from sepsis. Infection following medical termination of pregnancy is reported to occur in 0.02%–0.92% of cases.[15,16] Death resulting from infection and fatal toxic shock after medical abortion with mifepristone is a known, but very rare, risk (1.1/100 000).[15] Although the RCOG[2] recommends universal prophylactic antibiotics effective against *C. trachomatis* and anaerobes to reduce the risk of infection after medical abortion, the WHO[17] does not. At MSIA, all women are screened for *C. trachomatis*, unless they decline, and for other STIs based on a risk assessment. MSIA has upgraded its warnings to women regarding serious infections and also now provides an opt-in SMS service that reminds women 3–5 days after their visit about the after-care phone number and signs and symptoms of complications.

The regimen we used is similar to those recommended by the WHO[17] and the RCOG,[2] with buccal administration of misoprostol. Vaginal misoprostol has been associated with deaths from toxic shock syndrome in the United States[18] and some women may prefer buccal, rather than vaginal, administration. In addition, oral misoprostol is not sufficiently effective beyond 49 days of gestation.[1,2,17] Randomised controlled trials have shown mifepristone with buccal misoprostol to have efficacy similar to or greater than mifepristone with vaginal[7] or oral[19] misoprostol for terminating pregnancies up to 56 and 63 days, respectively. Our study provides further support for using 200 mg of mifepristone, which is lower than the 600 mg dose approved in the US and Europe.[1] Randomised controlled trials directly comparing the two mifepristone doses have shown similar efficacy for the 200 mg and 600 mg doses.[3,6] A Cochrane meta-analysis also found no difference in failure rates between the 200 mg and 600 mg doses.[20]

In our study, all women were informed of the need for mandatory follow-up to confirm pregnancy termination; contact with most women was achieved. Those who did not attend the clinic were telephoned and, if telephone contact was not possible, a registered letter was sent (the letter included a pregnancy test kit to facilitate home-testing). Despite these efforts, follow-up information was



GBP-PET00274

missing for around 17% of women. The loss to follow-up in our real-world setting of mifepristone use was higher than that observed in rigorous clinical trial settings (1.7%–8.6%).[3-5,8,9,21] As might be expected in clinical practice, not all patients may return for follow-up, even if instructed to attend a follow-up visit to assess treatment outcome. Given the emotional issues surrounding abortion, women who felt the abortion was complete and had no physical complications may have been reluctant to return to the clinic. While this is of concern, a recent study using early telephone follow-up after medical abortion to determine the need for further evaluation found that women who initially had not required evaluation returned to the clinic of their own accord if they experienced problems, such as bleeding or continuing pregnancy.[21] This finding suggests that women who experience adverse effects or feel that the abortion is not complete are likely to seek appropriate medical care. Indeed, in our study, about one-third of women did call the MSIA after-care service about issues such as pain or bleeding. While many women required reassurance only, some callers were referred to the clinic or a hospital for further assessment. In addition, it is possible that some women received follow-up care elsewhere. Not all women with complications, however, will decide to seek follow-up care and, in very rare cases (eg, one out of 13 345 cases in our study), this can have serious consequences. Understandably, such cases can raise concerns about the safety of home-based versus clinic-based administration of misoprostol. Although misoprostol could be administered in a clinic under medical supervision, home-based administration of misoprostol has been associated with a low complication rate, is preferred by women, and is common practice in France and the US.[1,22] Further, clinic-based administration of misoprostol would not necessarily enhance outcomes as medical abortion complications can occur hours or days after misoprostol is administered.

Overall, there was a high level of satisfaction with the mifepristone–buccal misoprostol regimen used, with most women who completed the study questionnaire reporting the bleeding, pain/cramps, and overall experience to be as they had expected or better than expected. Satisfaction with the EMA method used in our study was similar to that reported in other studies.[1,23,24] Notably, there has been a significant uptake of medical abortion in our clinics, with about a third of women requesting an abortion up to 63 days of gestation opting for the medical method (data not shown).

Our mifepristone–buccal misoprostol EMA method could be used outside a hospital setting. The diagnosis and initiation of treatment (mifepristone) can be conducted in a clinic and the second part of the treatment (misoprostol) can be carried out by the woman at home, with 24-hour access to after-care services to manage any issues. This arrangement, along with the 24–48-hour window for misoprostol administration, allows the abortion process to take place in the privacy of the woman's home and at the time of her choosing, factors known to be of importance to women undergoing an abortion.[1,23,24] The clinic- and home-based nature of the mifepristone–buccal misoprostol regimen makes it feasible for use in regional centres of Australia. These centres may have smaller hospitals than urban areas, but have the facilities and staff to manage spontaneous miscarriage.[24] The MSIA clinics are located in major metropolitan areas and women are provided with discharge letters. Any woman contacting the after-care service can be referred back to the MSIA clinic or to her local doctor or, if necessary, a nearby accident and emergency facility. In clinical

5 Results of patient survey on the early medical abortion method, April 2010 – August 2011

Women were asked (i) to describe the severity of their bleeding (A; *n* = 6330) and pain/cramps (B; *n* = 6381); (ii) whether the bleeding (C; *n* = 6233), pain/cramps (D; *n* = 6340), and overall experience (E; *n* = 6265) were better than expected, as expected, or worse than expected; (iii) whether they would choose the method again (F; *n* = 6335); and (iv) whether they would recommend the method to a friend (G; *n* = 5196). ◆

practice, proximity to emergency services should be evaluated when considering the use of the mifepristone–buccal misoprostol regimen. The potential need for access to appropriate 24-hour emergency help could limit the use of this regimen in more remote areas of Australia.

The observational nature of our study allowed assessment of the mifepristone–buccal misoprostol regimen in a real-world setting. However, as discussed, one of the study limitations was the relatively high rate of loss to follow-up. As a result, it was not possible to accurately determine the complete abortion rate; instead the known failure rate was reported. In addition, the use of multiple databases for data collection led to some small discrepancies in the datasets used for the analyses (eg, different total numbers of EMAs), because of differences in how the data were collected.

In conclusion, our Australian study of 13 345 EMAs has shown that mifepristone followed by buccal misoprostol has a low failure rate, including a low ongoing pregnancy rate. The regimen, which involved self-administration of misoprostol and completion of the abortion process at home, had a favourable safety profile and was well accepted by the women in this study. While the potential risk of serious infection should be kept in mind and monitored, these results indicate that the mifepristone–buccal misoprostol regimen is an effective option for Australian women seeking an abortion up to 63 days of gestation.

Medical termination of pregnancy at 63 to 83 days gestation

Elaine V. Gouk *Specialist Registrar*, **Karen Lincoln** *Specialist Registrar*, **Anu Khair** *Associate Specialist*, **Joanne Haslock** *Sister*, **June Knight** *Staff Nurse*, **Derek J. Cruickshank** *Consultant*

Department of Obstetrics and Gynaecology, South Cleveland Hospital, Middlesbrough

Objective To assess the efficacy of a medical regimen for the termination of pregnancy within the gestational age range of 63 to 83 days.

Design Prospective observational study.

Setting Gynaecology department within a district general hospital.

Population Women attending the pregnancy advisory clinic between June 1996 and December 1997.

Methods The medical regimen used was mifepristone 200 mg orally followed after 36 to 48 h by misoprostol 800 μg administered vaginally.

Main outcome measures The success rate of the medical termination of pregnancy regimen, where success was defined as achieving complete abortion without the need for secondary intervention by either surgical or repeat medical means.

Results Primary medical termination of pregnancy was chosen by 253 (80·8%) of the 313 women and was successful in 239 (94·5%). Repeat medical treatment achieved completion of the abortion in a further three women (1·2%) and surgical evacuation of the uterus was required in 10 (4·0%). One woman declined further intervention after failed medical treatment but subsequently miscarried.

Conclusions The combination of mifepristone and misoprostol is effective for the termination of pregnancy for gestations of 63 to 83 days.

INTRODUCTION

The efficacy and acceptability of medical termination of first trimester pregnancies up to 63 days of gestation have been established[1]. Various medical regimens have been used, but those with the most favourable results have involved the sequential administration of mifepristone and a prostaglandin. Comparative trials have shown that a reduction in the oral dose of mifepristone from 600 mg to 200 mg does not affect the efficacy[2,3]. In the United Kingdom the most commonly used prostaglandin preparations are gemeprost and misoprostol. Misoprostol is much cheaper and does not require special storage facilities. The results of trials in very early first trimester and second trimester termination of pregnancy have shown that misoprostol is as effective as gemeprost[4–6]. Misoprostol is absorbed by the oral route but vaginal administration is associated with fewer side effects and improved efficacy[7,8].

Over 47% of the 154,315 terminations performed in England and Wales in 1995 were carried out at gestations of between 9 and 12 weeks[9]. Within the gestational age range of 63 to 83 days there has been little research into the efficacy of medical termination of pregnancy and the standard management is surgical.

At South Cleveland Hospital, before June 1996, the choice of surgical or medical termination of pregnancy using the combination of mifepristone and misoprostol was offered only to women with a pregnancy of less than 63 days. Medical termination of pregnancy was also used at gestations of 84 days or more. For women undergoing termination at gestations of 63 to 83 days, the only treatment offered was surgical. The aim of the present study was to assess the efficacy of extending the early first trimester medical termination management to those with gestations of 63 to 83 days.

METHODS

Women requesting termination of pregnancy attended the clinic in the gynaecology department and all the cases reported fulfilled the criteria of the 1967 Abortion Act. All women underwent a transvaginal ultrasound scan to confirm the gestational age. From June 1996, women with gestations of 63 to 83 days who had no medical contra-indications to the mifepristone–misoprostol regimen were offered termination by vacuum aspiration or medical treatment. They were informed

Correspondence: Dr E. V. Gouk, Department of Obstetrics and Gynaecology, North Tees General Hospital, Hardwick, Stockton on Tees TS19 8PE, UK.

© RCOG 1999

that the success rate for the medical treatment at this gestation was not known and that if it failed they could proceed with the surgical treatment. Written consent for medical treatment was obtained.

Oral mifepristone 200 mg was administered either on the same day as the clinic visit or within the following two days, depending on the availability of the allocated beds in the gynaecology ward. The woman was allowed home half an hour after mifepristone administration, with an appointment to return for admission to the gynaecology ward after a further 36 to 48 h. She was advised that in some cases abortion may occur at home following the mifepristone.

After admission, misoprostol 800 μg was administered vaginally. All loss was assessed by staff for the presence of products of conception. If none were passed within eight hours of misoprostol administration, a speculum examination was performed and any products of conception in the vagina or cervix were removed. Unless there were complications, women were discharged home on the same day.

Women who had not responded to the medical treatment within 24 hours of misoprostol administration were offered surgical termination of pregnancy. If they had had some bleeding but had not passed definite products of conception they were offered, as an alternative to directly proceeding with a surgical termination, a repeat transvaginal ultrasound scan and review at the clinic the following week. Women who had passed products of conception consistent with a complete abortion had follow up at six weeks arranged with their general practitioner. No formal hospital follow up appointment was given. The women were advised to report to the hospital if there was an increase in the bleeding, if the bleeding had not subsided over the following 10 days, or if they developed pain or any other problem. When products of conception had been passed after the medical treatment but there was doubt about the completeness of the abortion, a follow up transvaginal ultrasound scan and clinic review were arranged for approximately 10 days later.

At the time of the initial clinic visit, the women were given a treatment information leaflet which included a telephone number and named members of staff to contact if there were any concerns or complications. They also had direct access to the clinic or gynaecology ward during the medical treatment and for six weeks after the termination.

All women undergoing termination of pregnancy received a 10 day course of oral doxycycline. Rhesus negative women received anti-D at the time of the abortion. Future contraceptive plans were established at the time of the initial assessment in the clinic.

The data were collected prospectively. Fisher's exact test and Armitage's χ^2 test for trend[10] were used for statistical analysis.

RESULTS

From June 1996 until December 1997, 313 women underwent a termination of pregnancy at 63 to 83 days of gestation. Of these, 253 (80·8%) chose medical treatment and 60 (19·2%) opted for primary surgical termination of pregnancy. The age range for those undergoing medical termination was 14 to 42 years with a median of 22 years. Of the 253 women, 151 (59·7%), were nulliparous.

Successful medical management was defined as complete abortion without the need for secondary intervention either by further prostaglandin administration or surgical evacuation of the uterus. The medical management was successful in 239 (94·5%) of the 253 cases. Table 1 shows the success rates for the various gestations within the 63 to 83 day range. There was no obvious trend between gestational age and success rate and Armitage's χ^2 test for trend proved insignificant (P = 0·44).

The outcomes for women undergoing medical management are illustrated in Fig. 1. In four cases (1·6%) complete abortion followed the administration of mifepristone alone. All four women were nulliparous and the gestational ages were 63, 64, 69 and 81 days.

Of the 235 women with successful medical termination after receiving misoprostol, no definite products of conception were seen by staff in four cases. In those cases where definite products of conception were identified and the time to achieve abortion after misoprostol administration was recorded, the range was from 70 to 690 minutes with a median of 290 minutes (Fig. 2).

In total there were 14 failures (5·5%) in the medically managed group. When there had been no response to medical treatment 24 hours after misoprostol administration, the women were offered surgical termination. Three women, however, requested continuation of medical management and after repeat prostaglandin therapy all three proceeded to complete abortion.

After medical management ultrasound scans were performed in 30 (11·9%) cases. Only two of these resulted from referrals with suspected complications. In one there was increased bleeding on the second day at home and in the other case slight bleeding persisted for three weeks. In both cases no treatment was required

Table 1. Success rates for medical termination of pregnancy at varying gestations.

Gestation (days)	Group size (n)	Successful (n)	Success rate (%)
63–69	127	120	94·5
70–76	75	73	97·3
77–83	51	46	90·2

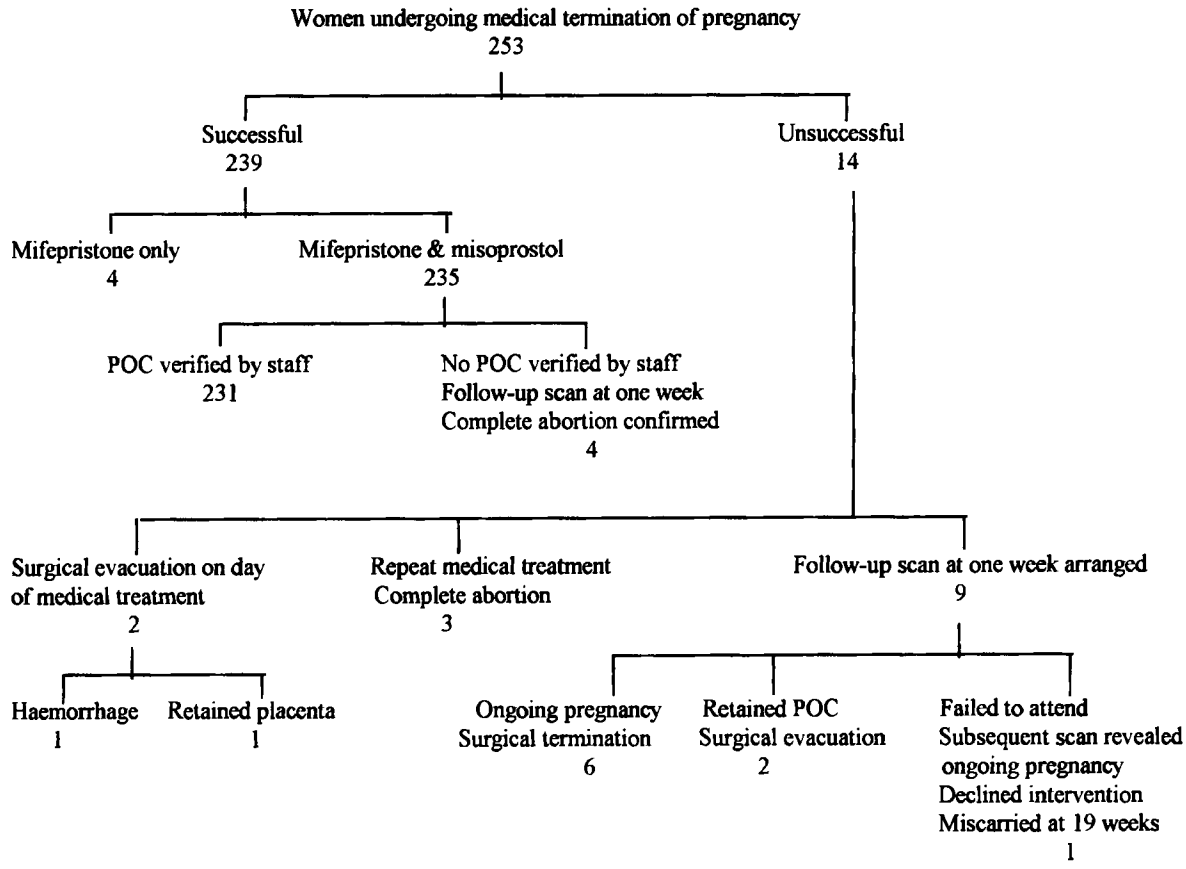

Fig. 1. Outcomes of medical management (POC = products of conception).

and the scans did not show signs of retained products of conception. In three cases a scan was organised to confirm complete abortion before inserting an intrauterine contraceptive device. The remainder of the scans were performed either because no definite products of conception had been seen or to assess the completeness of the abortion, and the details of the outcomes have already been outlined.

No analgesia was requested by 181 (71·5%) of the 253 women undergoing medical management. Nulliparous and multiparous women did not differ in this respect ($P = 1$). Oral analgesia only (Co-proxamol) was required by 63 women (24·9%). Nine women (3·6%) required intramuscular opioid analgesia. There was no statistical difference ($P = 0{\cdot}32$) between the opioid analgesia requirements of the nulliparous women (4·6%) and the multiparous women (2·0%). There was a statistically significant trend ($P = 0{\cdot}039$, Armitage's χ^2 test for trend) for increasing analgesic requirements with increasing gestational age, with some form of analgesia being required for 22·0% of women with gestations of 63 to 69 days, 34·7% at 70 to 76 days and 35·3% at 77 to 83 days.

Gastrointestinal side effects, mainly nausea and vomiting, were reported by 10 women (4·0%), of whom eight required anti-emetic treatment. Heavy bleeding was reported by seven (2·8%). In four women there was a brisk loss of short duration at the time of the abortion, requiring intramuscular ergometrine administration. In a fifth woman a moderate loss was reported at home. There were no clinically significant alterations in the haemoglobin concentrations in this group. There was clinically significant blood loss in two women (0·8%). In one there was heavy bleeding at the time of abortion,

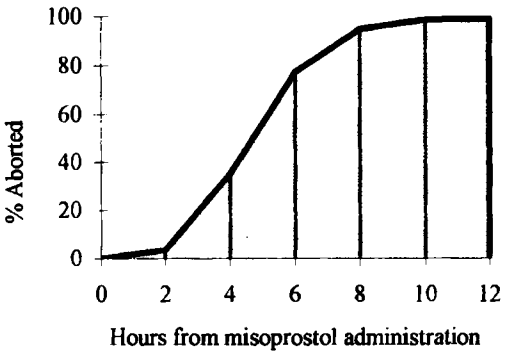

Fig. 2. Time to achieve abortion following misoprostol administration.

GBP-PET00279

resulting in a fall in the haemoglobin concentration by 2 g/dL. The bleeding promptly resolved and oral iron therapy was the only treatment required. In the other woman surgical evacuation of the uterus and transfusion of two units of blood were required. There was one reported case of post-abortion pyrexia. Of the 253 women who commenced medical termination of pregnancy only six (2·4%) required overnight stay in the hospital.

DISCUSSION

The success rate of 94·5% reported in this study is similar to other studies for gestations of less than 63 days[1,2,4,7]. This is in contrast to the reported decline in efficacy with increasing gestation observed by Spitz *et al.*[11], although in that study the misoprostol was at a lower dose and administered orally. We did not demonstrate a trend between efficacy and gestation, although our study does not have the power to pick up a slight trend.

Repeat misoprostol administration has been shown to increase the abortion rate of a medical management regimen[12]. Ashok *et al.*[13] have recently published the results of 120 cases of medical termination of pregnancy at 9 to 13 weeks of gestation using vaginal misoprostol 800 μg followed by repeat misoprostol 400 μg three hourly on two occasions as required, and they reported a success rate of 95%. In our study the repeat administration of misoprostol 800 μg improved the complete abortion rate with medical management to 95·7%.

The uptake of medical termination of pregnancy was remarkably high in our study given that the women were aware that the success rate for such treatment at 63 to 83 days of gestation was not known and may be low. It is, however, consistent with the chosen method of termination by the women seen in this unit at gestations of less than 63 days. In 1994 Cameron *et al.*[14] reported on the progressive rise in uptake of medical termination of pregnancy. The fact that the woman has a choice is important. A woman who undergoes termination of pregnancy by the method of her choice is more likely to be satisfied with the treatment[15].

A comparative study of blood loss in medical and surgical termination of early first trimester pregnancies reported a statistically, but not clinically, significant increased blood loss in the medically managed group[16]. Rodger *et al.*[17] reported a median blood loss of 74 mL during early first trimester medical termination of pregnancy and a positive correlation between increasing gestation and haemorrhage. In our study, however, the transfusion rate was only 0·4%, which is similar to the 0·7% reported for gestations of less than 63 days[1].

The low rate of gastrointestinal side effects in this study possibly reflects the fact that the women were not asked to record any side effects. Most of the gastrointestinal side effects associated with medical regimens are mild. Our recorded rate more accurately reflects the more severe side effects which were reported by the women requiring anti-emetic or anti-diarrhoeal agents.

Reported analgesic requirements for early medical termination of pregnancy vary greatly between centres, ranging from 12·5%[12] to 68%[11]. The trend for increasing analgesic requirement with increasing gestational age in this study supports the previously reported association between pain and gestation at time of abortion[18].

The risk of developing post-abortion infective complications can be significantly reduced by the administration of prophylactic antibiotics at the time of the pregnancy termination[19]. A prophylactic antibiotic regimen was used in this study, but a preferred regimen would have included metronidazole in addition to the doxycycline[20]. In this study there was only one recorded case of post-abortion infection requiring antibiotic treatment. The majority of women, however, were not seen for review at the hospital and therefore the number treated for post-abortion infection by their general practitioner is not known. Medical termination of pregnancy in the early first trimester is associated with a lower rate of infection, as assessed clinically, compared with surgical treatment[18].

CONCLUSION

Sequential oral mifepristone and vaginal misoprostol are an effective medical regimen for the termination of pregnancy at 63 to 83 days and offer an alternative to conventional surgical management.

Review article

Alternatives to ultrasound for follow-up after medication abortion: a systematic review

Daniel Grossman*, Kate Grindlay

Ibis Reproductive Health, Oakland, CA 94612, USA

Received 25 May 2010; revised 3 August 2010; accepted 31 August 2010

Abstract

Background: Requiring a follow-up visit with ultrasound evaluation to confirm completion after medication abortion can be a barrier to providing the service.

Study Design: The PubMed (including MEDLINE), Cochrane Central Register of Controlled Trials and POPLINE databases were systematically searched in October and November 2009 for studies related to alternative follow-up modalities after first-trimester medication abortion to diagnose ongoing pregnancy or retained gestational sac. We calculated the sensitivity, specificity, positive predictive value and negative predictive value compared with ultrasound or clinician's exam. We also calculated the proportion of cases in each study with a positive screening test.

Results: Our search identified eight articles. The most promising modalities included serum human chorionic gonadotropin measurements, standardized assessment of women's symptoms combined with low-sensitivity urine pregnancy testing and telephone consultation. These follow-up modalities had sensitivities ≥90%, negative predictive values ≥99% and proportions of "screen-positives" ≤33%.

Conclusions: Alternatives to routine in-person follow-up visits after medication abortion are accurate at diagnosing ongoing pregnancy. Additional research is needed to demonstrate the accuracy, acceptability and feasibility of alternative follow-up modalities in practice, particularly of home-based urine testing combined with self-assessment and/or clinician-assisted assessment.

1. Introduction

Routine follow-up visits after medication abortion are recommended or required by most medication abortion protocols, primarily to diagnose ongoing pregnancies [1–6]. While ongoing pregnancy is relatively rare following early medication abortion, occurring in approximately 0.4%–3% of women with the mifepristone–misoprostol regimen [7–9] and in 5% with the misoprostol-alone regimen [10], several studies have shown that the incidence of ongoing pregnancy increases with increasing gestational age [7,9,11,12].

Ongoing pregnancy is typically identified during a follow-up visit via ultrasound or clinician's exam, and although pelvic ultrasonography is not required by the FDA-approved mifepristone label [13], many US facilities employ it to detect ongoing pregnancy [14]. Routine use of ultrasound adds considerable costs to medication abortion provision, and it may not be widely available in low-resource settings [15]. Furthermore, attending follow-up visits incurs additional expenses to women, including travel costs, lost wages and childcare costs [16]. The number of abortion providers, particularly in rural areas and certain states, has declined in the United States [17–19], resulting in some women traveling farther to obtain care and further compounding the difficulties and costs of attending a follow-up visit. The health system itself is also impacted when clinics have no-shows and cancelations, for which they are not reimbursed [16]. Due to these factors, there is growing interest to consider alternative ways to identify ongoing pregnancy following medication abortion.

This systematic review examined the evidence regarding alternative modalities of follow-up that do not require ultrasound evaluation. We focused on the accuracy of these alternative modalities in detecting ongoing pregnancy

or retained gestational sac compared with the gold standard of ultrasound (or clinician's exam if ultrasound was not performed).

2. Methods

2.1. Sources

Investigators systematically searched the PubMed (including MEDLINE), Cochrane Central Register of Controlled Trials and POPLINE databases in October and November 2009 to identify studies evaluating alternative modalities of follow-up after first-trimester abortion using the following search terms: ("Abortion, Induced" [Majr] OR "Abortion, Therapeutic" [Majr]) AND ("Office Visits" [Mesh] OR "Outcome Assessment (Health Care)" [Mesh] OR "Postoperative Care" [Mesh] OR "Aftercare" [Mesh] OR "Ambulatory Care" [Mesh] OR "return visit" OR "aftercare" OR "follow-up visit" OR "post-operative care") NOT ("Pregnancy Trimester, Second" [Mesh] OR "second trimester"). We reviewed articles that had at least the abstract in English. The bibliographies of relevant articles were reviewed to identify other pertinent publications, and we also contacted prominent researchers and colleagues to identify articles that were in press.

2.2. Study selection

We reviewed titles and abstracts to identify studies related to follow-up after first-trimester abortion. We included prospective cohort studies, diagnostic test evaluation studies, clinical trials and pilot studies that examined modalities of follow-up that are an alternative to ultrasound for diagnosing ongoing pregnancy after medication abortion. While ongoing pregnancy is the primary outcome of interest, we also included studies that examined follow-up modalities to diagnose retained gestational sacs after medication abortion if ongoing pregnancy was not specifically identified. We decided to use ongoing pregnancy and retained gestational sac as the outcomes of interest because they can be objectively diagnosed with ultrasound, as opposed to other complications of medication abortion, such as incomplete abortion, that are clinical diagnoses. We assessed study quality primarily by focusing on whether the reader of the alternative modality was blinded to the result of the reference test (usually ultrasound) and whether the alternative modality involved a standardized assessment. We excluded studies related to second-trimester abortion, unsafe abortion, medication abortion regimens, service delivery, legal analysis and abortion beliefs or attitudes.

In order to compare alternative follow-up protocols, we calculated the sensitivity, specificity, positive predictive value (PPV) and negative predictive value (NPV) for diagnosing ongoing pregnancy or retained gestational sac, along with 95% confidence intervals (CIs) for these measures [20], compared with the gold standard of ultrasound [5] or clinician's exam. We also calculated the proportion of all cases in the study with a positive screening test. This measure is useful to compare the proportion of clients using the follow-up modality that would be referred for further evaluation (such as ultrasound). The three measures that we focused on were sensitivity (the proportion of women with ongoing pregnancy or retained gestational sac who were correctly identified by the modality), NPV (the proportion of women with negative test results who were correctly diagnosed) and the proportion with a positive screen. We contacted the authors to confirm our calculations and in one case reviewed the actual study data. Of note, in some articles, the accuracy measures were reported for diagnosing successful expulsion rather than ongoing pregnancy. Because ongoing pregnancy is the potentially concerning outcome, we recalculated accuracy measures for diagnosing ongoing pregnancy or retained gestational sac whenever possible.

We included participants who presented for unscheduled visits before going through the follow-up modality or algorithm being studied as "screen-positives" since these women end up receiving additional evaluation from the perspective of the clinic system. Any ongoing pregnancies or other complications among these self-referred women are also accurately detected. Therefore, our measures of accuracy relate more to how the modality performs in the context of a service, rather than the accuracy of the modality alone.

We did not conduct meta-analyses due to heterogeneity across studies with respect to the follow-up modalities studied and the outcomes measured.

3. Results

The literature search identified 393 articles. Among these, we identified eight studies that compared two or more follow-up modalities [12,15,21–26], including women's self-assessment, clinicians' assessment, serum human chorionic gonadotropin (hCG) measurements, urine pregnancy testing (UPT) and combinations of the above.

3.1. Women's self-assessment

Our review identified two studies that examined women's self-assessment for diagnosing ongoing pregnancy or retained gestational sac compared with ultrasound or physician's exam [12,24]. We identified a third study that examined women's self-assessment for diagnosing incomplete abortion [27], but it was excluded from our analysis due to the vagueness in definition of the outcome.

The first study was conducted in 1994–1995 among 2121 US women pregnant up to 63 days' gestation who were administered mifepristone 600 mg orally and misoprostol 400 mcg orally 48 h later [12]. At follow-up (Day 15), 1980 women were asked if they felt expulsion had occurred. Women's self-assessment correctly predicted 95 of the 111 ongoing pregnancies that were confirmed by the clinician

Table 1
Accuracy of women's self-assessment to detect ongoing pregnancy or retained gestational sac after medication abortion

Study	*n*	No. of ongoing pregnancies	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Screen-positive
Harper et al. [12]	1980	111	85.6% (77.3%–91.3%)	19.2% (17.4%–21.0%)	5.9% (4.8%–7.2%)	95.7% (93.0%–97.5%)	81.1%
Creinin et al. [24]	50	27[a]	51.9% (32.4%–70.8%)	65.2% (42.8%–82.8%)	63.6% (40.8%–82%)	53.6% (34.2%–72%)	44.0%

[a] Reported retained gestational sac rather than ongoing pregnancy.

(via pelvic exam or ultrasound). Among women who thought expulsion had occurred, 4% were judged to have ongoing pregnancies by clinicians, and these women were concentrated at gestational ages ≥50 days [12]. This study had 86% sensitivity to detect ongoing pregnancy (95% CI 77%–91%) and 96% NPV (95% CI 93%–98%), and 81% of women screened positive and would therefore be referred for additional follow-up, such as ultrasound (Table 1).

The second study examined 50 women's assessments of complete abortion after administering methotrexate intramuscularly and misoprostol vaginally up to 56 days' gestation [24]. On Day 9, women were asked if they felt they had passed the pregnancy. Women's self-assessment correctly predicted 14 of the 27 retained gestational sacs that were confirmed by ultrasound [24]. This study had a lower percentage of women who screened positive: 44%; however, the sensitivity was 52% (95% CI 32%–71%) and the NPV was 54% (95% CI 34%–72%) (Table 1).

3.2. Clinical assessment

Our review identified three studies that compared clinical assessment of ongoing pregnancy or retained gestational sac with ultrasound [15,23,26]. Two of these studies compared both clinical assessment and women's self-assessment of ongoing pregnancy with ultrasound [15,26], and one study compared clinical assessment alone with ultrasound [23].

In the first study, conducted in 2002–2003, 931 US women pregnant up to 63 days' gestation were administered mifepristone 200 mg orally and misoprostol 800 mcg vaginally 6–8 or 24 h later [15]. Six to 8 days after the mifepristone treatment, after reviewing the subjects' diary and discussing the events that followed after taking misoprostol, clinicians asked the women if they felt they had passed the pregnancy. The clinicians could also ask for additional information to aid with their evaluation. The clinicians made a non-standardized assessment of completion based on this history and performed an ultrasound to determine if the gestational sac was still present. Women's and clinicians' assessment correctly predicted 8 of the 16 retained gestational sacs that were confirmed by ultrasound [15]. This study had 50% sensitivity (95% CI 26%–75%) and 99% NPV (95% CI 98%–99.6%), and 6% of women screened positive (Table 2).

In the second study conducted in 2008, 139 women up to 63 days' gestation in the United States were administered mifepristone 200 mg orally and misoprostol 800 mcg vaginally or buccally according to client preference [26]. Seven days after taking mifepristone, 133 women were contacted by a clinician via telephone and asked a standardized set of questions for the clinician to assess for expulsion. If either the woman or clinician believed she had not passed the pregnancy (*n*=8), she was asked to return for a follow-up ultrasound within 7 days; if both clinician and woman believed she had passed the pregnancy (*n*=125), the woman was told to use high-sensitivity (HS) UPT on Day 30. One woman was not contacted for UPT, and 3 women who had positive or inconclusive urine pregnancy results did not return for follow-up — their pregnancy status was therefore unknown, and they were excluded from our analysis. An ultrasound was performed for the 26 women with positive or inconclusive urine pregnancy results who came in for a clinic visit. All of the four ongoing pregnancies were identified via the protocol — one was identified during an unscheduled office visit prior to the first phone call, two were identified based on the women's and clinicians' assessments during the phone call and the remaining one was identified during an unscheduled interim visit after the

Accuracy of serum hCG measurements to detect ongoing pregnancy after medication abortion

Study	*n*	No. of ongoing pregnancies	Sensitivity (95% CI)	Specificity (95% CI)	PPV (95% CI)	NPV (95% CI)	Screen-positive
Fiala et al. [21]	217	2	100.0% (19.7%–100%)	98.1% (95.0%–99.4%)	33.3% (6.0%–75.9%)	100.0% (97.8%–100%)	2.8%

call [26]. This study had 100% sensitivity (95% CI 40%–100%) and 100% NPV (95% CI 96%–100%), and 16% of women screened positive (Table 2).

In the study that evaluated the ability of the clinician alone to predict ongoing pregnancy, 40 women up to 49 days' gestation were administered mifepristone 200 mg orally and misoprostol 800 mcg vaginally 6–8 h later [23]. Twenty-four hours after taking misoprostol, women were questioned about the side effects that occurred following the mifepristone/misoprostol. Three women had retained gestational sacs, and the clinician correctly predicted one [23]. This study had 33% sensitivity (95% CI 2%–88%) and 95% NPV (95% CI 81%–99%), and 8% of women screened positive (Table 2).

3.3. Serum hCG measurement

Several studies have shown that serial serum hCG measurements are accurate markers of ongoing pregnancy after medication abortion [28–31]. Our review identified three studies that compared a regimen of hCG follow-up with ultrasound or some other means of determining completion [21,32,33]. While all of these studies demonstrated that hCG testing was feasible in their respective settings, only one had cases of ongoing pregnancy that allowed for accuracy calculations [21]. In this study, conducted in 1999, 217 women pregnant up to 49 days' gestation in Austria were administered mifepristone 600 mg orally, followed 48 h later by misoprostol 400 mcg orally, which was repeated 3 h later if no bleeding occurred. Transvaginal ultrasound was performed, and serum hCG was collected on the day of mifepristone administration and again on Days 6–18. A positive test was defined as a ratio of post-treatment hCG to pre-treatment hCG of 0.2 or higher (or a decline of less than 80%). Both ongoing pregnancies identified by ultrasound were identified by hCG measurement. In fact, in both cases, hCG levels increased [21]. This study had 100% sensitivity (95% CI 20%–100%) and 100% NPV (95% CI 98%–100%), and 3% of women screened positive (Table 3).

3.4. UPT

Our review identified three studies that compared UPT with ultrasound [22,25,26]. The first was conducted in 2002–2003 among 1080 US women pregnant up to 63 days' gestation who were administered mifepristone 200 mg followed by misoprostol 800 mcg vaginally 6–8 or 24 h later [22]. At 1 week and 2 weeks after taking mifepristone, women underwent low-sensitivity (LS) and HS UPT, with transvaginal ultrasonography as the reference standard to detect the true absence or presence of a gestational sac. At the 1-week visit, ultrasound diagnosed a retained gestational sac in 14 women. None of the LS tests and two of the HS tests produced false-negative results. At the 2-week visit, 6 women with retained gestational sacs were detected by ultrasound. One of the LS tests and two of the HS tests were falsely negative [22]. At Week 1, the LS test had 100% sensitivity (95% CI 73%–100%) and 100% NPV (95% CI 96%–100%), and 87% of women screened positive; the HS test had 86% sensitivity (95% CI 56%–98%) and 96% NPV (95% CI 86%–99%), and 93% of women screened positive. At Week 2, the LS test had 83% sensitivity (95% CI 37%–99%) and 99.6% NPV (95% CI 97%–99.9%), and 62% of women screened positive; the HS test had 67% sensitivity (95% CI 24%–94%) and 99% NPV (95% CI 96%–99.8%), and 66% of women screened positive (Table 4).

The largest study of alternative follow-up modalities after medication abortion, conducted in 2005–2007, prospectively evaluated five algorithms, all of which included a clinic-based LS UPT plus clinicians' and/or women's assessment compared with ultrasound [25]. For the study, 3103 US women pregnant up to 63 days' gestation were given mifepristone 200 mg followed 6–72 h later by misoprostol 800 mcg orally, buccally or vaginally. Participants maintained a symptom diary that recorded whether they observed the expulsion of the pregnancy and whether they experienced heavy bleeding, pain or cramps. At a follow-up visit 7–14 days after mifepristone, women indicated on a questionnaire whether they still felt pregnant or had any symptoms of pregnancy. Clinicians reviewed the symptom diary at the follow-up visit, and at some of the sites they performed a physical exam. Clinicians then made a final assessment about whether the abortion was complete based on the woman's symptoms and exam. A urine specimen was obtained for an LS pregnancy test, which was performed by a laboratory technician. A clinician then performed a vaginal ultrasound.

Four algorithms that relied on clients' self-assessment plus the LS UPT (each included additional and less stringent self-assessment criteria) were evaluated, and a fifth algorithm added the clinicians' assessment. For the purposes of the analysis presented here, we included 49 women who presented for an unscheduled visit prior to the follow-up visit, which we interpret as a "screen-positive" self-assessment, although they technically presented for a visit before going through the algorithm. Twenty-two ongoing pregnancies were observed in this study; 20 of them were detected by algorithms 1 and 2, 21 by algorithm 3 and all

[a] Reported retained gestational sac rather than ongoing pregnancy.

were detected by algorithms 4 and 5 [25]. The most stringent self-assessment plus LS test algorithm (algorithm 1) had 91% sensitivity (95% CI 69%–98%) and 100% NPV (95% CI 99.6%–100%), and 33% of women screened positive; the least stringent self-assessment plus LS test algorithm (algorithm 4) had 100% sensitivity (95% CI 82%–100%) and 100% NPV (95% CI 99.7%–100%), and 65% of women screened positive. The fifth algorithm with the clinicians' assessment had 100% sensitivity (95% CI 82%–100%) and 100% NPV (95% CI 99.7%–100%), and 36% of women screened positive (details of algorithms 1, 4 and 5 are presented in Table 4).

In the study by Perriera et al. [26] described above, women performed an HS UPT at home on Day 30 (see details of study in Section 3.2). There were no ongoing pregnancies identified by urine testing alone (all were identified prior to performing the urine test), so it was not possible to calculate accuracy measures for the urine testing component of the algorithm [26].

4. Discussion

Our review identified eight studies that evaluated follow-up modalities that could be used instead of ultrasound to detect ongoing pregnancy or retained gestational sac after medication abortion. However, the fact that the outcomes of interest after the mifepristone regimen are so rare makes it difficult to evaluate protocols that aim to detect them. Several of the studies had fewer than 10 cases of ongoing pregnancy or retained gestational sac [21–23,26]. While this highlights the safety and efficacy of medication abortion, for this analysis, it resulted in large CIs for the sensitivity and PPV measures, which make interpretation of the findings difficult. It is also important to note that PPV is dependent on the prevalence of ongoing pregnancy in the population studied, and it is therefore not surprising that the study using the methotrexate regimen [24] had a higher PPV for women's self-assessment than the study using the mifepristone regimen [12].

Additional limitations of this review include the fact that the outcome of interest was not consistently defined in the studies, varying between ongoing pregnancy and retained gestational sac. The disparate nature of the follow-up modalities studied and the outcomes measured precluded any meta-analysis of the results. In addition, only one of the studies [25] explicitly mentioned that the readers of the index test and reference standard were blinded to the results of the other test.

Despite these limitations, we are able to draw some conclusions about alternative follow-up modalities after first-trimester medication abortion. In general, the self-assessments and clinicians' assessments that were standardized and that used detailed questions or criteria were more accurate than non-standardized, single-question modalities. The two women's self-assessment studies were based on

single-question, non-standardized criteria, and both resulted in sensitivities <90% [12,24]. The non-standardized clinicians' assessments [15,23] also had low sensitivities, each ≤50%, and were less accurate than the modality employing standardized clinicians' assessment [26].

The most promising follow-up modalities include serum hCG measurements [21], LS UPT combined with a standardized assessment of women's symptoms [25], and standardized telephone consultation (perhaps followed by HS UPT) [26]. These follow-up modalities had sensitivities ≥90% and NPVs ≥99%, and they resulted in a proportion of "screen-positives" ≤33%.

Measuring serum hCG levels is a promising alternative to ultrasound for follow-up because of its high accuracy [21] and because it may be more accessible than ultrasound; however, it still incurs high costs. Including before-and-after hCG tests can add between $100 and $200 to the overall cost of medication abortion [34]. Nonetheless, hCG testing does not necessarily require a visit with the clinician and can simplify follow-up for some women. For example, women who live in a rural area could have their blood drawn at a nearby laboratory. It also allows providers to offer the method even if they do not have access to ultrasound. Furthermore, it is likely that ectopic pregnancies can be detected with this protocol because, although they can produce low hCG levels, they would be unlikely to have a decline in hCG level to 20% or less by the follow-up visit [32].

Another promising follow-up modality is UPT performed later than 1 week after abortion, combined with self-assessment or clinicians' assessment. UPT alone after 1 week had relatively high sensitivities; however, it resulted in a large proportion of women screening positive [22], and therefore a large number of women would be referred for additional follow-up. The study by Clark et al. [25], however, showed that adding a standardized assessment resulted in a lower proportion of screen-positives, while maintaining high sensitivity and NPV. The CIs of these measures were also narrow due to the study's large size. Algorithm 5 of the Clark et al. study, which included women's self-assessment, an LS UPT and clinical assessment, was highly sensitive with a high NPV, and only 36% would be referred for additional evaluation by ultrasound, making it a promising modality in settings where an in-person visit is feasible but access to ultrasound is limited. The low PPVs of this and many of the other modalities are a reflection of how rare ongoing pregnancy is, and the proportion with a positive screen is a more useful measure to compare the modalities.

It is important to note that as more elements of the self-assessment were added to the algorithms in the Clark et al. study, the proportion of women with a positive screen increased [25]. With algorithm 1, only 33% of women would be referred for further evaluation, while with algorithm 4, which included additional and less stringent self-assessment criteria, 65% would be referred for additional follow-up. Taking into account the 95% CIs, however, no significant difference in sensitivity was observed between the two algorithms. While the study suggests that LS UPT combined with a few discrete questions could be an accurate way to perform follow-up without ultrasound, the urine test that was used was performed by a laboratory technician and was not designed for home use. Additional research is needed on the use of home-based LS UPT after medication abortion documenting outcomes that are comparable with the current standard of care.

Although its small sample size is a significant limitation, the study by Perriera et al. [26] of telephone follow-up with standardized questions is also promising both because of the modality's high sensitivity to detect ongoing pregnancy and high NPV and the relatively low proportion of women with a positive screen. In practice, this means that only 16% of all medication abortion clients would be referred (or self-refer) for an in-person clinic visit. Although telephone follow-up may not be feasible in all settings, the findings of Perriera et al. suggest that the limited questions that were asked of participants could also be used in a clinic to triage those who need ultrasound or other follow-up evaluations [26]. More research on this algorithm is needed with a larger sample size.

Alternative follow-up modalities are particularly useful in settings where access to ultrasound may be limited. They do not prevent women who choose to attend a routine follow-up visit from doing so; they can, however, allow for greater options for those women who may find these visits to be a burden or expensive. Additional research with adequate sample sizes is needed to demonstrate the accuracy and feasibility of home-based urine testing combined with self-assessment and/or clinician-assisted assessment. More studies in low-resource settings of alternative follow-up, either at home or in a clinic without the use of ultrasound, are also required. It is critical that these studies clearly define the outcome of interest, such as ongoing pregnancy, and follow recommended guidelines for reporting studies of diagnostic accuracy, including blinding the readers of the index and reference tests [35]. The elements of any clinical assessment should also be standardized in order to be able to replicate the follow-up protocol in other settings.

Effectiveness and Acceptability of Medical Abortion Provided Through Telemedicine

Daniel Grossman, MD, Kate Grindlay, MSPH, Todd Buchacker, RN, Kathleen Lane, and Kelly Blanchard, MSc

OBJECTIVE: To estimate the effectiveness and acceptability of telemedicine provision of early medical abortion compared with provision with a face-to-face physician visit at a Planned Parenthood affiliate in Iowa.

METHODS: Between November 2008 and October 2009, we conducted a prospective cohort study of women obtaining medical abortion by telemedicine or face-to-face physician visits. We collected clinical data, and women completed a self-administered questionnaire at follow-up. We also compared the prevalence of reportable adverse events between the two service delivery models among all patients seen between July 2008 and October 2009.

RESULTS: Of 578 enrolled participants, follow-up data were obtained for 223 telemedicine patients and 226 face-to-face patients. The proportion with a successful abortion was 99% for telemedicine patients (95% confidence interval [CI] 96–100%) and 97% for face-to-face patients (95% CI 94–99%). Ninety-one percent of all participants were very satisfied with their abortion, although in multivariable analysis, telemedicine patients had a higher odds of saying they would recommend the service to a friend compared with face-to-face patients (odds ratio, 1.72; 95% CI 1.26–2.34). Twenty-five percent of telemedicine patients said they would have preferred being in the same room with the doctor. Younger age, less education, and nulliparity were significantly associated with preferring face-to-face communication. There was no significant difference in the prevalence of adverse events reported during the study period among telemedicine patients (n=1,172) (1.3%; 95% CI 0.8–2.1%) compared with face-to-face patients (n=2,384) (1.3%; 95% CI 0.9–1.8%) (82% power to detect difference of 1.3%).

CONCLUSION: Provision of medical abortion through telemedicine is effective and acceptability is high among women who choose this model.

LEVEL OF EVIDENCE: II

Mifepristone was approved by the U.S. Food and Drug Administration in September 2000. Early medical abortion using mifepristone with misoprostol is effective and highly acceptable to U.S. women with some preferring it over vacuum aspiration.[1–3] Medical abortion is not a surgical procedure and can be offered by nonspecialist clinicians,[4] a fact that led some to believe that its availability would improve access to abortion services in the United States. However, a recent analysis found that almost all medical abortion-only providers were located within 50 miles of a large-volume surgical abortion provider.[5]

In approximately 15 states, certified nurse–midwives, physician assistants, and nurse practitioners are permitted to provide medical abortion.[6] In the remaining states, laws that limit provision of abortion to physicians have been applied (or assumed to apply) to medical abortion as well.

Telemedicine, the delivery of health care services at a distance using information and communication technology, has been used in many fields of medicine to improve access to services. For example, telemedicine has been used to provide specialist consultation to primary care services and to deliver rural outpa-

tient care, generally with patient outcomes that are comparable to in-person treatment.[7] In 2008, Planned Parenthood of the Heartland, a clinic network located in Iowa that provided 74% of all abortions in the state that year,[8] had 17 clinic sites. Three of these clinics had an on-site physician, whereas an additional three sites intermittently offered abortion care when a physician traveled to the clinic; the remaining 11 clinics did not provide abortions. In June 2008, Planned Parenthood of the Heartland launched a program to provide medical abortion using telemedicine at clinic sites not staffed by a physician to improve access to early abortion and reduce physician travel to outlying clinics. The objective of this study was to estimate the effectiveness and acceptability of the telemedicine provision model compared with the standard practice of a face-to-face visit with a physician.

MATERIALS AND METHODS

Between November 2008 and October 2009, women seeking medical abortion at six Planned Parenthood of the Heartland clinics in Iowa were invited to participate in the study. At four sites, medical abortion was offered only through telemedicine; at one site it was offered only with a face-to-face physician visit; and at one site both models were offered, depending on physician availability. Women seeking abortion at Planned Parenthood of the Heartland called a central call center, which gave them information about the nearest clinic and soonest appointment and informed them whether the service would be provided by telemedicine or not, and women selected the appointment they preferred. In the areas served by the telemedicine clinics, there was no other abortion clinic closer than the closest physician-staffed Planned Parenthood clinic. Once at the clinic, women who chose medical abortion and were eligible for the method (including being pregnant at 63 days gestation or less and not having other standard contraindications[9]), were 18 years old or older, able to speak English, and able to give informed consent were eligible to participate in the study.

Clinical information was collected at the participants' first clinic visit, including demographic information and gestational age according to ultrasonography. Participants were given the standard medical abortion regimen at the clinics: 200 mg mifepristone administered orally followed 24–48 hours later by 800 μg misoprostol administered buccally at home.[10] All women had ultrasonography performed by a trained technician, received information about medical abortion, and underwent standard informed consent for the abortion. A physical examination was not routinely done, consistent with the standard of care.[9] For face-to-face visit patients, one of two physicians reviewed the patient's medical history and ultrasonographic images and had a brief discussion with the patient. If the patient was eligible for a medical abortion, the physician handed her the mifepristone and misoprostol tablets, observed her swallow the mifepristone, and gave her final instructions. For those who received services through telemedicine, clinic staff uploaded the patient's medical history and ultrasonographic image to a secure server for the physician to review. One of the same two physicians then had a discussion with the patient using video teleconference equipment that was linked through a dedicated Multiprotocol Label Switching data connection. If the patient was eligible for medical abortion, the physician entered a password into her computer that remotely unlocked a drawer in front of the patient containing the mifepristone and misoprostol tablets. The physician observed her swallow the mifepristone and gave her final instructions through the video teleconference.

Women were scheduled for a follow-up visit within 2 weeks after receiving mifepristone. Pelvic ultrasonography was performed at follow-up to confirm completion of the abortion. If the abortion was incomplete, women were given the option of expectant management, additional misoprostol, or vacuum aspiration; ongoing pregnancies were treated with vacuum aspiration. If a telemedicine patient required a nonemergent vacuum aspiration, she was scheduled at a physician-staffed clinic for the procedure. If the abortion was not complete at the time of this visit, another visit was scheduled. Clinical information was collected at each follow-up visit, including the ultrasonographic result, any medications given, and whether a vacuum aspiration was performed. Effectiveness of medical abortion was defined as the proportion of women with a complete abortion not requiring a surgical procedure, including vacuum aspiration.

Once the abortion was complete, participants were asked to fill out a self-administered questionnaire focusing on their experience with the abortion service, including satisfaction with the service they received. If participants did not return for follow-up, they were contacted at least three times by phone and once by mail to schedule either an in-person follow-up visit or a telephone interview to complete the questionnaire. Information on adverse events was collected from participants at each follow-up visit or

Copyright© American College of Obstetricians and Gynecologists
GBP-PET00290

during the telephone interview, and medical records from other facilities were reviewed when relevant.

All statistical analyses were performed using STATA 10.1. χ^2 analyses and *t* tests were used to compare study participants to all medical abortion patients aged 18 years or older seen during the study period to assess potential selection bias and to compare demographic, clinical, and acceptability information between telemedicine and face-to-face study participants. All analyses among cohort participants were conducted among women with complete follow-up information.

Univariable and multivariable analyses were conducted to identify potential associations between service delivery model (telemedicine compared with face-to-face) and the primary effectiveness and acceptability outcomes. To account for the possibility that a patient's experience might vary by the clinic she attended, clinic site was introduced into the multivariable model as a random effect, and the standard error was adjusted with a modified-sandwich estimator using STATA's vce (cluster clustervar) option for cluster-correlated data.[11,12] Automated forward selection was used to build the multivariable models with the entry level set at $P<.20$. Demographic and clinical covariates with univariable significance of $P<.20$ not entered during forward selection were next added to the model in order of ascending univariable *P* value and were included in the final model if their inclusion changed the predictor variable's effect estimate by 10% or more. Gestational age was forced into the multivariable model assessing effectiveness because of evidence that the prevalence of ongoing pregnancy after medical abortion increases with increasing gestational age.[1] Covariates were added using these rules up to the maximum number of allowable covariates in a multivariable model based on the rule: number of events/10.[13]

Sample size was based on the acceptability outcome of overall satisfaction, because we anticipated that effectiveness would be comparable between groups. We also anticipated that acceptability of the telemedicine service would be high but might be somewhat lower than the standard provision model. Assuming 90% of women in the standard provision group reported being satisfied or very satisfied with their experience,[10] a sample of 219 in each group was needed to detect a difference in acceptability among telemedicine patients of 10% or more (two-sided $\alpha=0.05$, power=80%). Recruitment was continued until the desired sample of participants with follow-up data was obtained.

Because of the relatively small sample size of the cohort study, we also analyzed deidentified data on all adverse events after medical abortion reported to the Planned Parenthood Federation of America and Danco Laboratories by Planned Parenthood of the Heartland between July 1, 2008 (shortly after telemedicine was initiated) and October 31, 2009 (shortly after cohort recruitment ended). Planned Parenthood affiliates are required to report the following adverse events: ongoing pregnancy, emergency room treatment, hospitalization, transfusion, unrecognized ectopic pregnancy, allergic reaction, infection requiring intravenous treatment, and death. We calculated the prevalence, 95% confidence intervals (CIs), and χ^2 analyses of any adverse event, ongoing pregnancy, or blood transfusion, comparing telemedicine with face-to-face patients during this period. We also conducted a multivariable analysis of any adverse event comparing telemedicine with face-to-face patients during this period adjusting for possible confounders.

All cohort study participants gave informed consent to participate in the study. They received a $10 gift card for completing the questionnaire. The study was approved by Allendale institutional review board.

RESULTS

The study flow diagram is shown in Figure 1. Fifty-six percent of patients aged 18 years or older seen during the study period were enrolled into the study. Reasons for nonparticipation were not collected, although study staff noted that fewer patients were enrolled on busy clinic days, possibly because staff did not have time to thoroughly explain the study. After excluding seven patients, 578 women were included in the cohort study. Among the 281 telemedicine patients, 205 (73%) had an in-person and 18 (6%) had a phone follow-up interview; 58 (21%) were lost to follow-up. Among the 297 face-to-face patients, 196 (66%) had an in-person and 30 (10%) had a phone follow-up interview; 71 (24%) were lost to follow-up. The proportion of patients that attended an in-person visit was not significantly different between the two groups ($P=.07$).

Age, marital status, and race were similar between cohort study participants and all patients receiving medical abortion aged 18 years or older seen during the study period. A lower proportion of study participants were Latina (4% compared with 7%, $P=.008$) and had a maximum completed education of 12 years or less (52% compared with 58%, $P=.03$). Table 1 shows the enrollment demographic and clinical information for cohort study participants with follow-up data. Among study participants, telemedicine and face-to-face patients were similar in terms of age, marital status, race, ethnicity, parity, and gesta-

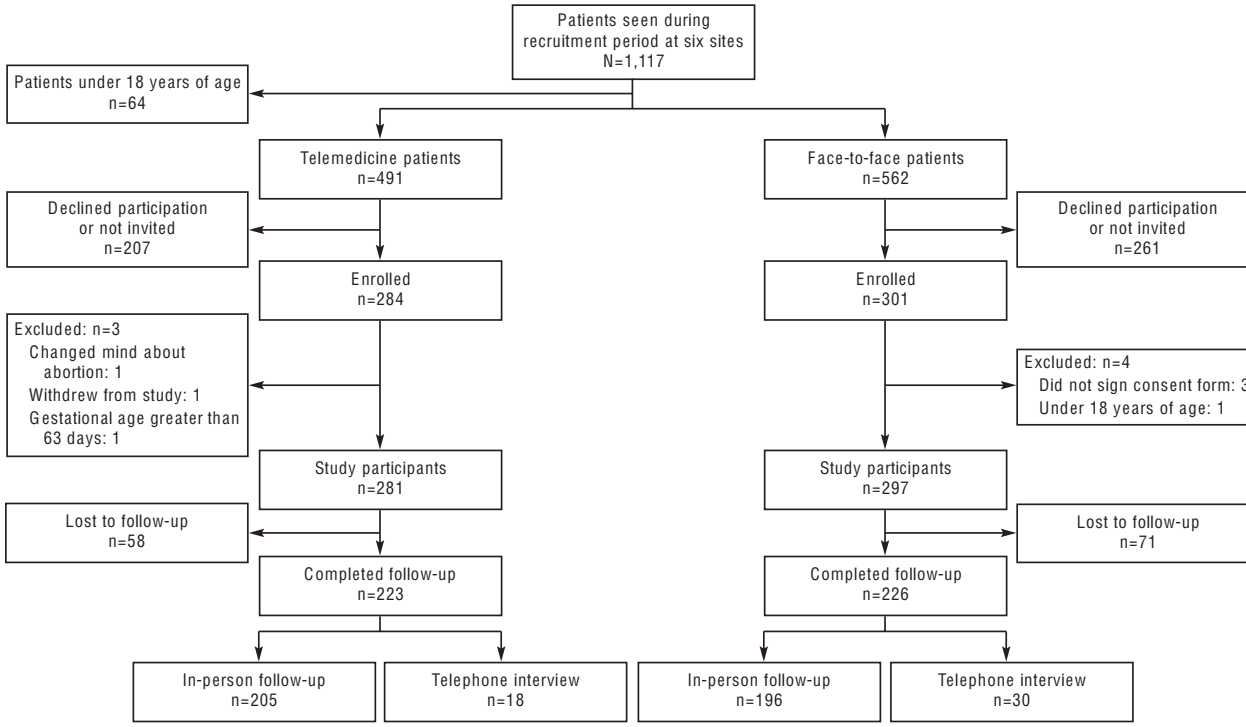

Fig. 1. Flow of patients through the study.
Grossman. Telemedicine Provision of Medical Abortion. Obstet Gynecol 2011.

tional age. Compared with telemedicine participants, more face-to-face participants had a maximum completed education of 12 years or less (58% compared with 46%, P=.01) and reported a prior abortion (38% compared with 26%, P=.006).

Follow-up information was obtained a median of 15 days after enrollment for those with in-person visits and 27 days after enrollment for those who had phone interviews. At follow-up, eight women (three telemedicine and five face-to-face patients) were given an additional dose of misoprostol and scheduled for a second follow-up visit.

Contraceptive uptake postabortion was slightly higher among participants with a face-to-face visit. Eighty-eight percent (n=199) of face-to-face participants and 80% (n=179) of telemedicine participants were given or had started a contraceptive method by the time of the follow-up visit or phone interview (P=.02). Use of specific contraceptive methods was not significantly different between the cohorts, except more face-to-face participants were given condoms (21% compared with 6%, P<.001) or had an intrauterine device inserted (23% compared with 12%, P=.005) at the follow-up visit.

Two of the 223 telemedicine patients underwent vacuum aspiration for ongoing pregnancy (n=1) or incomplete abortion (n=1), and one woman elected to continue an ongoing pregnancy for a total effectiveness of 98.7% (95% CI 96.1–99.5%). Six of the 226 face-to-face patients underwent vacuum aspiration and one underwent dilation and curettage for ongoing pregnancy (n=2) or incomplete abortion (n=5) for a total effectiveness of 96.9% (95% CI 93.7–98.5%). The odds of successful abortion with telemedicine compared with face-to-face provision was not significantly different in the multivariable model, which adjusted for within-cluster correlation and gestational age (odds ratio [OR] 2.34, 95% CI 0.84–6.55).

There were no deaths or hospitalizations among the cohort study participants. Adverse events, including emergency room visits and visits to other clinics, occurred among 2.5% of participants and were not statistically different between groups (P=.78). One telemedicine participant received a blood transfusion in an emergency room. The telemedicine participant who decided to continue with an ongoing pregnancy reported her child was normal at 7 months of age.

Table 2 shows the prevalence of adverse events among all patients undergoing medical abortion from July 1, 2008, to October 31, 2009. A total of 46 adverse events were reported (1.3% of 3,556 medical abortions). No deaths were reported. There was no

* Other race includes women who reported more than one race and women who reported their race as Native American or Alaska Native.

significant difference in the prevalence of any adverse event, ongoing pregnancy, or blood transfusion between women who received services through telemedicine compared with face-to-face provision. With a one-sided α of 0.05, this sample size had 82% power to detect an increase in the prevalence of any adverse event from 1.3% among face-to-face patients to 2.6% among telemedicine patients. The odds of any adverse event among telemedicine compared with face-to-face patients was not significantly different in the multivariable model, which adjusted for within-cluster correlation, marital status, Latina ethnicity, and race (OR 0.96, 95% CI 0.48–1.91).

Table 2. Adverse Events Among All Medical Abortion Patients, July 1, 2008, Through October 31, 2009

	Telemedicine (n=1,172)	Face-to-Face (n=2,384)	*P*
Any adverse event	1.3 (0.8–2.1)	1.3 (0.9–1.8)	.96
Ongoing pregnancy	0.9 (0.5–1.7)	1.0 (0.6–1.4)	.94
Blood transfusion	0.3 (0.1–0.9)	0.1 (0.04–0.4)	.23

Data are % (95% confidence interval) unless otherwise specified.

Table 3 shows information on acceptability of abortion services. Overall satisfaction was very high among participants, although more telemedicine patients (94%) reported being very satisfied compared with face-to-face patients (88%), which was significantly different in the univariable analysis (P=.03). However, when adjusted for within-cluster correlation (no additional covariates met the multivariable model inclusion criteria), this difference was no longer significant (OR 2.10, 95% CI 0.75–5.92).

More telemedicine patients (90%) said they would recommend the medical abortion service to a friend in a similar situation than face-to-face patients (83%, P=.04). In the multivariable model, which adjusted for within-cluster correlation, age, education, and prior abortion, telemedicine patients had greater odds of saying they would recommend the service compared with face-to-face patients (OR 1.72, 95% CI 1.26–2.34).

Patients in both groups reported liking similar aspects of the service, including the staff (58%), information received (30%), and the fact that they did not feel judged (11%). A minority of patients reported dislikes, and a significantly higher proportion of face-to-face patients (32%) complained about the waiting time in the clinic compared with telemedicine patients (7%, P<.001).

We asked women several questions about the factors that influenced their decision about what abortion method to have and which clinic to go to. Seventy-one percent of participants said they strongly wanted medical abortion when they were making their decision (no difference between cohorts), and 94% of participants said having the abortion as early as possible was very important to them (no difference between cohorts). However, 69% of telemedicine patients said having the abortion close to home was very important compared with 58% of face-to-face patients (P=.02).

Three fourths of patients reported being satisfied with the conversation with the doctor (the video teleconference for those receiving telemedicine services), and this did not differ between the two groups (P=.89). Among telemedicine patients, 99% said it was easy to see the doctor, and 99% said it was easy to hear the doctor; 89% said they felt comfortable asking the doctor questions during the video teleconference.

One fourth of telemedicine patients said they would have preferred being in the same room with the doctor. Participants were allowed to write in comments about this response, which generally indicated that although they would have preferred to be in the same room, because that was not an option, they were satisfied with the video teleconference. These open responses are representative of some of the comments participants gave: "I am always generally more comfortable dealing with serious issues in person" and "It was rather irritating, but probably faster/more convenient. (I'm a face to face person)."

In multivariable analysis, the following covariates were associated with a preference for being in the same room with the physician: age 18–25 years (compared with 26 years or older; OR 1.58, 95% CI 1.20–2.09); education 12 years or less (compared with more than 12 years; OR 1.80, 95% CI 1.51–2.14); and nulliparous (compared with parous; OR 1.71, 95% CI 1.15–2.54).

DISCUSSION

We found that provision of medical abortion through telemedicine had comparable clinical outcomes to the face-to-face provision model with equivalent success rates and a low prevalence of adverse events. Both the high success rate and low prevalence of adverse events for the telemedicine service are similar to those reported for medical abortion in the literature.[1,10,14] Although contraceptive uptake was slightly higher among the face-to-face cohort, this was most likely the result of the limited number of providers trained to insert intrauterine devices at telemedicine sites.

Acceptability was high among both groups of women in this study, and these results were similar to other studies on medical abortion with buccal misoprostol.[10,15] We found one measure of acceptability–willingness to recommend the service to a friend–to be significantly higher among telemedicine patients, even after controlling for confounders. The fact that telemedicine patients reported high levels of satisfaction may be related to the convenience of receiving services closer to home or earlier in pregnancy, both of which were important for this group. Our results do not indicate that telemedicine patients were coerced to have a medical abortion despite this being the only method available at the clinics they accessed, because a high proportion reported strongly wanting medical abortion from the outset, and this did not differ from face-to-face patients. The fact that telemedicine patients had a restricted choice at the clinics they attended, if anything, might have biased them to have lower levels of satisfaction compared with face-to-face patients, who also had the option of aspiration abortion.

We found that 25% of telemedicine patients would have preferred a face-to-face visit with the physician, and this was more common among younger, less educated, and nulliparous women. Another study of clinic-based medical abortion found that older age was an independent predictor of a positive experience, whereas education level was not.[16] In our study, participants were told at the time they scheduled their appointment whether they would receive abortion services through telemedicine or not. It seems that some decided to have the abortion through telemedicine perhaps because the clinic was closer to their home or because they could get an appointment sooner, although ideally they would have preferred to be in the same room with the physician. This finding highlights the importance of informing women about what the telemedicine service involves so patients can weigh the options about which service they prefer.

This study has several limitations. Participants were not randomized and instead selected the treatment they received (telemedicine compared with a face-to-face visit), which might have introduced selection bias. However, because this was the first study of telemedicine provision of medical abortion, we felt it was important for women to be well informed of the two provision models and be allowed to choose which they preferred. In the future, a randomized controlled trial might be possible among women who have no real preference between the two models as has been done to compare medical and surgical abortion.[17,18] Overall, 56% of patients aged 18 years or older seen during the study period agreed to participate in the cohort study, and participants were somewhat more educated and less likely to be Latina than the general medical abortion clinic population. This might have introduced selection bias, although the acceptance rate likely affected both cohorts similarly. In addition, 22% of participants were lost to follow-up despite multiple attempts to contact them. Although this loss to follow-up is high, it is similar to proportions reported in the literature[19] and did not differ between cohorts. Finally, our results are specific to the provision models offered in this clinic system, and we cannot generalize our findings to other service delivery settings.

In states where physicians are required to perform medical abortion, the findings from this study indicate that telemedicine can be used to provide medical abortion in an effective and highly acceptable manner. Future research should evaluate whether

telemedicine provision improves access to services for women in rural areas as well as whether there are cost savings associated with the model. Just as telemedicine has been used to extend the reach of physicians in other disciplines, this provision model has the potential to provide abortion services earlier in pregnancy and closer to a woman's home and to help overcome the barriers to abortion access in the United States.[20]

ABSTRACT

Objective(s): To estimate the effectiveness, acceptability, and feasibility of medication abortion with mifepristone dispensed by a mail-order pharmacy after in-person clinical assessment.
Study Design: This is an interim analysis of an ongoing prospective cohort study conducted at five sites. Clinicians assessed patients in clinic and, if they were eligible for medication abortion and ≤ 63 days' gestation, electronically sent prescriptions for mifepristone 200 mg orally and misoprostol 800 mcg buccally to a mail-order pharmacy, which shipped medications for next-day delivery. Participants completed surveys three and 14 days after enrollment, and we abstracted medical chart data.
Results: Between January 2020 and April 2021 we enrolled 240 participants and obtained clinical outcome information for 227 (94.6%); 3 reported not taking either medication. Of those with abortion outcome information (N = 224), 216 (96.4%) completed day-3 and 212 (94.6%) day-14 surveys. Of the 224 that took medications, none reported taking past 70 days' gestation, and complete medication abortion occurred for 217 participants (96.9%, 95% CI 93.7%-98.7%). Most received medications within three days (82.1%, 95% CI 76.5%-86.9%). In the day-3 survey, 95.4% (95% CI 91.7%-97.8%) reported being very (88.4%) or somewhat (6.9%) satisfied with receiving medications by mail. In the day-14 survey, 89.6% (95% CI 84.7%-93.4%) said they would use the mail-order service again if needed. Eleven (4.9%, 95% CI 2.5%-8.6%) experienced adverse events; two were serious (one blood transfusion, one hospitalization), and none were related to mail-order pharmacy dispensing.
Conclusions: Medication abortion with mail-order pharmacy dispensing of mifepristone appears effective, feasible, and acceptable to patients.
Implications: The in-person dispensing requirement for mifepristone, codified in the drug's Risk Evaluation and Mitigation Strategy, should be removed.

tion be dispensed only in clinics, medical offices, and hospitals, by or under the supervision of a certified prescriber; this restriction is codified in the drug's Risk Evaluation and Mitigation Strategy (REMS) [1]. During this time a considerable amount of data has been collected on the safety of pregnancy termination with mifepristone [2]. In addition, a recent study found that dispensing mifepristone at brick-and-mortar pharmacies after in-person assessment by a clinician was effective and acceptable to patients seeking abortion, with a low prevalence of adverse events (AEs) [3].

A growing proportion of U.S. patients obtain medications from mail-order pharmacies [4]. Mail-order pharmacy dispensing of mifepristone could further allow medication abortion patients to bypass geographical obstacles to the service and receive abortion care earlier in pregnancy [5–7]. Considering the declining number of abortion providers in the U.S. [8,9], it could also help increase the number of clinicians willing and able to provide medication abortion by enabling them to avoid cost and logistical challenges of stocking and dispensing mifepristone in their facilities, thereby improving access to care [10].

Under an Investigational New Drug Application (IND) from the FDA, we began a prospective cohort study of the acceptability, feasibility, and effectiveness of dispensing medications for abortion using a mail-order pharmacy following an in-person assessment for eligibility. In April 2021, the FDA announced it would suspend the in-person dispensing requirement for mifepristone during the COVID-19 public health emergency. We conducted this interim analysis at the midpoint of planned recruitment to provide additional information to the FDA as it considers the future of the mifepristone REMS after the emergency ends.

2. Material and Methods

From January 2020 to April 2021, we enrolled patients at five clinics in four states seeking medication abortion who consented to receive their medications from a mail-order pharmacy; two clinics had not previously provided abortion care. The Institutional Review Boards (IRBs) of the University of California San Francisco (UCSF), Albert Einstein College of Medicine, Kent Hospital, and Alameda Health System approved the study. Site investigators completed the mifepristone Prescriber Agreement Form. Clinicians evaluated patients in person for medical eligibility according to the mifepristone label after confirming interest in medication abortion. Patients were eligible for the study if they were aged 15 years or older, spoke English or Spanish, were willing to administer misoprostol buccally as mandated by the FDA, and had a gestational duration of $\leq$ 63 days (to reduce the chance that shipping delays might result in a participant taking mifepristone past 70 days' gestation). Clinicians at study sites determined gestational duration based on patients' history, confirmed by physical examination or ultrasound.

Those interested and eligible provided written informed consent. Patients signed the mifepristone Patient Agreement Form and received instructions on medication use. All participants were scheduled for clinical follow-up, which varied at sites and included: (1) in-person ultrasonography one to two weeks after mifepristone, (2) serum human chorionic gonadotropin (hCG) measurements on the day of enrollment and one to two weeks after mifepristone, or (3) a telephone call one week after mifepristone with a home urine pregnancy test four weeks after mifepristone, sometimes accompanied by a telehealth visit. If clinical follow-up did not occur, we relied on patients' self-report of abortion outcome in their survey responses, as done in prior research [3].

Treating clinicians electronically prescribed each participant mifepristone 200 mg and misoprostol 800 mcg, as well as analgesics, antibiotics, antiemetics, or contraceptives at their discretion. Clinicians instructed participants to take misoprostol buccally 24 to 48 hours after mifepristone. The mail-order pharmacy processed the prescriptions according to their standard "next-day delivery" workflow and shipped the medications to each participant's preferred address.

Three days later, we emailed participants a Qualtrics survey link to collect information about whether their medication package delivery time was "reasonable" or "too long," whether the package had been damaged or opened, and whether their confidentiality might have been compromised in any way. We also collected information on participants' sociodemographic characteristics, satisfaction with receiving the medications by mail, if and/or when they took or planned to take the medications, whether they thought they had "passed the pregnancy," and whether they had any new medical problems related to their abortion. We asked those who reported a prior medication abortion, "How would you compare your experience of getting the pills this time by mail compared with last time in the clinic?".

Two weeks later, we emailed participants a second survey, which included similar questions about taking the medications, medical problems for which they sought further care, clinic follow-up, and abortion completion. Participants who believed their abortion was complete were asked how they knew that, including whether they had an ultrasound, blood tests, a negative urine pregnancy test, a normal period, whether their pregnancy symptoms went away, or for some other reason (with an open response). We also asked about their overall medication abortion experience and whether they would recommend mail-order dispensing of mifepristone to a friend. We also asked, "If you were to have an undesired pregnancy in the future and chose to have a medication abortion, would you want to get the pills by mail again?".

Six or more weeks after enrollment, personnel from each participating site entered de-identified data about all visits or contact with the patient into an electronic REDCap form. We used these data abstracted from medical records, in combination with survey data, to identify abortion outcomes and AEs occurring within six weeks of enrollment, including any emergency department visits at least possibly related to the medication abortion. We considered serious AEs to be death, hospitalization, blood transfusion, or surgery, according to FDA criteria [11,12].

Participants received electronic gift cards at enrollment ($15) and after completing each survey ($25 each). The study paid for the medication abortion, including the cost of clinical visits, mifepristone, misoprostol, pharmacy dispensing fees, and shipping.

We evaluated the effectiveness of medication abortion as the proportion of participants who had a complete abortion with medications alone. We used data abstracted from clinic records for this outcome; if the patient did not have follow-up with the clinic, we used self-reported survey data to document abortion outcome, similar to prior research [3]. We evaluated safety as the proportion who had any AE that was at least possibly related to the medication abortion. For acceptability, we assessed the proportion of participants reporting in the day-14 survey they would use mail-order dispensing again if needed and the proportion reporting they were "satisfied" or "very satisfied" with the medication abortion. For feasibility, we measured the proportion who received packages within three days, reported the packages they received remained intact, and reported their confidentiality was maintained. We calculated binomial 95% confidence intervals for main outcomes in Stata 15 (College Station, TX).

The planned sample size for the ongoing study is a minimum of 440 participants. This will give us approximately 80% power to estimate acceptability of the care model and over 90% power to estimate effectiveness and demonstrate if these estimates are within a 5% non-inferiority margin of published estimates for facility-dispensed medication abortion. Prior research with patients ob-

GBP-PET00298

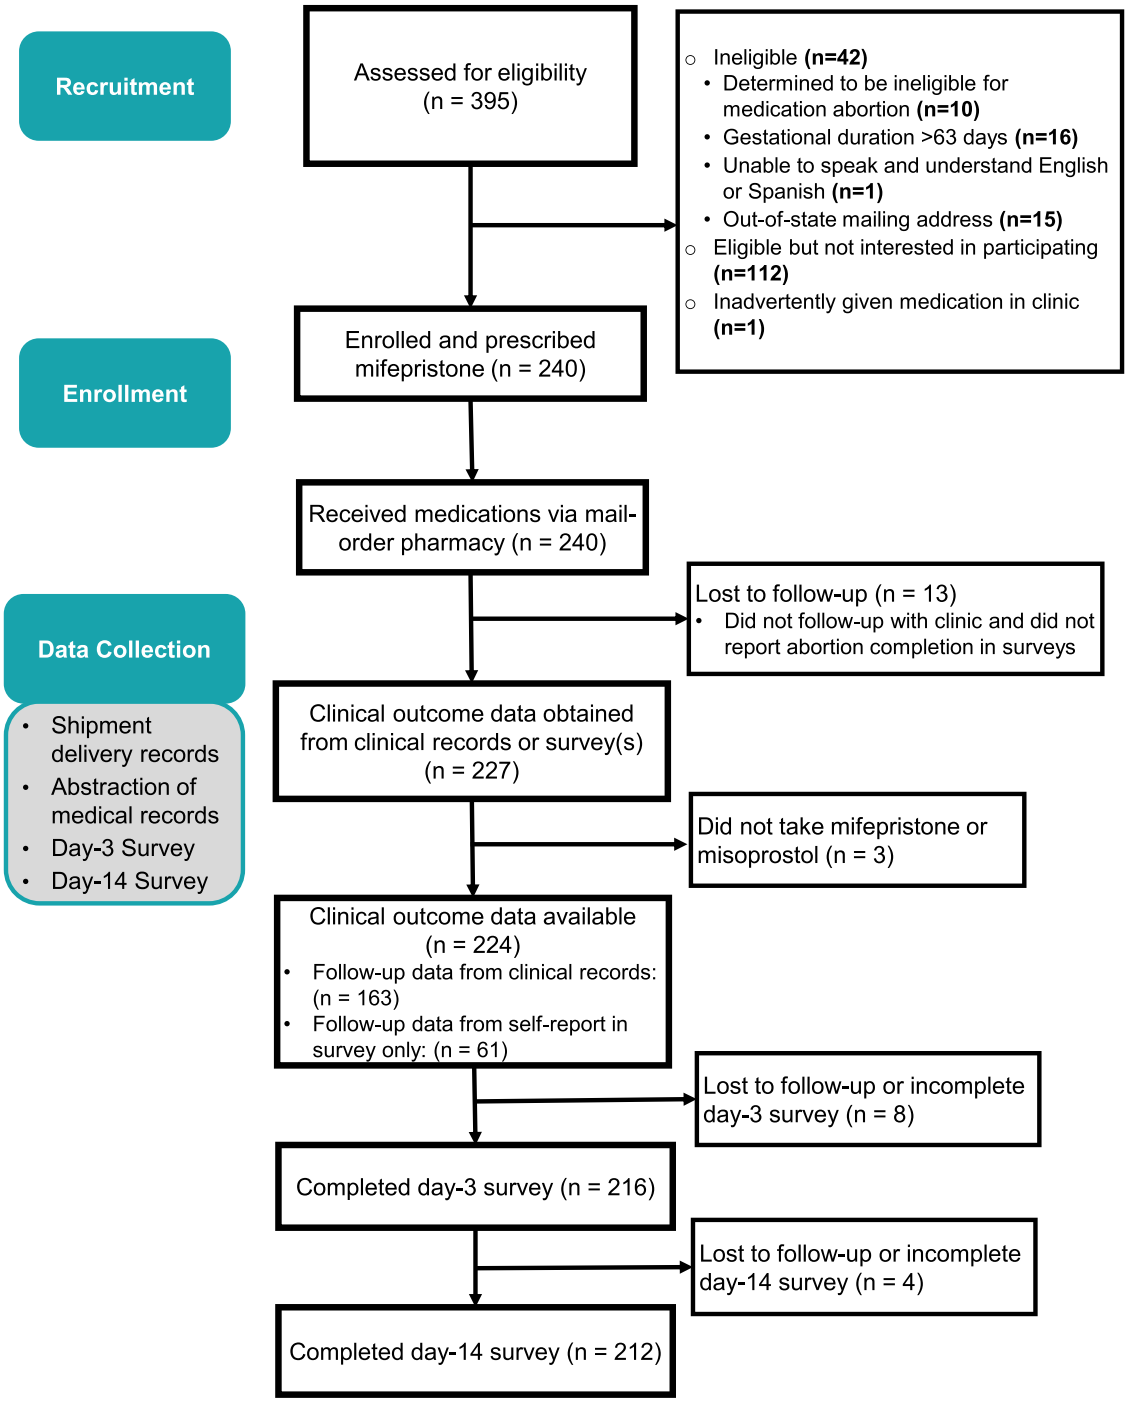

Fig. 1. Study flow of patients seeking medication abortion who were evaluated in person and then received mifepristone from a mail-order pharmacy in the U.S. in 2020 to 2021

taining medication abortion with in-person mifepristone dispensing has estimated the proportion who would use medication abortion again as 89.7% [13] and overall effectiveness as 97.4% [14].

3. Results

Clinic staff assessed 395 patients for eligibility and enrolled 240 participants; 155 were ineligible or declined to participate (Fig. 1). All enrolled participants received the study medications by mail. We obtained clinical outcomes for 227 participants (94.6%); 13 (5.4%) participants were lost to follow-up. Three participants reported not taking mifepristone or misoprostol; two returned the package, and one reported losing it. We excluded them from the analysis, leaving a final sample of 224 participants.

Table 1 shows the characteristics of study participants; of note, as of the time of this interim analysis, we had not recruited any minors. Table 2 shows the delivery time for the medication package; the details of when and how participants reported using the medications, including gestational duration on date of taking mifepristone, initial misoprostol dosage and route of administration, and interval between medications; and abortion outcome, including how abortion outcome was assessed. Overall, 217 of 224 participants (96.9%, 95% CI 93.7%-98.7%) had a complete abortion with medications alone, including eight (3.6%) who received

† 4 participants underwent procedural abortion and 1 continued the pregnancy.
‡ Some participants reported more than one history-based response.

a second dose of misoprostol 800 mcg. Five participants (2.2%) had ongoing pregnancies, and two (0.9%) had incomplete abortions treated with uterine aspiration. One of the participants with an ongoing pregnancy elected to continue the pregnancy; we contacted her last at 31 weeks' gestation, and she reported her pregnancy was uncomplicated. No participant was found to have an ectopic pregnancy. We present outcomes by gestational duration in Supplemental Table 1.

Eleven participants (4.9%, 95% CI 2.5%-8.6%) had an AE that was determined by the site and principal investigators to be at least possibly related to the medication abortion; however, the investigators determined that none of these AEs would have been avoided by dispensing medications in person rather than with the mail-order pharmacy. All participants with an AE reported taking the medications at ≤ 70 days' gestation as instructed. Among those with an AE, 10 had an emergency department visit (one reported two visits for the same problem), and two had a possible serious AE (one received a blood transfusion, and one reported being hospitalized overnight but received no additional treatment).

Packages arrived within three days for 184 of 224 participants (82.1%, 95% CI 76.5%-86.9%); most reported packages were in good condition (97.2%, 95% CI 94.1%-98.9%) and that confidentiality was uncompromised (96.8%, 95% CI 93.4%-98.7%) (Tables 2 and 3). Of those who reported compromised confidentiality, three said someone found the medications, three reported other privacy concerns, and one reported that both someone found the medications and they had other privacy concerns. Medications were not affected in any cases where the package was reported damaged. All who reported the date they took mifepristone had a gestational duration of ≤ 70 days on that date.

For the day-3 survey, we excluded eight of 224 (3.6%) participants missing data on satisfaction with receiving medications by mail. In the survey, 206 (95.4%, 95% CI 91.7%-97.8%) reported being very (88.4%) or somewhat (6.9%) satisfied with receiving medications by mail. Among those who reported a prior medication abortion ($N = 78$), 89.7% reported their experience of getting the pills this time by mail was better (55.1%) or the same (34.6%) compared with last time in the clinic (Table 3).

No	9	4.2
Not sure	13	6.1

* Among participants who had abortion outcome data available and completed day-14 survey.

For the day-14 survey, we excluded 12 of 224 (5.4%) participants missing data on overall satisfaction with medication abortion. In this survey, 193 (91.0%, 95% CI 86.4%-94.5%) reported satisfaction with their overall medication abortion experience, and 190 (89.6%, 95% CI 84.7%-93.4%) said that they would use the mail-order service again if needed (Table 4). Most said they would recommend medication abortion (91.0%) and mail-order dispensing (94.3%) to a friend.

4. Discussion

Preliminary findings from this study suggest that medication abortion with mail-order pharmacy dispensing of mifepristone was effective, feasible, and acceptable to patients seeking early abortion. Outcomes were similar to those reported when mifepristone has been dispensed in a clinic [13-20], with few serious adverse events.

While most participants received their medications within three days, 18% experienced a longer wait. We conservatively restricted enrollment to participants at ≤ 63 days' gestation to account for potential delays in delivery; however, given evidence supporting mifepristone use up to 77 days' gestation [21], this was likely overly restrictive.

The study may have limited generalizability given that we recruited only in four states with few restrictions on abortion care. This model is not possible in the 19 states that require physicians to be in the same room with the patient when mifepristone is dispensed [22]. This interim analysis is also limited by the sample size. The full analysis will include at least four more sites, including in two new states, and up to 385 additional participants. A strength of the study is its low loss to follow-up.

We look forward to completing recruitment for the study in the coming year, which will provide more precise estimates of the effectiveness, acceptability, and feasibility of medication abortion with mail-order pharmacy dispensing of mifepristone. However, these interim results, together with studies of other care models that include mailing pills for medication abortion [23–26] and pharmacist dispensing at brick-and-mortar pharmacies [3], support the removal of the FDA's in-person dispensing requirement for mifepristone.

Clinical Trial Registration

Clinicaltrials.gov, NCT03913104.

Acknowledgments

We thank the clinic and research staff at each of the study sites for assisting with recruitment and data collection, as well as the staff at American Mail Order Pharmacy.

OBJECTIVE: To estimate effectiveness and acceptability of medication abortion with mifepristone dispensed by pharmacists.

METHODS: We conducted a prospective cohort study at eight clinical sites and pharmacies in California and Washington State from July 2018 to March 2020. Pharmacists at participating pharmacies underwent a 1-hour training on medication abortion. We approached patients who had already been evaluated, counseled, and consented for medication abortion per standard of care. Patients interested in study participation gave consent, and the clinician electronically sent a prescription to the pharmacy for mifepristone 200 mg orally, followed 24–48 hours later by misoprostol 800 micrograms buccally. Participants were sent web-based surveys about their experience and outcomes on days 2 and 14 after enrollment and had routine follow-up with study sites. We extracted demographic and clinical data, including abortion outcome and adverse events, from medical records. We performed multivariable logistic regression to assess the association of pharmacy experience and other covariates with satisfaction.

RESULTS: We enrolled 266 participants and obtained clinical outcome information for 262 (98.5%), of whom two reported not taking either medication. Of the 260 participants with abortion outcome information, 252 (96.9%) and 237 (91.2%) completed day 2 and 14 surveys, respectively. Complete medication abortion (primary outcome) occurred for 243 participants (93.5%, 95% CI 89.7–96.1%). Four participants (1.5%, 95% CI 0.4–3.9%) had an adverse event, none of which was serious or related to pharmacist dispensing. In the day 2 survey, 91.3% (95% CI 87.1–94.4%) of participants reported satisfaction with the pharmacy experience. In the day 14 survey, 84.4% (95% CI 79.1–88.8%) reported satisfaction with the medication abortion experience. Those reporting being very satisfied with the pharmacy experience had higher odds of reporting overall satisfaction with medication abortion (adjusted odds ratio 2.96, 95% CI 1.38–6.32).

CONCLUSION: Pharmacist dispensing of mifepristone for medication abortion is effective and acceptable to patients, with a low prevalence of adverse events.

Medication abortion with mifepristone and misoprostol is approved by the U.S. Food and Drug Administration (FDA) for use through 70 days of gestation. Extensive research has documented the safety and effectiveness of medication abortion, as well as high levels of patient satisfaction.[1] Since mifepristone's approval in 2000, the FDA has required that the drug only be dispensed in clinics, medical offices, or hospitals, a restriction that is codified in the mifepristone Risk Evaluation and Mitigation Strategy.[2] The FDA instituted these restrictions likely because of the limited experience with medication abortion in the United States in 2000. However, there is no evidence that in-person dispensing improves safety, and medications associated with more risks to the patient do not have similar restrictions.[3]

Twenty years later, such evidence is still lacking, and countries such as Australia and Canada have approved mifepristone without dispensing restrictions.[4,5] The mifepristone Risk Evaluation and Mitigation Strategy may be a barrier to access; a national survey of obstetrician–gynecologists found that the number who would provide medication abortion might double if this dispensing restriction were removed.[6] The American College of Obstetricians and Gynecologists advocates the removal of the mifepristone Risk Evaluation and Mitigation Strategy.[7]

Pharmacists dispense medications and controlled substances for all types of indications, including sensitive health issues such as sexually transmitted infections and erectile dysfunction. Currently, 12 states permit pharmacists to prescribe hormonal contraception[8]; a recent national survey found that 65% of all pharmacists were interested in such prescribing.[9]

We performed this study under an FDA Investigational New Drug application to document clinical outcomes with and the acceptability of medication abortion when mifepristone is prescribed by clinicians and dispensed by pharmacists. We also sought to identify factors associated with satisfaction with the pharmacist-dispensing model, as well as to explore whether satisfaction with the pharmacy experience was associated with overall satisfaction with medication abortion.

METHODS

We performed a multicenter prospective cohort study of patients undergoing medication abortion who agreed to obtain pharmacist-dispensed mifepristone. The Institutional Review Boards (IRBs) of the University of California San Francisco (UCSF), Kaiser Permanente Northern California, and the University of Washington approved the study, with reliance on the University of California San Francisco IRB granted by the IRBs of the University of California, Davis, and the University of California, San Diego.

From July 2018 through March 2020, we enrolled patients at eight study sites in California and Washington State, each of which was paired with a nearby pharmacy that agreed to dispense mifepristone. Each of the clinical sites provided medication abortion before the study with clinic dispensing of mifepristone; patients obtained other prescribed medications at pharmacies. Six of the eight clinics partnered with an affiliated pharmacy in the same or adjacent building (n=5) or 1.5 miles away (n=1). Two clinics partnered with independent pharmacies, one of which was located in an adjacent building, and the other was located 1.5 miles away. Study investigators trained participating pharmacists on medication abortion and mifepristone dispensing using a standardized 1-hour presentation at the beginning of the study and as needed when new participating pharmacists were hired. At all study pharmacies, leadership permitted pharmacists to participate in the study if interested, including undergoing training, and committed to having coverage during study recruitment times by a pharmacist who could dispense mifepristone. Of note, three chain pharmacies near potential clinic sites declined to participate. Each clinical site principal investigator completed the mifepristone Prescriber Agreement Form.

Clinicians included physicians, physician assistants, and nurse practitioners. Research staff provided study details, including study coverage of clinical costs (see below) to patients only after the clinician had completed all medically necessary requirements for medication abortion. All patients approached for the study had already been fully evaluated for medication abortion medical eligibility according to the FDA-approved mifepristone labeling and local standard of care, signed the mifepristone Patient Agreement Form and any clinic-specific consent form, and received mifepristone use and follow-up instructions. Clinical follow-up options were site-specific and included returning for an in-clinic ultrasonography examination approximately 1–2 weeks later, obtaining serum human chorionic gonadotropin measurements on the day of taking mifepristone and 1–2 weeks later, or performing telephone follow-up 1 week later with a home urine pregnancy test 4 weeks after mifepristone.

Downloaded from http://journals.lww.com/greenjournal by sl6yvs0MKJE1wUGOMnU7tlU3v0m0wsUEvEmkLFcAWwq8NuJu3lOJlv19CtTWyh1PCJ83Jf71WvGwlUjynK2goSgAv5GFxzkg9L480MVZS9uoVh7f4mF5GKRcizU9NF9qlN6stVhDyNjlb33JsssNnEyjSaXxWfysDybROGo24BRO55ONcvN6g== on 04/28/2025

Participants were eligible for the study if they spoke English or Spanish, were age 15 years or older (18 years or older at two study sites), had been fully evaluated and consented for medication abortion with a gestational age of 70 days or less confirmed by ultrasonography, and were willing to go to the study pharmacy to obtain mifepristone and to use misoprostol buccally per the FDA-approved mifepristone label. Participants also had to be willing and able to be contacted by email, telephone, or text message to complete survey data collection. Eligible and interested participants provided written study informed consent, including Health Insurance Portability and Accountability Act authorization to allow clinical data abstraction from their medical record.

A clinician then electronically prescribed mifepristone 200 mg and misoprostol 800 micrograms, along with analgesics, antibiotics, antiemetics, or contraceptives, as needed. The prescribing clinician instructed participants to use the mifepristone at an agreed-on time and take the misoprostol buccally 24–48 hours after swallowing the mifepristone, consistent with the FDA-approved labeling.[10] Participants went to the pharmacy to obtain the prescribed medications. A trained pharmacist dispensed the mifepristone and other prescribed medications, maintained a study log and provided brief counseling, unless declined by the patient.

On the day after enrollment, the University of California San Francisco study team emailed participants a link to a web-based survey (day 2 survey) in Qualtrics to collect sociodemographic information, including self-described race and ethnicity. Given the evidence of negative health care experiences during pregnancy among people of color due to racism,[11] we believed it was important to collect race and ethnicity information to explore associations with satisfaction outcomes. Participants also confirmed whether they obtained the medications at the pharmacy, and if and when they took or planned to take the medications. If they had taken the misoprostol, we asked the route of administration. If a participant obtained the medications and decided not to take them, we asked what they did or planned to do with the medications; if a participant reported they still had the medications, a survey prompt instructed them to return the medications to the pharmacy or the clinic. Participants were asked whether they thought the pregnancy had already been expelled and whether they had had a medical problem that required them to go to a hospital, emergency department, or doctor's office since starting the medication abortion, and, if so, we asked participants to provide details.

In addition, the day 2 survey assessed participant experiences obtaining mifepristone at the pharmacy with multiple choice questions as well as open-response fields for those who reported dissatisfaction to explain their responses. We asked whether the wait time at the pharmacy was "reasonable" or "too long." All participants were asked, "Did you feel that you got enough information from the pharmacist about how to use the medications?" with response options of "Yes," "No, I would have liked more information from the pharmacist," and "No, but I got all the information I needed from the doctor or nurse in clinic." We asked participants who reported having had a prior medication abortion, "How would you compare your experience of getting the abortion pill this time in the pharmacy compared with last time in the clinic?" with response options of "This time was better," "Last time was better," "They were both the same," or "Not sure."

Two weeks after enrollment, we sent participants an email link to the day 14 survey, which had similar questions about taking the medications, medical problems for which they sought care, follow-up with the clinic, use of additional misoprostol, and whether they thought the abortion was complete and reasons why they thought it was complete. If a participant reported being unsure whether the abortion was complete, a survey prompt instructed the participant to contact the clinical site and asked permission to follow-up with them again after the visit.

The day 14 survey also included questions about the patient's experience with the overall medication abortion experience and whether they would recommend medication abortion to a friend in a similar situation who decided to have an abortion. We also asked whether they would recommend that the friend "get the abortion pill at the pharmacy like you did." Finally, we asked, "If you have another medication abortion in the future, how would you feel about the way you get the service?" Responses options were "I would prefer to have medication abortion be available through many primary care providers and providers of women's health care (doctors and nurses) and I would like to pick up my abortion pill at the pharmacy," "I would prefer to have medication abortion available only in select clinics where the abortion pill can be given to me directly in clinic," "Either way is fine," or "Unsure." The day 14 survey also included open-response questions that allowed participants to elaborate on their responses.

Participants who did not complete the surveys were sent reminders by text, email, or phone, depending on their contact preferences. Those who had not

Downloaded from http://journals.lww.com/greenjournal by sl6yvs0MKJE1wUGOMnU7tlU3v0m0wsUEvEmkLFcAWwq8NuJu3lOJlv19CtTWyh1PCJ83Jf71WvGwlUjynK2goSqAv5GFxzkg9L480MVZS9uoVh7f4mF5GKRcizU9NF9qlN6stVhDyNjlb33JsssNnEyjSaXxWfysDybROGo24BRO55ONcvN6g== on 04/28/2025

yet completed the day 2 survey received a longer day 14 survey, including the day 2 survey items. The surveys remained open for 1 month.

Six or more weeks after participants enrolled, site investigators abstracted data from patient charts and entered the de-identified data into an electronic REDCap form. Abstracted data included demographics, clinical information from the initial visit, and information about any follow-up visits or contacts with the patient related to the medication abortion, including whether the abortion was complete, additional treatments given, and adverse events. Adverse events were also identified from the patient surveys. Adverse events were captured up to 6 weeks after participants were recruited into the study, and any ongoing adverse events were followed until resolution. Adverse events were defined as serious using the FDA criteria and included death, hospitalization, blood transfusion, and surgery.[12,13]

Study participants received a $25 electronic gift card for completing each survey. Participants that had to travel from the clinic to the pharmacy also received a small stipend to cover travel expenses. The study covered the cost of mifepristone, misoprostol, and pharmacy dispensing fees, as well as the cost of other medications and clinical care related to the medication abortion provided during the initial and follow-up visits at some sites, depending on whether the site was able to bill for the service in the usual fashion or not.

We aimed to recruit a minimum of 300 and up to 350 patients for this study, which we thought was feasible during the study period. With a sample size of 300, if the proportion of patients with a complete abortion is 95%, the 95% CI of that proportion is ±3.1%; with a sample of 350, the interval is ±2.7%.

We examined four outcomes related to clinical experience and satisfaction with the pharmacist-dispensing model. These included two clinical outcomes: 1) effectiveness of medication abortion (primary outcome) and 2) adverse events, as well as two patient satisfaction outcomes that we examined in multivariate mixed-effects logistic regression analyses: 3) satisfaction with the pharmacy experience at day 2 and 4) satisfaction with the overall medication abortion experience at day 14. Effectiveness of medication abortion was defined as the proportion of participants who had a complete abortion with medications alone and did not undergo vacuum aspiration. Given the accuracy of patient self-assessment of abortion completion,[14,15] we used self-reported survey data to document abortion outcome if the participant did not have follow-up contact with the clinic. Satisfaction outcomes were based on participants' ratings on a Likert scale. On the day 2 survey, we asked participants "Overall, how satisfied were you with your experience at the pharmacy when you got the abortion pill?" with response options "Very satisfied," "Somewhat satisfied, "Somewhat dissatisfied," and "Very dissatisfied." On the day 14 survey we asked, "Looking back on your experience overall, how satisfied were you with the abortion pill?" with the same response options. We dichotomized responses to the two questions by those who were very satisfied compared with all other responses. We calculated 95% CIs using the binomial method.

We performed multivariable mixed-effects logistic regression analyses to explore associations between participant and pregnancy characteristics and our two patient satisfaction outcomes (satisfaction with pharmacy experience and satisfaction with overall medication abortion experience). We used mixed-effects regression with random intercepts for recruitment site to account for clustering. Independent variables included the following demographic and pregnancy characteristics, selected a priori based on our hypotheses and previous literature[16]: age, race and ethnicity, highest completed level of education, relationship status, parity, gestational age in days at the initial clinic visit, and prior abortion experience (none, previous medication abortion, or previous procedural abortion only). We also adjusted for whether the participant reported receiving adequate information from the pharmacist about medication abortion and pharmacy wait time (reasonable or too long). We included a dichotomized measure of satisfaction with treatment by pharmacy staff as an independent variable in the analysis of satisfaction with the pharmacy experience outcome. To assess whether the pharmacy experience contributed to overall satisfaction with the medication abortion experience, we also included satisfaction with the pharmacy experience as an independent variable to model this outcome.

To account for missing covariate data, we conducted multiple imputation then deletion methods, using chained equations.[17] We excluded participants with missing outcome data after performing multiple imputation. All demographic variables and pharmacy experience responses were collected from patient surveys except gestational age at the clinic visit, which came from clinical charts. Missing survey data for age, race and ethnicity, and parity were obtained from patients' clinical chart data when available.

We conducted all analyses using Stata 15 and reported significance at $P<.05$. Open-ended survey responses were sorted by relevance to study intervention and organized under unifying themes.

Grossman. Pharmacist Dispensing of Mifepristone. Obstet Gynecol 2021.

RESULTS

Study recruitment began in July 2018 and was halted before reaching our desired sample size in March 2020 owing to the coronavirus disease 2019 (COVID-19) pandemic, which limited the ability to have research staff in clinical facilities and lengthen patient visits for the purposes of research consent. Research staff assessed 499 patients for eligibility, of whom 233 were ineligible (n=163) or declined to participate (n=70) (Fig. 1). We enrolled 266 participants, all of whom received the study medications from the pharmacy. The median number of participants recruited at the eight sites was 27 (range 8–74). Medication abortion and study outcome information was available for 262 participants (98.5%); the other four were lost to follow-up. In addition, one participant opted not to have a medication abortion and returned the medications to the study site, and one reported flushing the medications down the toilet after having a spontaneous pregnancy loss. The characteristics of the 260 participants (97.7%) who took the medications and have abortion outcome data are presented in Table 1. The median gestational age was 46 days at the time of initial clinic visit. Two hundred forty-six participants (94.6%) reported the date they took mifepristone; all had a gestational age of 70 days or less on that date.

We obtained abortion outcomes for most participants (n=235, 90.4%) based on completed clinical follow-up, with the remainder based on survey responses. Follow-up assessments are detailed in online Appendix 1, available online at http://links.lww.com/AOG/C227. Complete abortion occurred for 243 participants (93.5%, 95% CI 89.7–96.1%) with medication alone. Twenty-seven participants received a second dose of misoprostol, including 18 who ultimately had a complete abortion. Seventeen participants were diagnosed with incomplete abortion based on symptoms and ultrasonography findings, all of whom underwent vacuum aspiration. No participant had an ongoing pregnancy. Outcomes by gestational age are presented in Appendix 2, available online at http://links.lww.com/AOG/C227.

Four participants (1.5%, 95% CI 0.4–3.9%) had an adverse event possibly related to the abortion. Three participants went to an emergency department: one received intravenous fluids for dehydration, one reported heavy bleeding and was treated with pain medication, and one was diagnosed with pelvic inflammatory disease after an aspiration for incomplete abortion. None were hospitalized. In addition, one participant reported at a follow-up visit that she had transient pain and swelling in her cheeks after taking the misoprostol buccally, which had resolved and was thought to be a possible allergic reaction. After review by the site principal investigators, no adverse event was thought to be related to pharmacist dispensing. No participant reported a serious adverse event, and none were identified in chart abstraction.

Downloaded from http://journals.lww.com/greenjournal by sl6yvs0MKJE1wUGOMnU7tlU3v0m0wsUEvEmkLFcAWwq8NuJu3lOJlv19CtTWyh1PCJ83Jf71WvGwlUjynK2goSqAv5GFxzkg9L480MVZS9uoVh7f4mF5GKRcizU9NF9qlN6stVhDyNjlb33JsssSNnEyjSaXxWfysDybROGo24BRO55ONcvN6g== on 04/28/2025

For survey data, we excluded 8 of 260 (3.1%) participants missing pharmacy satisfaction data and 23 of 260 (8.8%) participants missing overall medication abortion satisfaction data. Participants completed the day 2 survey a median of 2 days after enrollment (interquartile range 1–4 days) and completed the day 14 survey a median of 16 days after enrollment (interquartile range 14–21 days). Table 2 shows participants' satisfaction as reported in the day 2 survey (n=252). Among survey respondents, 91.3% (95% CI 87.1–94.4%) reported being very (68.7%) or somewhat (22.6%) satisfied with their experience at the pharmacy, and 96.8% (95% CI 93.8–98.6%) reported being very (79.8%) or somewhat (17.1%) satisfied with their treatment by pharmacy staff. Four-fifths (79.4%) of participants said the wait time in the pharmacy was reasonable.

Participants who were less than very satisfied with the pharmacy experience (n=76) or treatment by pharmacy staff (n=42) gave open-ended responses describing their dissatisfaction. Common themes cited included complaints about long wait times (n=38), confusion on the part of pharmacists or staff regarding dispensing (n=27), perceived negative pharmacist attitudes (n=10), inadequate pharmacist knowledge about the medications (n=8), initially not receiving all prescribed medications (n=8), and privacy not adequately maintained (n=4), among others. Some participants pointed to more than one factor that contributed to their dissatisfaction.

In the day 2 survey, most participants reported they received adequate information from the pharmacist (59.9%) or reported they did not receive enough information from the pharmacist but received all the information they needed from the clinician they had seen previously (38.1%). Only four participants (1.6%) reported that they would have liked more information about how to use the medications from the pharmacist.

Among the 48 participants who reported a prior medication abortion, most said the current experience was the same (n=22, 46%) or better (n=17, 35%) as receiving the medications in the clinic. Eight (17%) were unsure and one (2%) reported the experience as worse. In an open-response field, participants wrote they appreciated the ability to schedule when they would take the medications, which improved convenience and allowed them to have more control over when the abortion would take place. Although some participants saw this model of care as allowing more privacy and social support, a few thought the model was less private and felt less supported by the pharmacy staff compared with the clinic staff.

Table 3. Acceptability and Satisfaction at Day 14 Survey Among Women Having Medication Abortion and Receiving Mifepristone at a Pharmacy (n=237)

	n (%)
Overall satisfaction with medication abortion	
Very satisfied	155 (65.4)
Somewhat satisfied	45 (19.0)
Neither satisfied nor dissatisfied	23 (9.7)
Somewhat dissatisfied	12 (5.1)

No	10 (4.2)
Depends	42 (17.7)
Unsure	9 (3.8)
Future model preference reported	
Prefer to have medication abortion available through primary care and pick up at pharmacy	147 (62.0)
Prefer to have medication abortion available only in select clinics where pill is given directly in clinic	13 (5.5)
Either way	68 (28.7)
Unsure	7 (3.0)
Missing	2 (0.8)

Table 3 shows measures of satisfaction collected from the 237 (91.2%) women who completed the day 14 survey. Overall, 84.4% (95% CI 79.1–88.8%) reported being very (65.4%) or somewhat (19.0%) satisfied with their medication abortion experience. The majority said they would recommend medication abortion (67.9%) and pharmacist dispensing (74.3%) to a friend in a similar situation. When asked how they would prefer to obtain medication abortion in the future, if needed, the majority (62.0%) said they would prefer to have medication abortion available through prescriptions from primary care clinics with medications dispensed in pharmacies. Only 5.5% said they would prefer to have the service only available in select clinics where the medications are dispensed directly to patients in clinic. About one quarter (28.7%) said either way was fine, and 3.0% were unsure.

Table 4 shows the results of multivariable mixed-effects logistic regression analyses exploring factors associated with patient satisfaction with the pharmacy and medication abortion experience. Those reporting

excessively long wait times had lower odds of satisfaction with pharmacy dispensing (adjusted odds ratio [aOR] 0.04, 95% CI 0.01–0.13), and those who reported being very satisfied with the treatment by pharmacy staff had higher odds of satisfaction with pharmacy dispensing (aOR 16.79, 95% CI 6.00–46.98). Those who reported that they were very satisfied with the pharmacy experience had higher odds of being very satisfied with their medication abortion overall compared with those who were somewhat satisfied or dissatisfied with the pharmacy experience (aOR 2.96, 95% CI 1.38–6.32).

DISCUSSION

In this study, medication abortion provision with pharmacist dispensing of mifepristone was effective and acceptable to patients. Among participants with follow-up data, 93% had a complete abortion, and none had an ongoing pregnancy. These outcome proportions are similar to those reported in the literature when the medications are dispensed by a clinician.[18,19] Few patients (1.5%) had adverse events, and none were related to pharmacist dispensing.

We also found that the vast majority of patients were satisfied with the model of care, and overall satisfaction was similar to other studies of medication abortion with clinician-dispensed mifepristone, which have found that 87–88% were satisfied with the method.[19,20] Satisfaction with the pharmacy and treatment by pharmacy staff, reported on the day 2 survey, were somewhat higher than overall satisfaction with medication abortion reported later. This is not surprising given that overall method satisfaction is correlated with symptoms and outcomes of the medication abortion,[21] which might not yet have been apparent by the day 2 survey. The vast majority reported they received adequate information–either from the clinician or pharmacist–and more than 90% indicated their support for pharmacist dispensing of mifepristone in the future.

Although satisfaction with this model was high, the open-ended responses point to areas for improvement that could be addressed through additional training of pharmacists and pharmacy staff. The finding that elements of the pharmacy experience, such as wait time and treatment by the pharmacy staff, were associated with satisfaction with the pharmacy experience, which in turn was associated with overall abortion satisfaction, is similar to research on other pharmacy services.[22]

It is a reassuring finding that one-third of participants who had had a prior medication abortion reported that the current experience of getting the medications at the pharmacy was better. The open-ended responses suggest that patients appreciated the convenience of being able to schedule when to take the medications. Since the FDA approved updated labeling for mifepristone in 2016, patients are no

Downloaded from http://journals.lww.com/greenjournal by sl6yvs0MKJE1wUGOMnU7tlU3v0m0wsUEvEmkLFcAWwq8NuJu3l0OJlv19CtTWyh1PCJ83Jf71WvGwlUjynK2goSqAv5GFxzkg9L480MVZS9uoVh7f4mF5GKRcizU9NF9qlN6stVhDyNjlb33JsssNnEvjSaXxWfysDybROGo24BRO55ONcvN6g== on 04/28/2025

longer required to take the pill in the facility after it is dispensed,[10] although some state laws still require this. It is also notable that two participants did not proceed with the medication abortion after completing their clinic visit and filling the prescription. Other studies that allow patients to take the mifepristone at home after receiving it in the clinic or that mail the medications patients have also reported that a very small number of patients choose not to proceed with the abortion.[23,24]

One concern that has been raised with allowing clinicians to issue prescriptions for mifepristone is that some pharmacists may refuse to fill the prescription, limiting the feasibility of this model.[25] In our study, the participating pharmacies were required to have a pharmacist on duty during clinic hours who had been trained in the study protocol and was willing to dispense mifepristone. As a result, all participants were able to fill their prescriptions when they went to the pharmacy. We also collected survey and interview data with the pharmacists at the study pharmacies to evaluate their perceptions of the model, which will be reported separately. Although we did not have challenges with individual pharmacists refusing to dispense mifepristone, we did have difficulty obtaining study approval at chain pharmacies. If the dispensing requirement for mifepristone is eliminated, some pharmacies may refuse to stock the medication, as has been reported for ulipristal acetate emergency contraception,[26] highlighting a potential role for mail-order pharmacies once the Risk Evaluation and Mitigation Strategy is removed.

This study has several strengths, including low loss to follow-up and standardized pharmacist training. It also has several limitations. We had to stop recruitment early because of the COVID-19 pandemic, reaching 89% of our planned minimum sample size. However, the effect of the reduced sample size on the precision of our estimates was small. The sample size is similar to the only other published report on providing medication abortion in the United States without in-clinic dispensing (n=190 with abortion outcome data).[24] In addition, our findings may have limited generalizability given that no chain pharmacy participated; patient experiences at chain pharmacies theoretically may be different. Finally, satisfaction with the pharmacy experience may increase over an extended time as pharmacy staff become more accustomed to dispensing mifepristone.

This study, together with another report of a direct-to-patient telemedicine service in which patients received the medications by mail,[24] demonstrate that medication abortion may be offered with a high level of effectiveness and satisfaction and low prevalence of adverse events without requiring mifepristone to be dispensed in the clinic or medical office. These data further support eliminating the dispensing requirement for mifepristone and allowing pharmacies to dispense the medication.

Frequently Asked Questions About the Largest Study on Chemical Abortion

Jamie Bryan Hall, Director of Data Analysis, Ethics and Public Policy Center
Ryan T. Anderson, President, Ethics and Public Policy Center

MAY 7, 2025

The report we released last week is the largest-known study of the abortion pill, based on analysis of data from an all-payer insurance claims database that includes 865,727 prescribed mifepristone abortions from 2017 to 2023. We found that 10.93 percent of women experience sepsis, infection, hemorrhaging, or another serious adverse event within 45 days following a mifepristone abortion. This means that the real-world rate of serious adverse events following mifepristone abortions is at least 22 times as high as the summary figure of "less than 0.5 percent" in clinical trials reported on the drug label.

Some have raised questions about our data and methodology. We address some of those below. And will be updating this document with additional questions and answers and clarifications as needed.

1. How did you confirm solely from ICD-10 codes that the hospitalization or ER visits were related to the abortion? Isn't it possible that a person who had a medical abortion could end up at the ER within 45 days for something completely unrelated, such as a car accident or broken bone?

The emergency room visits included in the report are only those related to the chemical abortion, based on the diagnosis and procedure codes in the insurance records, and are counted only if treatment for a serious complication related to the chemical abortion took place. Thus, if a woman took the chemical abortion pill and then got into a car accident or broke a bone, that did not count. Likewise, if a woman took the chemical abortion pill and had mild cramping related to the chemical abortion, that also did not count. Only an ER visit when the woman was treated for a serious adverse event related to the chemical abortion was counted.

This led us to exclude 72% of emergency room visits that took place within 45 days of abortion from our analysis because they were either not serious enough or were unrelated to the chemical abortion. That is, 98,483 ER visits that occurred within 45 days of the chemical abortion involved diagnoses not clearly related to the chemical abortion or not medically serious, such as COVID-19 exposure, nicotine dependence, asthma, and anxiety disorder.

Moreover, our findings are consistent with existing FDA information: in the serious adverse event section, the Mifeprex label reports abortion-related ER visits of up to 4.6%, and this study identified a nearly identical rate of 4.7%.

The reason we reported on ER visits is because the FDA does so on the drug label for mifepristone.

2. What if one woman experienced multiple serious adverse events? Aren't you inflating the percentage of women who experience a serious adverse event?

Our reported 10.93% rate of serious adverse events means that women experienced at least one serious adverse event in 10.93% of pregnancies for which a mifepristone abortion was prescribed. We ensured that each pregnancy was counted only once, even if a woman experienced multiple serious adverse events within the same category or across different categories. 10.93% is simply the ratio of the sum of women who experienced one or more serious adverse events associated with the prescribed mifepristone abortion of a given pregnancy to the total number of pregnancies for which a mifepristone abortion was prescribed. It is not, as some have erroneously suggested, a rate of how many serious adverse events women experienced, on average, per pregnancy aborted with mifepristone.

3. Why have you included ectopic pregnancy as an adverse event associated with medical abortion? The pill can't cause a pregnancy to move from the uterus, so why include that as a condition that resulted from taking the medication?

We do not claim or suggest that mifepristone causes ectopic pregnancies. The warning on the first page of the FDA-approved drug label requires that ectopic pregnancy be ruled out as a condition prior to using mifepristone, precisely because the use of mifepristone by a woman with an ectopic pregnancy poses extraordinary, heightened risk to her health. As noted on page 5 of our report, only events occurring within 45 days *following* the abortion are included. The study reports 3,062 cases of ectopic pregnancy. These are cases in which a woman was diagnosed with this condition only after she had already taken mifepristone. This failure to properly diagnose the ectopic pregnancy before the abortion attempt placed each of these women's life at risk.

This reinforces why, at minimum, the safety protocols requiring an in-person doctor visit should be restored to protect women's health. Without a doctor visit, how can the FDA expect women with ectopic pregnancies to follow the FDA requirement that ectopic pregnancies be ruled out prior to a chemical abortion and thereby avoid the extreme risk of a chemical abortion for them? This data clearly shows that in over 3,000 cases in our data alone, the FDA, the manufacturer, and the prescriber of mifepristone failed these women who had pre-existing ectopic pregnancies and did not know it.

4. Could you be including miscarriage care as if it were an abortion? After all, isn't it accurate that you included patients who were only prescribed mifepristone and not also given misoprostol? Since the protocol for medical abortion is to take both medications, is it possible that your data includes some patients who were given mifepristone for other conditions, including miscarriage?

No, we were very careful to exclude miscarriage care in our report by requiring any mifepristone only prescription was accompanied by a Z332 code (encounter for elective termination of pregnancy) or Z640 (problems related to unwanted pregnancy).

5. Didn't you simply label everything a serious adverse event? How did you define it and then code for it?

We based our analysis on the official FDA definition of a serious adverse event and then identified treatment and diagnosis codes that matched that definition. For an event to be counted in our serious adverse event rate, it had to meet three criteria:

1. It aligned with the FDA's definition of a serious adverse event—for example, it was life-threatening, required hospitalization, or led to surgical intervention.
2. It occurred within 45 days of the medication abortion.
3. It was reasonably related to the abortion, as previously described.

The events we included covered hospitalizations for hemorrhage, sepsis, blood transfusions, surgical procedures after failed abortions, and complications from confirmed ectopic pregnancies. We limited our analysis to severe (Grade 3) and life-threatening (Grade 4) events as defined by the NIH's Common Terminology Criteria for Adverse Events (CTCAE). We were not yet able to include Grade 5 events (deaths).

Critics imply that the FDA definition of serious adverse event is simply whatever the FDA chose to count on the drug label. However, the drug label does not contain a definition of "serious adverse event," only an incomplete yet overlapping list of categories (three diagnoses, one treatment, and two places of service) *with* reported data, followed by a list of post-marketing categories *without* reported data (which includes "ruptured ectopic pregnancy"). We cited and followed the official FDA definition of the term (linked above); to then say that we use "a broader definition of 'serious adverse event' than the FDA" is highly misleading.

6. Can you explain what "other abortion-specific complications" includes in the paper's serious adverse events by category section? It accounts for around half of the serious adverse event rate but I don't see any more specifics about those 49,169 "other abortion-specific complications."

Other abortion-specific complications include problems like damage to the woman's internal organs from the abortion, fetal tissue remaining inside the woman's uterus after the abortion, kidney failure, as well as life-threatening mental health diagnoses occurring after the abortion.

These are overwhelmingly DRG 770 (Abortion with D&C, Aspiration Curettage, or Hysterotomy) and DRG 769 (Postpartum and Post Abortion Diagnoses with Operating Room Procedure) codes that were determined to be severe or life-threatening following CTCAE version 5. Furthermore, we limited mental health codes to only those that met the criteria for life-threatening in order to not overestimate that category. There were just a few diagnosis codes (representing a small share of the cases) that met our inclusion criteria, namely R45850 (Homicidal ideations) and R45851 (Suicidal ideations). Many women who were counted in the other categories in Figure 1 of our report also experienced an event that fell within this category.

7. Why wasn't this paper peer-reviewed?

The point is not peer review, but replicability. We have made our study fully replicable for anyone who wants to analyze the insurance claims data. The replicability crisis, well-documented in the press and denied by no responsible person, is the evidence that peer review guarantees little.

We stand behind our analysis of healthcare claims data which is why we are asking the FDA to conduct its own review of this data. Real world data in which money changed hands based on the treatment of patients and coding by doctors brings a higher level of confidence. The dataset is available for purchase and our methodology is public. This study is fully replicable, and we encourage others to replicate it.

The peer-review process is broken. It is terribly biased against conservatives, especially social conservatives, particularly pro-lifers. The paper would have been leaked, so as to prepare hostile responses, if it were ever published to begin with. Given the extensive pro-abortion bias in the peer-review process, there are, effectively, no opportunities to publish peer-reviewed analysis that offer major substantive critiques of the abortion pill or abortion.

8. Why should we trust insurance claims data?

Insurance claims data is a cornerstone of public health and safety monitoring. The FDA, CDC, NIH, CMS, and countless peer-reviewed journals rely on it precisely because it reflects real-world outcomes across massive populations. For example:

- The **FDA Sentinel Initiative** uses claims and electronic health record data to monitor post-market safety of medical products.
- The **CDC's Vaccine Safety Datalink (VSD)** uses claims data from millions of individuals to monitor vaccine safety.
- The **Centers for Medicare & Medicaid Services (CMS)** conduct quality assessments and cost analyses through large-scale claims-based research.

Peer-reviewed journals such as *JAMA*, *The New England Journal of Medicine*, and *Health Affairs* regularly publish studies based on administrative claims.

It is especially vital for medications like mifepristone, where:

- Controlled trials have small samples, carefully recruited healthy patients, physician oversight, and limited follow-up.
- Post-marketing surveillance (e.g., FAERS) is passive and incomplete.
- Reporting requirements were loosened in 2016, obscuring complications.

Our analysis examines hundreds of thousands of real-world chemical abortion events—across settings, payors, and demographics—and identifies follow-up care patterns at scale. This is real-world data, in real-world clinical settings, in which real money changed hands from public and private payors as a result of real serious harm faced by real women. These women, and hundreds of thousands like them, were seriously harmed, not carefully protected in idealized clinical studies.

The Abortion Pill Harms Women: Insurance Data Reveals One in Ten Patients Experiences a Serious Adverse Event

Jamie Bryan Hall, Director of Data Analysis, Ethics and Public Policy Center
Ryan T. Anderson, President, Ethics and Public Policy Center

April 28, 2025

Summary

- This largest-known study of the abortion pill is based on analysis of data from an all-payer insurance claims database that includes 865,727 prescribed mifepristone abortions from 2017 to 2023.
- 10.93 percent of women experience sepsis, infection, hemorrhaging, or another serious adverse event within 45 days following a mifepristone abortion.
- The real-world rate of serious adverse events following mifepristone abortions is at least 22 times as high as the summary figure of "less than 0.5 percent" in clinical trials reported on the drug label.
- The FDA should immediately reinstate its earlier, stronger patient safety protocols to ensure physician responsibility for women who take mifepristone under their care, as well as mandate full reporting of its side effects.
- The FDA should further investigate the harm mifepristone causes to women and, based on objective safety criteria, reconsider its approval altogether.

Danco Laboratories markets Mifeprex as "the safe and effective abortion pill," but our research shows that mifepristone abortion, as currently practiced in the U.S., is not safe and effective.[1] The manufacturer and the FDA rely on the results of 10 clinical trials with a total of 30,966 participants, less than 0.5 percent of whom reportedly experienced serious adverse reactions. In contrast, we analyzed real-world insurance claims data for 865,727 prescribed mifepristone abortions, broadly representative of women who obtain mifepristone abortions in the U.S. today, and we find a serious adverse event rate of 10.93 percent—at least 22 times as high as the summary figure reported on the drug label. In light of this research, we urge the FDA to reinstate earlier, stronger patient safety protocols and reconsider its approval of mifepristone altogether. Women deserve better than the abortion pill.

Our Key Findings

10.93 percent of women experience sepsis, infection, hemorrhaging, or another serious or life-threatening adverse event within 45 days following a mifepristone abortion, far greater than the summary figure of "less than 0.5 percent" in clinical trials reported on the drug label. *Figure 1, next page.*

[1] Danco Laboratories, "The Safe and Effective Abortion Pill | Mifeprix (mifepristone)," https://www.earlyoptionpill.com (accessed April 14, 2025)

Figure 1

Serious Adverse Events by Category

	Number with adverse events	Serious adverse event rate
Sepsis	824	0.10%
Infection	11,707	1.34%
Transfusion	1,257	0.15%
Hemorrhage	28,658	3.31%
Hospitalization (related to the abortion)	5,699	0.66%
ER visit (related to the abortion)	40,960	4.73%
Ectopic pregnancy	3,062	0.35%
Other life-threatening adverse events (cardiac, pulmonary, thrombosis, anaphylaxis, surgery)	1,956	0.22%
Repeated (surgical) abortion	24,563	2.84%
Other abortion-specific complications	49,169	5.68%
Overall	94,605	10.93%

Note: The overall serious adverse event rate of 10.93% is adjusted for the fact that some women suffer from adverse events in multiple categories.

Simply stated, mifepristone, as used in real-world conditions, is not "safe and effective."

Our real-world post-market observational study of mifepristone is, to our knowledge, the most comprehensive study of chemical abortion safety ever conducted in the U.S.:

- We identify and include 865,727 prescribed mifepristone abortions, 28 times as many as were included in all FDA-cited clinical trials combined.
- Our dataset is more recent, no earlier than 2017, while the FDA approval of mifepristone relies entirely on data from more than a decade ago.
- The women in our dataset are broadly representative of the women who obtain mifepristone abortions in the U.S.; they are not a prescreened group of generally healthy women recruited into various clinical trials conducted at different times around the world.
- The women in our dataset receive (or fail to receive) pre- and post-abortion healthcare of the real-world quality that prevails in the U.S. today, not the carefully controlled regimen of care that ordinarily prevails in a clinical trial.

Policy Implications

The FDA should reinstate the original patient safety protocols that were required when mifepristone was first approved. Doing so will likely reduce the harms to women and permit better monitoring to determine whether this drug should remain on the market:

- Prescribing mifepristone and misoprostol for the termination of pregnancy should require at least three in-person office visits by the patient—as originally required by the FDA.
- Mifepristone should be prescribed only by physicians—as originally required by the FDA—who have read and understood the prescribing information.
- Mifepristone should be administered only in a clinic, medical office, or hospital, by or under the supervision of a physician, able to assess the gestational age of an embryo and to diagnose ectopic pregnancies—all of which was originally required by the FDA.
- Physicians must be able to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.
- Healthcare providers should be required once again to report to the FDA (and manufacturers of mifepristone) all serious adverse events resulting from the use of mifepristone.
- Mifepristone should only be prescribed to a woman who is confirmed by a physician to be in the first seven weeks of pregnancy—as originally required by the FDA.

Background on FDA Approval and Regulation of Mifepristone

Mifepristone was developed by the French pharmaceutical company Roussel Uclaf S.A. and brought to the United States at the urging of President Clinton and after Congressional pressure. The FDA approved it under a little-used approval process for "certain new drug products that have been studied for their safety and effectiveness in treating serious or life-threatening illnesses and that provide meaningful therapeutic benefit to patients over existing treatments."[2] Thus, to grant approval in this manner, the FDA had to consider an unwanted pregnancy a "serious or life-threatening illness" and find that mifepristone was more effective than surgical abortion in treating it. The FDA's decision cites minimal data: clinical trials with only 859 participants in the U.S. and 1,800 in France.[3]

The original FDA-approved drug label for Mifeprex (the brand name of mifepristone) from September 2000 indicated use of the drug for "the medical termination of intrauterine pregnancy through 49 days' pregnancy."[4] It required several modest safeguards for women's health:

> Treatment with Mifeprex and misoprostol for the termination of pregnancy requires three office visits by the patient. Mifeprex should be prescribed only by physicians who have read and understood the prescribing information. Mifeprex may be administered only in a clinic, medical office, or hospital, by or under the supervision of a physician, able to assess the gestational age of an embryo and to diagnose ectopic pregnancies. Physicians must also be able to provide surgical intervention in cases of incomplete abortion or severe bleeding, or have made plans to provide such care through others, and be able to assure patient access to medical facilities equipped to provide blood transfusions and resuscitation, if necessary.[5]

During the Obama and Biden administrations, the FDA chipped away at these initial safeguards, risking women's health in order to increase access to abortion. Under the current Risk Evaluation and Mitigation Strategy (REMS) in effect since 2023:

1. a mifepristone abortion now requires as a little as one telehealth visit with any approved healthcare provider (not necessarily a physician),
2. a woman may self-administer drugs obtained from a mail-order pharmacy, and
3. the prescriber need not report any adverse events unless he or she knows that a patient has died. *Figure 2.*

Figure 2

Weakening FDA Safeguards for Mifepristone

	2000 Clinton Initial Approval	2016 Obama REMS Changes	2023 Biden REMS Changes
Required number of in-person visits	3	1	0

2 Alliance for Hippocratic Medicine v. FDA, Complaint, https://adflegal.org/wp-content/uploads/2022/11/Alliance-for-Hippocratic-Medicine-v-FDA-2022-11-18-Complaint.pdf
3 Mifeprex (mifepristone) drug label, September 2000, page 3, https://www.accessdata.fda.gov/drugsatfda_docs/label/2000/20687lbl.pdf
4 Mifeprex (mifepristone) drug label, September 2000, page 6, https://www.accessdata.fda.gov/drugsatfda_docs/label/2000/20687lbl.pdf
5 Mifeprex (mifepristone) drug label, September 2000, page 14, https://www.accessdata.fda.gov/drugsatfda_docs/label/2000/20687lbl.pdf

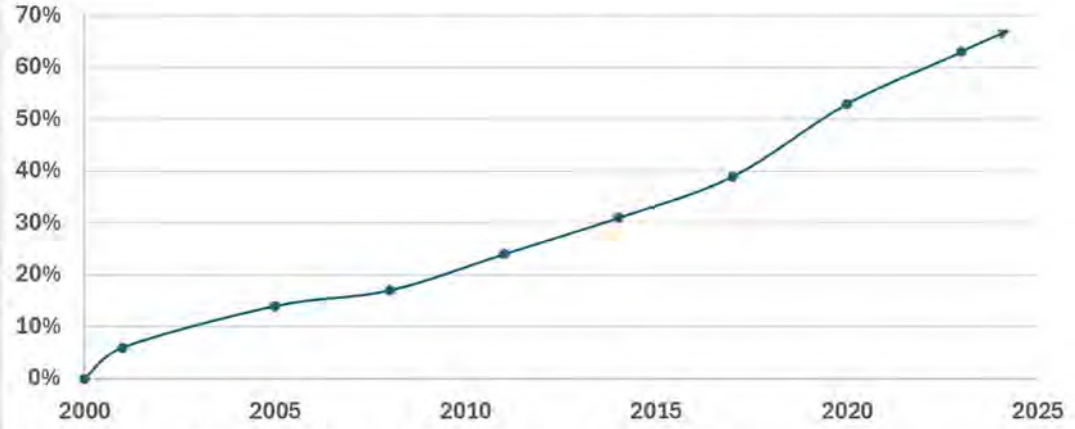
The current FDA-approved drug label refers to the results of 10 clinical trials with a total of 30,966 participants, less than 0.5 percent of whom reportedly experienced serious adverse reactions.[6] But these figures are based entirely on data from trials taking place more than a decade ago.

The Increasing Market Share of Chemical Abortion

Increased access to chemical abortion has coincided with a rapid increase in its prevalence. Chemical abortions—the vast majority of which are performed using a combination of mifepristone and misoprostol—now account for roughly two-thirds of all abortions in the United States. *Figure 3.*

In fact, Danco Laboratories boasts that more than 5 million U.S. women have used its abortion pill since it was approved in 2000.[7] Thus, it has become increasingly important to understand the risks and harms to women from chemical abortion in general and from mifepristone in particular.

How We Identified Mifepristone Abortions



In our data, a mifepristone abortion was identified in one of three ways:

1. procedure code S0199: medically induced abortion by oral ingestion of medication including all associated services and supplies,
2. a prescription for mifepristone (with or without misoprostol within the next 3 days), or
3. a diagnosis code for elective termination or unwanted pregnancy, along with other billing coding consistent with manufacturer instructions for reimbursement for a mifepristone abortion for a given state and insurer combination.[8]

Following this method, we identified a total of 865,727 mifepristone abortions prescribed for a total of 692,873 women from 2017 to 2023. This includes 566,446 women, each of whom had one such abortion, and 126,427 women with multiple such abortions.

Figure 3

Chemical abortion has increased rapidly since approval in 2000 and now accounts for approximately two-thirds of all abortions.

Source: Guttmacher Abortion Provider Census and Monthly Abortion Provision Study, via https://www.guttmacher.org/2024/03/medication-abortion-accounted-63-all-us-abortions-2023-increase-53-2020

6 Page 7 of the drug label states, "Serious adverse reactions were reported in <0.5% of women. Information from the U.S. and non-U.S. studies is presented in Table 2." Table 2 on page 8 indicates that some categories of serious adverse reactions were observed at higher rates in some trials, but this is never discussed in the text, leaving only the previous statement with which to interpret the table. See Mifeprex (mifepristone) drug label, January 2023, https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s026lbl.pdf

How We Identified Serious Adverse Events

We followed the official FDA definition of "serious adverse event."[9] To do so, we identified relevant ICD-10 diagnosis codes and CPT/HCPCS procedure codes for adverse events from multiple sources:

- CDC Severe Maternal Morbidity (SMM) indicators,[10]
- CMS Diagnosis-Related Group (DRG) 770 and 769 codes,[11]
- FDA Adverse Events Reporting System (FAERS) reports (interpreted and translated into diagnosis and procedure codes by the doctors on our team),[12] and
- a small number of (mostly gynecological) codes suggested by our doctors.

These codes were then graded by a team of physicians using the the NIH Common Terminology Criteria for Adverse Events (CTCAE version 5), which categorizes adverse events by severity on a 5-point scale.[13] We included CTCAE Grade 3 (severe) and Grade 4 (life-threatening). We did not include Grade 1 (mild) or Grade 2 (moderate). (Grade 5 is death, which would count as a serious adverse event under the FDA definition but could not necessarily be observed in the insurance claims data. We hope to show the rate of death in a subsequent report.)

For reporting, we have grouped the relevant diagnosis and procedure codes as follows:

1. The mifepristone label divides serious adverse events into six categories identified in the clinical trials: sepsis, infection, transfusion, hemorrhage, hospitalization, and emergency room visit. Only those hospitalizations and emergency room visits with abortion-related diagnosis and procedure codes are included in our analysis.
2. FAERS received reports of various events that our doctors judge to be life-threatening and have grouped into broad categories: ectopic pregnancy, surgery, cardiac, pulmonary, thrombosis, and anaphylaxis.
3. Repeated (surgical) abortion procedures are considered serious adverse events.
4. Other abortion complications include codes specifically related to an abortion or miscarriage, as well as life-threatening mental health diagnoses, etc.

We consider only serious adverse events that occurred within 45 days following the abortion. This is conservative, as some adverse events may present later (and studies relied on by the FDA used a timeframe as long as 72 days). Additionally, the likelihood of a subsequent pregnancy within this timeframe is negligible, which ensures that adverse events are related to the abortion rather than to a subsequent pregnancy.

Our Data

Our team has purchased access to a commercially available all-payer health insurance claims database including de-identified data for all U.S. patients during the years 2017 to 2023. It includes information on hospital and office visits, diagnoses, procedures, and prescriptions processed through private health insurance, Medicaid, Medicare, TRICARE, and the Department of Veterans Affairs (VA). The data excludes transactions for which the insurer is also the provider (as is the case with some HMOs and much VA care), as well as cash pay transactions (which are disproportionately common for abortion). This dataset provides longitudinal tracking of medical diagnoses, procedures, and prescriptions for each patient and is widely used in academic and regulatory research.

Our Research Project Team

Our research project was conducted and validated by a team of data scientists, analysts, and engineers, with assistance from our clinical team of board-certified obstetricians and gynecologists. Members have a history of academic research and peer-reviewed publication.

Conclusion

Our research shows unequivocally that mifepristone abortion, as currently practiced in the U.S., is considerably more dangerous to women than is represented on the FDA-approved drug label. The FDA should immediately reinstate its earlier, stronger patient safety protocols to ensure physician responsibility for women who take mifepristone under their care, as well as mandate full reporting of its side effects. The FDA should further investigate the harm this drug causes to women and, based on objective safety criteria, reconsider its approval altogether. Women deserve better than the abortion pill.

This paper is the first in a series investigating women's health and abortion using real-world data.

The Abortion Pill Harms Women: Insurance Data Reveals Repeated Abortion Attempts Due to High Failure Rate

Jamie Bryan Hall, Director of Data Analysis, Ethics and Public Policy Center
Ryan T. Anderson, President, Ethics and Public Policy Center

MAY 12, 2025

Summary

- The real-world failure rate of mifepristone abortion—at least 5.26 percent, or about one in 19 cases—is double the failure rate from the U.S. clinical trials and roughly two-thirds higher than the combined failure rate from all clinical trials reported on the FDA-approved drug label.
- Combined with our prior finding that 10.93 percent of women experience a serious adverse event and adjusting to avoid double-counting, we find that 13.51 percent of women—roughly one in seven—experience at least one serious adverse event or repeated abortion attempt within 45 days of first attempting a mifepristone abortion.
- This largest-known study of the abortion pill is based on analysis of data from an all-payer insurance claims database that includes 865,727 prescribed mifepristone abortions from 2017 to 2023.
- The FDA should immediately reinstate its earlier, stronger patient safety protocols to ensure physician responsibility for women who take mifepristone under their care, as well as mandate full reporting of its side effects.
- The FDA should further investigate the harm this drug causes to women and, based on objective safety and effectiveness criteria, reconsider its approval altogether.

Danco Laboratories markets Mifeprex as "the safe and effective abortion pill," but our research shows that mifepristone abortion, as currently practiced in the U.S., is not safe or effective.[1] The manufacturer and the FDA rely on the results of clinical trials in which less than 0.5 percent of participants reportedly experienced serious adverse reactions and all but 2.6-3.8 percent obtained a complete abortion by taking mifepristone plus misoprostol.[2] In contrast, we analyzed real-world insurance claims data for 865,727 prescribed mifepristone abortions, broadly representative of women who obtain mifepristone abortions in the U.S. today, and we find a serious adverse event rate of 10.93 percent and a failure rate of at least 5.26 percent. In light of this research, we urge the FDA to reinstate earlier, stronger patient safety protocols and reconsider its approval of mifepristone altogether. Women deserve better than the abortion pill.

1 Danco Laboratories, "The Safe and Effective Abortion Pill | Mifeprex (mifepristone)," https://www.earlyoptionpill.com (accessed April 14, 2025)
2 Page 7 of the drug label states, "Serious adverse reactions were reported in <0.5% of women." Effectiveness data are reported in Table 3 on page 13. See Mifeprex (mifepristone) drug label, January 2023, https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s026lbl.pdf

Repeated Abortion Attempts Following Failure of Mifepristone Abortion Regimen

According to the insurance data, 5.26 percent of women undergo a second abortion attempt within 45 days of the first, indicating that the first mifepristone abortion attempt failed.[3] Curiously, although the drug label does not appear to contemplate the possibility of a second abortion attempt using mifepristone for the same pregnancy, we regularly observe this in the insurance claims database. *See Table 1.*

The real-world failure rate of mifepristone abortion—at least 5.26 percent,[4] or about one in 19 cases—is double the failure rate of 2.6 percent from the U.S. clinical trials and roughly two-thirds higher than the combined failure rate of 3.2 percent from all clinical trials reported on the FDA-approved drug label.[5]

Safety and Effectiveness

As we previously reported, 10.93 percent of women—roughly one in ten—experience sepsis, infection, hemorrhaging, or another serious adverse event within 45 days following a mifepristone abortion.[6] Combined with the 5.26 percent of women who undergo a second abortion attempt following the failure of the mifepristone abortion regimen and adjusting to avoid double-counting, we find that 13.51 percent of women—roughly one in seven—experience at least one serious adverse event or repeated abortion attempt within 45 days of first attempting a mifepristone abortion. *See Table 2.*

Table 1

Repeated Abortion Attempts After Failed Mifepristone Abortion Attempts

Type	Number of pregnancies with repeated abortion attempts	Rate of occurrence
Repeated mifepristone abortion attempt after failed mifepristone abortion attempt	27,896	3.22%
Surgical abortion procedure after failed mifepristone abortion attempt	24,563	2.84%
Both	6,961	0.80%
Either	45,498	5.26%

Note: The insurance claims database includes 865,727 pregnancies with prescribed mifepristone abortion. These rates of occurrence are per pregnancy. The repeated abortion attempts in this table are subsequent attempts to abort the baby after the first attempt failed. Some patients had multiple pregnancies with abortion attempts in the database; this is *not* what is being measured in this table.

3 We also observe that 1.58 percent of women are prescribed a second dose of misoprostol but not a second dose of mifepristone, a possibility suggested on the drug label for cases in which the woman is no longer pregnant but fetal remains have not been fully expelled from her body. These are not counted as repeated abortion attempts, but repeated use of misoprostol has side effects that pose further harm to women.

4 We do not consider here those cases in which a woman gave birth following a mifepristone abortion attempt, which in a technical sense also indicate that the regimen failed to perform as intended. If these cases were also included, the failure rate would be slightly higher.

5 Table 3 on page 13 of the drug label reports surgical intervention in 2.6 percent of 16,794 cases in U.S. trials and 3.8 percent of 18,425 cases in non-U.S. trials. This averages to 3.2 percent of 35,219 cases overall. See Mifeprex (mifepristone) drug label, January 2023, https://www.accessdata.fda.gov/drugsatfda_docs/label/2023/020687Orig1s026lbl.pdf.

6 Jamie Bryan Hall and Ryan T. Anderson, "The Abortion Pill Harms Women: Insurance Data Reveals One in Ten Patients Experiences a Serious Adverse Event," Ethics and Public Policy Center, April 28, 2025.

Table 2

Safety and Effectiveness of Mifepristone Abortion

Type of event	Number of pregnancies	Rate of occurrence
Serious adverse event following mifepristone abortion attempt	94,605	10.93%
Repeated abortion attempt following failed mifepristone abortion attempt	45,498	5.26%
Both	23,165	2.68%
Either	116,938	13.51%

Note: The insurance claims database includes 865,727 pregnancies with prescribed mifepristone abortion. These rates of occurrence are per pregnancy.

Conclusion

Mifepristone abortion as currently practiced in the U.S. is not safe or effective. As our previous paper showed, the real-world rate of serious adverse events following mifepristone abortions is at least 22 times as high as reported on the drug label. Now we also find that its failure rate is significantly higher than reported on the drug label. Altogether, roughly one in seven women who are prescribed a mifepristone abortion experiences a severe adverse event or undergoes a repeated abortion attempt soon afterwards due to the failure of the mifepristone abortion regimen.

In light of these findings, the FDA should immediately reinstate its earlier, stronger patient safety protocols to ensure physician responsibility for women who take mifepristone under their care, as well as mandate full reporting of its side effects. The FDA should further investigate the harm this drug causes to women and, based on objective safety and effectiveness criteria, reconsider its approval altogether. Women deserve to know the truth. Women deserve better than the abortion pill.

This paper is the second in a series investigating women's health and abortion using real-world data. It is based on the same data and follows the same methodology as described in "The Abortion Pill Harms Women: Insurance Data Reveals One in Ten Women Experiences a Serious Adverse Event" and its accompanying documentation.

FEBRUARY 2025

Maternal Mortality Rates in the United States, 2023

by Donna L. Hoyert, Ph.D.

This report presents maternal mortality rates for 2023 based on data from the National Vital Statistics System. A maternal death is defined by the World Health Organization as "the death of a woman while pregnant or within 42 days of termination of pregnancy, irrespective of the duration and the site of the pregnancy, from any cause related to or aggravated by the pregnancy or its management, but not from accidental or incidental causes" (1). Maternal mortality rates—the number of maternal deaths per 100,000 live births—are shown in this report by age group and race and Hispanic origin.

This report updates a previous one that showed maternal mortality rates for 2018–2022 (2). In 2023, 669 women died of maternal causes in the United States, compared with 817 in 2022 (2) (Figure 1, Table). The maternal mortality rate for 2023 decreased to 18.6 deaths per 100,000 live births, compared with a rate of 22.3 in 2022.

In 2023, maternal mortality rates decreased significantly for White non-Hispanic (subsequently, White) and Hispanic women (Figure 2, Table). The observed decrease for Asian non-Hispanic (subsequently, Asian) and increase for Black non-Hispanic (subsequently, Black) women was not statistically significant. In 2023, the maternal mortality rate for Black women was 50.3 deaths per 100,000 live births and was significantly higher than rates for White (14.5), Hispanic (12.4), and Asian (10.7) women.

Rates decreased significantly for women ages 25–39 and age 40 and older between 2022 and 2023 (Figure 3, Table). Rates in 2023 were 12.5 deaths per 100,000 live births for women younger than age 25, 18.1 for those ages 25–39, and 59.8 for those age 40 and older. The rate for women age 40 and older was nearly five times higher than the rate for women younger than age 25. Differences in the rates between age groups were statistically significant.

Data sources and methods

Data are from the National Vital Statistics System mortality file (3). Consistent with previous reports, the number of maternal deaths does not include all deaths during pregnancy or among recently pregnant women but only those deaths with the underlying cause of death assigned to *International Statistical Classification of Diseases, 10th Revision* codes A34, O00–O95, and O98–O99. Maternal mortality rates are per 100,000 live births, based on data from the

National Vital Statistics System natality file. Maternal mortality rates fluctuate from year to year because of the relatively small number of these events, and possibly because of issues with the accuracy of reporting maternal deaths on death certificates (4). Efforts to improve data quality are ongoing, and these data will continue to be evaluated for possible errors. Data are shown for only the four largest race and Hispanic-origin groups for which statistically reliable rates can be calculated, and numbers and rates are suppressed for those groups for which statistically reliable rates cannot be calculated (5). Additional details and data on provisional maternal mortality rates are available (6,7).

ABSTRACT

Objectives: This study aimed to compare demographics and clinical outcomes between patients who did not undergo investigations and those who underwent investigations before receiving a prescription for medication abortion (MA) during the first 6 months of the COVID-19 pandemic. Outcomes include success rates, adverse events, pathways to completion, and loss to follow-up rates.

Methods: We conducted a retrospective medical record review of 1452 patients presenting for MA between 23 March 2020 and 30 September 2020. Descriptive statistics, 2 × 2 chi-square tests, and Fisher exact tests were used to compare characteristics and outcomes between groups.

Results: Of the 1307 patients who received a prescription, 895 (68.5%) were in the no-test group and 412 (31.5%) were in the test group. The success rate was 95.2%, with no significant difference between groups (94.0% and 95.8%, $P = 0.194$). Rates of adverse events were low, with 28 patients presenting for emergency department visits (2.1%), 62 having clinically significant retained products of conception (4.7%), 5 with heavy bleeding requiring treatment (0.4%), 16 with ongoing pregnancy (1.2%), and 3 requiring ectopic pregnancy management (0.2%). Completion of abortion was verified in 1034 patients (80.5%), and the loss to follow-up rate was 22.6%, with no difference between the groups (82.1% vs. 79.8%, $P = 0.341$; and 21.4% vs. 23.1%, $P = 0.477$; respectively).

Conclusions: We found that clinical outcomes were consistent across the 2 groups, with high success rates and low adverse event rates. Our study contributes to the growing body of evidence that allows for individualized care implementing selective use of low- and no-test MA protocols.

RÉSUMÉ

Objectif : Comparer les données démographiques et les résultats cliniques entre les patientes qui ont eu ou non des évaluations avant de recevoir une ordonnance d'avortement médicamenteux (AM) dans les six premiers mois de la pandémie de COVID-19. Les critères de jugement sont le taux de réussite, les événements indésirables, les voies d'accès jusqu'à l'avortement complet et le taux de perte au suivi.

Méthodes : Nous avons réalisé une étude rétrospective des dossiers de 1452 patientes ayant demandé un AM entre le 23 mars 2020 et le 30 septembre 2020. Des statistiques descriptives, des tests chi-carré au format 2 × 2 et des tests exacts de probabilité de Fisher ont été utilisés pour comparer les caractéristiques et les résultats entre les groupes.

Résultats : Des 1307 patientes qui ont reçu une ordonnance, 895 (68,5 %) étaient dans le groupe sans évaluation et 412 (31,5 %) dans le groupe avec évaluation. Le taux de réussite était de 95,2 %,

sans différence significative entre les groupes (94,0 % p/r à 95,8 %; $P = 0,194$). Le taux d'événements indésirables était faible : 28 patientes se sont présentées à l'urgence (2,1 %), 62 ont eu une rétention cliniquement significative du produit de conception (4,7 %), 5 ont eu des saignements abondants nécessitant un traitement (0,4 %), 16 ont eu une grossesse évolutive (1,2 %) et 3 ont eu besoin d'une prise en charge de grossesse ectopique (0,2 %). L'avortement complet a été vérifié chez 1034 patientes (80,5 %), et le taux de perte au suivi était de 22,6 %, sans différence entre les groupes (82,1 % p/r à 79,8 %; $P = 0,341$; et 21,4 % p/r à 23,1 %; $P = 0,477$, respectivement).

Conclusion : Nous avons constaté que les résultats cliniques étaient comparables entre les deux groupes, que le taux de réussite était élevé et que le taux d'événements indésirables était faible. Notre étude contribue au nombre croissant de données probantes qui permettent d'individualiser les soins en mettant en œuvre l'utilisation de protocoles sélectifs d'AM avec ou sans évaluation.

INTRODUCTION

The COVID-19 pandemic introduced novel challenges and significantly exacerbated the current and historic threat to abortion access, a critical and time-sensitive health care service. While there are a variety of appropriate protocols for providing medication abortion (MA), the first step is generally confirming a likely intrauterine pregnancy (IUP) before prescribing medication through some combination of in-clinic physical examination, medical imaging, and/or laboratory testing. Despite evidence that medical imaging is not always needed to ensure a successful and safe MA,[1–14] many providers express concern with proceeding without first verifying gestational age (GA) through ultrasound examination.[15]

In a survey of 100 abortion clinics in the United States, most (87.0%) implemented protocol changes in response to the COVID-19 pandemic. A large proportion of clinics reported changes to telehealth for follow-up (71.0%), initial consultation and screening (41.0%), and reducing the frequency of Rhesus factor testing (43.0%). A much smaller proportion of clinics (15.0%) were able or willing to forgo ultrasound assessment before medication administration.[16] A similar study reviewing protocol changes at 55 sites in the United States during the COVID-19 pandemic revealed that only 27.0% reported proceeding with MA without first confirming eligibility via ultrasound.[17]

In response to the COVID-19 pandemic, numerous professional organizations endorsed protocols for medication abortion requiring minimal or no testing (hereafter referred to as 'low/no-test protocols') to support providers' ability to continue providing MAs while abiding by local/provincial restrictions to in-person care.[18–21] A survey of Canadian abortion providers reported a transition away from in-person provision of MA, with most respondents indicating a rapid uptake of low/no-test protocols.[22] Willow Reproductive Health Centre ("Willow"), a high-volume family planning clinic in Vancouver, British Columbia, Canada, had provided telemedicine MAs for patients living outside of Vancouver Coastal Health Authority for many years, using various low-test protocols.[11] Responding to the shift in health care due to the COVID-19 pandemic, Willow initiated a clinic-wide no-test protocol for MA provision.

Regarding terminology, various protocols categorized as low/no-test abortion protocols fall under the umbrella of telemedicine abortion. Generally, a no-test protocol refers to those that forgo all testing (laboratory testing, medical imaging, and physical examination) through the entire course of an MA and determine completion using only an at-home urine pregnancy test (UPT). Protocols that forgo routine dating ultrasound but include any other testing during the process would be considered low-test. The initiation of a fully no-test protocol at Willow in response to the COVID-19 pandemic allowed a unique research opportunity to provide a Canadian perspective on safety and effectiveness of a no-test MA protocol. For the sake of our study, we analyzed the outcomes of patients who received a prescription without any prior testing (herein referred to as the "no-test group") and compared them with those of patients who did have testing before being provided a prescription (herein referred to as the "test group").

Our study aimed to describe demographics and clinical outcomes, including success rates and adverse events, of the no-test group and test group during the first 6 months of the COVID-19 pandemic. Secondary outcomes included analysis of methods through which patients were confirmed to have completed the MA process (pathways to completion) and loss to follow-up rates compared between these 2 groups. This analysis contributes to a growing body of evidence informing clinical decisions and counselling for eligible people seeking abortion, and provides further information on the risks and benefits of no-test MA as an alternative option to in-clinic abortion care.

GBP-PET00334

METHODS

We conducted a retrospective chart review of all 1452 MA patients presenting to Willow between 23 March 2020 and 30 September 2020. The study was approved by the University of British Columbia Clinical Research Ethics Board (UBC CREB number H21-00104), with additional permission granted by the Executive and Medical Directors of Willow.

Protocol Outline

A change to a clinic-wide no-test MA protocol was initiated in late March 2020 and became the primary method of providing MA until late September 2020, when some regional pandemic restrictions eased, and more patients could be safely seen in the clinic again. During a virtual consultation, patients were deemed eligible and provided with a mifepristone and misoprostol prescription. Eligibility was based on a positive at-home UPT, GA of $<10^0$ weeks as determined by patient-reported certain last menstrual period (LMP) in those with a regular cycle and no history of hormonal contraception within the last 6 months, and the absence of ectopic pregnancy symptoms or risk factors (no severe/unilateral pain, vaginal bleeding or spotting, previous ectopic pregnancy, previous pelvic inflammatory disease, previous tubal surgery, assisted reproductive technology, or intrauterine device [IUD] in situ). Patients were then scheduled for 2 virtual follow-up appointments (at 1 week and 4 weeks after mifepristone administration). Consultations were provided virtually and patients were advised to call the clinic or on-call doctor if there were any concerns between appointments. Completion of abortion was determined with either a negative at-home UPT or a negative UPT during IUD insertion at the clinic.

Data Extraction

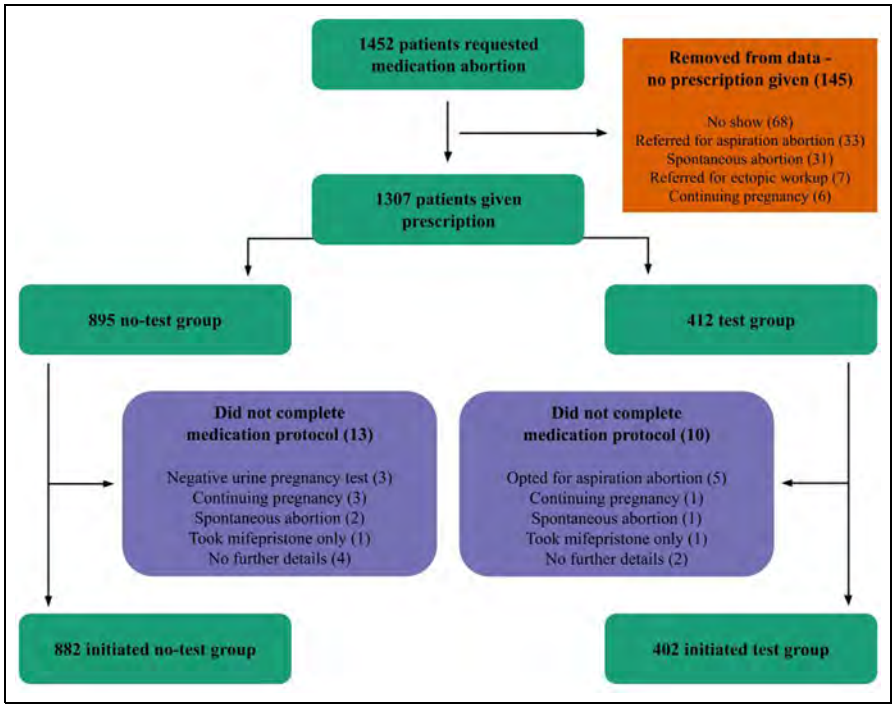
For each patient, we recorded age, place of residence, and payment method. Clinical data points collected were GA at time of abortion, method of GA determination, anemia risk, ectopic pregnancy risk, obstetric history, date of initiation, confirmation of completion, method of determining completion, number of patients lost to follow-up, and adverse events. The chart review was performed by 2 data abstractors who were familiarized with the clinic policies and processes during the study period.

Data Analysis

We developed and used a standard form within the REDCap platform[23] and extracted all study variables, assigning a project-specific identification number in place of potentially identifying personal information. The resulting data set was then assessed for completeness and accuracy by one of the listed authors, who served a prescribing physician throughout the study period. Of the initial sample, 145 patients failed to attend their initial appointment or did not receive medication for other reasons and were excluded from further data analysis (Figure). The remaining 1307 medical records were included in further data analysis. Primary outcomes were success rates and adverse events of MA. Secondary outcomes were pathways to completion and loss to follow-up rates.

Characteristics and outcomes were compared across 2 groups: (1) "no-test group"—those who did not have any laboratory testing, ultrasound, or physical examination before receiving the prescription, and (2) "test group"—those who had laboratory testing, ultrasound, and/or physical examination before receiving the prescription. Of note, some patients sought care at Willow with pre-existing investigations ordered by an external physician who does not provide abortions. These patients were assigned to the test group despite potential eligibility for no-test MA if initially assessed by a Willow physician. Descriptive statistics were generated for the study cohort, and 2×2 chi-square tests and Fisher exact tests (where cell counts were <5) were used to investigate the associations between the 2 groups and our outcomes of interest. Data analysis was conducted using Microsoft Excel (Microsoft Corp.), Stata v17 (StataCorp),[24] and Social Science Statistics.[25]

RESULTS



Of the 1452 patients presenting to Willow and requesting MA during our study period, a total of 1307 patients were given a prescription for mifepristone and misoprostol. Of the 1307 patients who received a prescription, the no-test group comprised 895 (68.5%) patients, with 882 ultimately initiating the MA process. The test group consisted of 412 (31.5%) patients, with 402 initiating the MA process. The MA process was not initiated for 23 patients (13 no-test group vs. 10 test group) who self-reported that they did not take the medications for various reasons (Figure).

Demographics

Patient age ranged from 15 to 46 years, with a median of 29 years. A total of 718 (54.9%) patients had a home address listed within Fraser Health, while only 444 (34.0%) patients had a home address listed within Vancouver Coastal Health. Most patients (94.0%) had these services covered by provincial insurance. GA determined by LMP was significantly associated with whether patients were assigned to the test or no-test group ($P < 0.000$), with

Case 6:25-cv-01491-DCJ-DJA Document 54-9 Filed 02/03/26 Page 235 of 253 PageID #: 3218

Figure. Summary of medication abortions performed at Willow between 23 March 2020 and 20 September 2020.

higher GA correlating with a lower likelihood of receiving a no-test abortion. As expected, the test group had a significantly higher proportion of patients with elevated risk for anemia or ectopic pregnancy compared with the no-test group (21.1% vs. 1.3% and 29.6% vs. 0.9%, respectively, $P < 0.000$ for both variables) (Table 1).

Success Rates and Adverse Events

Successful MA was defined as no ongoing IUP and no retained products of conception (RPOC) requiring aspiration. The success rate was 95.2% overall, with no significant difference in the likelihood of having a successful MA between the test and no-test groups (94.0% and 95.8%, $P = 0.194$) (Table 2). Rates of adverse events were low overall, with 28 patients presenting for emergency department visits (2.1%), 62 patients having clinically significant RPOC (4.7%), 5 patients with heavy bleeding requiring treatment (0.4%), 16 patients diagnosed with ongoing IUP (1.2%), and 3 patients requiring ectopic pregnancy management (0.2%). Of note, 3 patients in the no-test group were identified at some point during the process to have been beyond the 10^0 week gestational limit at the time of medication administration. There were no statistically significant differences between the no-test and test groups for any of these adverse events (Table 3).

Pathways to Completion and Loss to Follow-Up

Completion of abortion was verified in 1034 patients (80.5%), with no statistically significant difference between the test and no-test groups (82.1% vs. 79.8%, $P = 0.341$) (Table 4). The overall loss to follow-up rate was 22.6%, with no statistically significant difference between the test and no-test groups (21.4% vs. 23.1%, $P = 0.477$). The highest rate of loss to follow-up occurred after the 1-week visit in both the test group (72.7%) and the no-test group (61.8%) (Table 5).

DISCUSSION

We found that pertinent demographic information and clinical outcomes were consistent for all patients receiving MA throughout our study period, regardless of whether tests were ordered before prescribing the medication. Patients access abortion services at all ages throughout their reproductive years, as reflected in the distribution of patient age in our findings. Within the Canadian context of single-payer health care, the cost of MA was covered through provincial insurance for the vast majority of patients, with the remaining patients paying out of pocket.

Unexpectedly, most patients receiving MA during this study period had a home address listed within Fraser Health Authority, despite Willow being located within

Vancouver Coastal Health Authority. This is likely influenced by the regional lack of access to abortion outside of the Vancouver Coastal Health Authority. This illustrates the importance of increasing access to abortion for patients within their home community, who must otherwise travel longer distances to access this care. Although no-test MA is an excellent way to improve this health disparity for eligible patients, those needing testing for their abortion would benefit from clinics and services within their own health region.

A 2010 prospective trial of 4484 patients seeking MA found that of those determined to be within the 9^0 week GA limit, only 1.6% were over the limit on ultrasound, supporting the safety of forgoing routine ultrasound.[12] A systematic review found that only 2.5% to 11.8% of

patients who would have been eligible to receive medication on the basis of LMP alone were ineligible by ultrasound, which provides further support that LMP alone can be used to determine eligibility for MA.[13,14] Appropriately, in our study, patients with GA by LMP approaching the 10^0 week cutoff and those deemed high-risk for anemia or ectopic pregnancy were more likely to receive tests before receiving a prescription. Of note, another 7 patients were not eligible for MA (under either test or no-test protocol); therefore, no prescription was given and they were referred for workup of ectopic pregnancy. Accurately determining high-risk individuals for complications such as those related to ectopic pregnancy, anemia, and misdating, and excluding them from no-test MA eligibility enhances the safety profile of these protocols. This has also been observed in previous studies on low/no-test MA,[1,3–7,9,10] and highlights the importance of a thorough and focused individualized history when considering provision of MA under these protocols.

Patients seeking abortion at Willow who had undergone previous investigations were assigned to the test group, which may account for a slight inflation in the number of patients in that group. However, we found that these pre-existing investigations might influence the prescribing physician's decision-making when determining eligibility for no-test MA. Maintaining strict eligibility criteria for assigning no-test versus test groups during data analysis was essential to assessing the safety of proceeding with a prescription without ordering any investigations.

Early findings from the United States[5,9] and Scotland[7] suggest that no-test protocols are safe and effective, with low complication rates. An analysis of over 52 000 MAs performed in the United Kingdom bolstered these findings, highlighting not only the safety and effectiveness, but also the acceptability and enhanced accessibility of low/no-test MA for patients.[1] Furthermore, a systematic review including 21 studies with a total of 10 693 patients

also found no-test MA to be a safe and effective option.[8] We defined a successful MA as no ongoing IUP or RPOC requiring aspiration following medication administration. Unsurprisingly, success rates and adverse events in our sample were generally consistent with other data on no-test MA protocols.[1,5,7–9]

We found a high success rate and a low adverse event rate, with no significant difference between the test and no-test groups. A potential limitation to our findings is that adverse events were self-reported at the time of follow-up or determined through retrospective medical record review, and may have been documented inconsistently across providers at the clinic. Records exterior to the clinic (e.g., patient hospital records) were not obtained. The reasons for emergency department visits were not analyzed and may include visits during which only supportive measures were provided to assist the patient through the normal and expected clinical course of an MA. However, we believe that most clinically significant adverse events were captured, as this topic was discussed with patients at all follow-up appointments, providing ample opportunity for them to share this information.

We were able to verify completion in most cases through various means, including ultrasound before and after medication, negative at-home UPT, negative UPT at the time of IUD insertion, aspiration (for RPOC or ongoing IUP), serial human chorionic gonadotropin testing, or subsequent unrelated appointment(s) at Willow. There were no notable differences in pathways to completion between the test and no-test groups. This provides further evidence that multiple pathways to determining completion are safe and appropriate[26,27] as long as close follow-up is initiated for rare instances of complication or MA failure. Willow has continued to offer virtual follow-up options for patients, despite moving away from no-test MA as the standard protocol for most patients because of the easing of pandemic restrictions. This approach allows for safe, trauma-informed, patient-centred care by increasing options for patients who prefer virtual follow-up. Some reasons for this preference may include travel time, associated travel cost, cost of childcare, ability to follow-up discreetly (e.g., abusive or controlling partners), work and life commitments, avoidance of pelvic ultrasound, or patient preference to avoid medicalized environments (e.g., due to previous trauma within the medical system).[28]

Table 5. Loss to follow-up rates in patients accessing medication abortion through Willow Clinic between 23 March 2020 and 30 September 2020

Follow-up	No-test = 895, n (%)	Test = 412, n (%)	Total = 1307, n (%)	*P* value

Case 6:25-cv-01491-DCJ-DJA Document 54-9 Filed 02/03/26 Page 239 of 253 PageID #: 3222

The overall loss to follow-up rate was 22.6%, which is higher than the rates reported in other similar studies, ranging from 4.2% to 18.5%.[5,6,9,11,29,30] There were no differences in loss to follow-up rates between the test and no-test groups. Loss to follow-up was most likely to occur after the 1-week visit in both groups. This may be explained by the patient's confidence in completion based on their history and discussion with an abortion provider at the 1-week visit. Given this reassurance at the first follow-up visit and the well documented success rate of medication abortion, patients may have assumed completion upon resuming regular menstruation, felt it unnecessary to confirm completion with a UPT, and/or failed to provide these results to the clinic.

CONCLUSION

Our study findings provide further data about the risks and benefits of forgoing ultrasound or laboratory testing before initiating MA. The safety of no-test MA protocols continues to be documented and studied. However, some providers may remain hesitant because of ongoing fears of litigation or disciplinary action from governing bodies when faced with complications or unfavourable outcomes, hostility from colleagues practising outside the field of abortion care, and more widely the potentially violent political environment surrounding abortion care. Abortion access is not equitable in low-resource settings, marginalized communities, rural and remote areas, and for patients with low access to health care services. Our study findings contribute to the growing body of evidence that allows for individualized care implementing selective use of low and no-test protocols, particularly in situations where the risks of the aforementioned legal or professional ramifications are outweighed by the benefits of increasing accessibility to patients. Accessibility is a cornerstone of providing equitable care. Therefore, it is important to offer flexibility in providing various aspects of in-person, low-test, or no-test protocols on an individualised basis. This approach prioritizes patients by centring their unique and often complex circumstances, which is essential when considering the safety of their care.

Background: In 2015, the Tabbot Foundation launched a nationwide direct-to-patient telemedicine service to enable women to obtain medical abortion without visiting an abortion provider.

Aims: We aimed to describe results from the first 18 months of this service.

Materials and Methods: To have an abortion through the Foundation, a woman obtained screening tests locally and had a telephone consultation with a Foundation doctor. If she was eligible, mifepristone, misoprostol and other medications were sent to her by mail. After taking the drugs, the woman obtained follow-up tests at local facilities and had a consultation with Foundation professionals. The Foundation charged $250 to patients with Medicare eligibility and $600 otherwise. We summarised clinical data collected by the service.

Results: Between June 2015 and December 2016, 1010 women received medications, of whom 56% lived outside of major cities. Ninety-five percent of packages were sent within 15 days after registration. Of the 965 women who took misoprostol, outcomes were definitively documented for 754 (78%), of whom 96% had a complete abortion without surgical intervention, and 95% had no face-to-face clinical encounter after treatment. Of women with Medicare cards, 72% paid no out-of-pocket charges other than to the Foundation. Nearly all women (781/802; 97%) were highly satisfied.

Conclusions: The direct-to-patient telemedicine medical abortion service was effective, safe, inexpensive and satisfactory. It disproportionately served women in parts of Australia with limited access to abortion facilities. This experience may be instructive for others desiring to use telemedicine to enhance access to abortion.

KEYWORDS

abortion, access, Australia, telemedicine

INTRODUCTION

Although surgical abortion has been available in Australia for decades, the introduction of medical abortion has been slow. Mifepristone was effectively banned until 2006, when a limited number of providers were authorised to import and distribute the drug under strict conditions. In 2012, 23 years after approval was given to market the drug in France, a registered mifepristone product finally became available in Australia. Measures were instituted to facilitate access: in particular, unlike most other countries, Australia allowed distribution of the drug by prescription in pharmacies, dramatically increasing the number and distribution of certified dispensers.[1] In 2013 mifepristone and misoprostol were added to the Pharmaceutical Benefits

GBP-PET00342

Scheme, which subsidises the cost of the drugs. Nevertheless, by 2016 use of medical abortion was substantially less than anticipated,[2] and obtaining medical abortion remains difficult for many Australian women.[3–5]

To address this problem, the Tabbot Foundation, based in Sydney, New South Wales, launched a direct-to-patient telemedicine service in June 2015 to enable women to obtain medical abortion without visiting a medical practitioner. In this paper, we present observations from the first 18 months of this service.

MATERIALS AND METHODS

The Tabbot Foundation Service

The specific procedures for providing abortion evolved somewhat over the course of the first 18 months (http://www.tabbot.com.au/). A basic description of the service follows.

Each woman who contacted the Foundation was screened by telephone to confirm that she desired an abortion and met preliminary criteria. These criteria included the following: she had a positive pregnancy test, was <8 weeks gestation by menstrual dating, lived ≤60 minutes from a medical facility, had no major medical illnesses or history of severe dysmenorrhea, identified someone to be with her during treatment, spoke English and could pay by electronic fund transfer. In addition, because laws in the Australian Capital Territory, Northern Territory and South Australia specified that abortions must be performed in an approved medical facility, women from those jurisdictions were required to have an address in another state where they could receive and ingest the abortifacients.

If preliminary criteria were met, Foundation staff referred the patient to facilities of her choice for a screening ultrasound, haemoglobin, blood type and quantitative serum human chorionic gonadotropin (HCG) concentration. The results were reviewed by a Foundation doctor (a gynaecologist or general practitioner with training in abortion provision), who then spoke with the patient by telephone to confirm eligibility, discuss instructions and expectations, and agree on a follow-up plan. A woman was considered eligible if she was projected to have an intrauterine pregnancy of ≤63 days gestation by ultrasound at the proposed abortion date and no medical contraindications (chronic adrenal failure, haemorrhagic disorder, current anticoagulant or long-term corticosteroid therapy, inherited porphyria, allergy to the abortifacient drugs or intrauterine device in place). If the patient was deemed eligible for the service, the Foundation charged $250 if she had a Medicare card or $600 otherwise. The service then authorised a central pharmacy to send a package containing abortifacient drugs, ancillary medications and a urine pregnancy test to her specified address by express mail. Initially, a few patients chose to receive their drugs at a surgical abortion clinic in Tasmania that shared a medical director with the Foundation or at a pharmacy. Rh-negative patients were referred to local hospitals to receive Rh(D) immunoglobulin. A 24-h toll-free phone number was provided to all patients.

A Foundation nurse contacted each patient on the planned misoprostol ingestion date to check her status. Each patient was instructed to obtain a second serum quantitative HCG concentration seven days after misoprostol ingestion. Abortion outcomes were assessed by reviewing these results and through scheduled phone calls with Foundation staff. Complications such as excessive or insufficient bleeding and inadequate pain relief were actively managed with additional misoprostol or analgesics; hospital referrals were made when necessary. Active follow-up was discontinued when Foundation clinicians determined that no further care was needed. All patients were instructed to perform the urine pregnancy test at home 28 days after treatment and to contact the Foundation if the results were positive.

In the first year of the service, the standard abortifacient regimen was mifepristone 200 mg orally followed 40-45 h later by misoprostol 800 μg buccally. In August 2016, all patients were provided with additional misoprostol 200 μg to take sublingually thrice daily for two days. A specific combination of analgesics, anti-emetics and an antibiotic was also recommended.

Analysis

De-identified information was transferred from the electronic medical record into an analysis database. Some data from six patients were obviously invalid: three patients had recorded dates of registration, drug shipment authorisation and misoprostol ingestion that did not occur in that order, one had an interval of 273 days between registration and drug shipment authorisation, and two had intervals of ≥274 days between registration and ultrasound. Our analyses considered these dates as missing. Patients' addresses were classified according to the 2011 Australian Statistical Geography Standard Remoteness Area classification, which reflects relative access to services.[6] For this analysis, we defined a complete medical abortion as one that met any of these criteria: serum HCG concentration declined by ≥80%, urine pregnancy test was negative, ultrasound showed complete abortion, or a clinician diagnosed complete abortion without surgery. We defined a patient to have had full follow-up if she had had a complete medical abortion according to the analysis definition, a uterine evacuation, or an ongoing pregnancy that she planned to continue. We used descriptive statistics to describe the women who accessed the service, the process indicators and the outcomes. We used χ^2 tests to test associations between remoteness area classification and source of initial introduction to the service and between abortifacient regimen and outcomes. We considered a P-value <0.05 as statistically significant. The Allendale Investigational Review Board (Old Lyme, CT, USA) approved the analysis.

RESULTS

Between 11 June, 2015 and 23 December, 2016, 1409 people registered with the Foundation (Table 1). Most lived outside

†Percents exclude women in whom age at registration could not be determined due to data errors.
‡A clinic in Tasmania that shared a medical director with the Tabbot Foundation.
§Percents exclude women who had ultrasound but gestational age could not be determined due to data errors and women who did not have any ultrasound recorded.
¶Percents exclude women with unknown Rh status.

major cities; a third lived in Tasmania. Overall, 57% discovered the service through the internet, and a third were referred either by a surgical abortion clinic in Tasmania that shared a medical director with the Foundation (9%) or by another clinical provider or advisory service (24%). Registrants in major cities were significantly more likely than other women to have used the internet (69% vs 48% respectively; $P < 0.001$), and less likely to have been referred by medical professionals (20% vs 45%, respectively, $P < 0.001$).

A total of 399 registrants (28%) withdrew from the screening process before medications were sent. The records of 200 (50%) of these women include no screening test results or Foundation doctor consultation; 178 (45%) were missing at least one test and/or the doctor consultation; and 21 (5%) had all tests and the doctor consultation but did not provide payment. Only seven of the valid ultrasound results received showed gestational ages of >63 days at registration. Most women who withdrew did not report a reason for discontinuing, but some indicated that they decided to continue the pregnancy or to have an abortion elsewhere. Some were deterred by harassment when obtaining the required screening tests or by misinformation about medical abortion in the community. A few had suspected ectopic or molar pregnancies.

The Foundation provided medications to 1010 of the 1409 registrants (72%). The characteristics of these women were similar to those of the full registrant population (Table 1). All women who were sent packages had recorded gestational ages of <63 days by ultrasound at drug shipment authorisation, except one whose recorded gestational age was 66 days and four whose gestational ages were unavailable. Nearly all (970/1010; 96%) had at least one contact with Foundation staff after drug shipment authorisation.

Progress through the process was efficient (Table 2). Patient evaluation and drug shipment authorisation were completed within 15 days for more than 95% of women who ultimately

1479828x, 2018, 3, Downloaded from https://obgyn.onlinelibrary.wiley.com/doi/10.1111/ajo.12800, Wiley Online Library on [28/04/2025]. Gestational age in days by ultrasound on day of misoprostol ingestion‡	962	33	51	62	69

†Table excludes three cases in which registration, drug prescription and misoprostol ingestion if any were not recorded as having occurred in that order and one case in which an interval of 273 days was recorded between these dates.
‡Row excludes 44 who did not take misoprostol or provided no relevant information after shipment.
§Row excludes 44 who did not take misoprostol or provided no relevant information after shipment, 12 whose last contacts were on the day of misoprostol ingestion, and two whose last contacts were recorded as having occurred >100 days after misoprostol ingestion.

TABLE 3 Abortion outcomes among women who took misoprostol and had full follow up

	N = 754 *n* (%)
Abortion outcome	
Complete abortion without surgical evacuation	727 (96%)
Surgical uterine evacuation†	26 (3%)
Continuing pregnancy	1 (0.1%)
Clinical encounters after package mailed	
Hospital admission†	21 (3%)
Outpatient face-to-face encounter	16 (2%)
No clinical encounter	717 (95%)

†One woman had a transfusion

received medications. This interval was shorter for the 16% of women who had ultrasounds before registration than for those who had ultrasounds on or after registration (median three vs seven days, respectively). Of the 962 women who had a valid date of misoprostol ingestion recorded, nearly all took the drug within 10 days after drug shipment authorisation. Sixteen women reported having taken the misoprostol at gestational ages of more than 63 days, but all were less than 70 days.

Of the 1010 women who were sent medications, 31 (3%) provided no relevant information after shipment, and 14 (1%) reported that they did not take the misoprostol. Most of the latter group reported that they had either miscarried or decided not to have a medical abortion. Of the other 965 women, full follow-up according to our analysis definition was accomplished in 754 (78%). Of those, 96% had a complete abortion without surgical uterine evacuation, and 95% had no face-to-face clinical encounter (other than for providing the HCG specimen) after the package was sent (Table 3). Neither abortion outcomes nor the incidence of face-to-face encounters changed significantly after the introduction of the extended misoprostol dosing in August 2016 (data not shown).

A total of 211 women who took misoprostol did not have full follow-up by the analysis definition. Of these women, seven were known to have been admitted to hospital and seven had outpatient consultations with outside providers for symptoms related to the abortion. The outcomes of these encounters were not ascertained. Foundation clinicians using clinical judgment (i.e., criteria other than those defined for this analysis) determined that 75 of the 211 women (35%) ultimately had complete medical abortions without a face-to-face clinical encounter.

From February 2016, the Foundation began asking each woman at discharge how much she had spent on abortion-related tests and other care in addition to the Foundation charge. Of the 584 women with Medicare cards who had full follow-up by the analysis definition and provided this information, 421 (72%) paid no additional costs. The other 163 women reported additional costs ranging from $30 to $310 with a median of $130.

Women were asked at the last contact to rate their satisfaction with the process. Of the 802 who responded, 781 (97%) rated it a 1 (highly satisfied) on a scale of 1–5.

DISCUSSION

Telemedicine is increasingly recognised as an important approach for increasing access to abortion and for enhancing patients' privacy and autonomy.[7] For more than a decade, several international organisations have been mailing abortifacient drugs across international boundaries to women in countries where abortion is illegal or severely restricted.[8,9] In the United States of America, videoconferencing is being used in several states to evaluate patients and authorise provision of these drugs at clinics that have no authorised prescribers on site.[10] A Canadian doctor instituted a program that counsels and evaluates women by videoconference and then sends medications to their homes by mail.[11] Research has shown that these programs are safe and well accepted by patients.

1479828x, 2018, 3, Downloaded from https://obgyn.onlinelibrary.wiley.com/doi/10.1111/ajo.12800, Wiley Online Library on [28/04/2025]. The Tabbot Foundation program is the first known nationwide telemedicine service to legally offer abortion directly to patients without an in-person visit to an abortion provider. Our analysis of data from the first 18 months of this service indicates that it worked well. It provided abortions to over 1000 women from all but one of the Australian states and territories. Nearly all of these women were counselled, screened and sent the medications within 15 days after initial registration. Of those with full follow up, 96% completed the abortion without surgical evacuation, consistent with outcomes of in-person medical abortion.[12–14] Only 5% of treated women required any subsequent face-to-face clinical encounter. Of women with Medicare cards, 72% paid only $250 total out of pocket, considerably less than the median of $470 for medical abortion obtained from a large provider organisation in Australia.[3] Nearly all patients were highly satisfied.

The service was used disproportionately by women outside of major cities: 60% of women who received abortion drugs from the Foundation lived in regional and remote communities, compared to 29% of the Australian population (Fig. 1).[15] This finding is encouraging because these communities are underserved by abortion clinics[5,16,17] and constitute a priority population group for health interventions in Australia.[18] Notably, whereas most registrants from major cities discovered the service from internet websites, fewer than half of non-urban women did so; for the latter group, referrals from medical providers were relatively more important. Ensuring that health professionals in non-urban settings inform patients about the option of telemedicine is key to realising its potential for enhancing service in these areas.

One limitation of our study is that only 76% of the women who were sent medications either had full follow-up according to our analysis definition or reported not having taken the misoprostol. This proportion is somewhat lower than the 87% reported in a recent series of in-person medical abortions in Australia.[14] Also, information about outcomes after face-to-face encounters was incomplete. However, 96% of patients had at least one post-treatment contact with the Foundation, and every patient was sent a urine pregnancy test to perform at home four weeks after treatment. Symptom-based follow up with or without pregnancy testing has been validated in several studies[19,20] and is now routinely offered after in-person medical abortion by organisations in the UK, Norway and Australia.[14,21,22] Nevertheless, our analysis may have missed some abortion failures or complications. In addition, our dataset lacked some information of potential interest, such as confirmation of mifepristone ingestion, the number of misoprostol doses taken, confirmation of receipt of Rh(D) immunoglobulin and incidence of side effects.

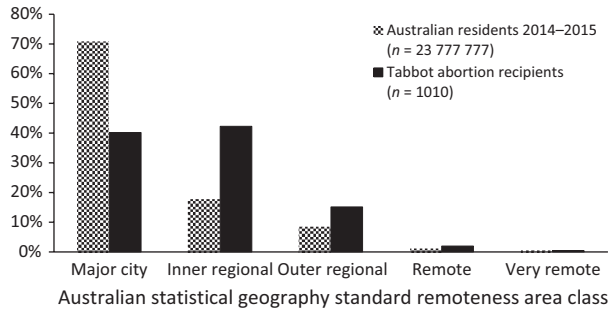

FIGURE 1 Australian resident population and Tabbot abortion recipients by Remoteness Area class. Australian resident population data estimated by Australian Bureau of Statistics.[17]

The Foundation encountered several challenges in implementing its service. From the outset, considerable planning was needed to ensure compliance with the unique regulations in each Australian state and territory. Finding facilities that would administer Rh(D) immunoglobulin to Rh-negative women promptly and nonjudgmentally has been problematic. Some surgical abortion providers dissuaded women from choosing medical abortion, citing excessive pain and bleeding.

The Foundation's experience yields recommendations for maximising the efficiency and success of a direct-to-patient telemedicine service. Standardised protocols and an electronic medical record are essential to effectively managing large numbers of patients. A well-designed website that provides full information to patients before and after treatment facilitates registration, screening and follow up. Communication with patients can be accomplished satisfactorily using telephone and text; videoconferencing, which has been required by North American telemedicine abortion services, is unnecessary. Indeed, a videoconferencing requirement can impede access by women who do not have the needed equipment and a reliable internet connection. Sending the medications to patients by mail from a central source can be preferable to issuing prescriptions, particularly in settings with a limited number of pharmacies that stock mifepristone and misoprostol or with high levels of stigma about abortion. Finally, providing adequate analgesics to minimise side effects is critical for acceptability.

The launch of the Tabbot Foundation service in 2015 was a turning point for abortion care in Australia. The following year, a second home-based telemedicine abortion service was introduced that also provides services in most Australian states and territories.[23] With the commencement in July 2017 of the Termination of Pregnancy Law Reform Act in the Northern Territory, which removed the requirement that abortion must be provided in hospitals, in-home abortion through one or both services is now available to over 93% of women in the country, excluding only those in South Australia. We hope that Australia will serve as a model for other nations desiring to use telemedicine to increase access to abortion care.

Medical Compared With Surgical Abortion for Effective Pregnancy Termination in the First Trimester

Luu Doan Ireland, MD, MPH, Mary Gatter, MD, and Angela Y. Chen, MD, MPH

OBJECTIVE: To compare efficacy between medical and surgical abortion at 9 weeks of gestation or less.

METHODS: We performed a retrospective cohort study comparing efficacy of medical compared with surgical abortion before 64 days of gestation at Planned Parenthood, Los Angeles, from November 2010 to August 2013. Electronic medical records were reviewed for ongoing pregnancies after the initial abortion procedure. Data were also collected on complications occurring within the immediate postabortal period (8 weeks postabortal) including unanticipated aspiration and major adverse events (emergency department presentation, hospitalization, perforation, transfusion, infection). Chi square test and logistic regression were used to compare the primary outcomes between cohorts.

RESULTS: Data were collected from 30,146 women with pregnancies seeking termination before 64 days of gestation. Sociodemographic and clinical characteristics were similar in the medication and surgical abortion groups. Efficacy of pregnancy termination was 99.6% for medication abortions and 99.8%% for surgical abortions ($P<.001$). The medication abortion group was more likely to undergo an unanticipated aspiration, for ongoing pregnancy or persistent pain, bleeding, or both (2.1% compared with 0.6%, respectively, odds ratio 1.6, 95% confidence interval 1.1–2.3). These rates were unchanged after controlling for gravidity, parity, and body mass index. There was no difference in major adverse events between the two groups.

CONCLUSION: Medication abortion and surgical abortion before 64 days of gestation are both highly effective with low complication rates.

LEVEL OF EVIDENCE: II

See related editorial on page 3.

Pregnancy termination at 9 weeks of gestation or less accounts for 65.9% of all abortions in the United States.[1] Although surgical abortion remains the mainstay of first-trimester abortion care, the incidence of medical abortion is rising, accounting for 36% of abortions at 9 weeks of gestation or less.[2] In 2000, the U.S. Food and Drug Administration approved the use of mifepristone for medical abortion at 49 days of gestation or less. The approved regimen included 600 mg mifepristone followed by 400 micrograms of misoprostol taken orally 48 hours later.[3] The current evidence-based regimen results in higher efficacy before 64 days of gestation with fewer side effects[4–6] and entails 200 mg mifepristone followed by buccal, sublingual, or vaginal administration of 800 micrograms of misoprostol between 24 and 48 hours later.[7] First-trimester surgical abortion entails uterine aspiration under local anesthesia with oral premedication or intravenous sedation. Both methods are highly effective with failure rates that are below 5% for either method.[8–10] However, there are few comparative studies of efficacy between early surgical and medical abortion.[11] Most used outdated medication regimens and surgical techniques such as sharp curettage. These results may not be generalizable to women currently seeking early pregnancy termination.[12–15] The primary objective of this retrospective cohort study is to compare

efficacy, the proportion of pregnancies successfully terminated by the initially chosen method, between medical abortion, using the current evidence-based regimen, and surgical abortion at 9 weeks of gestation or less. We hypothesize that the two methods of pregnancy termination are similar in efficacy.

MATERIALS AND METHODS

This historical cohort study was conducted at Planned Parenthood, Los Angeles, a high-volume health care system providing abortion services at 15 sites throughout the Los Angeles area. The study included a convenience sample of 30,146 women with pregnancies before 64 days of gestation who underwent surgical or medical abortion at Planned Parenthood, Los Angeles, from November 1, 2010, to August 31, 2013. Staff physicians performed or supervised all surgical abortions. These were conducted under local anesthesia with paracervical block and the addition of either oral nonsteroidal antiinflammatory drugs or intravenous sedation. Although women undergoing surgical abortion were not routinely scheduled for follow-up visits,[16] patients were counseled to return for persistent bleeding, pain, or with any other postoperative concerns. Women seen in follow-up and identified to have ongoing pregnancies were offered reaspiration or medical abortion. Advanced practice clinicians provided all medical abortions. The evidence-based regimen of 200 mg mifepristone orally at the time of the clinic visit followed by a single dose of 800 micrograms of buccal misoprostol 24–48 hours later was used for all medical abortions. One-week follow-up appointments were scheduled with advance practice clinicians for repeat ultrasonography to confirm abortion completion. All ongoing pregnancies identified at this visit underwent aspiration by a physician. Women with persistent vaginal bleeding or pain and intrauterine debris on ultrasonography were offered either aspiration with a physician or repeat misoprostol. Provided women met gestational age criteria by ultrasonography on the initial visit and had no contraindications to either method of abortion, they were given the option to choose their preferred method of termination. Contraindications to medical abortion included anemia with a hemoglobin of less than 10, chronic steroid or anticoagulant use, suspected ectopic pregnancy, intrauterine device in place, or inability to adhere to the medical abortion regimen or return for a follow-up visit. Contraindications to surgical abortion included hemoglobin of less than 8, molar gestation greater than 12 weeks in size, or any significant medical comorbidity.[17]

Planned Parenthood, Los Angeles, uses an electronic practice management system that electronically tracks all patients served within our system. Data collected includes visit date, patient demographics, gestational age by ultrasonography, and type of procedure performed. Internal quality assurance studies are routinely performed to ensure accuracy and we have previously published a description of these practices.[18] A separate electronic database stores all information regarding complications associated with abortion, including but not limited to ongoing pregnancies, incomplete abortion, emergency department presentations, and hospital transfers. Complications are recorded into this adverse event database as they occur by clinic staff and are reported by health care providers from outside institutions. This database has been verified by random chart audit.

In this study, data were collected through review of electronic medical records and the electronic practice management system by two of the three authors (M.G. and L.D.I.). Demographic data collected include patient age, racial and ethnic background, and income level. Clinical characteristics recorded include gestational age by ultrasonography, gravidity, parity, body mass index (BMI, calculated as weight (kg)/[height (m)]^2), type of abortion procedure, surgical documentation, and confirmation of medical abortion completion. Complications during the 8 weeks after pregnancy termination were collected through the adverse event database. The study was approved by Planned Parenthood Federation of America and the institutional review board at the University of California, Los Angeles (IRB #13-001941).

The primary outcome of this study was the difference in efficacy between medical and surgical abortion at 9 weeks of gestation or less using the evidence-based medication abortion regimen and aspiration for surgical procedures. This measure was defined as successful termination of pregnancy after the initial abortion procedure. To identify a 1% difference in efficacy between abortion methods with 80% power and $P<.05$, we needed at least 2,319 women per group. Ongoing pregnancies were identified in each group to determine efficacy of each abortion method. Secondary outcomes included complications such as unanticipated aspiration. This measure was defined as aspiration during a separate encounter after the initial procedure in the surgical abortion group and any aspiration in the medical abortion group. With few exceptions, these were performed at Planned Parenthood, Los Angeles, clinics during follow-up visits. These were done for ongoing pregnancy or persistent pain, bleeding, or both, with

ultrasound findings suggestive of retained clot, debris, or products of conception. Persistent bleeding, pain, or both were defined as symptoms that were unacceptable to the patient. The decision to recommend aspiration was based on the discretion of the evaluating physician and individualized for each patient. Patients undergoing medical abortion returning with persistent symptoms were also offered the option of repeat misoprostol. A previously published study with an overlapping data set demonstrated only 1.2% of women chose repeat misoprostol over aspiration.[19] Data were also collected on major adverse events occurring in the 8 weeks after the abortion. Major events included emergency department presentation, hospitalization, perforation, transfusion, and infection.

Statistical analyses were completed using SAS 9.3. For bivariate analyses, *P* values for comparing proportions were computed using Fisher's exact or the permutational χ^2 test. The *P* values for comparing continuous variables between the medical and surgical abortion groups were computed using *t* tests in cases in which the data followed a normal distribution and nonparametric Wilcoxon rank-sum test otherwise. Differences were regarded as statistically significant if $P<.05$. Multivariate logistic regression was used to determine associations of the simultaneous associates of age, race–ethnicity, income level, gravidity, parity, gestational age, and BMI with the risk of ongoing pregnancy. Because there were few ongoing pregnancy events, a simultaneous multivariate evaluation of all seven covariates was not possible so a bivariate screening was carried out using abortion type with each of the six covariates. Regression analyses were repeated with respect to the risk of unanticipated aspiration. A hierarchical, backward stepdown regression with a liberal $P<.10$ variable retention criterion was carried out using all seven potential predictors and the six two-way interactions with medical compared with surgical abortion. Restricted cubic splines were used to determine if the relation of age or BMI to the log odds was linear. Adjusted ongoing pregnancy risk and aspiration risk were computed using the logistic regression model to adjust for these covariates.

RESULTS

After a thorough review of medical records, a total of 30,146 women who met our inclusion criteria were identified with 13,221 undergoing medical abortion and 16,925 undergoing surgical abortion (Fig. 1). The groups had similar sociodemographic characteristics (Table 1). The mean age at abortion was 25.7 years (25.4 years and 25.9 years in the medical and surgical abortion groups, respectively). The mean gestational age at the time of abortion was nearly identical between the two groups (6.7 weeks compared with 6.9 weeks, respectively). Body mass index, gravidity, and parity were similar for both groups (Table 1).

Eighty-four percent of patients undergoing medical abortion received follow-up within 8 weeks for their initial visit (Fig. 1). Of 13,221 women undergoing medical abortion, 15.9% were lost to follow-up. Women who underwent surgical abortion only returned if they had persistent symptoms or postoperative concerns. Eighteen percent of these women returned for a follow-up visit. Women in the medical abortion group who did not return to the clinic within 8 weeks of their initial abortion procedure were considered lost to follow-up. Women who were lost to follow-up were considered to have undergone uncomplicated, complete abortions. Additional analyses showed no significant differences in demographic or clinical characteristics between patients undergoing medical abortion who followed up and those who did not.

There were a total of 79 ongoing pregnancies after the initial abortion procedure accounting for 0.2% of the total sample. There were 52 ongoing pregnancies in the medical abortion group for an efficacy of 99.6%. Surgical abortion was 99.8% effective with 27 ongoing pregnancies in this group (Table 2). Although the rate of ongoing pregnancy was low, women undergoing medical abortion had a four times higher risk of abortion failure than those undergoing surgical abortion (unadjusted odds ratio [OR] 4.0, 95% confidence interval [CI] 3.1–5.1) (Table 3). All ongoing pregnancies in the medical abortion group underwent aspiration. In the surgical abortion group, 22 of 27 women with ongoing pregnancies underwent repeat aspiration. Of the remaining five women, three opted to undergo medical abortion for ongoing pregnancy and two opted to continue their pregnancies. We attempted to assess the effect of clinical and demographic variables on efficacy. However, the rate of ongoing pregnancy was too low to simultaneously evaluate all eight clinical and demographic characteristics. Nevertheless, we found that abortion type and gestational age had a significant effect on efficacy. In the medical abortion group, the risk of ongoing pregnancy increased by 50% for each week of gestational age (adjusted OR 1.5, 95% CI 1.1–1.9) (Table 4). Conversely, the risk of ongoing pregnancy decreased by 60% with each week of gestational age among women undergoing surgical abortion (adjusted OR 0.4, 95% CI 0.3–0.5).

There were a total of 382 unanticipated aspirations, accounting for 1.3% of our sample. Of the

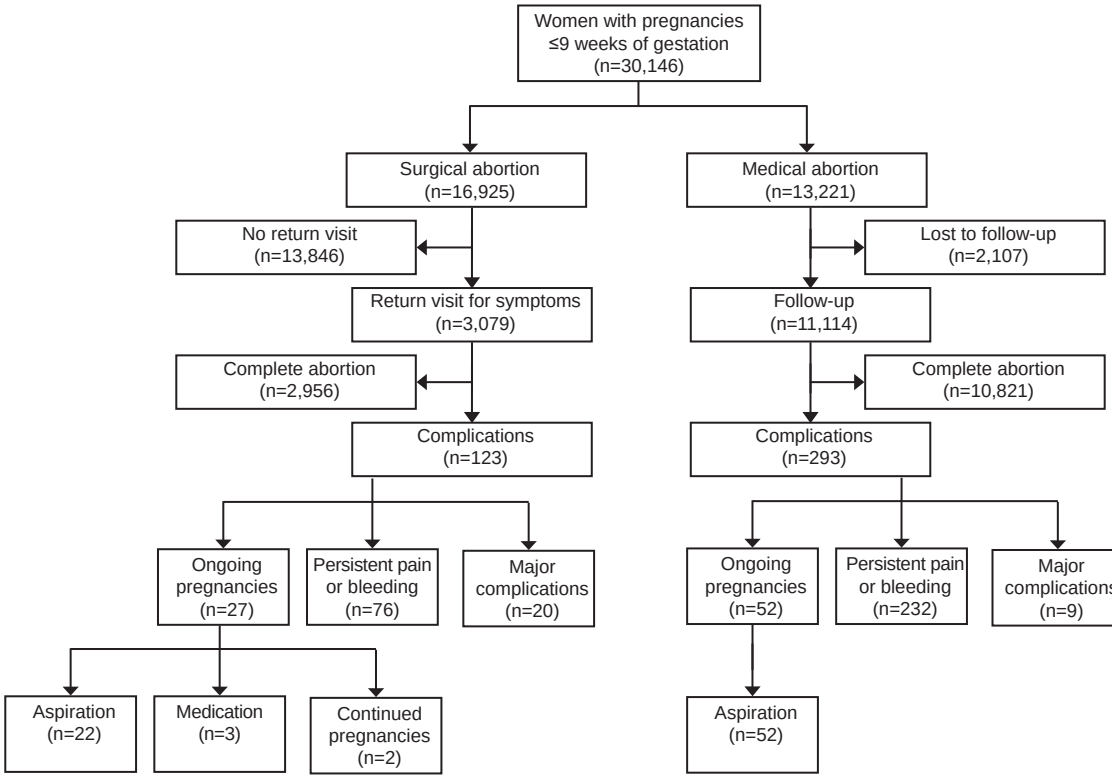

Fig. 1. Flowchart of patients undergoing medical or surgical abortion at 9 weeks of gestation or less.
Ireland. First-Trimester Medical vs. Surgical Abortion. Obstet Gynecol 2015.

13,221 women who underwent medical abortion, 2.2% underwent unanticipated aspiration. Of the 16,925 women who underwent surgical abortion, 0.6% underwent unanticipated aspiration (unadjusted OR 1.6, 95% CI 1.1–2.3) (Table 3). Persistent pain, bleeding, or both was the most common reason for an unanticipated aspiration. Among women seeking medical abortion, 1.8% underwent unanticipated aspiration for these reasons compared with 0.4% in the surgical abortion group ($P<.001$) (Table 5). A smaller proportion of aspirations occurred as a result of pregnancies ongoing after the initial procedure (0.4% medical abortion compared with 0.1% surgical abortion, $P<.001$). In the medical abortion group, four women requested surgical completion of abortion after initiation of the medication regimen.

In our regression analysis, only abortion type, patient age, and gestational age had a significant effect on a woman's risk of unanticipated aspiration (Table 4). In both the medical and surgical abortion groups, the risk of unanticipated aspiration increased by 3% with each year of patient age (adjusted OR 1.03, 95% CI 1.01–1.04). Gestational age had a more significant effect on the risk of unanticipated aspiration. With each advancing week of gestational age, this risk increased in the medical abortion group (adjusted OR 1.3, 95% CI 1.1–1.4) and decreased in the surgical abortion group (adjusted OR 0.7, 95% CI 0.6–0.8).

We reviewed chart data on major complications occurring in the 8 weeks after pregnancy termination. These complications included emergency department presentation, hospitalization, uterine perforation, infection, and hemorrhage requiring transfusion. Overall, 29 women, or 0.1% of the total sample, experienced one of these complications with no significant difference between treatment groups (OR 1.2, 95% CI 0.7–1.8) (Table 4). Frequency of any adverse events including unanticipated aspiration for persistent symptoms, ongoing pregnancies, and major complications was low at 1.9% of the total sample. This risk was higher in the medical abortion group than the surgical abortion group (OR 6.6, 95% CI 5.5–8.0).

DISCUSSION

Medical and surgical abortion at 9 weeks of gestation or less is similar in efficacy with success rates of greater than 99% in both groups. Although there is a statistically significant difference in the risk of

There are few comparative studies of medical and surgical abortion in the first trimester. One retrospective cohort study of 932 women comparing medical and surgical abortion found completion rates of 90.2% and 94.5%, respectively.[20] Higher completion rates of 96.5% for medical abortion and 99.9% for surgical abortion[21] were found in a prospective cohort study of 2,550 women seeking early abortion in family medicine clinics. The remaining comparative studies utilize outdated regimens for medication abortion or surgical techniques that are not generalizable to women currently seeking early pregnancy termination.

One of the greatest strengths of this study is a robust and diverse sample of urban women from 15 Planned Parenthood, Los Angeles, affiliate clinics. The surgical and medical abortion protocol is uniform throughout each site, thus minimizing potential bias from variation in abortion provision. Planned Parenthood's electronic medical record and practice management system provides a reliable and validated way to track patients served within the system. Internal quality assurance studies are routinely performed to maintain integrity of the data. This standardized method of data entry and documentation was critical to minimize information bias.

There are several limitations to this study. Women were not randomized to abortion type. Therefore, selection bias may explain some of the variation in efficacy and complications between the two cohorts. Sixteen percent of the medical abortion group failed to follow-up in the clinic to confirm completion of abortion. This may have resulted in an overestimate of efficacy and underestimate of complications related to medical abortion. Additionally, although we sought to identify the effect of BMI, gravidity, and parity on efficacy, the frequency of ongoing pregnancy in our sample was too low to define these relationships.

Given Planned Parenthood, Los Angeles' uniform and comprehensive reporting system, we are confident that we successfully captured all of the abortion failures and complications in women who return to us for care. It is a limitation of our study, however, that we cannot capture complications that occurred in patients who sought follow-up at other health care facilities. However, because most patients who obtained abortions at Planned Parenthood, Los Angeles, would have had to pay for follow-up medical care delivered outside of the system, but not within the system, patients were financially incentivized to return to our

Any adverse event	13.2 (11.9–14.5)	21.6 (19.1–24.2)	6.6 (5.5–8.0)	6.6 (5.5–8.0)	<.001

OR, odds ratio; CI, confidence interval.
* Major complication includes emergency department presentation, hospitalization, infection, perforation, and hemorrhage requiring transfusion.

institution for care. Furthermore, Upadhyay et al[22] recently evaluated outcomes for all Medicaid-funded abortions in California in 2011 by examining billing codes for the abortion procedure as well as any complications treated at any institution in the 6 weeks after pregnancy termination. They identified a rate of ongoing pregnancy in patients undergoing medical abortion of 0.13% and 0.04% in patients undergoing first-trimester surgical abortion. These numbers are comparable to our present findings.

In conclusion, our findings on efficacy and complication rate of first-trimester medical and surgical abortion are consistent with prior findings.[8,9] Efficacy was greater than 99% in both groups. In the medical abortion group, efficacy decreased with gestational age, corresponding to previously published literature.[19] Efficacy increased with advancing gestational ages in the surgical abortion cohort, likely related to earlier gestations being smaller and easier to miss during an aspiration procedure. The rate of serious complications was 0.1% in each group. In this study, we evaluated a third, and perhaps the most common, adverse event: unanticipated aspiration. A repeat or unanticipated aspiration is a safe and readily available procedure to manage persistent postabortal symptoms or ongoing pregnancy. However, this adverse event comes with increased cost, patient time, discomfort and inconvenience, and clinician time. Although an infrequent event in either group, we did find the risk of unanticipated aspiration to be more than three times higher in the medical abortion group.

Overall, the efficacy of medical and surgical abortion at 9 weeks of gestation or less is extremely high and complications are infrequent. Provided they are appropriate candidates for either method, they should be counseled on both medical and surgical options when seeking pregnancy termination.

Table 4. Logistic Regression Model

Variable	Adjusted OR (95% CI)	*P*
Predictors of ongoing pregnancy		
Medical abortion vs surgical abortion*	4.5 (2.3–8.6)	<.001
Gestational age (/wk)†		
Medical abortion	1.5 (1.1–1.9)	.003
Surgical abortion	0.4 (0.3–0.5)	<.001
Predictors of unanticipated aspiration		
Medical abortion vs surgical abortion*	3.9 (3.1–5.0)	<.001
Patient age (/y)‡	1.03 (1.01–1.04)	.002
Gestational age (/wk)		
Medical abortion	1.3 (1.1–1.4)	<.001
Surgical abortion	0.7 (0.6–0.8)	<.001

OR, odds ratio; CI, confidence interval.
* At average gestational age of 6.8 weeks.
† At average patient age of 25.7 years.
‡ Effect of patient age on unanticipated aspiration was the same for both medical and surgical abortion.

Table 5. Reasons for Unanticipated Aspiration in Women Who Underwent Abortion at 9 Weeks of Gestation or Less

Aspiration	Medical Abortion	Surgical Abortion	*P*
n (%)	13,221 (43.9)	16,925 (56.1)	
Aspiration for ongoing pregnancy	52 (0.4)	22 (0.1)	<.001
Aspiration for persistent pain, bleeding, or both*	232 (1.8)	76 (0.4)	<.001
All aspirations	284 (2.1)	98 (0.6)	<.001

* Aspiration for persistent pain, bleeding, or both in the presence of ultrasound findings concerning for retained products of conception or intrauterine debris.

Accepted 25 May 2014. Published Online 18 July 2014.

Objective To assess nurse-midwife provision of early medical termination of pregnancy (TOP) in a high-resource setting where ultrasound examination for dating of pregnancy is part of the protocol.

Design Randomised controlled equivalence trial.

Setting Out-patient family planning unit at a university hospital.

Population Women seeking early medical TOP.

Methods A total of 1180 women were randomised, without any prior examination, to counselling, examination, and treatment by either nurse-midwife or gynaecologist. Ultrasound was performed in all cases by the allocated provider.

Main outcome measures The primary outcome was efficacy, defined as the successful completion of TOP without need for vacuum aspiration. Secondary outcomes were safety, defined as need for hospitalisation or blood transfusion, and acceptability, defined as preferred provider were the women to have a medical TOP in the future.

Results A total of 481 women in the nurse-midwife group and 457 women in the doctor group were available for the final analysis. The effectiveness of provision of medical TOP by nurse-midwife providers was superior to that provided by doctors (risk difference 1.6%, 95% confidence interval 0.2–3.0%, which was within the set margin of equivalence). There were no significant differences in safety parameters. Women examined and counselled by a nurse-midwife were significantly more likely ($P < 0.001$, 95% confidence interval 0.308–0.394) to prefer seeing a nurse-midwife for the consultation were they to have another medical TOP in the future.

Conclusions These findings show that nurse-midwife provision of early medical TOP in a high-resource setting, where ultrasound is part of the protocol, is effective, and can be safely implemented with high acceptability among women.

Keywords Abortion, medical abortion, midlevel provision.

Introduction

According to the World Health Organization (WHO) and the Guttmacher Institute, approximately 47 000 women die every year as a result of unsafe termination of pregnancy (TOP). Almost all these deaths occur in developing countries where access to safe TOP services is limited.[1] In addition to legal limitations, access to providers may be a limiting factor in gaining access to safe TOP. Task shifting is defined as a process of delegating appropriate tasks from doctors to specialised providers, and has been found to increase productivity within healthcare systems.[2] Studies from Africa show that the training of specialised non-doctor healthcare providers to perform tasks traditionally

© 2014 Royal College of Obstetricians and Gynaecologists

reserved for doctors can help build sustainable, cost effective, and equitable healthcare services in both maternal healthcare and post-TOP services.[3–5] In developing countries TOP services may or may not include pregnancy tests and/or ultrasound examination. Midlevel provision of medical TOP in Nepal, where ultrasound is not routine, has recently been shown to be effective and acceptable.[6] The midlevel provision of surgical TOP has been shown to be equally safe and effective as that performed by doctors.[7]

In high-resource settings where TOP is legal it is generally a safe procedure; however, access to TOP may be limited by the scarcity of doctors willing to perform TOPs. In the USA, midlevel provision of medical TOP is becoming increasingly common. A wide variety of healthcare provider categories are involved in this care.[8] The physical and pelvic examination before a TOP is traditionally performed by a doctor, and an ultrasound for dating of pregnancy is usually part of the protocol. Also, increased access to induced TOP in high-resource settings could thus be achieved by task sharing/shifting in TOP care.

The primary objective of this trial was to show that nurse-midwives can provide early medical TOP as effectively as doctors in a high-resource setting where TOP services are provided by doctors and ultrasound dating of pregnancy is part of the protocol. To show this the trial was designed as a randomised equivalence trial. Secondary objectives were to assess the safety and acceptability of nurse-midwife provision of medical TOP.

We could show that task shifting in medical TOP in high-resource settings, where vaginal ultrasound dating of pregnancy is part of the protocol, is highly effective. The results will be important for healthcare systems and the provision of safe TOP in many settings.

Methods

In Sweden, TOP is legal upon request by the woman up to 18 weeks and 0 days of gestation, and must be performed by a doctor. Permission was granted by the National Board of Health and Welfare and by the Ethical Review Board of Stockholm to allow midwives to independently provide medical TOP according to the study protocol. Nurse-midwives in Sweden may prescribe doxycycline for *Chlamydia trachomatis* infection but not antibiotics for bacterial vaginosis.

The study was registered at Clincaltrials.gov, NCT01612923, and followed the modified CONSORT (Consolidated Standards of Reporting Trials) reporting guidelines for equivalence trials.

The trial was conducted at the out-patient family planning clinic of the Karolinska University Hospital, Sweden. Women made an appointment by calling the clinic by telephone, and were informed about the study at that time and asked if they would be willing to participate. If they were healthy, had a pregnancy of 63 days or less according to their last menstrual period, and wanted a medical TOP they were further informed of the study at the first visit to the clinic. Women were eligible to participate if they were 18 years or older, had no contraindication for medical TOP, and were in good general health with no continuing medication for chronic disease. If the women were eligible after interviewing and accepted participation they signed informed consent before they were randomised and prior to any examination had been performed. Women were allocated to the nurse-midwife arm or to the standard-care arm. In the nurse-midwife arm the examination, including the ultrasound dating of pregnancy and contraceptive counselling, was performed by the nurse-midwife. In the standard-care arm the examination, including the ultrasound dating of pregnancy and contraceptive counselling, was performed by a doctor, and further information and dispensation of medication was performed by a nurse-midwife. The gestational length was determined by measurement of gestational sac diameter or crown–rump length of the fetus, in all cases. The ultrasound was performed by the allocated provider. All women were screened for *Chlamydia trachomatis* and bacterial vaginosis according to Swedish clinical practice.

Women were excluded from both groups after examination if the ultrasound showed predefined exclusion criteria, such as a gestational length of over 63 days, evidence of pathological pregnancy, or an adnexal mass.

Two nurse-midwives experienced in medical TOP and contraceptive counselling received theoretical and practical training in vaginal ultrasound examination of early pregnancy. These nurse midwives were the sole providers in the nurse-midwife arm. There were a total of 34 doctors in the standard-care arm, reflecting the number of doctors involved in TOP care in the clinic. These doctors had varying training and experience. Some had only a few months of training, whereas others were senior consultants with long experience. The recruitment for the study began on 28 February 2011 and ended on 25 July 2012.

Randomisation was achieved through the consecutive opening of numbered opaque and sealed envelopes containing a computer-generated randomisation allocation code, in blocks of ten women, at a ratio of 1 : 1. The study was not blinded.

A woman randomised to the nurse-midwife group (intervention) was examined, counselled, informed, and treated by one single nurse-midwife. Women allocated to the standard-care group (control) were examined and counselled by a doctor, and then received additional information about the practical details and medication from a nurse-midwife, according to clinical routine. Participating nurse-midwives did not perform any regular nurse-midwife

© 2014 Royal College of Obstetricians and Gynaecologists

tasks during the study period, to avoid possible bias. Medical TOP was performed according to the WHO recommended protocol, and did not differ between the groups.

All women received mifepristone 200 mg (Mifegyne®; Nordic Drugs, Limhamn, Sweden) given in the clinic according to Swedish law. The women had a free choice to administer 800 μg of misoprostol (Cytotec®; Pfizer, Sollentuna, Sweden) vaginally at home or in the clinic 24–48 hours after mifepristone administration. If no bleeding occurred within 3 hours, women were instructed to take an additional dose of 400 μg of misoprostol orally.[9] Women were advised to take prophylactic pain treatment consisting of acetaminophen (paracetamol) 1 g (Alvedon®; Astra Zeneca, Södertälje, Sweden) and Diclofenac 100 mg (Voltaren®; Novartis, Täby, Sweden) at the time of vaginal misoprostol administration.

Contraceptive counselling and prescription was performed by a nurse-midwife or by a doctor, according to allocation. Follow-up in all cases was by low-sensitivity urinary human chorionic gonadotropin (hcg) test (cut-off 500 iu/ml; ANL-produkter AB, Alvsjo, Sweden), performed by a nurse-midwife not involved in the study, according to clinical routine, after approximately 3 weeks. Two attempts to contact women were made if women did not attend for follow-up, after which they were considered lost to follow-up.

If the urinary hCG test was positive, a serum hCG test was performed and the patient was referred for evaluation with vaginal ultrasound to rule out continuing pregnancy. The primary outcome measure was efficacy, assessed through the successful completion of TOP without the need for vacuum aspiration. Secondary outcome measures were safety, defined as the need for hospitalisation or blood transfusion, and acceptability of the procedure. The efficacy and safety were assessed by self-administered questionnaires and electronic patient records, which were completed after the initial examination and counselling, and also at the follow-up visit. Records were also checked if the patient was lost to follow-up. Complication was defined as the need for causal treatment at an unscheduled visit up to 6 weeks after the TOP, such as treatment with misoprostol, antibiotics, or treatment for anaemia. Acceptability was assessed in self-adminstered questionnaires by women stating whether they would prefer standard treatment by a gynaecologist or a nurse-midwife were they ever to have another medical TOP.[10,11]

In addition, the need for a second opinion from a doctor for nurse-midwives, or from another doctor in the case of the standard-care arm, and the reasons for this were recorded. Second-opinion consultations were performed immediately by other doctors in the clinic to avoid any delay of the TOP. The contraceptive method prior to the TOP and the prescribed method intended to start after the TOP were reported, as well as the actual method started (e.g. intrauterine contraception/implants inserted).

This study was designed as a two-sided equivalence trial with the overall efficacy of medical TOP assumed to be 95% in both groups. A clinically significant margin of equivalence was set to 5% based on what was believed to be of clinical importance to the patients. To demonstrate two-sided equivalence within a margin of 5%, with 80% power, and a confidence interval of 95% ($\alpha = 0.05$), 400 women in each group would be sufficient. To compensate for loss to follow-up and patients not completing the medical TOP, 1180 patients were randomised. All statistical calculations except the generalised estimating equation were made using SPSS 20 (IBM Corporation, Somers, NY, USA). For comparison of groups with regard to skewed data the Mann–Whitney *U*–test was used. For variables with a normal distribution the Student's *t*–test was used. For categorical variables, comparison between groups were made using the chi-square test. The equivalence between nurse-midwife providers and doctors was assessed using a generalised estimating equation. The generalised estimating equation allows for treatment as a fixed factor and provider as a random factor, and thereby enables adjustment for the difference in providers' enthusiasm and competence. This analysis was performed in the PROC GENMOD procedure of SAS 9.3 (SAS Institute, Gary, NC, USA).[12] In addition, the risk ratio (risk of failure in the standard group divided by risk of failure in the nurse-midwife group) for the primary outcome was added. Results were regarded as statistically significant for $P < 0.05$. Analysis was per protocol, according to recommendation, and followed the CONSORT guidelines for equivalence trials.[13]

Results

A total of 1180 women were randomised, with no prior physical examination, to examination and counselling by a nurse-midwife ($n = 597$) or by a doctor ($n = 583$). A total of 105 women in both groups were excluded after examination but prior to mifepristone intake, for predefined reasons, with the numbers and reasons not differing between the groups (Table S1). Seven women in the standard-care group did not receive the allocated treatment because of sudden illness of the allocated provider. Unfortunately, these women were not followed-up and no results are available. Thus, 1068 women received and completed the allocated intervention. In the nurse-midwife group 54 women were lost to follow–up, compared with 76 women in the standard-care group (130 women in total, $P = 0.038$). The flow of patients is presented in Figure 1. Analysis was performed per protocol. There were no significant demographical differences between the groups (Table 1).

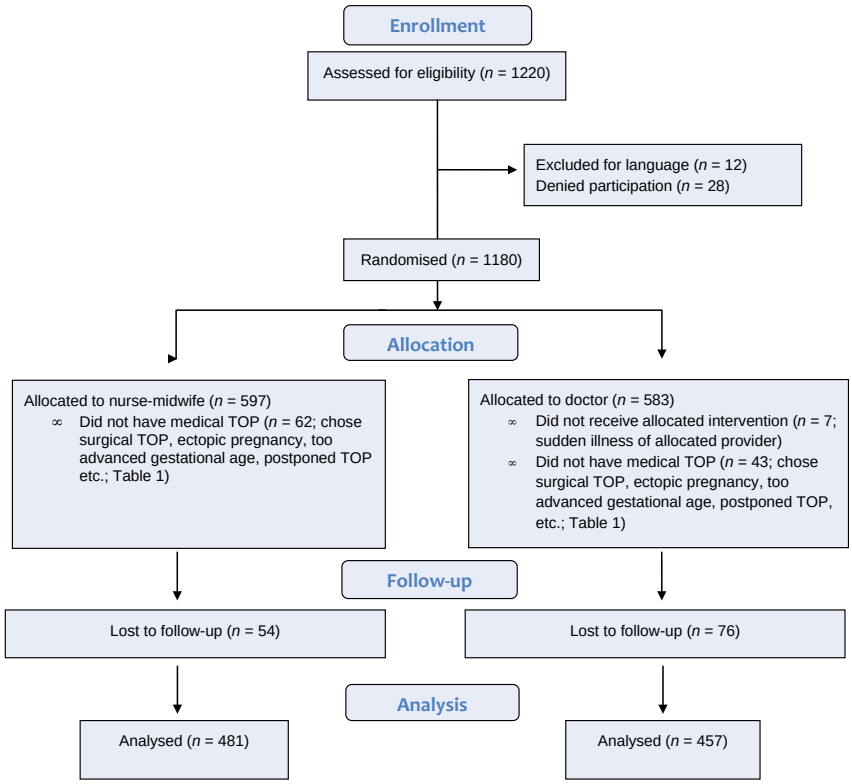

Figure 1. Consort flow chart.

Table 1. Demographic characteristics of women

	Allocated to nurse-midwife *n* = 535 Median (range)	Allocated to doctor *n* = 533 Median (range)
Age	27 (18–47)	27 (18–46)
Gestational age at ultrasound (days)	45 (30–63)	45 (28–63)
Gravidity	2 (0–13)	2 (0–14)
Parity	0 (0–5)	0 (0–6)
Miscarriage	0 (0–4)	0 (0–5)
TOP, surgical	0 (0–3)	0 (0–5)
TOP, medical	0 (0–4)	0 (0–5)
Vaginal deliveries	0 (0–5)	0 (0–6)
Caesarian section	0 (0–3)	0 (0–3)

There were no statistically significant differences between the groups.

An overview of primary and secondary outcome measures is given in Table 2. Reasons for surgery are given in Table S2. The risk difference for efficacy was 1.6%, with a 95% confidence interval (95% CI) of 0.2–3.0% ($P = 0.027$). Although the trial was designed to show equivalence, the results show superiority for the nurse-midwife group, with a risk ratio for the primary outcome of 2.5 (95% CI 1.4–4.3) for the doctor group.

The overall complication rate was 4.1% for the women randomised to a nurse-midwife (20/493, 41 missing), and 6.1% for women randomised to a doctor (29/472, 61 missing, 95% CI −0.7 to 5%, $P = 0.14$). Reasons for complications are given in Table S3. There were no serious complications and no blood transfusions were given.

The percentage of unscheduled visits was 9% among women randomised to nurse-midwives (44/489, 45 missing), and 9.7% for women randomised to doctors (46/473, 60 missing, 95% CI −3 to 4.5%, $P = 0.7$). One patient had a continuing pregnancy at an unscheduled visit. She was successfully treated with a repeat medical TOP, according to her choice.

No significant differences existed between the groups in satisfaction with information, contraceptive counselling, feeling of calm and safety before, during, or after the TOP, with high satisfaction rates above 92% for all variables in both groups. There were no significant differences in perceived bleeding or worse pain experience on day of expulsion, or in the experience of the procedure, as compared with expectation (data not shown).

Women randomised to doctors were significantly more likely to choose home administration of misoprostol (310/

533) compared with women randomised to nurse-midwives (266/535, 95% CI 2.5–14.3%, $P = 0.006$).

Doctors needed a second opinion in 4% of cases (21/533) compared with 26% of cases (139/535) for nurse-midwives (95% CI 18–26%, $P < 0.001$); however, the frequency of ultrasound consultations for nurse-midwives went down as the study progressed, indicating a learning curve. Reasons for consultations are given in Table 3. The women allocated to nurse-midwives spent significantly shorter time in the family planning unit during the first visit (mean 42 minutes, SD 18.3 minutes), compared with the doctor group (mean 60 minutes, SD 24.1 minutes, $P < 0.001$). Women randomised to nurse-midwives were significantly more likely (95% CI 11.8–22.5%, $P < 0.001$) to prefer seeing a nurse-midwife again were they to have another TOP, although the majority were indifferent (Table 4). Patients randomised to nurse-midwives were more likely (200/535 women, 37.4%) to prefer their allocated provider than women randomised to doctors (12/533 women, 2.3%, 95% CI 30.8–39.4%, $P < 0.0001$).

Women who were examined and counselled by nurse-midwives had long-acting reversible contraceptives (LARCs) inserted within 3 weeks of the TOP (intrauterine contraception and implant, 290/532, three missing), significantly more often than women examined and counselled by doctors (241/528, five missing, 95% CI 3.2–15.2%, $P = 0.004$).

Discussion

Main findings

In this equivalence trial we showed the superior efficacy of nurse-midwife provision of early medical TOP in healthy women, when compared with standard doctor provision, in a setting where vaginal ultrasound examination for the dating of pregnancy is part of the protocol. We also found that nurse-midwives were significantly more likely to prescribe LARCs as post-TOP contraception.

Strengths and limitations

One strength of this study is that women were randomised after standard telephone screening without any prior examination. An additional strength is that the results can be generalised to high-resource settings, as ultrasound dating of the pregnancy was part of the protocol to confirm gestational length. Furthermore, women were able to choose home administration of misoprostol. To help women avoid another unwanted pregnancy, the provision of post-TOP contraception is crucial. The LARCs (intrauterine contraception and implants) have been shown to decrease the rate of repeat TOPs.[14] Therefore, the prescribed contraceptive method was studied.

This study also has limitations. As this is the first study on task shifting to the midlevel provision of induced TOP, including ultrasound dating of pregnancy, we limited participation to healthy women. The study was not blinded. It is possible that acceptability was influenced by the involvement of highly motivated nurse-midwives, but blinding of the provider did not seem feasible. The deeper involvement in family planning may also have influenced these midwives to prescribe more LARCs to women, compared with the doctors who only performed TOP as part of their training or rotations. The results our study also show that at follow–up, a larger proportion of women in the nurse-midwife group had returned to the clinic to have the LARCs inserted. The rate of patients lost to follow-up is comparable with a recent study from Scotland,[15] and is comparable with most studies in TOP practice.

Interpretation

Previous studies have shown that task shifting has a place in caesarean section provision, and in the provision of surgical TOP;[3,4,7] however, task shifting has so far been limited to low-resource settings. A recent study from Nepal investigated the midlevel provision of medical TOP;[6] however, in the Nepal study randomisation was undertaken after bimanual pelvic examination to estimate uterine size. Thus, women were already examined before the randomisation. It is well known that midlevel providers can provide the TOP drugs and the counselling. In our present study, women were self-referred and randomised before any part of the consultation had been performed. Furthermore, vaginal ultrasound dating of pregnancy was part of the routine protocol. This is another important difference to the study from Nepal, in which ultrasound examination for dating of pregnancy was not part of the protocol.[6] It is well documented that medical TOPs can be performed without any ultrasound examination;[16–18] however, ultrasound dating of the pregnancy is part of the protocol in many high-resource settings, and the results of the Nepal study may therefore not be applicable. In contrast to other studies on task shifting in TOP care, we also studied the provision of post-TOP contraception. The equivalence trial model was purposely chosen instead of the approach of inferiority trial, as midlevel provision of medical TOP may have profound advantages for women, such as being able to access TOP services where there are none available today, and shorter waiting periods to receive an appointment. A lower efficacy could therefore be tolerated; however, the study showed superiority for the nurse-midwife group.

This study showed that although a majority of patients were indifferent to the provider being a nurse-midwife or doctor, the women who expressed a preference preferred nurse-midwives to a larger extent in both randomisation groups. A possible explanation of this result may be that an uncomplicated TOP is not necessarily viewed as a medical condition that warrants the attention of a doctor. It is likely therefore that women prefer a nurse-midwife to a doctor for the examination and counselling; however, nurse-midwives do not prescribe contraceptives to women with intercurrent disease, and nor do they oversee complicated pregnancies or deliveries. In this study, women with complications or women who made unscheduled visits for fear of complications were therefore examined by doctors. The doctor on call also performed any necessary surgery. Women in the nurse-midwife group received significantly shorter consultations, but this did not reflect in lower satisfaction rates among women concerning the information received. In the nurse-midwife group the nurse-midwife was the sole provider of information and also handed out all medication. It may be that the group allocated to standard care received duplicate information or had waiting times between seeing the nurse-midwife and the doctor. More women allocated to doctors chose home administration of misoprostol, which may have impacted on the time allocated for counselling. Decreasing the time patients spend in the family planning clinic must be seen as something that is beneficial to the patient and to the healthcare system. As midwives have lower salaries than doctors, the results also have economic implications.

Conclusion

This study shows that task shifting in medical TOP in high-resource settings, where vaginal ultrasound dating of

© 2014 Royal College of Obstetricians and Gynaecologists

pregnancy is part of the protocol, is highly effective. In addition, nurse-midwives spent shorter time on the consultation, which has potential economic impact on the healthcare system. Furthermore, women examined and counselled by nurse-midwives received LARCs to a greater extent than women examined and counselled by doctors. This may have an impact on repeat TOP rates. Task shifting in medical TOP may therefore have a positive impact on TOP care in low- as well as in high-resource settings. The increased involvement and responsibilities of nurse-midwives in medical TOP should be encouraged. Further studies should include an exentended gestational range.

Disclosure of interests

All authors declare that they have no conflicts of interest to report.

Contribution to authorship

The study was initiated by KGD, who had overall responsibility for the study. KGD, LM, RG, ES, and MJ were responsible for the project plan and planning, and KGD and LM were responsible for the training programme. HKK and KGD were responsible for conducting the study, the database design, analysis, and writing of the article. All authors assisted with writing the article.

Details of ethics approval

Permission was granted by the National Board of Health and Welfare and by the Ethical Review Board of Stockholm (permission number 2010/1828-31/3, 23 December 2010) to allow midwives to independently provide medical TOP, according to the study protocol. The study protocol was submitted with the ethics application on 11 November 2010, and was approved on 23 December 2010. Patient recruitment started in April 2011. No amendments were made to the protocol following ethics approval. Once approved by the regional ethics committee at Karolinska Institutet, all applications are publicly available. In addition, the protocol was also made available prior to and at a meeting convened by the WHO, Geneva, which was a consultation on the midlevel provision of medical abortion, with relevant material being circulated and shared before beginning the recruitment of patients for the trial. The trial was also registered at ClinicalTrials.gov after starting the study, but before recruitment had been completed (NCT01612923).

Funding

Funding was obtained from the Swedish Research Council (521-2009-2605), the Swedish Council for Working Life and Social Research (1404/08), Stockholm County Council, and Karolinska Institutet (ALF 2009–2012).

Acknowledgement

Time to streamline access to termination of pregnancy

Published Online 21 November 2014.

Unplanned and unwanted pregnancy is one of the major problems facing women worldwide. Although some may wish to continue unintended pregnancy, many will choose a termination of pregnancy (TOP). Most authorities now accept that access to safe TOP is a prerequisite for reproductive health (WHO 2007). Modern methods of TOP are extremely safe and effective, particularly in the first few weeks of pregnancy.

The major problem in providing safe TOP is not the method but its availability. As predicted in early publications, the simplicity of medical TOP provides the opportunity for widening the provision by using relatively unskilled health care workers (Rodger & Baird *Lancet* 1987;ii:1415–8). Several studies have reported that in low income countries, suitably trained mid-level providers (MLP) can provide safe and efficient TOP using both medical and surgical methods (Renner et al. *BJOG* 2013;120:23–31). This issue of BJOG reports the results of an RCT that examines the facilities necessary to deliver safe medical TOP in a high income country – Sweden (Gemzell et al. *BJOG* 2014;122:511–8). Women were randomised to care by either a team of doctors and nurses (standard service) or a team of trained midwives/nurses (MLP). Both groups achieved over 95% complete TOP with few complications. There was some evidence that women in the MLP arm were more satisfied with their experience and had a higher uptake of contraception. The authors suggest that this model could be more widely used in high income countries as a cost-effective service.

The suggestion of re-examining the 'skill mix' required for provision of medical services including TOP is topical and welcome, but the current trial leaves unanswered several questions about its general applicability. All women had a routine ultrasound to determine gestation. One asks how necessary this routine investigation is when safe TOP can be provided by assessing suitability on clinical grounds alone? (Warriner et al. *Lancet* 2012;377:1155–61). In the MLP arm, care was provided by one of two specially trained MLPs, compared with the standard arm with numerous doctors with variable levels of training. Furthermore, in the MLP arm, 26% of women were referred for a second opinion to a doctor, so clearly the MLP provision is limited to settings where both providers are readily available. While superficially it may appear cheaper for women to be seen by MLP, a rigorous examination of the cost-effectiveness of providing the service in different settings is needed before this model could be generally recommended.

In many countries, legal constraints severely limit access to safe TOP. Even in countries such as Sweden and the UK, the law requires TOP to be authorised by a registered medical practitioner and conducted in a hospital or registered premises. In the UK, repeated attempts to update the 1967 Abortion Act to accommodate developments in methods of TOP have failed. Only when there has been radical reform of the legal conditions surrounding TOP will it be possible to provide a safe and cost-effective service for unwanted pregnancy.

Modern methods to induce abortion: Safety, efficacy and choice

Nathalie Kapp [a, *], Patricia A. Lohr [b]

[a] Ipas, Chapel Hill, NC, USA
[b] British Pregnancy Advisory Service, Stratford Upon Avon, UK

A B S T R A C T

Abortion care is a fundamental part of women's reproductive health care. Surgical and medical abortion methods are safe and effective throughout the gestational age range wherein abortions are performed. Although risks increase with the gestational age of the pregnancy being terminated, rates of complications remain low and comparable between surgical and medical techniques. A high-quality abortion service should offer women a choice between abortion methods and provide the one they prefer.
© 2020 Elsevier Ltd. All rights reserved.

Introduction

Abortion is a common event in women's reproductive lives, affecting approximately 25% of all pregnancies [1]. Globally, 56 million induced abortions are estimated to occur each year for a rate of 35 abortions per 1000 women aged 15–44 years [1]. Safe services to terminate a pregnancy are, therefore, an essential aspect of women's health care.

Induced abortion using modern methods is very safe [2]. The chance of a woman dying from an induced abortion, when performed by a trained clinician, is manyfold lower than dying from a pregnancy carried to term [3]. However, abortions performed by unskilled providers or in environments lacking minimal medical standards, have high rates of maternal death and injury [4,5]. The informal use of misoprostol, which has become widespread, has decreased risks historically associated with unsafe methods of abortion [6]. Ensuring the safe provision of abortion – whether by training in

medical and surgical methods, securing the supply chain of quality medicines and equipment, or expanding access to services, is essential in reducing maternal morbidity and mortality worldwide.

Methods of induced abortion

Advances in abortion technologies now mean that either medical or surgical methods can be offered throughout a range of gestational ages of pregnancy. Surgical abortion methods include uterine aspiration, by manual or electric vacuum, and dilation and evacuation (D&E). Aspiration techniques are sufficient to evacuate the uterus up to about 14 weeks' gestation. As the pregnancy advances, safe removal of the increasing volume and density of tissue requires advanced cervical preparation, and the use of a combination of forceps and aspiration to remove the products of conception from the uterus through the cervix. D&E is used from 14 to approximately 24–26 weeks' gestation. Medical abortion relies on the use of medications: primarily a combination of mifepristone and misoprostol. This drug combination has been recommended in World Health Organization (WHO) guidance for safe abortion care since 2003 and included in the WHO Essential Medicines List since 2005. Where both drugs are available, they should be used in combination [2]. Misoprostol, mainly due to its various other non-obstetric and obstetric indications, is widely available; however, mifepristone, is not. Mifepristone is registered in only about 70 countries; where it is not available, misoprostol alone may be used to induce abortion.

In countries with reliable data, official statistics demonstrate that about half of all abortions are performed with medications [7]. The comparative proportions of surgical and medical methods vary by country [7]. In countries with few restrictions on abortion and with well-developed services, terminations occur early in pregnancy, at least 90% before 13 weeks' gestation [7]. In more restricted settings or in the immediate period after legal status changes, the proportion of women undergoing abortion at later gestations is greater [8–10].

Over the past 10 years, the proportion of abortions occurring at under 13 weeks' gestation, as well as those occurring under 9 weeks' gestation, and the proportion that are medically induced have all increased [7]. Trends of women seeking abortion care at earlier gestations have been documented in concert with the introduction and increasing popularity of medical abortion; whether this is a causal effect is unknown, but it is a positive one as the risk attributed to induced abortion is lower in earlier gestations [11]. Abortion-related mortality increases with gestational age from a rate of 0.1 per 100,000 procedures at 8 weeks gestation to 8.9 per 100,000 procedures at 21 weeks; thus, the earlier the abortion procedure takes place, the safer it is likely to be [12–14].

Safety and efficacy of surgical abortion techniques

Uterine aspiration is safer and less painful than the older technique of dilation and sharp curettage, and is therefore, the most widely recommended and utilized method of inducing abortion surgically in the first trimester [2,15]. There are two aspiration techniques: manual vacuum aspiration (MVA) and electric vacuum aspiration (EVA). In both, the uterus is evacuated using a rigid or flexible plastic cannula inserted through the cervix and attached to a vacuum source. During an MVA procedure, the vacuum is created by manually charging a 60 ml hand-held syringe (Fig. 1), whereas an electric pump creates an EVA's vacuum. The MVA procedure is quieter than an EVA, which is preferred by many women and may contribute to lower anxiety and pain levels [16]. Its low cost and portability make it more accessible, particularly to primary care or low-resource settings. The largest cannula that can be used with an MVA device is 12 mm. Thus, EVA is useful at higher gestational ages when larger cannulae are needed, and the sustained level of vacuum obviates the need to repeatedly empty a hand-held syringe.

A systematic review of 10 randomized controlled trials comparing MVA and EVA found no significant differences in efficacy as measured by the complete abortion rate, reported to be between 98 and 99% in both groups [15,17]. Less blood loss, albeit unlikely to be clinically significant, was reported among MVA patients under 50 days' gestation, as was less severe pain when compared with EVA. As gestational age increased, blood loss increased, and differences between the procedures in pain and blood loss disappeared. Procedure times averaged 5–6 min with either device; although EVA

Fig. 1. Manual vacuum aspirator.

procedures were statistically of shorter duration, the difference was about 30 seconds and unlikely to be clinically significant. Satisfaction with procedure and preference, as measured by electing to have the same procedure again if needed in the future, were similar between the two methods.

Major complications requiring an intervention or procedure, such as hemorrhage requiring transfusion, or uterine perforation or cervical laceration requiring repair occur in less than 0.1% of aspiration abortions, according to a recent systematic review of 57 studies [18]. In current practice, providers understand MVA and EVA are comparable in terms of efficacy and safety, and generally choose between them for reasons such as their preferences, characteristics of their facility, availability of supplies, and cost.

As the gestational age of pregnancy increases, surgical techniques require more than aspiration to remove the tissue. D&E primarily rely on the use of strong, elongated grasping forceps to remove the pregnancy (Fig. 2). The D&E technique requires the use of cervical priming agents, such as misoprostol over a period of hours, mifepristone over a day, or osmotic dilators over 1–2 days before the procedure [19]. By softening and opening the cervix, priming reduces the risk of cervical or uterine trauma and need for further mechanical dilation, and facilitates fetal extraction [13,20]. The amount of preparation required increases with gestational age and with certain patient characteristics, such as nulliparity and young age [19].

After cervical preparation is deemed adequate, and appropriate anesthesia or sedation is initiated, aspiration of the amniotic fluid is performed [20]. Following removal of the amniotic fluid, the uterus begins to contract, and forceps are used to remove the fetus in parts and the placenta. When all parts of the pregnancy are removed, a final aspiration is performed to ensure complete evacuation of the uterus, and hemostasis is achieved. Generally, the procedure takes 10–25 min, and after a short recovery, women return home the same day [21].

Safe provision of D&E requires advanced training and ongoing provision [2,20,22]. D&E is highly effective with minimal rates of complications, ranging from 0.05 to 4%, reported in various studies [13,20,22–26]. D&E is almost always effective; in rare cases additional time or agents for cervical preparation or mechanical dilation is needed to facilitate the procedure. The most common complications remain rare; hemorrhage, requiring transfusion occurs in approximately 0–1% of cases [26–28]. Infection occurs uncommonly following surgical abortion with routine prophylactic antibiotics, which are recommended by organizations, such as the American College of Obstetricians and Gynecologists, the Royal College of Obstetrics and Gynaecology, and the WHO, and ranges from 0 to 2% of cases [29]. When cervical preparation is undertaken, the complication of cervical laceration is low, and ranges from 0.02 to 3.3% [24,27]. Risk of cervical laceration, as in the first trimester, is increased with need for mechanical dilation, nulliparity, advanced gestation, and provider inexperience [23]. Uterine perforation occurs more commonly than in first trimester procedures, approximately in 0.2–0.8% of cases [27,30].

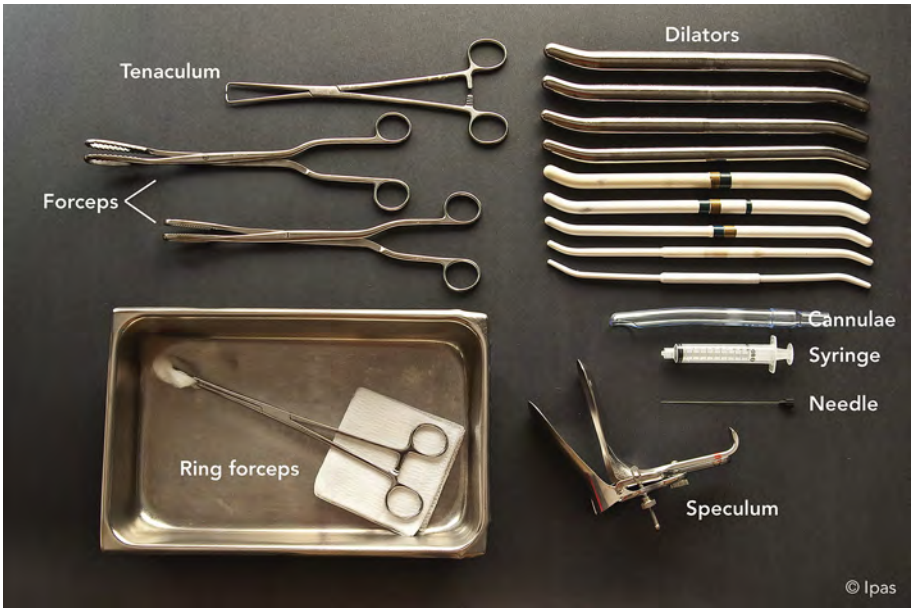

Fig. 2. Dilation and evacuation equipment.

Safety and efficacy of medical abortion techniques

Medical abortion, as for the surgical techniques, may be used at any gestational age [2]. The most effective regimen utilizes a combination of mifepristone, a progesterone receptor antagonist, followed by misoprostol, and a prostaglandin analog [31]. Changes to the regimen with increasing gestational age involve lowering the dose of misoprostol and repeating its administration, until the abortion is complete [32,33].

There are few contraindications to medical abortion drugs, primarily: confirmed or suspected ectopic pregnancy, hemorrhagic disorder, allergy, or intrauterine device (IUD) in place (after removal, medical abortion may be pursued) [2]. Additional contraindications for mifepristone include chronic adrenal failure, long-term systemic corticosteroid use, or inherited porphyria [34]. After administration of misoprostol, women typically experience bleeding and uterine cramping and pain; these symptoms are considered a normal part of the medical abortion process.

Medical abortion with mifepristone and misoprostol

A substantial body of evidence has documented the safety and efficacy of medical abortion with mifepristone and misoprostol in early pregnancy. Initial studies included gestational ages up to 7 weeks; subsequent research expanded the age range up to 9 and 10 weeks. A recent systematic review of 200 mg oral mifepristone followed by 800 mcg misoprostol administered buccally 24–48 h later in pregnancies up to 63 days gestation, documented an effectiveness of 96.7% among 33,846 women [35]. A prior review, which considered all administrative routes (buccal, oral, sublingual, and vaginal) and doses for misoprostol following 200 mg mifepristone up to 63 days' gestation, noted failure (defined as the need for surgical treatment) occurred in fewer than 5% of subjects among more than 45,000 abortions, and ongoing pregnancy was 1.1% [36]. Those who took misoprostol less than 24 h after mifepristone had a higher failure rate than among those employing a 24- to 48-h interval between medications (OR 2.1; 95% CI, 1.4–3.2) [36]. Oral administration of misoprostol at each dose level was associated with significantly higher failure rates than each of the other routes (sublingual, buccal, and

vaginal), while there was no difference between three nonoral routes. Finally, failure was also more likely among groups using 400 mcg misoprostol, when compared with 600 or 800 mcg.

Complications following medical abortion are rare: hemorrhage requiring a blood transfusion is reported at an estimated rate of 0.03–0.6% [35–37]; serious infection reported in recent systematic reviews range from 0.01 to 0.5% [30,35] and serious infection with fatal sepsis is extremely rare (<1/100,000, [64]). The most common adverse outcome from medical abortion is the need for a surgical uterine aspiration for treatment of retained products of conception, persistent pain, prolonged bleeding, or ongoing pregnancy [35,36]. Rates vary by the study population, gestational age, and regimen used, but are also influenced by providers' experience and comfort with medical abortion [30,35,36].

More recent data from two prospective trials comparing outcomes of the combination regimen between 57 and 63 days with 64–70 days, found that rates of successful abortion did not differ between the two gestational weeks, and there were likewise no differences in adverse events [38,39]. These data provided the evidence to extend outpatient medical abortion services globally through 70 days gestation in practice, and also through a regulatory pathway change in the label of one mifepristone drug (Mifeprex) [34].

Beyond 10 weeks' gestation, effectiveness of the combination regimen with only one misoprostol dose falls, making it necessary to repeat the dosing [32]. Available studies are fewer, reflecting that abortion for most women occurs early in pregnancy. Mifepristone followed 24–48 h later by misoprostol is the most effective regimen, up to 94% success within 24 h of initiation of misoprostol, and with a significantly shorter interval to abortion and fewer adverse effects than using misoprostol alone [32,40–43]. Median induction to abortion intervals range between 6 and 10 h; longer intervals are associated with higher gestational ages, as well as among nulliparous and older women [41,44–46]. While most abortions will be successful within 24 h, a small proportion will require several days to complete. Minor complications, such as needing a procedure for heavy bleeding or to remove a retained placenta, occur at a higher rate in more advanced gestations. In the largest cohort study of mifepristone-misoprostol abortion, including 1002 women between 13 and 21 weeks gestation, 8.1% required a uterine evacuation to remove a retained placenta, while two women needed an evacuation to terminate the pregnancy [44]. In this study, serious complications such as hemorrhage and blood transfusion were uncommon; they occurred in 8 women (<1%).

Uterine rupture, a serious complication of labor in obstetric literature associated with prostaglandin use in women with prior cesarean sections, is rare among abortion patients in the second trimester. In a meta-analysis of data from medical abortion studies in the midtrimester using the combined regimen or misoprostol alone, the overall rate of rupture was 0.08% with a rate among women with prior cesarean/hysterotomy of 0.28% [47].

Medical abortion with misoprostol alone

A recent systematic review of misoprostol-only regimens identified 38 trials contributing data from 12,829 women undergoing medical abortion up to 13 weeks gestation [48]. In the meta-analysis, 22% (95% CI, 18.8–25.5%) resulted in a surgical uterine evacuation; the odds of needing a surgical procedure decreased significantly as the amount of misoprostol in the initial dose increased and was lower in the trial groups that administered the dose vaginally, sublingually, or buccally compared with orally. Among groups receiving 800 mcg vaginally, surgical intervention occurred less commonly if women were permitted to take at least four doses, if they were taken over a period of 48 h, and if the tablets were moistened before vaginal insertion. Among 20 study groups comprised of 5338 women, which utilized at least 3 doses of misoprostol, with an initial dose of 800 mcg administered buccally, sublingually, or vaginally, the success rate (abortion without surgical intervention) was 87%.

Misoprostol-only medical abortion is associated with a low risk of complications: from the 38 trials included in the systematic review, 14 women were hospitalized, and 12 received blood transfusions, for an estimate of 0.2% rate of serious complications [48]. No death was reported in more than 12,000 women.

Beyond 13 weeks' gestation, misoprostol-only regimens continue to be both safe and effective with repeat misoprostol doses. The largest trial enrolled women from 13 to 20 weeks gestation in 7

countries, and found a fetal expulsion rate of 85% at 24 h and 94% at 48 h among those who had vaginally administered misoprostol [49]. The median time to fetal expulsion was 12 h (4.1–61.8 h) and parous women had significantly shorter abortion intervals. Other randomized trials with smaller sample sizes report abortion intervals between 10 and 15 h, and no difference in efficacy between vaginal and sublingual administration [50,51]. With a dosing interval of 6 h, compared with 3 h, the time to abortion is increased [52]. Major complications occurred in about 1% of women; in the largest trial of 681 women, 10 (1.5%) required a blood transfusion [49].

The value of choice between abortion methods

Contraindications to either medical or surgical abortion are few; therefore, most women will be eligible for either method throughout the first and second trimesters. Both methods can be provided in an outpatient setting, which further facilitates offering a choice. For medical abortion, as the gestational age progresses, some women may require an overnight stay but a recent study estimated its occurrence among only 11% of those undergoing abortion up to 18 weeks [53]. D&E can be safely provided as a day case, even when general anesthesia or deep sedation is used [22,54]. As the characteristics of the methods are markedly different, a woman's informed choice is the best decision-maker between surgical and medical abortion. Acceptability and satisfaction with the abortion process is greatest when women can choose between methods and receive their preferred method [2,55–58].

Characteristics of surgical abortion that are attractive to some are the short duration of the procedure, completion within an expected timeframe, low complication rate, and comfort with options for pain management during the procedure ranging from local anesthesia and oral analgesia to general anesthesia. Women who prefer medical abortion appreciate the characteristics of privacy – particularly in early gestations when women administer misoprostol and abort at home- the more natural-seeming process, which is akin to having a miscarriage, and avoiding an invasive procedure or administration of anesthesia [55,56,58]. In later gestations, medical abortion techniques allow seeing or holding the fetus after it is expelled, a wish some women have when the pregnancy is terminated for fetal indications [57,59].

Randomizing women between medical and surgical methods has been difficult given many women's strong preference for one method over the other; therefore, comparative trials are few and at least one was prematurely stopped because of slow enrolment [20,60]. The stronger preference in these studies has been for a surgical procedure, which women perceive as less painful, less psychologically traumatic, and faster [60,61]. In studies where women agreed to be randomized and acceptability assessed, higher satisfaction was reported with surgical abortion techniques over medical, primarily because of the length or volume of bleeding and pain associated with medical abortion [20,61–63]. In the most recent of such studies, 100% of those who were randomized to the D&E procedure reported they would choose it again when compared with 53% of those who were randomized to a medical abortion [61]. Additionally, significantly fewer women who had a D&E compared with medical abortion found the experience to be worse than expected. Given the strong preferences women may have regarding the characteristics of abortion techniques and the generally more positive experience women attribute to uterine aspiration and D&E when randomized to it, services should aim to provide both methods. Where trained providers or facility characteristics impede this ideal, referral mechanisms should be in place to best meet women's needs and preferences.

Conclusion

Abortion care is a fundamental part of women's reproductive health care. Surgical and medical abortion methods are safe and effective throughout the gestational age range wherein abortions are performed. Although risks increase with the gestational age of the pregnancy, rates of complications remain low and comparable between surgical and medical techniques. Women should be offered a choice between methods and receive the one they prefer.

Declaration of Conflict of Interest

Importance: Several medications have been used to achieve medical abortion in the first trimester of pregnancy. The most commonly used is the combination of mifepristone and misoprostol; however, different doses and routes of administration have been proposed.

Objective: The aim of this study was to summarize published data on the effectiveness, adverse effects, and acceptability of the various combinations of mifepristone and misoprostol in medical abortion protocols in the first trimester of pregnancy.

Evidence Acquisition: This was a comprehensive review, synthesizing the findings of the literature on the current use of mifepristone and misoprostol for first-trimester abortion.

Results: The combination of mifepristone and misoprostol seems to be more effective than misoprostol alone. Regarding the dosages and routes, mifepristone is administered orally, and the optimal dose is 200 mg. The route of administration of misoprostol varies; the sublingual and buccal routes are more effective; however, the vaginal route (800 μg) is associated with fewer adverse effects. Finally, the acceptability rates did not differ significantly.

Conclusions: Different schemes for first-trimester medical abortion have been described so far. Future research needs to focus on identifying the method that offers the best trade-off between efficacy and safety in first-trimester medical abortion.

Target Audience: Obstetricians and gynecologists, family physicians

Learning Objectives: After participating in this activity, the learner should be better able to discuss available combinations of mifepristone and misoprostol for first-trimester medical abortion; describe the recommended doses of misoprostol for first-trimester medical abortion; and assess the adverse effects caused by misoprostol when administered by different routes.

Early pregnancy failure and the associated induction of abortion are common complications in the first trimester of pregnancy, with a reported incidence of 15% to 20% of confirmed pregnancies.[1–4] In the last decades, medical abortion or medical management of missed miscarriage has emerged as an attractive alternative to surgical evacuation[5] and has a high level of patient acceptability without increasing the risk of infection.[4,6,7] To date, several guidelines recommend medical termination of pregnancy as a secure, efficient, and acceptable

option.[8,9] Furthermore, first-trimester medical abortion adds privacy and convenience to the procedure of abortion, is less invasive, and has a lower complication rate compared with the surgical approach.[10] Initially, regular prostaglandins and their analogs were used alone for medical abortion and resulted in a high rate of adverse effects and failure; therefore, there was a need of a new regimen that would optimize the effect, pending the use of mifepristone.[11]

The most broadly used prostaglandin for medical abortion is misoprostol. Misoprostol is a synthetic prostaglandin E_1 analog, originally established for the prevention and treatment of peptic ulcers; because of the uterine contractions that develop as an adverse effect, it is widely used in medical abortion, especially in the first trimester.[12] Misoprostol presents many advantages, including the fact that it is stable at room temperature, has fewer systemic adverse effects compared with other prostaglandins, and is inexpensive.[4,12–15] Misoprostol's uterotonic properties, including ripening and dilatation of the cervix and myometrial contractions, make it ideal for medical abortion, especially in developing countries because of its low cost.[4,16]

Mifepristone (previously known as RU 486) is a synthetic steroid with strong antiprogester-1 activity, originally established for its potential antiglucocorticoid activity.[4,17] Mifepristone's antiprogesterone activity on the decidua and myometrium[11] upsurges the production of endogenous prostaglandins by the endometrium, the sensitivity of the pregnant uterus to exogenic prostaglandins, the contractility of the myometrium, and the cervical softening and dilatation[16] and leads to decidual necrosis and uterine contractions, thus facilitating the medical abortion.[11] Initially, when mifepristone was used alone for first-trimester medical abortion, the success rate was relatively low (73%).[11] The finding that mifepristone can sensitize the myometrium to prostaglandins drove to the hypothesis that the combination of mifepristone and prostaglandins may provoke an enhanced effect on uterine contractions and, in turn, first-trimester medical abortion.[5,8,11,16,18–22] Therefore, mifepristone could be used to prime the myometrium and cervix before the use of a prostaglandin, to improve the success rate of medical abortion.[4] A series of studies have since found a high effectiveness and acceptability of mifepristone combined with misoprostol, for first-trimester abortion, using various routes and dosages; however, the optimal approach remains undetermined.[10,23–25]

The scope of this narrative review was to synthesize available data on the effectiveness, adverse effects, and acceptability of the various combinations of mifepristone and misoprostol in medical abortion protocols in the first trimester of pregnancy.

EVIDENCE ACQUISITION

The most relevant published studies on the combination of mifepristone and misoprostol for the first-trimester medical abortion were retrieved and analyzed, and a state-of-the-art review was conducted. An overview of the included studies is presented in Table 1, and a summary of best practices for first-trimester medical abortion is presented in Table 2.

COMBINATION OF MIFEPRISTONE AND MISOPROSTOL

The combination of mifepristone and misoprostol has been found to be the most effective for abortion than the use of misoprostol alone or the use of another regimen.[4,12,16,40–45] There is strong evidence supporting the use of mifepristone-misoprostol combination as an efficient regimen for medical abortion up to 70 days of gestation, and it has been approved by the US Food and Drug Administration.[20,46,47] On the other hand, there is no absolute lower gestational age limit.[46] Furthermore, failure of medical abortion in the first trimester of pregnancy (ongoing pregnancy or retained tissue) upturns with progressing gestational age through 70 days of gestation; patients should be informed for the possibilities of failure, particularly when the gestational age approaches 10 weeks.[47]

The use of 200 mg of oral mifepristone followed by 400 μg oral or 800 μg vaginal misoprostol for ≤49 or ≤63 days of gestation, respectively, is recommended by the World Health Organization.[48] The effectiveness of this combination ranges between 92% and 99% among women in the first trimester of pregnancy.[5,49] Chawdhary et al[10] found a success rate of 94% in the combination group (200 mg mifepristone, 800 μg misoprostol) versus 86% in the misoprostol alone group (total 1600 mg) for up to 63 days of gestation. Jain et al[50] compared the effect of 200 mg mifepristone combined with 800 μg vaginal misoprostol with that of 200 mg placebo in combination with 800 μg vaginal misoprostol (misoprostol doses were repeated if needed for up to 3 times). The success rate was higher in the first group (95.7% vs 88%; $P < 0.05$). In another similar study, the effectiveness was 83.8% in the combination compared with 67.1% in the misoprostol alone group; the difference referred to the outcome was noted after only 1 dose of misoprostol.[44] Blum et al[40] reported an efficacy rate of 92.9% of the combined regimen in contrast with 78% of the misoprostol-alone regimen; the ongoing pregnancy frequency in the misoprostol-only arm was 13.8%. In a study accomplished by Ngoc et al,[41] a success rate of 96.5% was estimated in the combination arm versus 76.2% in the misoprostol-only arm (relative risk [RR], 0.79; 95% confidence interval [CI], 0.73–0.86).

*Statistical significance found.
Mife, mifepristone; miso, misoprostol.

Importantly, the percentage of ongoing pregnancies in the first group was 16.6% compared with only 1.5% in the second group (RR, 1.62; 95% CI, 0.68–3.90).[41]

Moreover, regarding the need of additional surgical intervention, it is less common in the mifepristone pretreatment group than in the misoprostol-alone group (8.8% vs 23.5%).[44] Chu et al[45] found a 17% rate of surgical intervention for completing the abortion in the combination group and 25% in the placebo-misoprostol group (RR, 0.71; 95% CI, 0.53–0.95).

With regard to late first-trimester medical abortion, Dalenda et al[5] concluded that the combined regimen is as effective as the misoprostol-only regimen for medical abortion between 9 and 12 weeks of gestation; successful abortion occurred in 80.8% in the combination group and 77.4% in the misoprostol-only group ($P = 0.66$).

TABLE 2
Summary of the Best Practices for First-Trimester Medical Abortion

Parameters	Findings
Combination	• Mifepristone combined with misoprostol is the most effective.
Mifepristone dosage	• 200 mg oral, single dose • Lower doses for earlier gestations
Misoprostol route of administration	• The vaginal route is equally effective with the sublingual and buccal. • The vaginal route has the least adverse effects. • The oral route is the least effective and with most adverse effects. • The acceptability rates are almost the same.
Misoprostol dosage	• 800 μg for vaginal and sublingual • Second and third dose can amplify the effectiveness.
Administration intervals	• 48 h is widely accepted. • Flexibility can be effective too (24 or 48 or 72 h). • Simultaneous administration can be used for up to 49 d of gestation. • The acceptability rate has been found to be the same.

However, other studies that investigated late first-trimester medical abortions found a higher success rate in the combination groups: 94.6% in the study by Ashok et al[24] (10–13 gestational weeks) and 94.8% in the study by Hamoda et al[51] (64–91 days of gestation).

As for the adverse effects, misoprostol on its own is related to more adverse effects including fever, shivering, and gastrointestinal effects such as nausea, vomiting, and diarrhea; mifepristone has appeared to cause fewer complications.[5] Dalenda et al[5] emphasized the higher occurrence of abdominal pain in the misoprostol-only arm (71.4% vs 43.8%), probably due to the fact that misoprostol was used in a higher dosage to achieve successful results. On the contrary, Chu et al[45] found no difference in the presence of adverse effects, as did Ngoc et al,[41] except for the higher rate of diarrhea reported by the women in the misoprostol-only regimen group. One of the most significant adverse effects in medical abortion, which could also affect acceptability, is the longer duration of bleeding.[10] Nevertheless, the incidence of heavy bleeding resulting in blood transfusion is rare in both the combined and misoprostol-only regimens (2% vs 0.7%, respectively).[44] Regarding patient acceptability, both the combined and misoprostol-only groups seem to be acceptable for medical abortion (75.5% and 75.7%, respectively).[5] Moreover, Wiebe[52] showed that privacy of aborting at home and emotional support are very important for women (71.3% and 61% acceptability, respectively). In another report, 91.3% of patients who underwent medical abortion were satisfied with the method and would choose it again.[49]

Overall, although mifepristone is a more expensive drug compared with misoprostol, the higher success rate of the combined regimen leads to reduced overall time spent on the process of abortion (time off work, office visits, need of surgical management for ongoing pregnancies), which in turn results in a significantly reduced cost.[22]

It seems that the combination of mifepristone and misoprostol presents with advantages and is the criterion standard for first-trimester medical abortion, at least in high-income countries where mifepristone is available.

MIFEPRISTONE DOSAGE

Several studies have shown that 200 mg of mifepristone is as effective as 600 mg.[11,53] Moreover, a Cochrane review found that both 600 and 200 mg of mifepristone are equally effective in aborting during the first trimester (90.8% and 91.4%, respectively).[20] In a large study including 45,528 women, the use of 200 mg mifepristone followed by misoprostol achieved a complete abortion rate of 95.2%.[54] This equal effect of the 2 dosages may be due to the fact that after ingestion of either 200 or 600 mg, there is no difference in the peak concentration of serum mifepristone, possibly because mifepristone is bound to aracid glycoprotein.[53] Apart from the efficacy using 200 mg of mifepristone, it is also very practical as each tablet of mifepristone consists of 200 mg of mifepristone.[11] Following the finding that 200 mg of mifepristone was equally effective as 600 mg, some studies investigated the possibility that an even lower dose could be as effective. A systematic review compared 150 versus 200 mg of mifepristone (both combined with misoprostol) and found no difference in the efficacy (RR, 0.98; 95% CI, 0.96–1.01) or in the induction to expulsion time and the blood loss (mean difference, 0.01; 95% CI, 0.29–0.27; and 0.05; 95% CI, 0.23–0.32, respectively) between the groups.[55] A trial conducted in women at 63 days of gestation compared the efficacy of 100 versus 200 mg of mifepristone (each group additionally took 800 μg of misoprostol); there was no difference in the complete abortion rate (92.0% vs 93.2%; 95% CI, −1.0 to 3.5) or the incidence of adverse effects.[49] Creinin et al[56] evaluated the efficacy of 100 mg of mifepristone and reported that it is highly dependent on the dosage and route of administration of misoprostol. Moreover, in a study comparing 75 versus 150 mg of mifepristone in pregnancies up to 49 days of gestation, there was no significant difference in the rates of complete abortion (95.4% vs 96.3%).[57] Another study concluded that the use of 75 mg mifepristone followed by 400 μg misoprostol is effective (98.2%) in achieving abortion in up to 35 days of gestation.[58] Li et al[58] suggested that, for up to 35 days of gestation, lower doses of mifepristone

(50 or 75 mg) followed by a lower dose of misoprostol (200 μg oral misoprostol) are also effective and safe as higher doses; they also reported that lower doses of mifepristone and misoprostol lead to reduced adverse effects including bleeding.

Mifepristone is currently recommended at a single dose of 200 mg as this is as effective as the original 600-mg regimen. A lower dose may also be effective in earlier gestations, before 49 days; however, more studies are needed.

MISOPROSTOL ROUTE OF ADMINISTRATION

Several routes of misoprostol administration have been studied to date, including oral, vaginal, sublingual, and buccal (Table 1).

Oral Versus Vaginal

The vaginal application of misoprostol is widely accepted, and the use of 200 mg oral mifepristone followed by 800 μg of vaginal misoprostol 36 to 48 h later is the most commonly used combination regimen, with a reported success rate of 90% to 95%.[24,31,53,59] Oral misoprostol has been found to be less effective in medical abortion and leads to more adverse effects compared with vaginal misoprostol.[26,31] When pharmacologically comparing oral and vaginal administration of misoprostol, the oral route leads to a more rapid absorption and higher peak levels.[13] Moreover, Zieman et al[60] reported a 3 times higher systemic bioavailability of vaginally administered misoprostol compared with that of oral misoprostol. This may be explained by the finding that, although the vaginal route achieved slightly lower peak plasma levels and they developed more slowly, they were persistent for longer, up to 4 hours.[61] Another study compared vaginal (800 μg) with oral misoprostol (800 μg) regarding their efficiency in aborting a pregnancy of up to 63 days (both groups initially received 600 mg of mifepristone) and found higher efficacy (95% vs 87%; $P = 0.03$) and fewer adverse effects in the vaginal group.[26] In similar studies, von Hertzen et al[28] found that women in the oral group had nearly 3 times higher risk of failure than women in the vaginal group (RR, 2.8; 95% CI, 1.3–5.8), and Schaff et al[27] showed the superiority of vaginal misoprostol over 2 regimens of oral misoprostol (400 and 800 μg) for pregnancies up to 9 weeks, also suggesting that a repeated dose of misoprostol is safe and contributes to a better efficacy rate when needed. Accordingly, von Hertzen et al[28] found that a twice-daily repeated dose of 400 μg oral misoprostol increases the efficacy of the regimen, but at the cost of increasing the presence of adverse effects (diarrhea).

Regarding adverse effects, in one study, the incidence of fever, nausea, and vomiting is less with vaginal than with oral administration, but no differences were found in the presence of diarrhea and abdominal pain.[55] However, in another study by Arvidsson et al,[29] nausea was present in 47.9% of the cases in the oral group compared with 34.7% of the vaginal group, and vomiting incidence was double in the oral group (22.9% vs 10.2%). Arvidsson et al[29] also investigated the severity of associated pain by using the VAS assessment method and concluded that there is no statistically significant difference between the oral and vaginal groups. Similarly, regarding the associated bleeding, a series of studies found that it starts within 24 hours after using either oral or vaginal misoprostol with no reported difference in the duration or the quantity.[27,29,55]

With regard to acceptability, it was found higher in the oral group because of its practicality and the avoidance of uncomfortable vaginal examination.[62] Similarly, Arvidsson et al[29] found that 76% of women in the oral and 48% of women in the vaginal group would prefer an oral route in a possible future medical abortion procedure; of note, 4% of women in the vaginal compared with 7% of the women in the oral group would never choose medical abortion again.

The comparison between the vaginal and the oral route shows that the former is more effective and with fewer adverse effects; however, the oral route seems more acceptable to women.

Sublingual Versus Vaginal

In terms of efficacy and safety, researchers have also assessed the possibility of the sublingual route of misoprostol in first-trimester medical abortion (600–800 μg).[63] The sublingual route is more convenient, and dialysis could be easily observed in contrast to vaginal misoprostol.[12,31] Therefore, it can be easily taken at home.[31] Regarding pharmacokinetics, the sublingual route has the briefest onset of action and the highest peak concentration and bioavailability compared with oral and vaginal misoprostol.[12] Tang et al[31] studied the effectiveness of sublingual and vaginal misoprostol in pregnancies up to 9 weeks and found 98.2% (95% CI, 93%–99%) of complete abortion in the sublingual compared with 93.8% (95% CI, 88%–97%) in the vaginal group; this difference was not statistically significant as the study population was too small. Von Hertzen et al[33] reported that the sublingual route causes stronger uterine contractions after a shorter time interval compared with the vaginal group; it may thus lead to a shorter interval to abortion and probably a higher efficacy at later gestational weeks.

Moreover, the rates of adverse effects seem to be higher in the sublingually treated women (gastrointestinal, chills,

and fever).[31,32] However, the satisfaction rate was reported to be similar to that of the vaginal group[33]; both 800 μg sublingual and 800 μg vaginal misoprostol had a similar complete abortion and acceptability rate, although vaginal misoprostol was related to fewer adverse effects.[33] Based on these findings, the authors concluded that, if there is no special preference on the route, the optimal seems to be the vaginal.[33]

The comparison between the vaginal and the sublingual route shows a similar effectiveness and satisfaction rate and a higher rate of mostly mild adverse effects in the sublingual route. The latter may offer some advantages in later gestations; however, more studies are needed.

Oral Versus Sublingual

Fekih et al[35] found a complete abortion rate of 94.5% in the oral versus 92.1% in the sublingual group ($P = 0.7$). Moreover, Dahiya et al[12] found a rate of 95.5% complete abortion in the sublingual and 87.5% in the oral group, in pregnancies up to 56 days of gestation ($P = 0.166$; 95% CI, −0.194 to 0.033); both the rates of ongoing pregnancies and of adverse effects were higher in the oral group. Another study showed that the efficacy was similar in both sublingual and oral groups.[55]

The published data seem to favor the sublingual route over the oral one because the former has at least equal effectiveness and fewer adverse effects.

Buccal Versus Sublingual

With regard to the buccal route of administration of misoprostol, several studies compared its efficacy with that of other routes. The comparison of pharmacokinetics of sublingual and buccal misoprostol showed that the sublingual route achieved higher bioavailability and peak plasma concentration but also higher incidence of adverse effects, as well as lower acceptability.[27,36] Raghavan et al[36] showed that there is no difference in the efficacy (97%) achieved by both the sublingual and the buccal route after mifepristone administration (up to 63 days' gestation), which is in accordance with the results presented by other researchers.[31,34,36–38,64]

As for adverse effects, both sublingual and buccal routes are associated with low rates of adverse effects, with no disparity found between the 2 routes except the higher incidence of chills and shivering among women in the sublingual group.[36,37]

Overall, based on the studies published comparing the buccal and the sublingual route, it seems that there is no clear advantage of the one over the other.

Buccal Versus Oral

Winikoff et al[34] compared buccal versus oral misoprostol and demonstrated that the buccal route (96.2%), administered after mifepristone, is more effective in aborting late first-trimester pregnancies (57–63 days) than the oral route (91.3%) (RR, 0.95; 95% CI, 0.92–0.98). These results are in accordance with previous research.[27,28,30,34,53]

When comparing the adverse effects of buccal versus oral misoprostol, both are found to be acceptable and similar, except for the higher levels of fever and chills found in women taking buccal therapy.[34]

The buccal route seems to be more effective than the oral route, with similar acceptability and safety profile but a possible higher incidence of mild adverse effects.

Buccal Versus Vaginal

Compared with vaginal (93%), buccal administration of misoprostol (95%) has the same efficacy rates ($P = 0.51$).[38] In addition, no differences were found in adverse effects, except for a higher incidence of diarrhea, chills, nausea, and altered taste, which are more common after administering buccal than vaginal misoprostol.[38,39] The overall satisfaction rate was almost similar in the buccal (100%) and vaginal (92%) groups.[38,39]

Based on limited data, the buccal route offers similar effectiveness and satisfaction to the vaginal route, with a possible higher incidence of mild adverse effects.

MISOPROSTOL DOSAGE

Regarding the dosages of vaginal and sublingual routes, using 400 μg in either route led to a higher risk of failure of complete abortion and higher incidence of ongoing pregnancies compared with 800 μg and therefore should not replace the regimen of 800 μg (sublingual or vaginal).[33]

Furthermore, women who received 800 μg of oral misoprostol (2 doses of 400 μg) had a lower rate of ongoing pregnancies in comparison with women who took only 400 μg.[65] Schaff et al[27] found a complete abortion rate of 84% in the 400 μg oral misoprostol group and 92% in the 800 μg oral misoprostol group, which increased after a second dose to 91% and 95%, respectively ($P < 0.001$). In another study that considered different dosages of misoprostol, a similar rate of complete abortion was identified between 800 μg (95%) and 400 μg twice (92%) of oral mifepristone.[66] The women in the single 800-μg-dose group had higher rate of diarrhea (33%) than those in the sequential dose of 400-μg-dose group (22%; $P = 0.05$).[66] Shannon et al[30] compared 400 μg with 600 μg of oral misoprostol and found no difference in the complete abortion rate (94.7% vs 93.4%; $P = 0.975$) and the adverse effects caused.

A dosage of 800 μg of buccal misoprostol was effective for first-trimester medical abortion.[34,42] Moreover, Chong et al[42] suggested that a dose of 400 μg of buccal misoprostol is equally efficacious to the commonly used dose of 800 μg in aborting pregnancies up to 63 days. Raghavan et al[36] found that the combination of mifepristone and 400 μg buccal misoprostol achieved a 97.1% complete abortion rate. Furthermore, a dose of 400 μg buccal misoprostol, besides being equally effective, is more practical (as it consists of only 2 pills of misoprostol) and acceptable and causes fewer adverse effects than 800 μg of buccal misoprostol (nausea: 75.1% vs 54.1%, vomiting: 47.6% vs 22.2%, headache: 41.1% vs 17.7%, fever/chills: 47.6% vs 18.0%).[36,42]

Notably, the administration of a second or, if needed, a third dose of misoprostol was found helpful in achieving complete abortion and has led to an increase of the success rate to approximately up to 98%.[24,67–69] Ashok et al[24] found that approximately 30% of women at 70 to 83 days of gestation needed a second dose of misoprostol to complete the abortion procedure.

Overall, there is not enough evidence to support the reduction of the commonly used dose of 800 mg of misoprostol by any of the routes. However, some of the studies show that lower doses may be associated with equal effectiveness and fewer adverse effects, especially when using the buccal route.

ADMINISTRATION INTERVALS

The most widely used interval time between mifepristone and misoprostol administration is 48 hours and is the one approved by the US Food and Drug Administration.[70] Researchers have investigated shorter time intervals in search of an equally effective, more convenient, and faster regimen with minor adverse effects. Thus, von Hertzen et al[49] found an efficacy rate of 93.5% in the 24-hour interval group compared with 91.7% in the 48-hour-interval group (95% CI, −4.0 to 0.5). Another study determined that the interval can be reduced from 48 to 24 hours when mifepristone was followed by 800 μg vaginal misoprostol, while keeping the same efficacy, supporting the initiation of a more flexible interval time.[71] Heikinheimo et al[69] assessed the alteration from a 48-hour fixed interval to a 24-, 48-, or 72-hour flexible one in first-trimester medical abortion and concluded that there was no significant difference (94.9% vs 94.4%). In addition, Hekinheimo et al[69] found approximately 9% increase in medical abortion acceptance, when flexible intervals were used. Basu et al[72] found that a 72-hour interval had a higher efficacy rate (98.2% vs 94.2% vs 97.2%) after administration of mifepristone alone, and there was a trend to require fewer doses of misoprostol than the 24-/48-hour intervals.

Regarding intervals less than 24 hours, Guest et al[73] studied a 6-hour interval and found lower efficacy compared with the 36- to 48-hour-interval group (79% vs 92%). On the contrary, Creinin et al[74] found an equal efficacy rate in the 6- to 8-hour and the 23- to 25-hour groups (95.8% vs 98.1%). As for the pharmacokinetics, both oral mifepristone and vaginal misoprostol achieve peak plasma concentrations in 1 to 2 hours, but the sensitization to prostaglandins occurs 36 to 48 hours following mifepristone administration.[75,76] Several studies also evaluated the simultaneous administration of mifepristone and misoprostol, with varying efficacy rates of 90% to 98%.[50,76–78] Creinin et al[68] reported that the simultaneous administration offered a 95.1% efficacy compared with 96.9% in the 24-hour-interval group, supporting the noninferiority of one regimen over the other ($P = 0.003$). In another study, an efficacy rate of 94.5% was achieved in the simultaneous compared with 97.1% in the 24- to 48-hour-interval group,[79] which is in accordance with the findings by Goel et al. (95% vs 97.5%; $P = 0.56$).[70] Furthermore, Murthy et al. studied the simultaneous administration of the regimens for up to 49 days of gestation and found a complete abortion rate of 90%.[78] Similarly, Schreiber et al. studied the efficacy rates for pregnancies up to 63 days of gestation and found that expulsion occurred in 93% of women at 50–56 days and in 90% of women at 57–63 days of gestation after simultaneous administration.[77] Li et al, found 92.6% success rate when misoprostol was administered simultaneously.[80]

Regarding adverse effects in the different interval groups, studies have shown a time dependent correlation following mifepristone. More specifically, bleeding occurred in 55% in the 48-hour group,[81] 8% in the 24-hour group,[82] 5% in the 6 to 8-hour group[83] and minimal in the simultaneous group.[78] The duration of bleeding in the study by Chen et al., was the same between the groups of 6 to 8 and 24 hours.[84] Other adverse effects like nausea, vomiting and diarrhea were found significantly lower in the simultaneous group compared with the commonly used 24 and 48-hour interval.[56,68,74] These findings may be explained by the fact that the shorter the interval the lower the sensitivity to misoprostol and as a result fewer adverse effects related to misoprostol occur.[21] On the other hand, Goel et al[70] found no difference in the incidence of adverse effects between different intervals (simultaneous and 24-hour interval). With regard to pain occurrence, there was no difference between the various interval groups.[70]

Satisfaction rates differed in various studies; Guest et al[73] found a higher acceptance rate (97%) among

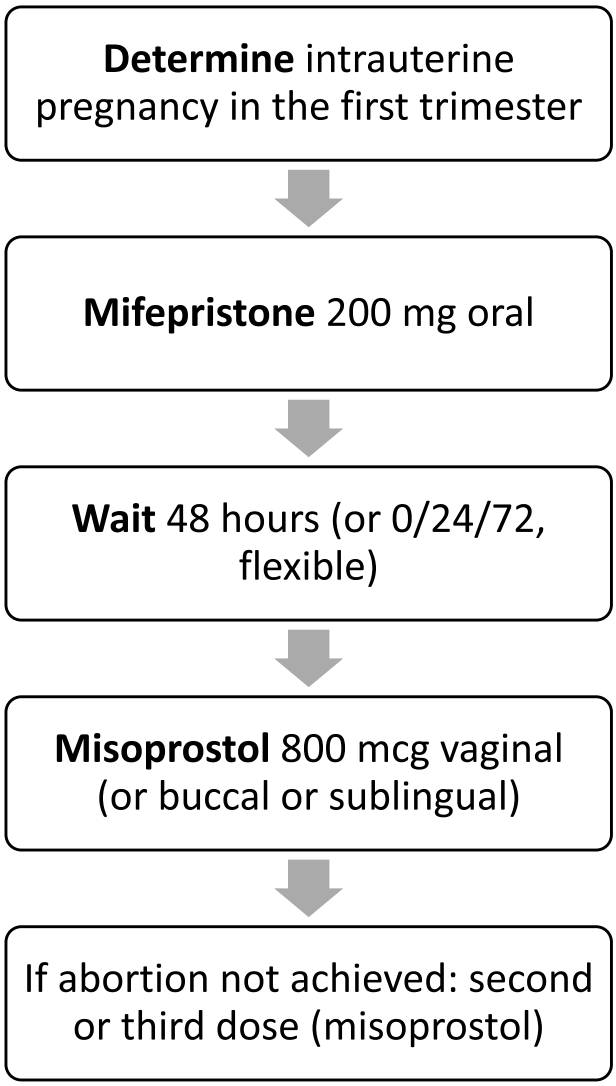

FIGURE 1. Suggested protocol for first-trimester medical abortion.

women in the lower interval (6 hours) compared with the 36- to 48-hour group (90%). Moreover, Schaff et al[67] found satisfaction rates of 86%, 79%, and 76% in the 24-, 48-, and 72-hour groups, respectively. Goel et al[70] found a similar acceptability rate between the different interval groups.

Overall, although this issue is far from resolved, there is some evidence that the shorter interval of administration may not significantly affect the effectiveness and may be associated with fewer adverse effects and a higher satisfaction rate.

CONCLUSIONS

To summarize, there are multiple ways to achieve medical abortion, but (i) the most popular and widely approved is the combination of 200 mg oral mifepristone followed by 800 μg vaginal misoprostol; (ii) the vaginal route is generally not preferred by women, and the buccal and sublingual routes have advantages compared with the originally used oral approach; and (iii) the most widely used interval time between mifepristone and misoprostol administration is 48 hours (Fig. 1). Of note, the dosage of mifepristone and misoprostol and the time intervals are not fully investigated, and there is some evidence that different gestations may require different regimens. It seems that more research is needed, and as in many cases, differences in effectiveness and adverse effects are not large; women's preferences, clinicians' familiarity, and logistics may allow for different regimens to be applied.

Abstract

Context: Direct-to-patient telemedicine abortion allows people to receive mifepristone and misoprostol for medication abortion in their home without requiring an in-person visit with a healthcare provider. This method has high efficacy and safety, but less is known about the person-centered quality of care provided with telemedicine.

Methods: We interviewed 45 participants from the TelAbortion study of direct-to-patient telemedicine abortion in the United States from January to July 2020. Semi-structured qualitative interviews queried their choices, barriers to care, expectations for care, actual abortion experience, and suggestions for improvement. We developed a codebook through an iterative, inductive process and performed content and thematic analyses.

Results: The experience of direct-to-patient telemedicine abortion met the person-centered domains of dignity, autonomy, privacy, communication, social support, supportive care, trust, and environment. Four themes relate to the person-centered framework for reproductive health equity: (1) Participants felt well-supported and safe with TelAbortion; (2) Participants had autonomy in their care which led to feelings of empowerment; (3) TelAbortion exceeded expectations; and (4) Challenges arose when interfacing with the healthcare system outside of TelAbortion. Participants perceived abortion stigma which often led them to avoid traditional care and experienced enacted stigma during encounters with non-study healthcare workers.

Conclusion: TelAbortion is a high quality, person-centered care model that can empower patients seeking care in an increasingly challenging abortion context.

INTRODUCTION

In the United States, over half of abortions are now medication abortions.[1] Medication abortion with mifepristone and misoprostol is a safe and effective method to end a pregnancy that offers the advantage of not needing the healthcare provider and patient to be in the same space.[2] The simplicity of medication abortion lends itself to telemedicine adaptation since patients already may take the medications at home. Telemedicine has expanded from medication pickup at a clinic distant from the provider to completely remote models with

 © 2022 University of Ottawa.

medications delivered by mail.[3,4] The challenges of providing abortion care during a global pandemic accelerated the adaptation of telemedicine for medication abortion.[5,6]

Recent evidence shows similar safety and efficacy of medication abortion when the medications were dispensed by mail, rather than in-person, with or without pre-abortion ultrasound.[7–9] The Gynuity TelAbortion project was the first to offer direct-to-patient telemedicine abortion in the United States, with patients receiving medications by mail after videoconference counseling.[10] Of 1157 abortions, 95% successfully completed a medication abortion; 85% of participants were very satisfied with the service, with 97% willing to recommend TelAbortion to a friend.[11]

The person-centered quality of care provided via direct-to-patient telemedicine abortion has not been evaluated as extensively as the efficacy. The Institute of Medicine and World Health Organization (WHO) name person-centeredness as one element of quality care.[12,13] Limited quality markers for abortion care that focus on patient experience exist beyond satisfaction, which typically is high since patients receive the care they present for, but fails to capture nuances of the care.[14,15] The person-centered framework for reproductive health equity (PCFRHE) is one model that emphasizes eight domains: dignity, autonomy, privacy/confidentiality, communication, social support, supportive care, trust, and health facility environment (Table 1).[16] These are placed into context of broader societal and community determinants of health equity, health seeking behaviors, and facility level factors, and can be used as outcome measures in evaluating reproductive healthcare, including TelAbortion.[16,17]

An important societal determinant of reproductive health that impacts person-centered outcomes is abortion stigma, a social phenomenon that ascribes negative attributes to someone seeking an abortion and "marks them as inferior to the ideals of womanhood" (p. 628).[18] In essence, seeking an abortion is seen as violating social expectations, for which people are discredited or discriminated against.[19] Abortion stigma can be further broken down into perceived stigma, or how people expect others will think of them; internalized stigma, like feelings of guilt or shame about having an abortion; and enacted stigma, overt discrimination.[20] Stigma motivates people seeking abortion care to keep it concealed.[21] Telemedicine abortion is unique in that it offers a level of privacy not possible for patients going into a clinic.

Evaluating direct-to-patient telemedicine abortion from a person-centered angle gives insight into patients' values and how all abortion care can be more responsive to patient needs beyond increasing access.[22] TelAbortion provides an ideal example of direct-to-patient telemedicine abortion as it started before and evolved during the COVID-19 pandemic, operated through sites in states with differing abortion access, and was designed to mirror standard abortion care.[11] Qualitative analysis allows for exploration of the entire abortion experience, including abortion stigma, and offers insight into ways to improve abortion care while highlighting the unique impact of telemedicine.[23] By framing our data within the eight domains of the PCFRHE, we aim to show that the experience of TelAbortion is person-centered care and can be a model for other direct-to-patient telemedicine abortion care.

TABLE 1 Definitions of the person-centered outcomes from the person-centered framework for reproductive health equity (adapted from Altshuler and Whaley[17] and Sudhinaraset et al[16])

Dignity	Receiving care in a respectful and caring setting
Autonomy	Supporting people in making their own healthcare decisions
Privacy/confidentiality	Ensuring privacy in the setting where care is provided and confidentiality in records
Communication	Explaining the condition and treatment clearly, providing information that is understandable
Social support	Allowing the companion of the patient's choice to be part of the care
Supportive care	Integrating care to be supportive of all the patient's needs, including pain control
Trust	Providing care that is truthful, ensuing patients are comfortable with their provider's competence
Environment	Offering a welcoming environment, including the full continuum of care

METHODS

We performed qualitative content and thematic analyses of semi-structured participant interviews to evaluate patient experiences of TelAbortion. The University of Hawai'i Institutional Review Board (#2019-00799) granted ethics approval.

Participant selection

We recruited participants from the Gynuity TelAbortion study in the United States who completed a medication abortion by mail without in-person interaction with a clinic. The TelAbortion study operated from existing abortion clinics, some of which had providers licensed in multiple states and therefore provided telemedicine in those states. Patients contacted a participating site and were offered TelAbortion or in-person care, or specifically contacted the clinic after finding out about TelAbortion from its website. If required by their provider, they obtained testing for Rh(D) type and an ultrasound. The ultrasound was often obtained from a healthcare provider in their community unaffiliated with the abortion clinic, typically facilitated by their TelAbortion provider. Participants underwent videoconference counseling with a provider from their site, and if eligible, were mailed the medications to take at home with 1–2 follow-up contacts.[10] Pre-abortion testing and the cost of the abortion were determined per the sites' usual medication abortion protocols and were not covered by the study. Each site slightly varied in how they implemented TelAbortion to fit into their existing abortion protocols.[11]

Case 6:25-cv-01491-DCJ-DJA Document 54-10 Filed 02/03/26 Page 42 of 239 PageID #: 3278

During the routine exit questionnaire, sites asked participants if they would be willing to be contacted for future research, then referred those patients to this study. Seven of the eight sites providing TelAbortion in January 2020 referred participants from eight states: two in the East (Maryland, New York), one in the South (Georgia), two in the Midwest (Illinois, Minnesota), and three in the West (Colorado, Hawai'i, Oregon). At the time of the study, the political landscapes in Georgia and Colorado were considered neutral or hostile to abortion care and access.[24]

We contacted interested participants up to three times to schedule an interview. We included English-speaking participants over age 18 who completed a TelAbortion in the previous six months. We capped recruitment at 10 participants per site to maintain geographic diversity, which was important to capture experiences from states with varied availability of abortion clinics and hostility toward abortion.

The initial protocol aimed for 40 participants recruited or until thematic saturation was reached. Because the COVID-19 pandemic started during the data collection timeframe, we increased our recruitment goal to explore the impact that the pandemic had on TelAbortion experiences.

Data collection

Introducing herself as a researcher from the University of Hawai'i, CK conducted semi-structured telephone interviews between January and July 2020. Questions focused on seeking abortion care, sources of information, barriers to abortion care, expectations for care, the abortion process, and ideas for improvement. Interviews lasted 30–75 min. Participants gave oral consent prior to starting the interview and received a $50 gift card to an online retail store for remuneration. We modified the interview guide throughout the interview process iteratively and added additional questions relating to the pandemic after its onset. We wrote notes after each interview and documented research team discussions in memos throughout the course of interviewing. We audio-recorded interviews and had them professionally transcribed verbatim.

Data analysis

Four team members (CK, JE, RD, RS), including two complex family planning physicians and two public health researchers, met regularly to discuss the interview transcripts as the interview process was ongoing, modify the interview guide as needed, and develop a codebook. We developed codes inductively from interview data and categorized them. Once interviews were complete, we further revised the codebook to be comprehensive and eliminate duplicate concepts. Two researchers coded each interview and one researcher coded all interviews. We compared coding between the study team members and resolved discrepancies with the full team. We used ATLAS.ti version 8.4.5 (ATLAS.ti GmbH, Berlin, Germany) for qualitative data management and coding. We use pseudonyms for the quotes presented to preserve confidentiality.

We identified themes with an iterative process using qualitative content analysis, a flexible, reflective, repetitious approach that examines common language, experience, and ideas.[25,26] Triangulation with memos written throughout the interview process and citation of verbatim evidence in this text confirm the credibility of the themes that emerged. Although we did not use PCFRHE to generate the interview guide, develop the codebook, or identify themes, we drew on the PCFRHE to organize the themes and contextualize our findings because person-centeredness emerged as a primary focus of the interviews.[16] This manuscript concentrates on the patient experience of TelAbortion; we presented themes relating to access to abortion care in a separate publication.[22]

RESULTS

We interviewed 45 participants who completed a TelAbortion, 23 prior to March 2020, the start of the COVID-19 pandemic in the United States and 22 after the onset. Study sites referred 124 people; we did not contact 28 due to saturation from their study site, 40 did not respond, eight were no longer interested in participation, two had scheduling conflicts, and one was under age 18 and therefore ineligible. The sample was diverse in age, race/ethnicity, and geography, with a median age of 29. Eighteen (40%) had a prior abortion (Table 2).

The patient experiences of TelAbortion encompassed the PCFRHE outlined by Sudhinaraset et al (Figure 1).[16] With the four themes that emerged, each person-centered outcome was represented as well as the interconnected societal and community determinants of health and health seeking behaviors. Abortion stigma, depicted at the highest level of the PCFRHE, was a thread throughout each of the themes, impacting how participants perceived TelAbortion and their expectations for abortion care, why they preferred staying at home versus going to a clinic, and their lived experiences of interacting with healthcare outside of TelAbortion. Every participant had some interaction with abortion stigma, whether from their personal complicated beliefs about abortion, the beliefs of their family or community, having a sense that they may be judged for their abortion and needed to keep it private, or by being discriminated against because they were having an abortion.

Participants felt well-supported and safe with TelAbortion

Across all sites, participants overwhelmingly reported feeling well-supported throughout their abortion process which created a sense of safety. Three of the person-centered outcomes contributed to the sense of support and safety: communication, supportive care, and environment.

Communication with the TelAbortion study team was frequent and thorough, which many participants noted gave them confidence

*Nine participants reported more than one race, so percentages do not add up to 100%.

in the process. In addition to oral communication, many participants appreciated written instructions which contributed to their sense of preparedness and therefore safety.

> I felt really safe…I got so much information in the video call. I did jot some things down, but I still thought like, "Oh, gosh, what if I can't remember when to take this and when to take that." And when the packet came, it was just so full of information, and everything was very clearly laid out. It was like, "Call here if you have an emergency." I felt very safe and very much if something went wrong, I would have help readily available. (Jeanne 40-year old, Illinois)

Most participants did not require any additional care beyond the standard TelAbortion protocol. For the three participants who did require further medical care, they felt like their care team continued to support them.

> I love everybody I spoke to. Even when I went to the downtown area for the D&C [dilation and curettage], the doctor…was very nice. She joked with me. I was like, "I'm dying." She was like, "No." So we joked and stuff. [The team] made me feel comfortable like we'd known each other, not just over a phone, not just over this abortion, but like you've been my doctor for a couple of years, and you know my background. (Amira, 30-year old, Georgia)

TelAbortion provided well-rounded supportive care through providing information for financial resources, giving patients pain medications, sending adjuncts like heating pads and tea, and being responsive to any concerns that arose during or after taking the medications.

> It was super convenient having it ship to your house, and especially everything that they added in it. They put some ibuprofen in there, and they put some condoms in there, they put a heating pack in there. Those little details put you at ease. (Shannon, 37-year old, Illinois)

By recognizing the challenges of obtaining care at a physical clinic and helping patients overcome them by providing an alternative, TelAbortion providers were perceived as highly supportive by many participants. Participants could stay in their home and manage the entire process in an environment in which most participants felt comfortable, which eased the other challenges associated with having a medication abortion.

A fundamental difference between traditional abortion care and direct-to-patient telemedicine abortion is the lack of an in-person interaction with the medical provider. Participants had mixed feelings about not being seen in-person, with some noting initial apprehension. Most participants did not comment on any concerns once they went through the experience. Some even thought it was beneficial not to be face-to-face, allowing them additional anonymity.

> It can be a touchy subject for some people to talk to about. They can feel like they're being judged or looked down upon by sitting in a small office. Being on the phone, I'm like, okay, you're in your safe place, you feel okay. Because at the end of the day, if I didn't want to continue, I could have just hit the End button, and then that's it. It's done. (Sarah, 27-year old, Hawai'i)

Difficulties with mailing delays for the packages and occasional challenges with video connections for the video visits were rare but did occur. Most participants reported that they were well supported by their providers, who stayed in communication and helped resolve these issues. Likewise, participants felt well-equipped to take the medications at home with remote medical supervision. TelAbortion offered person-centered communication and supportive care in a comfortable environment, their home.

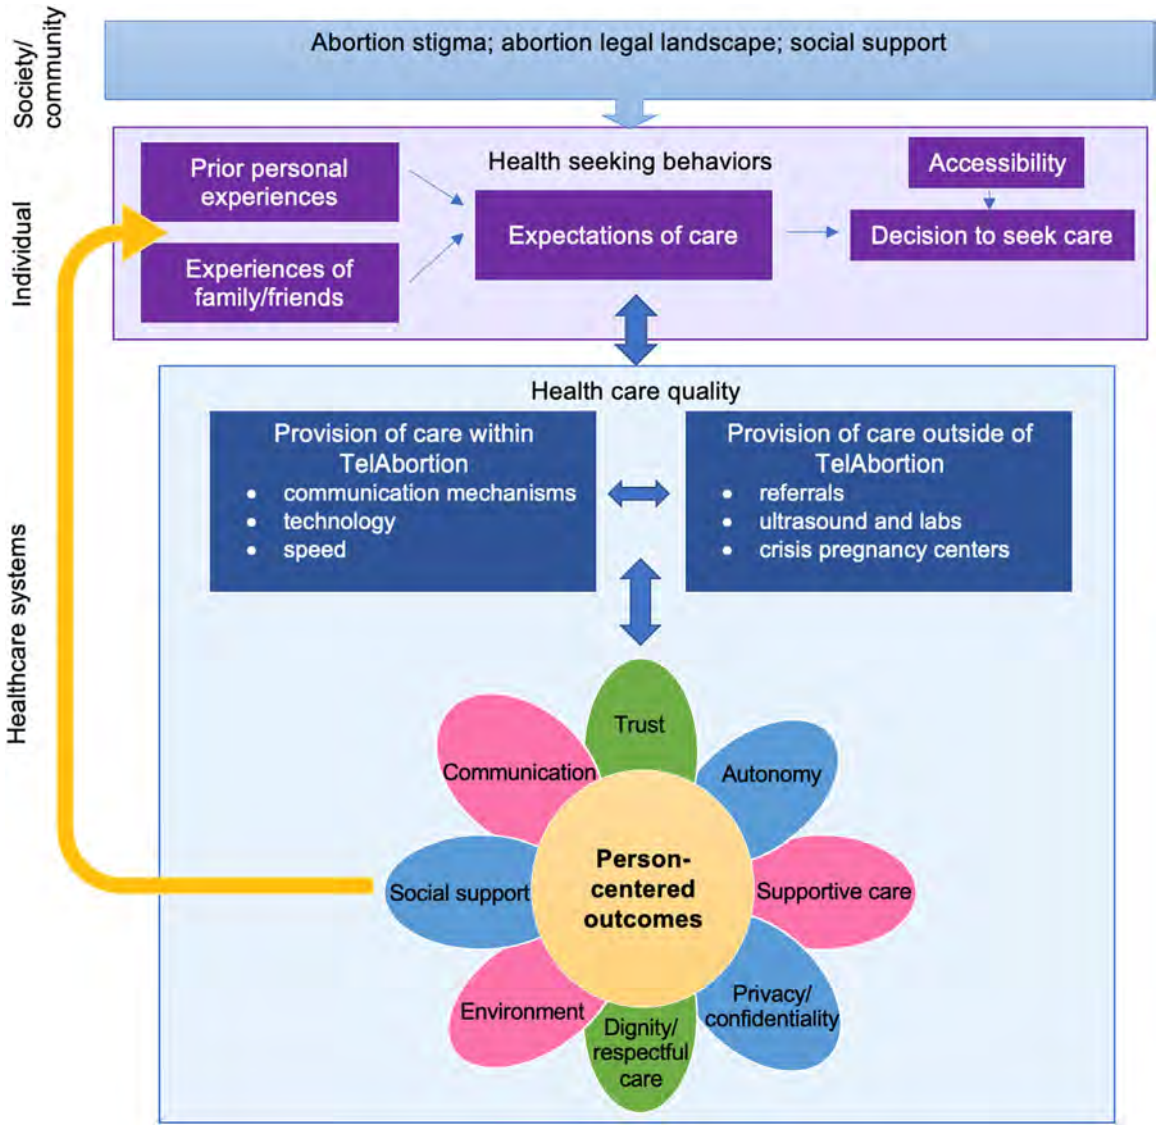

FIGURE 1 Adaptation of the person-centered framework for reproductive health equity (Sudhinaraset et al)[16] for telemedicine. Pink: Participants felt well-supported and safe with TelAbortion; Blue: Participants had autonomy in their care which led to feelings of empowerment; Green: TelAbortion exceeded expectations

Participants had autonomy in their care which led to feelings of empowerment

TelAbortion presented participants with an opportunity to take ownership of their care during a time when they often started by feeling powerless. Nearly all participants commented on how easy the process was once they had found TelAbortion. Being able to plan their visits and take the medications around their own schedule, without missing work or needing additional childcare contributed to the ease. Staying at home also allowed participants to control who was present when they went through the process. Many participants were concerned with a loss of privacy if they had gone into a clinic, so having their abortion entirely at home eliminated this concern. This autonomy meant they could ensure their privacy and involve the social support persons that made them feel most comfortable.

For many participants, completing the abortion quickly was imperative. They identified three main reasons for this urgency: (1) concerns about not being eligible for medication abortion if they waited longer; (2) fears about abortion not being safe later in pregnancy; and (3) emotional and physical difficulties with continuing to be pregnant. TelAbortion often expedited the process so participants received their medication package before they would have had an in-person appointment. They could choose to take medications when it worked best for them, rather than relying on a clinic schedule. Whether it was taking extra time for an intentional process or taking the medications as soon as they arrived in the mail, participants made this decision based on their own needs.

> It was on my own time when I was ready to take the pills in my own comfort zone. If I wanted to cry, I could cry. Nobody was here. That was the most important part of the process for me being able to just be home with the kids and not having to worry about where the kids are going to go, the babysitter and the daycare. (Amira, 30-year old, Georgia)

Having agency in decisions throughout the process transformed the experience into something empowering. TelAbortion not only changed the logistics of the process, but also shaped the emotional experience. It shifted more power to the participant, thus embodying person-centered care. A participant who had a recent in-clinic medication abortion before her TelAbortion compared her experiences:

> I kind of expected it to go like the first time but I felt a little more empowered that I was able to do it on my terms and my time and within the privacy of my own home…It was a sense of like, okay, that this is in my hands. I'm going to do this when I want whereas at [abortion clinic] it was like, okay, "here's this pill, down the hatch." And that's the moment that I'm like, wow, there's no going back once you take the pill. So for me to be able to ritualize that. I was actually with a really close girlfriend. And she supported me through…I think that being able to do it on your terms is a game changer…the freedom of making the choice when you're ready and in the circumstance that is comfortable for you. (Heather, 26-year old, Hawai'i)

The convenience of having medications mailed, ease of being able to work around their own schedule in their own environment, and autonomy of making these decisions was appreciated.

One area of assistance that some participants felt was lacking was emotional support following the abortion. Many participants described this as something that would be helpful for others but that they personally did not need. As 26-year-old Heather from Hawai'i stated, "And I feel like I'm usually pretty good with dealing with the emotional things but a lot of women maybe are not, and maybe this would be something that could be scarring for them and they would find other ways to try to heal that might not be so healthy."

Others did report that they could use additional support.

> I'm only 18, and I really just didn't know how to react to me being pregnant. I just felt really alone, just the fact that I couldn't tell anybody. But for anybody else that gets an abortion and stuff, for the best experience, it would be to always have somebody there, people that understand and accept you and accept the choice you're about to make. I just feel it would make them-- it would have made me more comfortable. (Alanah, 18-year old, Hawai'i)

Some participants felt disconnected from their social support and desired additional external support, but they saw this as more of a problem with society in general than with their abortion care.

> I wish that there was a space for women to speak about this and to process this, but I don't think that can be something attributed to your study…[TelAbortion] did a great job of offering support if I needed it and made it very specific where I can go and who I can talk to about that, which I was very grateful for. But the majority of the healing was talking with the other women, so, in a perfect world, I wish that there was a community around this, to support women in a different or more encompassing way. (Katherine, 29-year old, Oregon)

As the above participants described, this issue of support would likely not have been alleviated with in-person care.

TelAbortion exceeded expectations

Most participants had never received any healthcare via telemedicine and did not have many expectations for telemedicine itself. One participant had a prior TelAbortion and one participant had received medications through the mail from an entirely online service.

Conversely, most participants carried expectations of what an abortion would be like, which then influenced their perceptions and satisfaction with their actual experience. Twelve participants had a prior medication abortion and seven had a procedural abortion, which often shaped expectations. Expectations also arose from stories of other people's abortion experiences, their social spheres, popular culture, and the media. Some participants were unsure of abortion legality, as Aubrey, a 26-year old from Minnesota, explained, "I just wasn't sure if it was legal. I guess I never really thought about it or had to talk about it with anyone and all these politics and politicians were going around about how it's legal in this state and this person's going to make it illegal in this state, so I wasn't sure."

Expectations were heavily influenced by abortion stigma, both internalized and perceived. Table 3 juxtaposes participants' perceptions of abortion care with their actual experience. Stigmatized anti-abortion narratives, such as "you're basically killing a life" (19-year old, Oregon), "you're automatically a slut" (37-year old, Illinois), and "you're being selfish" (34-year old, Georgia) made the process more emotionally distressing, but many participants also embraced the idea of "It's my body, my choice" (26-year old, Illinois).

The resulting experience of TelAbortion was therefore much better than anticipated as seen in Table 3, superseding expectations of shame and judgment with person-centered outcomes of dignity and trust. When asked, all participants reported satisfaction with their care and report that TelAbortion offered a nonjudgmental, safe, and convenient way to access care. It centered the participant by making the process easy, prioritizing their needs, and treating them with respect.

> [I appreciated the] convenience, lack of judgment. And not just lack of judgment, but it was friendlier. It was so much friendlier. It was not just nonjudgmental but just happy to help in the decision that I had had to make, because it's not a pleasant decision. I don't think anybody's like, "Oh, yay. I get to go do this." It's shitty. But at the same time, if you're doing that, you're doing

TABLE 3 Comparison of expectations of what participants might encounter having an abortion and actual experiences of TelAbortion from in-depth interviews with TelAbortion participants

Expectation (participant identification)	Description of expectation	Description of actual experience
Judgmental abortion provider (Katie, 30-year old, Minnesota)	I did think that there would be a lot more judgment and stigma from the medical people that were operating the center.	They just kind of trusted you as an adult that you knew that this decision was right for you and they help in a really nonjudgmental manner, which I wasn't expecting.
Pressure to make a particular decision (Adriana, 34-year old, Maryland)	I really thought it would be extremely negative and that I would second guess my decision and that people would try to convince me to not have the process.	I realized that everybody who was participating and helped were really kind and really supportive, and nobody questioned my decision. And if anything, they just wanted me to feel comfortable while I was doing it.
Community stigma (Amanda, 26-year old, Minnesota)	There's billboards all over my city, just about, how life begins at conception and how babies have heartbeats at two days of—honestly, they're very much not about abortion. So the idea of when they said that there was protestors outside really scared me because I don't know how crazy those people are.	Where I live really played a role in it because of how people are so against it, and so being able to do it at home and nobody knew I was even doing it is very relieving.
Difficulty accessing abortion care (Nora, 29-year old, Oregon)	In Tennessee, I would have had to drive to Nashville, a 45-minute drive and sometimes I probably would have even hit a brick wall. You never know.	I was surprised at how just-- there was someone available. Someone was able to get me in right away. I didn't have to jump through hoops or anything to do it… It was pretty pleasant. I was pretty surprised at how easy and simple it was made for me. I really appreciate that.
Protestors (Jess, 32-year old, Colorado)	A lot of the clinics over there actually do get petitioners and protestors all the time. So a majority of the time when you are going to a Planned Parenthood out there, you are going to run into protestors and things like that. Just having to deal with that makes you feel worse about your decision and makes you feel more guilty about things.	It was nice because you do everything in the comfort of your own home. You don't have to go to a clinic and possibly have protestors there waiting. Saying, "You're going to do X, Y, Z," or objectifying or looking at you any sort of way just because you're seen going into a Planned Parenthood. Everything's at your home. All you have to do is wait for a package. Nobody knows it's from Planned Parenthood… You don't have anybody's views or opinions in the mix of what you're doing. It's basically your own personal business and that's what I liked about it…You're in the comfort of your own home.
Hostile clinic environment (Leanne, 36-year old, Colorado)	I went in there and it was weird because a lot of these [abortion] clinics are lockdown style and bulletproof glass. And I remember the one time like, "Man. This is kind of scary." And I realized it was because they would perform abortions. And so that kind of informed my decision too, just my memory of going into the wrong clinic to try and get birth control and being like, wait, it feels weird.	It was pretty cool, quote that "pretty cool". No, it was just really nice to have this option to be in my home. I could have done a few things better. But at the end of the day, I was just very grateful that I had access to the service.
Traumatic abortion process (Alanah, 18-year old, Hawai'i)	I honestly thought it would just be a terrible process because I had this one friend who was 12, and she got pregnant. But at the time, she was far along, so she had to get surgery. And I don't know, it just seemed like it really changed her. She just got so depressed, and it was such a painful experience. I thought, "I could never put myself through that." She made it seem like it was terrible, which is why I was scared.	It just seemed like I overreacted towards the process, I guess. I thought it was going to be something so heavy, something so scary, but it really wasn't. It was super easy. It was just getting your period and stuff like that. And I just want other girls to know it's not as scary as you think it is. If it's really what you want, it's not scary. It's just like getting your period.

> it for a good reason. And it was a much more pleasant experience. You can tell even from the way that the [TelAbortion website] is worded, they're there to help people and they have that perspective on it instead of it being a nasty business to be associated with. (Jen, 31-year old, New York)

Changing expectations surrounding abortion with participants reporting a good experience has downstream effects. Many participants shared their experience with friends and all said they would recommend TelAbortion if they knew of someone looking for abortion care. Since TelAbortion was highly acceptable to them personally, many felt a need to share with

others, so others would not be in the same situation of expecting a bad experience.

> I hope it [TelAbortion] keeps expanding to be an available product and service, and I really, really hope that it turns to something where people are more accustomed to this being the medical procedure it is… I think the stigma itself comes from the [lack of] availability of [abortion], and the availability of it will lead to the stigma changing. (Megan, 26-year old, Colorado)

Challenges arose when interfacing with the healthcare system outside of TelAbortion

Although communicating with their study team, receiving, and taking the medications generally was easy, participants encountered difficulties when interacting with other healthcare entities, either before finding out about TelAbortion or when obtaining labs or ultrasounds. Some participants were referred directly to TelAbortion from their provider without issues, but many did not feel comfortable talking to their healthcare providers or did not have a primary care provider that they could easily reach. In a few cases, participants were denied a referral and were treated poorly. One participant called her obstetrician's office "to ask if they had any information about it, and they shot me down about it and hung up" (20-year old, Oregon). In another case, a participant saw three different medical providers in-person before finally being referred to TelAbortion.

Most participants had to interact with some healthcare providers outside of their study site to obtain labs or ultrasound or pick up additional medications from a pharmacy. This led to logistical issues with finding nearby facilities, getting appropriate referrals, and having orders misplaced along the way, all of which delayed their abortion.

Interacting with outside providers put participants in the position of having to decide if they would disclose that they were having an abortion. Because of abortion stigma, this decision involved weighing risks.

> Because you had to get a referral for an ultrasound and stuff, and everybody that I talked to, I basically had to explain what I was doing and who it was for because they were just like, "Well, why isn't your OB prescribing this?" So I had to explain to everybody like, "Because I'm getting a fucking abortion." (Aubrey, 26-year old, Minnesota)

Others concealed their pregnancy intentions, due to perceived abortion stigma making them fear judgment. This resulted in uncomfortable situations, compromising trust and honesty in healthcare. Additionally, most outside healthcare workers assumed that a pregnancy would be welcome.

> I didn't feel comfortable talking to the person about what was going on. So of course, they were like, "Oh, congratulations." I'm like, "Yeah." I had to play along with that, and that felt really uncomfortable. (Jeanne 40-year old, Illinois)

Between the scheduling and travel logistics and discomfort with revealing or concealing their planned abortion, obtaining an ultrasound was often the hardest part of the entire abortion process. In some cases, participants went to crisis pregnancy centers (CPCs) for their ultrasound, often not realizing that CPCs are designed to convince patients to not obtain an abortion.

> And I can tell that they're against abortions and everything like that, so even though…I told her that I wasn't going to keep it. And she didn't have a nonchalant attitude about it…But I sucked it up, and all I really needed was the ultrasound, not their opinion…So I just went ahead and got the ultrasound. (Brittney, 24-year old, Georgia)

Other participants were aware of CPCs and purposely avoided them. Even when accessing traditional medical care, they faced judgment.

> I had a woman that was doing my vitals…And she was talking about the baby, and talking about the baby, and asking me questions, if I had a name picked out and all of that. And after I said, "Actually, I'm getting an abortion. I just need this stuff done so that I can get the abortion." And she gave me the meanest look. I told her, I said, "It's my choice." And she told me that there was a special place in hell for people like me. So that's the discrimination that I'm talking about, seeing that people don't know the situation. And they don't know that I'm trying to escape an abusive situation. (Marisa, 26-year old, Illinois)

These instances of enacted abortion stigma stood out as the most difficult parts of the abortion experience for these individuals. Even when prejudice was not explicit, participants explained that it was emotional to see the ultrasound, physically invasive with transvaginal ultrasounds, and added another step.

Multiple participants identified eliminating ultrasound requirements as a way to improve their TelAbortion experience. Many felt confident determining their pregnancy status without an ultrasound. As 27-year-old Rosa from Minnesota explained, "I already did take a pregnancy test, but I feel like I have to take [the ultrasound] with them so they are really sure that I am pregnant. I feel like I did the test more for them than I did it for myself."

Due to practice changes during the early COVID-19 pandemic, eight participants did not have an ultrasound before their abortion. These participants trusted their providers to ensure they did the necessary testing and were relieved to eliminate another step they thought was inconvenient or unnecessary.

Case 6:25-cv-01491-DCJ-DJA Document 54-10 Filed 02/03/26 Page 48 of 239 PageID #: 3284

> I didn't see the need of doing bloodwork or having an ultrasound and doing anything like that…If I was like 15 weeks, then okay, but it was only like 8 weeks. And if you don't need it, that's okay. It was convenient that I didn't have to do that. I didn't even have to go see a doctor. I'm like, "I don't want to do that. Just let me get this over with." (Regina, 35-year old, New York)

Each additional step in the process added time, money, and the potential for uncomfortable interactions. Many participants supported streamlining the process and making medication abortion more widely available. "I mean, it would've been easier if I could've just bought it at Target [laughter]. Why can't we find this on Amazon?" (Kelly, 36-year old, Minnesota).

Care provided entirely within the direct-to-patient telemedicine abortion process while eliminating external steps fulfilled participants' needs and minimized opportunities for judgment.

DISCUSSION

Patient experiences demonstrate that TelAbortion is person-centered care, which can be a model for other direct-to-patient telemedicine abortion care. Participants felt safe, supported, and empowered, which often exceeded their expectations for an abortion experience. Challenges participants encountered during their medication abortion through TelAbortion came from external factors, including the outside healthcare system and overarching abortion stigma.

The person-centered outcomes from the PCFRHE are applicable to and met by direct-to-patient telemedicine abortion with TelAbortion. The first theme illustrates how open communication, supportive care, and being at home led participants to feel safe and well supported. With this foundation of support, participants were then able to turn this experience into something comfortable and even empowering as shown in the second theme. With TelAbortion, participants could take control, particularly in terms of who else was involved, affording them privacy and support from others when desired. Participants' expectations about abortion often were negative but their interactions with their TelAbortion teams engendered trust and they felt their decisions were respected.

The impact of telemedicine on abortion care does have unique features since abortion is highly stigmatized, which influenced the support participants both needed and received. Participants assumed that others may have a traumatic abortion experience and need more support, despite their personal experience of having an abortion without emotional distress, which could be an empathetic reflex, but also may demonstrate internalized abortion stigma. Stigma around abortion care contributed to a lack of spaces to talk about abortion, or lack of patient comfort with talking about it, and thus affected the patient's sense of support when completing the abortion remotely.

Abortion stigma presented in three ways with our participants: a sense that abortion would be emotionally traumatic for others, expectations for a judgmental and arduous abortion experience, and discrimination from outside healthcare workers, consistent with internalized, perceived, and enacted abortion stigma.[20] Abortion stigma appropriately is at the highest level of the PCFRHE (Figure 1) as it affected aspects of participants seeking and receiving care and their perception of the quality of care given the change from expectations. Interestingly, there was not much geographic difference noted in experiences of abortion stigma. Those living in states where abortion is less restricted or even legally protected still encountered hostility toward abortion and demonstrated perceived and internalized abortion stigma. In this stigmatized context, having person-centered care was even more impactful, particularly in the domains of privacy, dignity, and trust. Being able to avoid hostile healthcare environments, feel safe at home, and gain autonomy by controlling elements of the process decreased the stigma felt.

The person-centered quality of care not only impacts the outcomes for an individual but also feeds back and changes personal and community level expectations for care, which then influences the decision to access care. We noted this with participants who had a prior abortion experience and were seeking something different with telemedicine abortion. The original PCFRHE emphasizes this bidirectional flow of poor-quality care leading that person and their community to be less likely to seek care or expect high-quality care.[16] Therefore, by providing person-centered care, these participants describe the opposite being true: after receiving high-quality care, they are more likely to tell others about it, and in turn, access to abortion care could increase.

Although responses to TelAbortion were overwhelmingly positive, areas for improvement did emerge. Providing emotional support resources to every patient and routinely asking about mental health at follow up encounters and providing referrals for additional care if needed would enhance the social support, especially when providing stigmatized care where patients are less likely to rely on their typical support networks. This challenge of providing emotional support is not unique to telemedicine abortion and could also be improved for those seeking traditional care.[27] While the abortion itself does not cause long-term adverse mental health outcomes, there can be significant trauma and stress from dealing with an unplanned and undesired pregnancy, so this support is important with any abortion care.[28] Perceived abortion stigma at the time of the abortion has been shown to increase psychological distress years later, so by decreasing stigma with direct-to-patient telemedicine abortion, participants may have better long-term outcomes.[29]

Another area to improve is lessening reliance on outside medical facilities for providing ultrasounds since this was often a challenging experience, whether in traditional healthcare facilities or CPCs. Eliminating pre-abortion ultrasounds where clinically appropriate can facilitate telemedicine and eliminate this burden; however, there still will be cases when ultrasound is required.[7] Educating sonographers on the range of reasons for early pregnancy ultrasounds and provision of non-judgmental care is essential.

A strength of this study is that it captured the experiences of people seeking abortion care before and during the COVID-19 pandemic. During the pandemic, participants were less likely to have other

options, but rather than having decreased satisfaction because options were limited, they appreciated telemedicine from a safety standpoint.[22] Participants' reasons for choosing telemedicine, satisfaction with care, and the person-centeredness of the care were consistent from before to during the pandemic, indicating that the value of direct-to-patient telemedicine abortion existed before, and likely will continue to exist after the current pandemic. Due to changing practices, people who received care during the pandemic were less likely to have had an ultrasound prior to their abortion and were comfortable trusting that their provider would have them do testing if necessary. The convenience of not having to physically attend any appointments and the privacy that afforded was notable in the group who did not have pre-abortion ultrasounds.

This study is limited by the self-selected nature of participants. We only interviewed people who opted to complete a TelAbortion instead of an in-clinic visit and therefore had the appropriate technology to use telemedicine. The perspectives of people who considered but declined TelAbortion are not represented and serve as a reminder that maintaining in-person care is still important for people who cannot access telemedicine or who prefer in-person visits. We anticipated that people with either very good or bad experiences were more likely to participate; subsequently all participants were satisfied with TelAbortion. Participants still provided suggestions to improve TelAbortion even when they were generally content with it. Another limitation is that all participants received their care in a study setting. They paid for their abortion, which simulates a non-study population, but the study staff may have been more attentive or persistent at follow-up than what routine clinical staff could provide in a non-study setting. Given the significance of good communication on patient experience, it is a critical component for any direct-to-patient telemedicine abortion service to provide. Finally, we acknowledge that the findings may not be generalizable outside of the specific TelAbortion model given the heterogeneity of telemedicine models.

Features of the TelAbortion model of direct-to-patient telemedicine abortion may be applied to other types of care. We have identified five ways in which telemedicine can be adopted in a person-centered way based on our participants' experiences: (1) Establish a means of open communication from the first contact with a phone line or messaging service; (2) Use a combination of oral and written patient education materials so that patients can ask questions during the encounter and have instructions to follow after the visit; (3) Offer a variety of times for scheduling and minimize scheduling delays; (4) Minimize reliance on outside healthcare systems when working with stigmatized care like abortion; and (5) Provide supportive care such as pain medications, emotional support resources, and recommendations for when having a support person available may help.

Provision of direct-to-patient telemedicine abortion will likely still be in demand after the current pandemic given its convenience, autonomy, and privacy. As new telemedicine services are developed, these principles can be a guide to emphasize person-centered care. TelAbortion demonstrates that direct-to-patient telemedicine abortion can be person-centered care and provide a high quality, empowering alternative to clinic-based care for people seeking care in a stigmatized abortion landscape.

FUNDING INFORMATION

This study was funded by The Society of Family Planning grant SFPRF20-04 and from an anonymous donor through Gynuity Health Projects. The funders did not have any role in the study conduct, analysis, or reporting.

CONFLICT OF INTEREST

COVID-19

ABSTRACT

Objective: To demonstrate the effectiveness of medication abortion with the implementation of telemedicine and a no-test protocol in response to the COVID-19 pandemic.
Study design: This is a retrospective cohort study of patients who had a medication abortion up to 77 days gestation at the University of Hawai'i between April and November 2020. Patients had the option of traditional in clinic care or telemedicine with either in clinic pickup or mailing of medications. During this time, a no-test protocol for medication abortion without prior labs or ultrasound was in place for eligible patients. The primary outcome was the rate of successful medication abortion without surgical intervention. Secondary outcomes included abortion-related complications.
Results: A total of 334 patients were dispensed mifepristone and misoprostol, 149 (44.6%) with telemedicine with in-person pickup of medications, 75 (22.5%) via telemedicine with medications mailed, and 110 (32.9%) via traditional in person visits. The overall rate of complete medication abortion without surgical intervention was 95.8%, with success rates of 96.8, 97.1, and 93.6% for the clinic pickup, mail, and clinic visit groups, respectively. Success for those without an ultrasound performed prior to the procedure was 96.6%, compared to 95.5% for those with ultrasound. We obtained follow-up data for 87.8% of participants.
Conclusions: Medication abortion was safe and effective while offering multiple modes of care delivery including telemedicine visits without an ultrasound performed prior to dispensing medications.
Implications: Incorporating telemedicine and a no-test protocol for medication abortion is safe and has the potential to expand access to abortion care. All care models had low rates of adverse events, which contradicts the idea that the Risk Evaluation and Mitigation Strategyincreases the safety of medication abortion.

1. Introduction

The COVID-19 pandemic greatly impacted the delivery of healthcare services. Healthcare providers and healthcare systems made rapid shifts from face-to-face medical visits to telemedicine, even for non-COVID positive patients [1]. This rapid increase in the use of telemedicine services since the start of the pandemic has been well accepted, with one retrospective study showing significantly higher patient satisfaction with telemedicine visits compared to in-person visits [2]. Although the body of evidence surrounding the implementation of telemedicine during the pandemic is still growing, early studies have demonstrated its utility in providing safe and satisfactory care to patients.

Prior to the COVID-19 pandemic, several medication abortion delivery models already included telemedicine. Clinic-to-clinic telemedicine models, which incorporate preabortion testing at a clinic remote from where the mifepristone provider is located, a videoconference with the provider, and dispensing abortion medications at a remote site, demonstrated no difference in rates of adverse events, ongoing pregnancy, or blood transfusion compared to in-person visits [3, 4]. Gynuity Health Project's TelAbortion study, in which patients received mifepristone and misoprostol via mail after a telemedicine visit, also demonstrated high abortion completion and low complication rates [5]. In addition, patients and

providers have found these telemedicine models to be acceptable and satisfactory forms of care delivery [4–6].

Hawai'i has the unique geographic challenge of being comprised of many islands with abortion care only offered on Oahu, Hawai'i Island, and Maui. This challenge was exacerbated by the pandemic, since the prepandemic practice of having patients fly in for a visit now has the added risk of COVID-19 exposure, plus varying limitations and quarantine requirements for interisland travel. In an effort to respond to the COVID-19 pandemic, our clinic expanded use of telemedicine and also adopted a new no-test medication abortion protocol for eligible patients while continuing to offer in person face-to-face visits for medication abortion. The no-test protocol is based on evidence demonstrating that preabortion testing with labs and ultrasound can often be safely omitted for many patients, thus eliminating the need for any in person visit prior to receiving a medication abortion [7]. With appropriate counseling from a clinician, much of the medication abortion process can be managed independently by patients, including confirmation of pregnancy, self-administration of medications, and management of side-effects [8]. Our clinic now offers a variety of models for medication abortion including traditional in-person visits and telemedicine visits with medications dispensed from clinic or by mail, while utilizing a no-test medication abortion protocol for eligible patients. The objective of this study was to describe our experience with these delivery models operating simultaneously.

2. Methods

2.1. Medication abortion protocol

We conducted a retrospective cohort study of patients seen via multiple care models between April 1, 2020 and November 30, 2020 during the COVID-19 pandemic in Hawai'i. Our primary objective was to describe our experience with medication abortion when multiple medication abortion service delivery models were offered to patients. The primary outcome we sought to describe was successful medication abortion, defined as medication abortion completed without any need for surgical intervention. We also described the proportion of patients who had an incomplete abortion (retained gestational sac or tissue without viable pregnancy), ongoing pregnancy (continued viable pregnancy after taking medications), took additional misoprostol beyond what was initially dispensed, received a blood transfusion, or sought care in an emergency room (ER) for an abortion-related concern.

Our family planning clinic is an academic practice with two locations on Oahu and one on Hawai'i Island, with centralized scheduling for abortion care. After April 1, 2020, patients contacting the clinic selected a medication abortion service delivery model depending on their clinical presentation, telemedicine capability, geographic location, and personal preferences, with some limitations. These options are outlined in Table 1. We also continued to offer surgical abortions throughout this time period. Eligibility determination (clinical history, assessment of gestational age) and counseling were conducted either in-person or via telemedicine using synchronous Zoom videoconferencing. Mifepristone consent forms were signed either in person or via telemedicine with an electronic consent. Patients who participated in the TelAbortion Project could have medications mailed to any address in Hawai'i. We also mailed medications to non-study patients under the U.S. District Court for the District of Maryland ruling that temporarily put a hold on the Risk Evaluation and Mitigation Strategy (REMS) in person dispensing requirement during the pandemic.

Patients who had a known last menstrual period (certainty within 1 week) that gave them a gestational age of 11 weeks or less, had regular periods and did not have any risk factors for ectopic pregnancy (prior ectopic pregnancy, tubal surgery, intrauterine contraception use at the time of conception) or symptoms of ectopic pregnancy (vaginal bleeding or pelvic pain in the past week) could forgo an ultrasound. If any of these criteria were not met or the patient desired an ultrasound, we referred the patient for an ultrasound prior to dispensing medications, or performed it while the patient already was in clinic. TelAbortion patients were required to have an ultrasound or pelvic examination performed before being mailed medications.

We provided medication abortion up to 77 days gestation. All patients were dispensed 200 mg mifepristone and 2 doses of 800 mcg misoprostol. We counseled patients to take oral mifepristone followed in 24 to 48 hours by 800 mcg misoprostol, either buccally or vaginally. If they did not start bleeding within 24 hours of their first dose of misoprostol, we advised that they take a second dose of 800 mcg misoprostol. For pregnancies at 63 to 77 days, we instructed patients to take a second dose of 800 mcg misoprostol four hours after the first dose. We required documentation of Rh type for patients above 70 days gestation and administered Rh-immune globulin either at our clinic or a location closer to the patient if more convenient.

Standard follow-up was a telemedicine visit by videoconference or telephone 1 to 2 weeks after ingestion of mifepristone and a high sensitivity urine pregnancy test taken 4 weeks after mifepristone, followed by a phone call from clinic staff. We dispensed urine pregnancy tests with the medications. We also offered patients the option of having an ultrasound at any convenient clinic 1 to 2 weeks after mifepristone ingestion or obtaining serial serum human chorionic gonadotropin (hCG) levels, particularly if they were going to be traveling out of state or desired a long-acting reversible contraceptive method sooner than 4 weeks after the abortion. If the initial telemedicine follow-up visit was concerning for ongoing pregnancy based on provider judgment of the lack of appropriate bleeding or continuation of pregnancy symptoms, we scheduled the patient for an ultrasound. Likewise, if a urine pregnancy test remained positive 4 to 5 weeks after the abortion, patients were advised to have a serum hCG or ultrasound. Patients could contact our on-call physicians at any time with issues or go to their local emergency room.

2.2. Data abstraction and analysis

We performed a retrospective chart review of all patients who initiated a medication abortion visit from April through November 2020. Authorization to perform a chart review was obtained from the Western Institutional Review Board. We excluded patients who were not dispensed the medications.

Researchers independently abstracted de-identified data from patient charts into a secure Qualtrics XM (Qualtrics, Provo, UT) database. We reviewed clinical notes, demographic data, lab results, outside provider notes, and emergency department records. Electronic medical records from the largest health systems in the state were accessible for review when assessing outcomes. We collected data on demographics, payor type, medical history, gestational age, testing done prior to the abortion, medications provided, medications taken, abortion outcome, and complications. If a patient had more than one medication abortion during the time period, we included all encounters. We reported gestational age at the time of dispensing medications based on either ultrasound dating if available or last menstrual period (LMP).

Successful medication abortion was determined by patient history, urine pregnancy tests, serum hCG, and/or ultrasound. Since our last patient included in the database received their medications by November 30, 2020, all patients were followed for at least 8 weeks to confirm abortion outcomes prior to chart abstraction.

Table 1
Service delivery models for medication abortion care at the University of Hawai'i between April and November 2020

Date initiated	Service delivery model	Additional information
April 1, 2020	**In Clinic Visit + Pick Up** – Ultrasound for gestational age dating only if indicated – In-Person Visit Dispensed Mifepristone and Misoprostol from the office during their visit	Was the standard model prior to April 2020 with ultrasound routinely performed
April 1, 2020	**Telemedicine Visit + Pick Up** – Ultrasound for gestational age dating only if indicated – Telemedicine Visit Dispensed Mifepristone and Misoprostol from office on Oahu or Hawai'i Island after their visit	Interaction in person typically lasted less than 5 minutes with a medical assistant dispensing medications.
Program began in 2016, ongoing on April 1, 2020	**Telemedicine + Mail (TelAbortion Project)** – Ultrasound for gestational age dating for all patients – Telemedicine Visit Dispensed Mifepristone and Misoprostol by mail	Only eligible up to 70 days gestation. Details described in previous publication [5].
October 1, 2020	**Telemedicine + Mail** – Ultrasound for gestational age dating only if indicated – Telemedicine Visit Dispensed Mifepristone and Misoprostol by mail	We mailed medications to patients who did not participate in the TelAbortion study under the US District Court ruling. Patients decided on this option if they wished to forgo an ultrasound or did not want to participate in a study.

Descriptive statistics were performed using SPSS Version 27 (IBM, Armonk, NY). We included all patients seen for medication abortion in our practice during the study time period. Pearson's chi-squared tests were used for the primary outcomes but no significant difference in outcomes based on method of dispensing mifepristone or if ultrasound was completed were noted, so they are not displayed.

3. Results

From April through November 2020, we dispensed mifepristone and misoprostol for 334 medication abortions, with a total of 330 unique patients. Patients did not vary demographically based on mode of dispensing medications, except by island where they lived, as shown in Table 2. Four patients (1.2%) had an early pregnancy loss, four (1.2%) stated they were terminating the pregnancy because of maternal health, and one individual stated the pregnancy had resulted from rape.

Figure 1 shows the breakdown of the different methods of receiving care, with two thirds completing a telemedicine visit and one third going to clinic. Of the 223 (66.8%) patients who had an ultrasound performed, 139 (62.3%) were performed prior to presenting to our clinic, 51 (22.9%) were performed for routine gestational dating after presenting to our clinic, 19 (8.5%) were required due to unsure LMP, and 14 (6.3%) due to a history of or symptoms concerning for ectopic pregnancy, 7 of whom had a prior ectopic. Two hundred and thirteen patients (63.8%) had a known Rh type prior to the abortion, either present in their medical records (173, 81.2%), self-reported (24, 11.3%), or ordered specifically for the abortion (16, 7.5%). Patients chose their route of misoprostol administration, with 148 (51.6%) choosing buccal, 93 (32.4%) vaginal, and 46 (16.0%) not reported.

The primary and secondary outcomes are presented in Table 3. Seven patients who were dispensed medications reported that they did not take them and were excluded from analysis of the outcomes. Twelve of 287 patients with follow up data underwent uterine aspiration, giving an overall rate of successful medication abortion of 95.8%. If 100% success is assumed for those without follow up data, 315 out of 327 (96.3%) had a successful medication abortion. If failure is assumed for all those without follow up, 275 out of 327 (84.1%) would have been successful. Of the 12 aspiration procedures done, there were three ongoing pregnancies, four incomplete abortions with a gestational sac present, four procedures for heavy bleeding and/or retained tissue, and one patient who changed her mind after taking mifepristone and desired a surgical abortion rather than taking misoprostol. The subgroups did not have any significant difference in the primary outcome.

Rates of follow up are presented in Table 4, with patient history obtained from over three-quarters of patients, followed by urine pregnancy test results, ultrasound, and serum hCG levels. The mean time from dispensing to taking medications was 1.8 ± 2.6 days and the mean interval from dispensing medications to obtaining the first follow up information was 19.0 ± 12.7 days. There were significant differences in these intervals between the cohorts as expected due to the specifics of each delivery model.

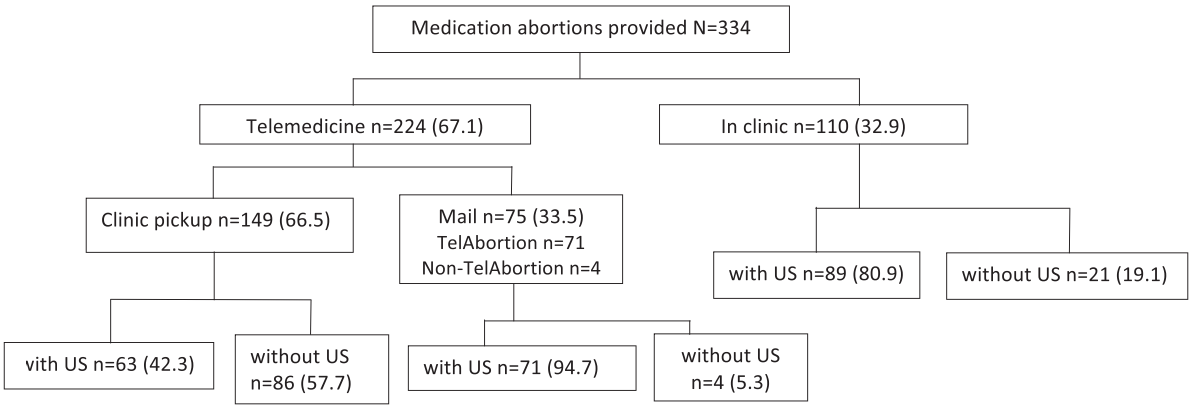

Fig. 1. Methods of providing medication abortion to patients at the University of Hawai'i between April and November 2020. US, ultrasound

Table 2
Demographic characteristics of patients who were dispensed mifepristone and misoprostol for a medication abortion through the University of Hawai'i between April through November 2020. Displayed as n (%) unless otherwise indicated

Characteristics	All Participants (N = 334)	In clinic (n = 110)	Telemedicine + pickup (n = 149)	Telemedicine + mail (n = 75)

Telemedicine + mail	72	50 [44–59]	69 (95.8)	67 (97.1)	2 (2.9)	0 (0)	4 (5.8)
With ultrasound	219	52 [45–59]	199 (90.9)	190 (95.5)	3 (1.5)	1 (0.5)	9 (4.5)
Without ultrasound	108	48 [44–55]	88 (81.5)	85 (96.6)	1 (1.1)	1 (1.1)	2 (2.3)

[a] Excludes 7 participants who were dispensed the medications but did not take them: 3 who were mailed medications and 4 who picked up the medications from clinic.
[b] Additional misoprostol beyond the 8 tablets dispensed routinely.
[c] ER visit = emergency room visit for any abortion-related concern.

Table 4
Follow-up methods used by 327 patients who received medication abortion care at the University of Hawai'i between April and November 2020

Mode of follow up	Total (n = 327)	In clinic (n = 110)	Telemedicine + pickup (n = 145)	Telemedicine + mail (n = 72)
Patient history	253 (77.4)	85 (77.3)	112 (77.2)	56 (77.8)
Ultrasound	66 (20.2)	28 (25.5)	23 (15.9)	15 (20.8)
Serum hCG	19 (5.8)	5 (4.5)	5 (3.4)	9 (12.5)
Urine pregnancy test	156 (47.7)	40 (36.4)	69 (47.6)	47 (65.3)
No follow up	40 (12.2)	16 (14.5)	21 (14.5)	3 (4.2)

hCG, human chorionic gonadotropin.
Displayed as n (%) with a denominator of the number who were dispensed the medications and did not have evidence that they chose not to take the medications. Patients often followed up by >1 method.

4. Discussion

This retrospective cohort study demonstrates high medication abortion effectiveness amongst people using telemedicine with medications dispensed in clinic or by mail, as well as traditional in person care. The medication abortion success is comparable to previously published data of people dispensed mifepristone in clinic [9, 10]. The 87.8% follow up rate is higher than many prior observational studies of medication abortion [11, 12]. We were able to access the records of the major medical systems in our state so even if the patient did not complete their follow up visit, we were able to obtain information about any visits within those systems. Therefore, it is highly unlikely that the sensitivity analysis scenario where all patients who did not follow up required a surgical procedure is true.

Rates of abortion success are similar for all methods of dispensing mifepristone and misoprostol. They are also similar for those who did and did not have an ultrasound performed prior to the abortion. A limitation of this study is that our patient population was relatively small and unsuccessful medication abortions are rare, so we were underpowered to make groupwise comparisons. No differences between groups were noted for the primary outcome, although the in clinic group trended towards lower success.

Complications were rare with only 2 patients requiring a blood transfusion, 4 who received additional misoprostol and 11 who went to an emergency room. We did not find any hospital admissions, missed ectopic pregnancies, unrecognized ongoing pregnancies, expulsion of a fetus at an advanced gestational age, infections, or hysterectomies. Given that all 3 groups had similar, low rates of adverse events, this does not support that the REMS increases the safety of medication abortion.

Telemedicine is an acceptable option for patients, with 60% of patients living on the islands with all options available using it. Although individuals generally were offered all the options for receiving care, some did not have a choice. Patients reporting an unsure LMP or who needed an interpreter were directed to in person care, whereas individuals living on islands other than Oahu or Hawai'i Island were preferentially offered medication abortion by mail since it would be more complicated for them to arrange a flight to our clinic. Sixty-two patients living on islands without abortion providers were able to have an abortion without flying to a different island. During this pandemic, both spending time at a healthcare facility and traveling puts patients at higher risk of being exposed to COVID-19. Telemedicine with either a quick in clinic pickup or mailing of medications decreases this risk of COVID-19 exposure and transmission.

It is important to highlight that technological barriers to using telemedicine may exacerbate existing health disparities rather than decreasing disparities by increasing access [13, 14]. This can lead to intervention-generated inequalities, widening the gap between those who own a device with videoconferencing capability, are comfortable using that technology, and have access to the internet versus those who do not have these resources. The same people who have access to technology are also likely to be more educated with more social and economic resources, reinforcing the already better health outcomes of this group [15]. In addition, interpreter services may not be as readily available for use in telemedicine, impacting the options available for those with low English proficiency [13]. A third of our patients still came to clinic, demonstrating that it is still important to offer a clinic option for those who have limited technology access, screen in to requiring an ultrasound, or prefer a face-to-face interaction.

This study provides evidence from a practical approach to incorporating telemedicine and eliminating routine testing from medication abortion care. Multimodal care delivery is feasible and did not decrease the safety and effectiveness of medication abortion compared to studies of patients receiving their care in clinic. There remains a role for in clinic care for a certain proportion of patients, such as those who face intervention-generated inequalities. More work should explore ways of reducing technological barriers, such as for our patients on islands with no local abortion provider who would otherwise take on the added burden of flying to a different island. However, our current model demonstrates that using a combination of methods to reach patients is safe and effective and allows us to tailor our care to our patients' specific circumstances and preferences.

Conflict of Interest

ABSTRACT

Objective: Given the substantial barriers to abortion access in the United States, many clinics now mail patients abortion medications. We examined whether dispensing the medications by mail prolonged time to medication use.

Study design: We analyzed data from no-test medication abortions with medication provided either by mail or in a clinic from 11 United States clinics from February 2020 to January 2021. We examined mean number of days from patients' first contact with the clinic to mifepristone ingestion, its two-component intervals (first contact to medication dispensing and dispensing to mifepristone ingestion), and pregnancy duration at mifepristone ingestion. We used Poisson regression to compare mean outcomes across three dispensing methods: in-person, mailed from the clinic, and mailed from a mail-order pharmacy.

Results: Among the 2600 records, patients took mifepristone on average at 49 days of gestation (95% CI, 47–51) and 7 days (95% CI, 4–10) after first contact. Mean time from first contact to mifepristone ingestion was 6 days when medications were dispensed in-person and 9 days when mailed ($p = 0.38$). While time from first contact to dispensing was similar across methods (6 days in-person, 5 days mailed, $p = 0.77$), more time elapsed from dispensing to mifepristone ingestion when medications were mailed (4 days from clinic, 5 days from mail-order pharmacy) versus dispensed in-person (0.3 days, $p < 0.001$). Time to mifepristone ingestion was shorter with higher pregnancy duration. Pregnancy duration at ingestion was similar across methods (48 days in-person, 50 days mailed).

Conclusions: Mailing medications did not significantly prolong time from patients' first contact with the clinic to mifepristone ingestion or increase pregnancy duration at mifepristone ingestion.

Implications: Abortion providers should offer a range of medication abortion dispensing options, prioritizing patient preference.

1. Introduction

The approval of mifepristone for medication abortion by the United States (US) Food and Drug Administration in 2000 included a requirement that the drug must be dispensed only in clinics, medical offices, or hospitals. In July 2020, a court order temporarily blocked this requirement, allowing clinicians and mail-order pharmacies to mail the medication directly to patients for the duration of the COVID-19 Public Health Emergency [1]. In 2021, the Food and Drug Administration removed the in-person mandate permanently [2]. This regulatory shift fundamentally changed abortion provision in the US. Many patients do not need an ultrasound or other in-clinic tests for eligibility assessment and can now obtain abortion care from home using telehealth, without any in-person visits to medical facilities. Several recent studies have demonstrated that this fully remote model is safe, effective, and highly satisfactory to patients [3–6].

One concern, however, is that the mailing process could delay treatment, potentially reducing the effectiveness of the medication abortion regimen. Two studies reported that, compared with patients who came to a clinic to obtain both screening ultrasounds and abortion medications, patients who were assessed by videoconference or telephone, had ultrasounds at separate facilities, and then received medications by mail, experienced longer intervals (by 5–7 days) between first contact with the abortion provider and medication use [7,8]. In one of these studies, the pregnancy duration on the day of mifepristone ingestion was also higher among patients who received pills by mail [7]. However, these studies could not determine the extent to which the observed differences were related to the mailing process, delays due to obtaining an ultrasound, or other factors.

No previous US studies have tested whether mailing medication was associated with delays in medication abortion in the context of no-test medication abortions. We sought to examine this issue using data from a large retrospective cohort study of the safety and effectiveness of medication abortion provided without pretreatment ultrasound or pelvic exam. Abortions were provided by multiple diverse clinics in the US between February 1, 2020 and January 31, 2021, preceding and following the July 2020 decision that first allowed for abortion medications to be mailed [4]. In all months, clinics dispensed mifepristone and misoprostol in-person, by mail from the providing clinic, or using a mail-order pharmacy. The objective of the current analysis was to determine whether mailing medications resulted in increased pregnancy duration or time to mifepristone ingestion.

2. Methods

The retrospective parent study collected data from 3779 abortions provided by 14 clinics for predefined time periods between February 2020 and January 2021 [4]. Within the original sample, 425 abortions were provided through the TelAbortion study, a prospective trial [9,10]. Trained clinic staff abstracted data from medical records for medication abortions provided without pretreatment ultrasound. Abstracted data included patient characteristics, abortion medication dispensing method, service dates, and medication administration timing. Abortion medications were provided in-person, by mail from the clinic, or using a mail-order pharmacy. The abortion medication dispensing method was determined by clinic protocol, or patient choice at clinics that offered multiple dispensing methods. Between February and June of 2020, nearly all patients in the sample other than the TelAbortion study obtained medications in-person. After a regulatory change in July 2020, clinics were able to dispense medications by mail outside of the TelAbortion study, either mailed directly from the clinic or from a mail-order pharmacy.

For this secondary analysis, we excluded data from three clinics where the first contact date was known to have been documented as the treatment date, as this would underestimate the intervals of interest. We also excluded abortions in which dates were not credible (e.g., mifepristone ingestion preceded first contact date), pregnancy duration was unknown, the patient took neither mifepristone nor misoprostol, the medications were dispensed in-person to someone other than the patient, or the dates of both mifepristone and misoprostol ingestion were unknown. The study was approved by the Allendale and University of California, San Francisco Institutional Review Boards.

2.1. Measures

The primary exposure was the medication dispensing method: in-person at the clinic, mailed from the clinic, or mailed from a pharmacy. Abortions with medications provided in-person included those with intake visits conducted in-person, without screening ultrasound or pelvic exam, and those with intake visits conducted via telehealth with medications picked up in-person. As a secondary exposure of interest, we examined pregnancy duration on the day of the first contact with the clinic.

The primary outcome was the number of days from the patient's first contact with the clinic to mifepristone ingestion. The date of first contact was defined as the date the patient scheduled the appointment via phone call or online, or otherwise the earliest date in the patient record regarding that abortion. If the date of mifepristone ingestion was missing, we conservatively substituted the date the patient used misoprostol, if available, in lieu of the date the patient used mifepristone, to avoid underestimating the intervals under study. We also assessed two components of this interval: days from first contact to medication dispensing and days from medication dispensing to mifepristone ingestion. The date of medication dispensing was defined as the date the medications were dispensed in-person, the package was mailed to patients, or a prescription was sent to a mail-order pharmacy.

For cases where abortion medications were mailed, we sought to estimate the days between mailing and delivery (the mailing interval) and the days between delivery and mifepristone ingestion. If the date of medication delivery was available, we recorded the days from medication dispensing to delivery as the mailing interval. For cases where the delivery date was not available, we used the mean mailing interval calculated among the cases with known delivery intervals as a proxy, separately for the mailed from clinic and mail-order pharmacy groups. The remainder of the interval from dispensing to mifepristone ingestion was recorded as the time from medication delivery to ingestion.

The secondary outcome was pregnancy duration on the date of mifepristone ingestion. We calculated this variable as the difference between the first date of the patient's last menstrual period and the date of mifepristone ingestion.

2.2. Statistical methods

We first described patient and abortion characteristics, overall and examined differences by medication dispensing group using Student's t-tests, chi-squared tests, and Fisher's exact tests. We compared the characteristics of cases that were missing mifepristone and misoprostol ingestion dates to those where mifepristone or misoprostol dates were known using chi-squared tests.

We used marginal estimates of results from multivariable Poisson regression models to estimate the adjusted number of days from first contact to mifepristone ingestion and to assess differences in the overall interval by medication dispensing method. Multivariable models controlled for patient age at abortion intake, race/ethnicity, pregnancy duration at first contact with the clinic,

[a] Fisher's exact test.

urban or rural residence, whether the patient paid out of pocket for the abortion, and TelAbortion Study participation. Next, we followed the same procedures to examine whether the two component intervals—first contact to dispensing and dispensing to ingestion—differed by medication dispensing method. Among the mailed cases, we also estimated the share of the dispensing to ingestion interval that was 1) from dispensing to delivery and 2) from delivery to ingestion.

We used Poisson models to estimate pregnancy duration on the day of mifepristone ingestion, overall and compared this interval by medication dispensing method, adjusting for patient age at abortion intake, race/ethnicity, urban or rural residence, whether the patient paid out of pocket for the abortion, and TelAbortion Study participation. In this model, we did not adjust for pregnancy duration at first contact because the outcome was a different measure of pregnancy duration.

To assess whether our findings were influenced by the inclusion of participants in the TelAbortion study, in which clinics had staff time dedicated to mailing medications from clinics, we conducted sensitivity analyses replicating all models excluding all TelAbortion participants. Finally, we tested whether the proportion of abortions where mifepristone was taken over 70 days of pregnancy duration differed by dispensing method using chi-squared tests.

All analyses used abortion as the unit of analysis. Standard error calculations accounted for clustering among abortions provided from the same clinic for all models. We used Stata version 17.0 (College Station, TX) for all analyses.

3. Results

The original study included 3779 abortions. We excluded 178 abortions provided by clinics that reported the intake date as the first contact date, abortions with dates that were not credible, abortions with medications dispensed in-person to someone other than the patient, and those with unknown pregnancy durations. Next, we excluded 1001 abortions because the dates of medication administration were unknown. Patients missing the date of mifepristone and misoprostol administration were first in contact with the clinic at slightly higher gestational ages (44 days among those for whom administration information was missing vs. 41 days), more likely to be white (50% vs. 42%) or to live in a rural area (21% vs. 14%), and less likely to be TelAbortion participants (5% vs. 14%). Those with missing mifepristone and misoprostol administration dates were slightly less likely to have picked up medication in-person (67% vs. 69%). After applying all exclusion criteria, we included 2600 abortions (69%) provided to 2594 patients between February 2020 and January 2021.

Table 1 describes the characteristics of the patients included in our sample. Most (69%) abortion medications in our sample were provided in-person to patients, whereas 20% were mailed to patients, and 11% from a mail-order pharmacy. All patient characteristics differed across dispensing methods. Each clinic contributed between 9 and 882 included abortions, and clinics varied in how many dispensing methods they offered (Appendix Table 1).

In adjusted analyses, the average interval between first contact and mifepristone ingestion was 6.9 days (Table 2). Patients who obtained medications in-person (6.0 days) had shorter intervals than those who received them by mail from the clinic (8.7 days) or from a mail-order pharmacy (9.0 days, $p = 0.38$).

We examined two components of the first contact to mifepristone ingestion interval (Table 3, Fig. 1). The average time from first contact to medication dispensing was 5 days and was similar across dispensing methods. However, the interval from dispensing to mifepristone ingestion differed significantly between the three methods. Time from medication dispensing to mifepristone ingestion was the shortest when the pills were dispensed in-person (< 1 day), 4 days when pills were mailed from the clinic, and 5 days when they were mailed from a pharmacy.

The date that the mailed medications were delivered to the patient was available for 374 of 514 cases (73%) in which medications were mailed from the clinic (all 374 provided through the TelAbortion study), and only 39 of 292 cases (13%) mailed from a pharmacy (all 39 provided from a single clinic). The interval from dispensing to delivery in these 413 cases for which the delivery date was available was on average 2 days in both the mailed from clinic and mail-order pharmacy cases and ranged from 0 – 10 days; 72% were 2 days or fewer,

Results are marginal estimates from multivariable Poisson regression models. Models are adjusted for age, pregnancy duration at first contact, urban/rural residence, race/ethnicity, out-of-pocket payment for the abortion, and participation in the TelAbortion Study, and standard errors are clustered at the clinic level.
Estimates for component intervals do not sum exactly to the estimates for overall intervals because they are modeled separately.
* $p < 0.05$.
** $p < 0.01$.
*** $p < 0.001$.
[a] p Value for comparison of mail-order pharmacy versus mailed from the clinic: $p = 0.01$.
[b] p Value for comparison of mail-order pharmacy to mailed from the clinic: $p < 0.001$.
[c] p Value for comparison of > 9 weeks versus 6– < 8 weeks: $p = 0.03$.

15% were 3–4 days, and 13% were 5–10 days. After assigning the mean mailing intervals for the remaining 393 cases without known delivery dates, we estimated that the mailing interval was similar between mailing methods; however, patients who received medications from a mail-order pharmacy (2.3 days) had a slightly longer delay between receiving and taking the medications than those who were mailed medications from clinics (2.1 days).

Time from first contact with the clinic to mifepristone ingestion was shorter with higher pregnancy duration at first contact, from 7.4 days for those with pregnancy durations less than 6 weeks to 3.4 days for those with pregnancy durations 9 weeks or more (Fig. 2). The time from first contact to medication dispensing was shorter with increasing pregnancy duration at first contact (Table 3). The interval from medication dispensing to mifepristone ingestion was

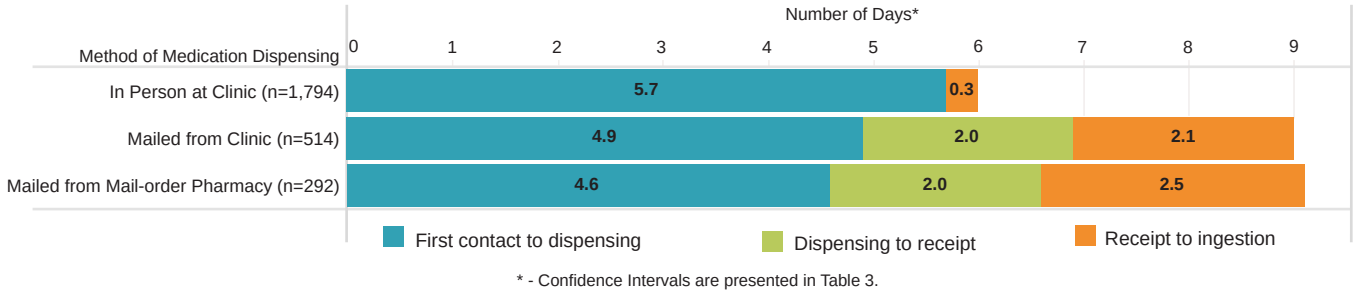

Fig. 1. Mean days from first contact to mifepristone ingestion among medication abortions provided in the US, February 2020–January 2021 (n = 2600).

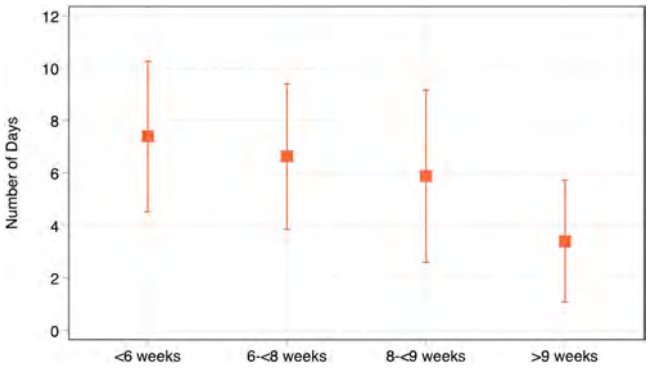

Fig. 2. Days from first contact to mifepristone ingestion among medication abortions provided by 11 clinics in the USA, by pregnancy duration at first contact with the clinic, February 2020–January 2021 (n = 2600).

longer for abortions with pregnancy durations 6 to < 8 weeks compared with those < 6 weeks, and shorter for those > 9 weeks compared with abortions with pregnancy durations 6 to < 8 weeks.

The average pregnancy duration at mifepristone ingestion was 48.7 days and was nearly identical across the dispensing method groups (Table 2). Older patients, those residing in urban areas, and patients who identified as Hispanic/Latinx versus white patients took medications at significantly lower pregnancy durations. The proportion of patients whose pregnancy durations were higher than 70 days on the date of mifepristone ingestion was similar among medication dispensing methods (2.8% for in-person, 1.6% for mailed from the clinic, and 2.4% for mail-order pharmacy, $p = 0.25$). The highest pregnancy duration on the date of mifepristone ingestion was 78 days. Results from sensitivity analyses excluding the 375 TelAbortion study participants yielded similar results (Appendix Table 2).

4. Discussion

In our sample of medication abortions provided without ultrasound or pelvic exam, we found that the average time from patients; first contact with the clinic to ingestion of mifepristone was one week. Time to mifepristone ingestion was 2–3 days longer when the medications were mailed to the patient than when they were dispensed in-person. Data from a sample of our cases suggest that the mailing process itself typically took only 1–2 days, which was consistent with the information on medication shipping times in 2020–2021 provided to us by Honeybee Pharmacy, one of several mail-order pharmacies that filled mifepristone prescriptions in the US during those years (email communication, April 2022). We estimate that patients who receive their medication by mail tend to take the pills on average 2 days after they were received. Additionally, our estimation of delivery dates was consistent with another of abortion medications dispensed from mail-order pharmacies, which found that 82% received the medications within three days [13]. In contrast, while it took somewhat longer to get an in-person appointment, most patients who obtained the medications in-person took the mifepristone that same day. However, a 3-day difference is unlikely to affect either safety or effectiveness of the treatment. The difference may reflect patient preference for taking the medications at the most convenient time once they are received by mail. Notably, the medication dispensing method had no apparent effect on the average pregnancy duration at mifepristone ingestion. The medication dispensing method also did not impact the proportion of patients who took the medications at more than 70 days of pregnancy duration.

The interval between first contact and mifepristone ingestion was shorter in patients whose first contact was later in pregnancy, due primarily to a shorter interval between first contact and medication dispensing. This finding may reflect both clinicians' and patients' desire to expedite treatment when patients are at later pregnancy durations. Medication abortion care provided earlier is consistent with patient-centered care, results in fewer side effects, and is more effective [11,12].

Our analysis has several limitations. We included only records where the patient provided medication administration dates, which may have biased our findings. Several important characteristics differed between patients whose medication administration dates were and were not known, which may have influenced time to mifepristone ingestion. Because some clinics do not maintain detailed records about when patients schedule appointments, the date of first contact for some records may have reflected a subsequent interaction, resulting in an underestimation of several intervals in our analysis. Similarly, the date of medication dispensing for the patients who received medications by mail could have reflected the date the clinician approved the medication for the patient or the date the package was mailed, which were not necessarily the same day for all patients although this would not impact overall time to mifepristone ingestion, the main outcome. Delivery dates were missing for most cases, which impaired our ability to investigate the dynamics of the post-dispensing interval among the cases where medications were mailed. Within the group that received abortion medications in-person, we were unable to distinguish between cases where the intake visit was conducted via telehealth or in-person. This may have obscured differences in the length of the interval between first contact and medication dispensing within this group, and underestimated differences in this interval between abortions with medications provided in-person and by mail. Finally, our data did not enable us to estimate the time from the patient's decision to terminate the pregnancy to treatment, which may be more salient to patients than the intervals we examined in this study.

Patients should be able to start their abortions at a time that is most convenient to them and decide whether they want to pick up the abortion medications at the clinic or receive them by mail. Patients should be informed about the small delay associated with obtaining medications by mail. In January 2023, the Food and Drug

Administration allowed for retail pharmacies to dispense mifepristone; however, important restrictions remain in place that limit access. Our findings support regulatory shifts to expand pharmacy access to the medication abortion regimen by demonstrating that patients take the abortion medications at a clinically acceptable time and early in pregnancy, regardless of how they receive the medications.

Acknowledgments

We thank the clinics that contributed data for the original study, including staff from Maine Family Planning, University of Hawaii, Planned Parenthood of the Rocky Mountains, carafem, Planned Parenthood of Montana, Planned Parenthood North Central States, Institute for Family Health, All Families, Cedar River Clinics, Long Beach Memorial Family Medicine, University of California Los Angeles Women's Health, Just the Pill, and Choix. We thank Nick Atwood, MPA, Jessica Nouhavandi, Pharm.D, and Brooklyn Sofley, BS for assistance with additional data on mailing times for this analysis. We appreciate data visualization support from Shomik Sarkar, MIMS.

Patient Acceptability of Telehealth Medication Abortion Care in the United States, 2021–2022: A Cohort Study

Leah R. Koenig, MSPH, Jennifer Ko, MLIS, Ena Suseth Valladares, MPH, Francine M. Coeytaux, MPH, Elisa Wells, MPH, Courtney R. Lyles, PhD, and Ushma D. Upadhyay, PhD, MPH

See also Munson and Hall, p. 152.

Objectives. Despite the recent expansion of direct-to-patient telehealth abortion care in the United States, patient experiences with the service are not well understood.

Methods. We described care experiences of 1600 telehealth abortion patients in 2021 to 2022 and used logistic regression to explore differences by race or ethnicity and between synchronous (phone or video) and asynchronous (secure messaging) telehealth abortion care.

Results. Most patients trusted the provider (98%), felt telehealth was the right decision (96%), felt cared for (92%), and were very satisfied (89%). Patients most commonly cited privacy (76%), timeliness (74%), and staying at home (71%) as benefits. The most commonly reported drawback was initial uncertainty about whether the service was legitimate (38%). Asian patients were less likely to be very satisfied than White patients (79% vs 90%; $P = .008$). Acceptability was high for both synchronous and asynchronous care.

Conclusions. Telehealth abortion care is highly acceptable, and benefits include privacy and expediency.

Public Health Implications. Telehealth abortion can expand abortion access in an increasingly restricted landscape while maintaining patient-centered care. (*Am J Public Health*. 2024;114(2):241–250. https://doi.org/10.2105/AJPH.2023.307437)

AJPH February 2024, Vol. 114, No. 2

In the wake of the June 2022 *Dobbs v Jackson* Supreme Court decision that allowed states to ban abortion, telehealth medication abortion has played a vital role in abortion provision and access in the United States. Telehealth can help mitigate surges in demand for abortion care in states where it remains legal.[1,2] For patients in states with abortion bans, telehealth services can also increase abortion access through methods like mail forwarding and mailing medications to a postal address or post office box in neighboring states over the border, minimizing the amount of travel required.

Medication abortion has emerged as the leading abortion method both within[3] and outside of[4] the health care system in the United States in recent years. Concurrently, there has been a rise in medication abortion provided via telehealth, facilitated by regulatory changes that allowed abortion medications to be mailed beginning in the COVID-19 pandemic.[5] Before the pandemic, telehealth abortion models were primarily "site-to-site," requiring patients to travel to abortion clinics, where they received ultrasonography and other in-person tests and then remotely consulted with a clinician who was at another location.[6,7]

Direct-to-patient telehealth abortion care first became widely available in the United States in 2020 and has been found to be safe and effective.[8–10] Since then, virtual clinics—online-only abortion providers—began providing this model of telehealth abortion care in states where it is legally permitted.[11–13] Patients are screened for eligibility

remotely by a clinician, receiving an ultrasound only if desired or medically indicated, and subsequently receive medications from a mail-order pharmacy.[14] In all medication abortion care models, patients typically take the medications, pass the pregnancy, and complete follow-up at home.[15] Patient–provider communication is either entirely over secure text messaging (asynchronous care) or with a videoconference or phone call (synchronous care).[16]

As of November 2023, telehealth for abortion was legally permitted in 24 states and Washington, DC (Figure A, available as a supplement to the online version of this article at https://ajph.org).[17] Between April 2022 and June 2023, the number of abortions provided by virtual clinics nearly doubled, accounting for almost 1 in 10 US abortions by June 2023.[2]

Despite the critical role that telehealth plays in maintaining access to abortion across an increasingly restricted landscape, the acceptability of direct-to-patient telehealth for abortion in the United States is not well understood. Evidence from the TelAbortion study has demonstrated US patients' positive experiences with synchronous telehealth abortion care within a clinical study.[9,18–20] No studies have examined differences in patient experiences between synchronous and asynchronous care. Telehealth medication abortion care models are less medicalized compared with in-clinic care, and differences in experiences by patient sociodemographic characteristics have not been documented. As ongoing legal cases threaten to curtail access to telehealth abortion, it is critical to understand how patients experience these models of care. Therefore, we aimed to explore the real-world acceptability of novel direct-to-patient abortion services provided by US virtual clinics and to examine differences in abortion care experiences between synchronous and asynchronous models and patient sociodemographic characteristics.

METHODS

We used data from the California Home Abortion by Telehealth (CHAT) Study, which evaluates the safety, effectiveness, and acceptability of telehealth abortion care provided by 3 United States–based virtual clinics. The CHAT Study began in California and increased in scope as virtual clinics expanded to provide care in 20 states and Washington, DC. The study collected electronic clinical data from all abortions provided by the participating clinics for a defined period between April 2021 and January 2022. During clinic intake, patients consented to share anonymized data with our research team. Patients approved for care between June 2021 and January 2022 were also invited to participate in a series of 3 surveys: 1 at abortion intake, another in the week after intake, and a final survey 4 weeks after intake. The baseline survey assessed patient sociodemographic characteristics and initial reasons for choosing telehealth. The first follow-up survey assessed medication administration and additional medical care received. The final survey assessed additional medical care received and experiences with the telehealth model including open-ended and closed-ended questions. Surveys were administered until all 3 surveys were completed by approximately 400 participants from each clinic. Participants received $50 as remuneration after the completion of all 3 surveys.

One clinic used synchronous communication with a phone or video call to screen patients for eligibility. The other 2 screened patients through asynchronous communication, which involved an online consultation form and subsequent communication via secure written messages. One of the clinics that screened patients through asynchronous communication by default also offered the option to request a synchronous intake appointment. Abortion costs from the 3 virtual clinics ranged from $199 to $239. During the study period, virtual clinics did not accept health insurance; however, each clinic offered financial assistance for the cost of the abortion via abortion funds.

Measures

We used several indicators of patient acceptability as the main outcome measures (Table A, available as a supplement to the online version of this article at https://ajph.org). We examined participants' reasons for choosing telehealth reported in the baseline survey; participants could select all reasons that applied. The remaining outcome measures were asked in the 4-week follow-up survey. We assessed overall satisfaction, with Likert scale response options categorized into "very satisfied" versus other responses. We assessed whether participants could trust the virtual clinic with their care, whether they felt cared for throughout the abortion process, and whether telehealth was the right decision for them using individual dichotomous items ("yes" vs "no" or "don't know"). Open-ended questions modeled the closed-ended items, assessing reasons for choosing telehealth, benefits of telehealth abortion, why they did or did not feel cared for,

GBP-PET00406

and how they felt like they could or could not trust the virtual clinic.

The baseline survey asked participants to identify the benefits and drawbacks of the telehealth abortion model in 2 select-all-that-apply items, with the option to write in other responses. Other responses were coded into closed-ended responses, the most common of which are represented in the results.

Our primary key predictor was whether patient acceptability outcomes differed between those who received synchronous and asynchronous abortion care. Our secondary key predictor was the participant's race or ethnicity. Covariates included categorized measures of participant age at abortion intake, pregnancy duration on the day of abortion intake, education level, and health insurance coverage. We included binary measures reflecting experiences of food insecurity in the past month, previous medication abortion, whether the participant was born outside of the United States, and whether their zip code corresponded to an urban, or a suburban or rural area.

Statistical Analysis

We reported sample characteristics using descriptive statistics and used the χ^2 and Fisher exact test to examine differences between the groups that received synchronous and asynchronous care. We used multivariable logistic regression to examine associations between participant and abortion model characteristics, and each patient acceptability indicator. Patient age (< 25 years; 25–29 years; 30–34 years; ≥ 35 years), pregnancy duration (< 35 days; 35–49 days; ≥ 50 days), and race or ethnicity categories (White; Black; Hispanic or Latinx; Asian, Native Hawaiian, or Pacific Islander; American Indian or Alaska Native, Middle Eastern or North African, or multiracial) were collapsed in the regression analyses to facilitate model convergence. We used predictive margins to calculate adjusted rates of each patient acceptability indicator.

Open-Text Responses

To illustrate meaning and provide context for the quantitative results, we purposively selected from the open-ended survey responses. L. R. K. and U. D. U. identified candidate quotes that corresponded to each patient acceptability indicator, among which L. R. K. selected final quotes for inclusion.

RESULTS

Originally, 1632 participants enrolled in the longitudinal surveys (32% of invited patients). Among those, we excluded 32 participants who took neither mifepristone nor misoprostol, resulting in an initial sample of 1600 survey participants in 20 states and Washington, DC. Ultimately, 1312 (82%) completed the 4-week follow-up survey.

We described sample characteristics in Table 1. At abortion intake, mean participant age was 29 years and mean pregnancy duration was 40 days (< 7 weeks). Across the sample, 53% identified as White; 14% as multiple races or ethnicities; 13% as Hispanic or Latinx; 9% as Black; 6% as Asian, Native Hawaiian, or Pacific Islander; 1% as American Indian, Native American, or Alaska Native; and 1% as Middle Eastern or North African. Nearly half (42%) had completed college or more education, and 21% experienced running out of food in the past month. Most (89%) participants were born in the United States and resided in urban areas (91%). More than half (56%) resided in the US West, 20% in the Northeast, and smaller proportions in the Midwest (12%) and South (12%). One third (29%) had a previous medication abortion and 59% had private health insurance. One third (31%) had a video or phone call during abortion intake (synchronous care). At the clinic that provided asynchronous care but offered the option to request synchronous care, 1% received synchronous care.

Motivations for and Benefits of Telehealth

We examined participants' reasons for choosing telehealth at baseline (Figure 1). The most common reasons for choosing telehealth were feeling more comfortable at home (75%) and privacy (59%). Participants explained the importance of these features in open-ended responses:

> I felt more comfortable and less anxious about the whole process from being able to be home. I really appreciate having the opportunity to be in the comfort of my own home for the abortion and with my spouse for the entire duration and not in a cold room with strangers to have an uncomfortable procedure. –Age 26 years, Georgia, synchronous care

More than half (58%) identified lower costs relative to in-clinic care as a reason for using telehealth, a theme that participants expanded on in open-ended responses:

> I couldn't afford a surgical or medical abortion from the clinic. [Telehealth care] is half the price of abortions where I live. –Age 21 years, Oregon, synchronous care

More than half (55%) of respondents endorsed a desire to have the abortion

as soon as possible, and many cited long waiting times at abortion clinics as a reason for choosing telehealth in open-ended fields:

> The biggest thing was time. [Clinics were] booked out for weeks, and I didn't want to wait weeks. –Age 32 years, Oregon, synchronous care

Meanwhile, 44% were motivated to use telehealth because it allowed them to take care of their own treatment. One participant explained,

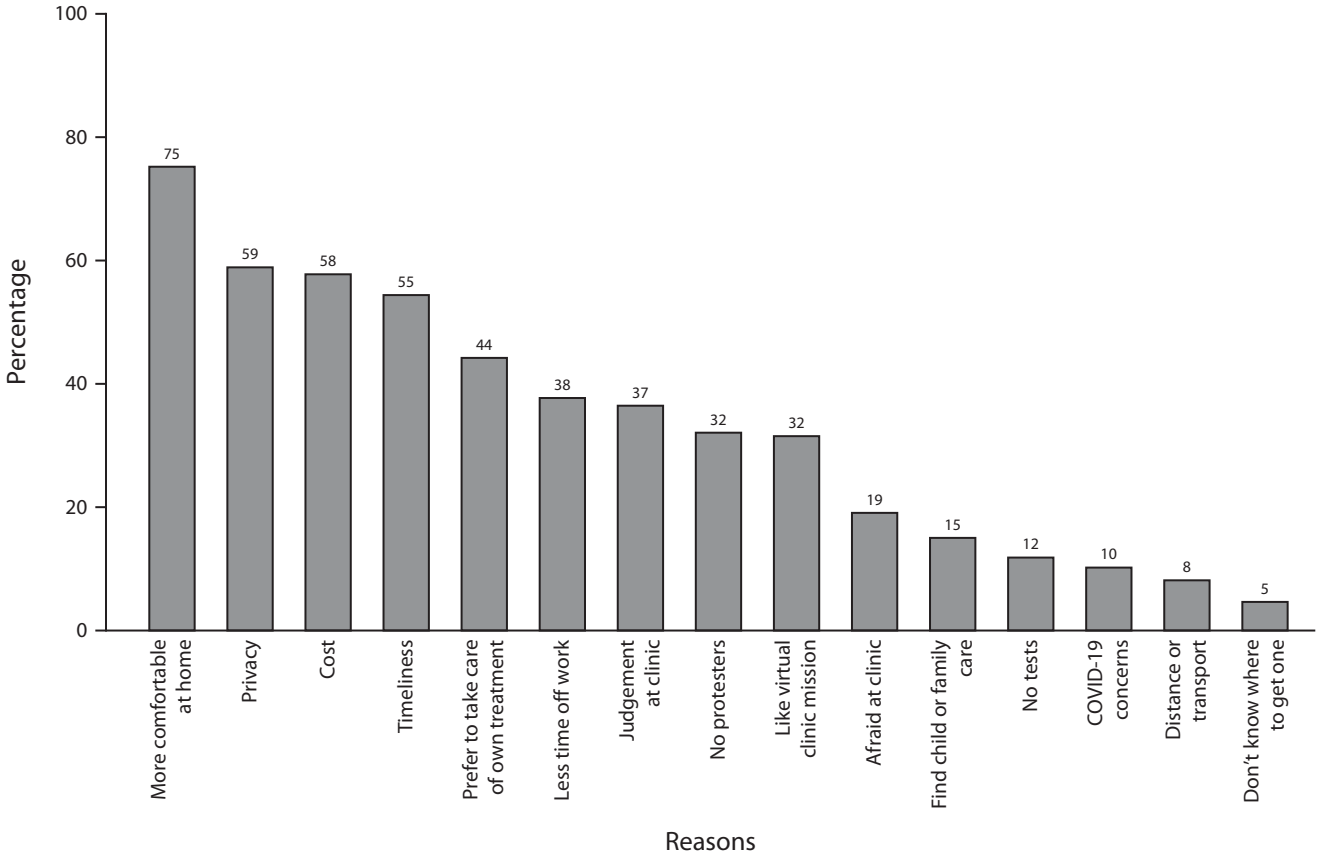

FIGURE 1— Reasons for Choosing Telehealth: United States, 2021–2022

Note. The sample size was 1600.

GBP-PET00409

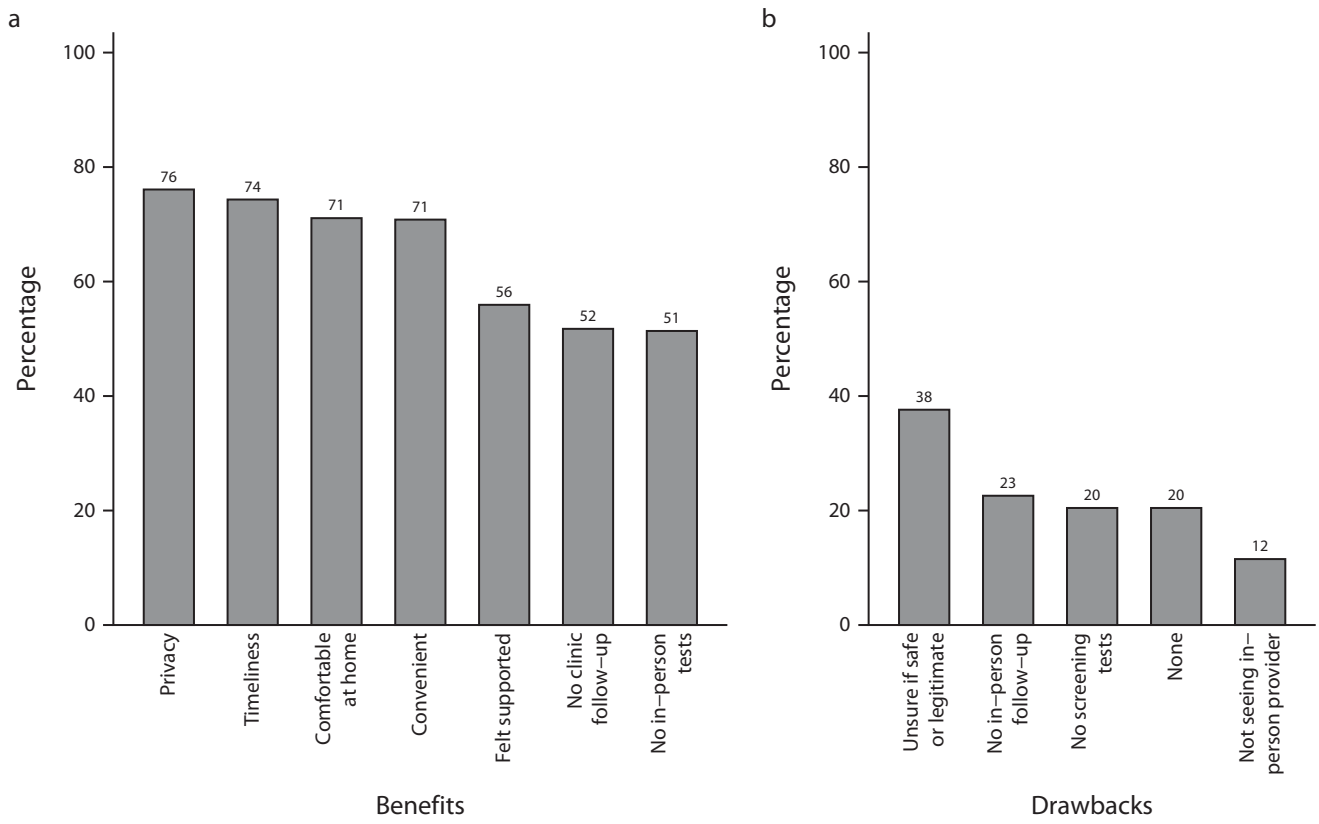

FIGURE 2— Telehealth Abortion (a) Benefits and (b) Drawbacks: United States, 2021–2022

Note. The sample size was 1312.

> I appreciate this experience of having the autonomy to be able to manage my own care with adequate support from a nurse practitioner. –Age 32 years, Illinois, asynchronous care

Similarly, another participant wrote,

> I felt more safe or secure, more empowered doing it my own way. –Age 26 years, California, asynchronous care

At the 4-week follow-up survey, the most common benefits of telehealth that participants cited were privacy (76%), expediency (74%), being more comfortable at home (71%), and convenience (71%; Figure 2). Overall, 56% of participants endorsed feeling supported as a benefit, and half cited not needing to go to the clinic for in-person screening tests (51%) or for follow-up (52%). One participant described their preference to have their abortion without ultrasound:

> At a stressful time, I don't want to be subjected to a vaginal ultrasound and blood work. If I know when I got pregnant, I don't need an ultrasound. –Age 36 years, Illinois, asynchronous care

Drawbacks of Telehealth

When asked about the drawbacks of telehealth, the most common response was uncertainty about whether the service was safe or legitimate (38%). Some participants described deciding to place their trust in the virtual clinic as a leap of faith:
