Currently, there are two types of RADV-related appeals processes described in our regulations at § 422.311: Medical record review-determination appeals and RADV payment error calculation appeals. RADV medical record review-determination appeal requirements and procedures are discussed at § 422.311(b)(3) and § 422.311(c)(2). Medical record review determination appeal is a two-stage administrative appeal process—the first step is a hearing by a hearing officer, followed by a CMS Administrator—level review. This appeal procedure provides MA organizations with an opportunity to appeal RADV medical record review determinations that are made by coders reviewing the medical record documentation submitted by MA

organizations undergoing RADV audit. The second type of RADV appeal, payment error calculation appeal, is discussed at § 422.311(c)(3). Payment error calculation appeal is a three-pronged appeal process: reconsideration, followed by a hearing officer review, followed by CMS Administrator—level review. This appeal process was specifically designed to afford MA organizations the opportunity to appeal CMS's contract-level RADV payment error calculation.

We proposed that the administrative appeals language described at § 422.311(b)(3) and § 422.311(c)(2) for RADV medical record review determination appeals and § 422.311(c)(3) for RADV payment error calculation appeals be replaced with new regulatory language proposed § 422.311(c)(1), that combines the two existing RADV appeal policies and procedures into one set of requirements and one process. We proposed to combine the two RADV appeals processes into one combined RADV appeals process that is comprised of three administrative steps: Reconsideration, hearing officer review, and CMS Administrator-level review. A three-step administrative appeals process comprising reconsideration, hearing officer review, and Administrator-levels of review is a common administrative appeals model used elsewhere within the Medicare managed care program, such as in appealing contract award determinations and intermediate sanctions. The combined RADV appeal process that we proposed at new § 422.311(c)(1), also has the benefit of simplifying what is today a complex two-track appeal process into one process. While both CMS and the MA industry will benefit from simplifying this process, MA organizations also obtain an additional level of review under the combined approach since MA organizations will be afforded a reconsideration appeal step for medical record review determinations that is today—not part of the existing RADV appeal process. Shortening the existing two-track appeal process should also reduce the resources and level of effort needed from both MA organizations and CMS in participating in a RADV appeal proceeding. Under this proposal, MA organizations can simply request to appeal their RADV audit findings one time and specify whether they want to appeal either their medical record review determination(s), payment error calculation, or both. The specific details regarding this proposed process follow. We proposed these changes based upon

our experience with RADV appeals and because we hope to reduce the burden associated with undertaking RADV appeals on both MA organizations and CMS. The details of the proposed policy and procedure follow.

(1) Issues Eligible for RADV Appeal

Current regulations at §§ 422.311(c)(2) et seq., and 422.311(c)(3) et seq., specify RADV-related medical record review and payment error calculation documents and issues eligible for the medical record review determination and payment error calculation appeal processes. We proposed to amend the policies and procedures around issues eligible for RADV appeals at § 422.311(c)(2) and § 422.311(c)(3) by combining proposed policies and procedures for the existing two-pronged appeal approach into one set of policies and procedures for RADV appeals at the new § 422.311(c)(2)(iv). At § 422.311(c)(2)(i), we proposed that as a general rule, MA organizations may appeal RADV medical record review determinations and RADV payment error calculation, though in order to be eligible to pursue these appeals, we specify at proposed § 422.311(c)(2)(i)(A) and (B) that MA organizations must adhere to established RADV audit procedures and requirements and adhere to RADV appeals procedures and requirements. At § 422.311(c)(2)(ii) we proposed that failure to follow RADV audit procedures and requirements and RADV appeals procedures and requirements will render the MA organization's request for RADV appeal invalid. Furthermore, at proposed § 422.311(c)(2)(iii) we stipulate that the MA organization's written request for medical record review determination appeal must specify the audited HCC(s) that have been identified pursuant to RADV audit as being in error, and further specify that MA organizations must provide a justification in support of the audited HCC(s) that the MA organization elects to appeal. At § 422.311(c)(2)(i)(iv) we proposed that for each audited HCC, MA organizations may appeal one medical record that has undergone RADV medical record review and that if an attestation was submitted to cure a signature or credential issue, that attestation may likewise be included in the HCC appeal. For example, if an MA organization submitted a medical record that did not contain a signature and/or credential—and the MA organization submitted an attestation to cure the error that CMS subsequently failed to accept—the MA organization could choose to appeal CMS's determination to not accept the submitted attestation. We reiterate that

the purpose of CMS-generated attestations is to cure signature and credential errors associated with an eligible submitted medical record and not to provide an opportunity for a provider or supplier to attest that a beneficiary has a certain medical condition. Evidence for the existence of the medical condition is found in a medical record.

We proposed to modify our language at § 422.311(c)(2)(i)(v) to clarify existing RADV appeals provisions which stipulate that MA organizations must adhere to the "one best medical record" policy. Under changes to the RADV audit methodology announced by CMS in February 2012, we now allow MA organizations to submit more than one medical record (that is, more than the "one best medical record") during the RADV audit process to validate an audited CMS-HCC. However, for purposes of appealing a CMS medical record review determination, we will not permit organizations to appeal multiple medical records but will instead—require that MA organizations identify a record from amongst those records submitted, and to submit that record for appeal. For each audited HCC, MA organizations may appeal only one medical record that has undergone RADV review. This policy was published in the February 2012 White Paper and is not included in this final rule.

At § 422.311(c)(2)(vi) we proposed that a written request for RADV payment error calculation appeal must clearly specify the MA organization's own RADV payment error calculation and must also specify where the payment error calculation was erroneous.

(2) Issues Not Eligible for RADV Appeals

At § 422.311(c)(3) we proposed documents and issues that are ineligible for RADV appeals. Consistent with the overall approach of combining into one RADV appeals process what was heretofore two separate RADV appeals processes—by way of this new proposed section, we propose to amend existing regulations at § 422.311(c)(3). At new § 422.311(c)(3), we proposed that MA organizations' request for appeal may not include HCCs, medical records or other documents beyond the audited HCC, selected medical record and any accompanying attestation that the MA organization chooses to appeal. We specify at § 422.311(c)(3)(ii) that the MA organizations may not appeal CMS's medical record review determination methodology or CMS's payment error calculation methodology. This is a

clarification to existing RADV regulations at § 422.311(c)(3)(D) which specifies that MA organizations may not appeal CMS's payment error calculation methodology. At § 422.311(c)(3)(iii) we specify that MA organizations may not appeal RADV medical record review-related errors when appealing RADV error-calculation issues since medical record review determination issues must be resolved before we can calculate RADV payment errors. And at § 422.311(c)(3)(iv) we specify that RADV errors that result from an MA organization's failure to submit a medical record are not eligible for appeal.

(3) Manner and Timing of a Request for RADV Appeal

We proposed to replace existing RADV regulations at § 422.311(c)(2)(iii) et seq., and § 422.311(c)(3)(iii) et seq., regarding the manner and timing of a request for RADV appeals. Again, at § 422.311(c)(5), we proposed to combine the formerly two separate sets of requirements and procedures into one RADV appeals process addressing the request for RADV appeal. At § 422.311(c)(5)(i) we proposed that at the time the Secretary issues her RADV audit report, the Secretary notifies audited MA organizations that they may appeal RADV HCC errors that are eligible for medical record review determination appeal and may appeal the Secretary's RADV payment error calculation. At § 422.311(c)(5)(ii) we specify that MA organizations have 30 days from the date of CMS's issuance of the RADV audit report to file a written request with CMS for RADV appeal. This request for RADV appeal must specify whether the MA organization requests medical record review determination appeal, whether the MA organization requests RADV payment error calculation appeal, or whether the MA organization requests both medical record review determination appeal and RADV payment error calculation appeal—and in each instance—the issues with which the MA organization disagrees, and the reasons for the disagreements. See proposed regulations at § 422.311(c)(6).

In proposed § 422.311(c)(5)(ii), we specify that while MA organizations may now elect to appeal either medical record review determination, payment error calculation, or both—they must notify CMS which issues they will appeal at the same time. This new provision replaces existing RADV appeals requirements regarding notification at § 422.311(c)(2)(iii) and § 422.311(c)(3)(iii)(C).

Medicare and Medicaid Programs; Policy and Technical Changes to the Medicare Advantage, Medicare Prescription Drug Benefit, Program of All-Inclusive Care for the Elderly (PACE), Medicaid Fee-For-Service, and Medicaid Managed Care Programs for Years 2020 and 2021

AGENCY: Centers for Medicare & Medicaid Services (CMS), HHS.

ACTION: Final rule.

SUMMARY: This final rule announces certain policies to improve program

integrity and payment accuracy in the Medicare Advantage (MA) program. The purpose of this final rule is to outline our audit methodology and related policies for the contract-level MA Risk Adjustment Data Validation (RADV) program. Specifically, this final rule codifies in regulation that, as part of the RADV audit methodology, CMS will extrapolate RADV audit findings beginning with payment year (PY) 2018 and will not extrapolate RADV audit findings for PYs 2011 through 2017. We are also finalizing a policy whereby CMS will not apply an adjustment factor (known as a Fee-For-Service (FFS) Adjuster) in RADV audits. We are also codifying in regulation the requirement that MA organizations (MAOs) remit improper payments identified during RADV audits in a manner specified by CMS.

DATES: This final rule is effective on April 3, 2023.

FOR FURTHER INFORMATION CONTACT: Joseph Strazzire, 410-786-2775 or David Gardner, 410-786-7791.

SUPPLEMENTARY INFORMATION:

I. Executive Summary

Contract-level Risk Adjustment Data Validation (RADV) audits are our main corrective action for overpayments made to Medicare Advantage organizations (MAOs) when there is a lack of documentation in the medical record to support the diagnoses reported for risk adjustment. The purpose of this final rule is to outline our audit methodology and related policies for the contract-level RADV program. Specifically, this final rule codifies in regulation our approach to the use of extrapolation, our decision to not apply an FFS Adjuster in RADV audits, and the payment years in which these policies will apply.

We are finalizing that, as part of the RADV audit methodology, CMS will extrapolate RADV audit findings. We are not adopting any specific sampling or extrapolated audit methodology, but will rely on any statistically valid method for sampling and extrapolation that is determined to be well-suited to a particular audit. Rather than applying extrapolation beginning for payment year (PY) 2011 audits as we proposed,

we are finalizing a policy whereby we will not extrapolate RADV audit findings for PYs 2011 through 2017 and will begin extrapolation with the PY 2018 RADV audit. As a result, CMS will only collect the non-extrapolated overpayments identified in the CMS RADV audits and Department of Health and Human Services Office of Inspector General (HHS-OIG) audits between PY 2011 and PY 2017, and will begin collection of extrapolated overpayment findings for any CMS and OIG audits conducted in PY 2018 and any subsequent payment year. We believe that this is an appropriate policy because it recognizes our fiduciary duty to protect taxpayer dollars from overpayments, and preserves our ability to collect on potentially significant amounts of overpayments made to plans beginning in PY 2018 using an extrapolation methodology. This final rule will also allow CMS to focus on conducting future RADV audits as soon as practicable after an MAO payment year concludes, which was the topic of significant public comment to the proposed rule. Lastly, we have determined that it is in the best interest of all parties to ensure that the contract-level RADV appeals process, which is also outlined in regulation, is able to successfully process all RADV appeals. By not using an extrapolation methodology prior to PY 2018, we expect to better control the total number of active appeals that are submitted in the first few years following finalization of this rule, which will alleviate burden on MAOs and CMS.

We are also finalizing a policy whereby CMS will not apply an FFS Adjuster in RADV audits because we have determined that an FFS Adjuster is not appropriate. As described at great length in this final rule, we have decided not to apply an FFS Adjuster in RADV audits because: (1) we believe, consistent with the D.C. Circuit's decision in *UnitedHealthcare Insurance Co. v. Becerra*, 16 F.4th 867 (D.C. Cir. August 13, 2021, reissued November 1, 2021), cert. denied, 142 S. Ct. 2851 (U.S. June 21, 2022) (No. 21-1140)), that the actuarial equivalence provision of the statute applies only to how CMS risk adjusts the payments it makes to MAOs and not to the obligation of MAOs to return improper payments (for example, payments for unsupported diagnosis codes); and (2) it would not be reasonable to read the Social Security Act (the Act) as requiring a reduction in payments to MAOs by a statutorily-set minimum adjustment in the coding pattern adjustment, while at the same

time prohibiting CMS from enforcing longstanding documentation requirements by requiring an offset to the recovery amounts calculated for CMS audits.

We are also codifying in regulation the requirement that MAOs remit improper payments identified during RADV audits in a manner specified by CMS. After the effective date of this final regulation, on a rolling basis (over a period of months, which will be communicated to MAOs by CMS), we will begin issuing the enrollee-level audit findings from the CMS RADV audits that have been completed, as well as recovering the enrollee-level improper payments identified in HHS-OIG audits.

Nothing in this rule changes the longstanding principle that a diagnosis code that is not documented in a patient's medical record is not a valid basis for CMS risk adjustment payments to an MAO. *UnitedHealthcare Ins. Co. v. Becerra*, 16 F.4th 867, 869 (D.C. Cir. 2021) ("Neither Congress nor CMS has ever treated an unsupported diagnosis for a beneficiary as valid grounds for payment to a Medicare Advantage insurer."). Nor does this rule change the longstanding obligation of an insurer to refund payments to CMS if it learns through any means that a diagnosis lacks support in the beneficiary's medical record. *Id.*

II. Background

A. General Overview of Risk Adjustment Payments in the MA Program

The Balanced Budget Act of 1997 (BBA), Public Law (Pub. L.) 105-33, established a new Part C of the Medicare program, known then as the Medicare+Choice (M+C) program, which became effective in January 1999. As part of the M+C program, the BBA authorized CMS to contract with public or private organizations to offer a variety of health plan options for Medicare beneficiaries. These health plans provide all Medicare Part A and Part B (also known as "Original Medicare," or "Medicare FFS") benefits, and most offer additional benefits beyond those covered under the Medicare FFS program. The M+C program in Part C of Medicare was renamed the Medicare Advantage (MA) program under the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (MMA) (Pub. L. 108-173), enacted in December 2003. The MMA updated and improved the choice of plans for beneficiaries under Part C and changed the way benefits are established and payments are made. As of August 2022, over 29 million individuals receive their

Medicare benefits through MA, which represents nearly half of the total Medicare beneficiary population.¹

Section 1853(a)(1)(C) of the Act requires that CMS risk-adjust payments made to MAOs. Risk adjustment strengthens the MA program by ensuring that accurate payments are made to MAOs based on the health status and demographic characteristics of their enrolled beneficiaries, and that MAOs are paid appropriately for their plan enrollees (that is, less for healthier enrollees who are expected to incur lower health care costs, and more for less healthy enrollees who are expected to incur higher health care costs). Making accurate payments to MAOs also ensures we are safeguarding Federal taxpayer dollars.

The current risk adjustment model employed to adjust MAO payments is known as the CMS Hierarchical Condition Category (CMS-HCC) model. This model functions by categorizing International Classification of Disease, Clinical Modification (ICD-CM)² diagnosis codes into disease groups called Hierarchical Condition Categories, or HCCs. Each HCC includes diagnosis codes that are related clinically and have similar cost implications. There are approximately 9,875 diagnoses mapped to 86 HCCs in the CMS-HCC Risk Adjustment Model for 2022.³ MA enrollee HCCs are assigned based on data submitted to CMS by MAOs. The HCCs contribute to an enrollee's risk score, which is used to adjust a base payment rate. Essentially, the higher the risk score for an enrollee, the higher the expected health care cost for the enrollee and the greater payment that is received by the MAO.

The CMS-HCC model was first used for payment in 2004 and has been recalibrated numerous times since then. When CMS recalibrates the CMS-HCC risk adjustment model, it uses data from Medicare FFS claims, using diagnoses in one year to predict the following year's expenditures. Claims data from beneficiaries enrolled in the Medicare FFS program are used to calibrate the CMS-HCC model, which produces a set of coefficients (also known as risk

¹ CMS, *CMS Fast Facts*, August 2022 Edition, pg.1, <https://data.cms.gov/sites/default/files/2023-08/4f0176a6-d534-47c1-b447-b074f014079a/CMSFastFactsAug2022.pdf>.

² The ICD-CM is a modification of the ICD, authorized by the World Health Organization, used as a source for diagnosis codes in the United States. The ICD-CM has been adopted by the Secretary as the standard medical data code set. See 45 CFR 161.1002.

³ Source: 2022 Midyear Final ICD-10 Mappings at <https://www.cms.gov/fileszip/2022-midyear-final-icd-10-mappings.zip>.

factors) that represent the marginal (additional) cost of each medical condition and demographic factor reported for a given beneficiary. (For additional information, see the Medicare Managed Care Manual, Ch. 7, section 70.1.4.) Each beneficiary's risk coefficients are added together to form a risk score for that beneficiary that is used to adjust the insurer's base payment rate for that beneficiary.

The diagnosis data that MAOs submit to CMS do not undergo a validation review by CMS before being relied on by CMS to calculate each enrollee's risk score and make payments. Because there is an incentive for MAOs to potentially over-code diagnoses to increase their payments, that is, to code diagnoses not properly substantiated by medical record documentation, CMS conducts post-payment audits of MAO-submitted diagnosis data from a selection of MAOs for specific payment years to ensure that the diagnoses they submitted are supported by their enrollees' medical records. These audits are called contract-level Risk Adjustment Data Validation (RADV) program audits. While RADV audits are intended to identify improper risk adjustment payments, they are not specifically designed to detect fraud,⁶ nor are they intended to identify all improper diagnosis submissions made by MAOs for risk adjustment payment.⁶

B. Purpose and Description of Contract-Level RADV Audits

The improper payment measurements conducted each year by CMS that are included in the HHS Agency Financial Report, as well as audits conducted by

the HHS-OIG, have demonstrated that the MA program is at high risk of improper payments. In fiscal year (FY) 2021 (based on calendar year 2019 payments), we calculated that CMS made over \$15 billion in Part C overpayments, a figure representing nearly 7 percent of total Part C payments.⁷ The HHS-OIG has also released several reports over the past few years that demonstrate a high risk of improper payments in the MA program,⁸ and for several years has identified the MA program as one of the top management and performance challenges facing HHS due to the high amount of improper payments.⁹ The Medicare program, including MA, has also been identified by the Government Accountability Office (GAO) as a high-risk program due to the risk of substantial improper payments.¹⁰

RADV audits are our main corrective action for overpayments made to MAOs when there is a lack of documentation in the medical record to support the diagnoses reported for risk adjustment. We select MAOs for RADV audits using a risk-based approach that focuses on HCCs that are more likely to be in error as identified by prior RADV audits, Part

C Improper Payment Measurements, and OIG findings, and other vulnerability analyses. RADV audits occur after the final risk adjustment data submission deadline for the MA contract year and after CMS recalculates the risk factors for affected individuals to determine if payment adjustments are necessary, as described at 42 CFR 422.310(g).¹¹ RADV audits are intended to confirm the presence of risk adjustment conditions (that is, diagnoses that map to HCCs) as reported by MAOs in medical record documentation. RADV audits confirm the presence of the diagnoses related to the enrollee's HCC profile through the review of certain categories of medical records submitted by the MAOs for the purpose of a RADV audit; specifically, inpatient hospital, hospital outpatient facility, and physician/practitioner (excluding suppliers of durable medical equipment, prosthetics, orthotics, and supplies) medical records. Risk adjustment discrepancies are identified when an enrollee's HCCs used for payment, which are based on MAO self-reported data, differ from the HCCs assigned based on the medical record review performed by CMS through the RADV audit process. Risk adjustment discrepancies can be aggregated to determine an overall level of payment error. In turn, payment error for a sample of contract enrollees can be used to calculate a total payment error estimate, for the larger universe of enrollees within an MAO contract from which a sample is drawn, within specified confidence intervals using statistical extrapolation.

C. History of the Contract-Level RADV Program

RADV audits have existed in various forms and approaches for over 20 years. RADV audits began for payment year (PY) 1999, when the amount of payment made to MAOs on a risk-adjusted basis was small (10 percent). During the audit period from PY 1999 until PY 2003, our RADV activity had an educational focus and was primarily intended to provide information that could be used by MAOs to improve the accuracy of the risk adjustment data submitted to CMS for payment. Payment adjustments (recoveries) were limited to enrollee-level adjustments for those enrollees sampled in the audits and were not extrapolated to the overall error of the

⁶ <https://www.cms.gov/Regulations-and-Guidance/Guidance/Manuals/Downloads/m180607.pdf>.

⁷ For example, the Department of Justice is responsible for pursuing potential violations of the False Claims Act, which includes certain elements of knowledge.

⁸ CMS contract-level RADV audits focus on specific MAO contracts to determine and recover improper payments. The HHS-OIG also undertakes audits of MAOs, similar to RADV audits, as part of its oversight functions. CMS can collect the improper payments identified during those HHS-OIG audits, including the extrapolated amounts calculated by the OIG. CMS also oversees the Part C Improper Payment Measurement, previously referred to as "national RADV," to determine a program-wide improper payment rate as required by the Payment Integrity Information Act of 2019 (Pub. L. 116-117). In addition to risk adjustment oversight conducted by CMS, HHS also oversees HHS-RADV, which was created by the Affordable Care Act to strengthen the integrity of the Affordable Care Act Marketplace by validating the accuracy of data submitted by issuers that is used to calculate the amount of funds transferred to issuers based on the actuarial risks of the individuals they enroll. Neither the Part C Improper Payment Measurement nor the HHS-RADV programs are subject to the provisions of this final rule.

⁹ HHS, FY 2021 HHS Agency Financial Report, pg. 211, <https://www.hhs.gov/sites/default/files/fy-2021-hhs-agency-financial-report.pdf>. CMS made over \$23 billion in total Part C improper payments. The improper payment measurement for the MA program in FY 2021 included both overpayments (\$11 billion) and underpayments (\$8 billion).

¹⁰ For example, see reports: Medicare Advantage Compliance Audit of Specific Diagnosis Codes That Anthem Community Insurance Company, Inc. For example, see reports: Medicare Advantage Compliance Audit of Specific Diagnosis Codes That Anthem Community Insurance Company, Inc. ¹³ See the May 23, 2014 final rule titled "Medicare Program: Contract Year 2015 Policy and Technical Changes to the Medicare Advantage and the Medicare Prescription Drug Benefit Programs Final Rule" (79 FR 29843, at 29926) for a more detailed discussion of the timing and execution of the RADV audit and appeals process.

contract. As a result, for the few MA plans we audited, payment recovery amounts were small.

Risk adjustment payments using the CMS-HCC risk adjustment model began for the first time in PY 2004. Because of various risk adjustment payment methodology changes required in the BBA and the Benefits Improvement and Protection Act of 2009 (BIPA) (Pub. L. 111-154), we provided a payment "phase-in" under the new risk adjustment methodologies from 2000 to 2007, when MAOs' payments were 100 percent risk-adjusted under the current methodology.¹² Under the new methodology that began in PY 2004, MAOs were required to submit diagnoses from multiple sites of care, which increased the administrative data burden on MAOs. Because of this burden and the associated phase-in of the new methodology, CMS considered PYs 2004 through 2006 as pilot years for the purpose of the RADV program and did not seek to recover improper payments for those payment years based on the audit results.

Improper payment recovery resumed for PY 2007, when we conducted two sets of RADV audits: (1) Pilot 2007, which involved 5 MA contracts; and (2) Targeted 2007, which involved 32 MA contracts. CMS began with the Pilot 2007 audit to test the methodology and make any needed changes before conducting the Targeted 2007 audit. CMS selected MA contracts after measuring the weighted average change in disease scores (risk scores) over the preceding 3-year period and grouping MAO contracts as high, medium, or low relative to other MA contracts that were eligible for a RADV audit. Through these two sets of audits, we recouped \$13.7 million. Payment adjustments were again limited to enrollee-level adjustments for those enrollees sampled in the audits and not extrapolated to the overall contract error. After CMS' findings were reported to each MAO, any MAO that disagreed with CMS' determinations could challenge them through an administrative dispute and appeals process that was established by regulation (75 FR 19678). This dispute and appeals process, as subsequently amended (75 FR 32858 and 79 FR 29844), remains in effect and allows for the appeal of the medical record review determination and/or the payment error calculation through a three-level administrative review process, as

outlined in 42 CFR 422.311. To date, CMS has not recovered based on RADV audit findings for audit years after PY 2007, as described more fully in this section of this rule.

1. Development of an Audit Methodology (PYs 2007 Through 2010)

After the RADV audits were conducted for PY 2007, CMS paused RADV audits for PYs 2008, 2009, and 2010. CMS used those years to continue refining the methodology for the RADV audits, including the consideration of statistical methods to calculate extrapolated improper payments based on the individual errors identified. The use of extrapolation would enable us to make contract-level payment adjustments rather than simply adjusting payments for specific enrollees from an audit sample, as we had done previously.

On December 20, 2010, we published an informal proposal on the CMS website that outlined our intended RADV methodology for: (1) selecting a statistically valid sample of enrollees from each audited MA contract; and (2) calculating a contract-level payment adjustment by extrapolating the results of that sample. We invited public comment on this proposed methodology.

2. Informal Proposal Comments and the FFS Adjuster

In response to the December 2010 informal proposal, some MAOs suggested that CMS cannot lawfully enforce the requirement of medical record documentation for diagnosis codes while making payments at the published rates. These MAOs argued that there is a difference in auditing standards between Medicare FFS and MA diagnosis data because, in contrast to the MAO-submitted diagnoses data, Medicare FFS data is "unaudited" by CMS. This difference purportedly exists because most FFS payments are made on the basis of the item or service provided and not the beneficiary's diagnosis or diagnoses. For example, an office visit is paid based on whether the evaluation and management service billed met Medicare coverage and payment rules, not based on what diagnoses are listed on the claim or in the medical record. As a result, they argued, the Medicare FFS data used to calculate MAO payments will understate the cost of treating various conditions and, because erroneous diagnoses in the FFS claims data are used to calibrate the MA payment model, CMS must either adjust payment rates (by raising them) or adjust documentation standards (by loosening

them) to resolve the alleged incompatibility between the payment rates and documentation standards. This proposed adjustment to the MAO payment rates and/or documentation standard is referred to as an "FFS Adjuster."

To understand the MAOs' argument about why an FFS Adjuster is needed, some background is important. These MAOs ground their arguments in section 1853(a)(1)(C)(i) of the Act, which requires the Secretary to adjust payments to MAOs for demographic and health-related risk factors so as to ensure "actuarial equivalence." As described previously, the Act requires that we calculate risk-adjusted payments to MAOs to ensure that MAOs are paid appropriately based on the enrollees' health status and demographic characteristics. The current risk adjustment model does this by calculating plan enrollees' risk scores and, in turn, using them to adjust the MAOs' base payment rates, which are the rates for the average beneficiary.

This system of risk adjustment rests on two important principles. First, MAOs' payments are calculated using the CMS-HCC risk adjustment model, which is published each time it is updated (see section 1853(b) of the Act).¹³ Second, an MAO may only report a diagnosis when that diagnosis is properly supported by the beneficiary's medical records. As we noted in our April 15, 2022 Health Plan Management System (HPMS) memorandum, *Reminder of Existing Obligation to Submit Accurate Risk Adjustment Data*, MAOs must submit data that conforms to all relevant national standards, including the International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) Guidelines for Coding and Reporting requirement that diagnoses be documented in patients' medical records. (See 42 CFR 422.310(d)(1); 45 CFR 162.1002(c)(2) and (c)(3).) The diagnosis codes and other risk adjustment information that MAOs submit directly affect the calculation of CMS payments to the MAO. A diagnosis code that is not documented in a patient's medical record is not a valid basis for CMS risk adjustment payments to an MAO. *UnitedHealthcare Ins. Co. v. Becerra*, 16 F.4th 867, 869, 877 (D.C. Cir. 2021). Medical records properly support a reported diagnosis when they comply with all CMS data and documentation requirements, which are described in current agency policy

¹² CMS, *Advance Notice of Methodological Changes for Calendar Year (CY) 2004 Medicare+Choice (M+C) Payment Rates*, 4-5 (March 28, 2003), <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/Downloads/Advance2004.pdf>.

¹³ <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/Announcements-and-Documents>.

documents, including the Medicare Managed Care Manual.¹⁴ In their annual contracts with CMS, MAOs agree to operate in accordance with applicable Federal statutes, regulations, and policies, including policies described in the Medicare Managed Care Manual. MAOs are also required to submit a sample of medical records for the validation of this risk adjustment data, as required by CMS (see 42 CFR 422.310(e)).

3. The 2012 Methodology

The feedback received from industry in response to the informal proposal in 2010 was considered by CMS, and on February 24, 2012, we issued on our website¹⁵ what we described as a final methodology for RADV contract-level payment error calculation, to begin with PY 2011 RADV audits (referred to herein as the "2012 methodology"). That methodology described sampling techniques and a statistical calculation to extrapolate from the sample selected, as well as the use of an FFS Adjuster.¹⁶ (Although the use of an FFS Adjuster beginning with PY 2011 RADV audits was included in the 2012 methodology, CMS has not issued final RADV audit results for PY 2011 audits or any subsequent year, and therefore, an FFS Adjuster has not been applied to any RADV audits issued by CMS to date.)

Sampling Technique: Under the 2012 methodology, up to 201 enrollees from each audited MA contract would be selected according to certain criteria. These criteria included, but were not limited to, the enrollee's: (1) continuous enrollment in the MA contract for the entire data collection year and January of the payment year; (2) lack of end-stage renal disease (ESRD) or hospice status for the entire data collection year and January of the payment year; (3) enrollment in Medicare Part B coverage for the entire data collection year; and (4) assignment of at least one CMS-HCC based on diagnoses submitted by the MAO for risk-adjustment payment. The RADV-eligible enrollees would then be ranked by risk score and divided into three equal strata (low risk score, average risk score, and high risk score), with an equal number of enrollees randomly selected from each stratum

(for example, 67 enrollees per stratum in the case of an audit of 201 enrollees).

Payment Error Calculation: After medical records were reviewed, payment errors would be calculated for each selected enrollee based on the number of months the person was enrolled in the selected MA contract (and also was not in ESRD or hospice status) during the payment year. A payment error amount for each stratum would be calculated, which could include both RADV-identified overpayments and underpayments, and an overall payment error estimate for the audited contract would be derived, along with a 99 percent confidence interval around the payment error estimate.

FFS Adjuster: As part of the 2012 methodology, we also stated that we would apply an FFS Adjuster before finalizing audit recovery. The 2012 methodology stated that the actual value of the FFS Adjuster would be calculated by CMS based on a RADV-like review of records submitted to support FFS claims data.

CMS subsequently conducted an extensive study regarding the impact of such errors in Medicare FFS claims data for the purpose of determining the appropriate value of an FFS Adjuster. This study found that, in fact, errors in Medicare FFS claims data did not have any systematic effect on the risk scores calculated by the CMS-HCC risk adjustment model and, therefore, did not have any systematic effect on the payments made to MAOs. On October 26, 2018, we published an Executive Summary and Technical Appendix of our FFS Adjuster study findings on the CMS website, which are available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Resources.html>. Additional information on this study can also be found in the November 2018 proposed rule.

4. The 2018 RADV Proposed Rule

In the 2018 proposed rule, to enhance transparency and provide ample notice to MAOs, we proposed to codify in regulation our methodological approach to RADV audits that would apply to all of the payment year audits that have not yet been finalized. These methodologies would apply to PY 2011 and subsequent years and include our proposals to use extrapolation and not apply an FFS Adjuster to our RADV audit findings.

5. Subsequent Federal Register Notices (2018, 2019, 2021, and 2022)

Since publication of the 2018 proposed rule, we have published

several related notices to further enhance transparency and encourage robust public comment:

- On December 27, 2018, we announced in the *Federal Register* (83 FR 56681) an extension of the comment period for the proposed RADV provisions until April 30, 2019, as well as a plan to release data underlying the October 26, 2018, FFS Adjuster Study.¹⁷
- On March 6, 2019, we issued a notice in the *Federal Register* (84 FR 8069) announcing the release of additional data underlying the FFS Adjuster Study, both on the CMS website and to those organizations who established data use agreements (DUAs) with the CMS Office of Enterprise Data Analytics (OEDA).¹⁸
- On April 25, 2019, we posted updates to existing documentation related to the study data, as well as additional data on the CMS website.¹⁹
- On April 30, 2019, we issued a notice in the *Federal Register* (84 FR 18215) granting an additional extension of the comment period for the proposed RADV provisions until August 28, 2019. We also announced that we would be releasing additional data underlying the FFS Adjuster study, including data containing Protected Health Information (PHI), to all parties who entered an applicable DUA with CMS and paid the required fee.²⁰
- On June 28, 2019, we issued a notice in the *Federal Register* (84 FR 30983)²¹ that we replicated the FFS Adjuster Study and published a summary of that replication as an addendum to the study on the CMS website.²² The purpose of this replication was to allow us to test our initial results and release a more complete set of underlying data. (Certain intermediate data elements, not saved as part of the implementation of the initial study, were preserved and published in the addendum.) The

results of the replication were broadly consistent with the initial implementation of the study. In addition, the addendum contained further discussion of the study's assumptions and methodology. We also released the programming language used to implement the replication of the study, and a description of the technical requirements for use of that programming language.

• In the October 21, 2021 *Federal Register* (86 FR 58245), we issued a notice that provided a 1-year extension of the timeline for publication of the final rule.²³

As part of this extension, we explained our determination that we were unable to meet the 3-year timeline for publication.²⁴ Based on extensive public comments received on the 2018 proposed rule and subsequent FFS Adjuster study and related data, along with delays resulting from the agency's focus on the COVID-19 public health emergency, we determined that additional time was needed to address the complex policy and operational issues that were raised. As such, we

extended the timeline to publish the final rule from November 1, 2021 to November 1, 2022.

• In the November 1, 2022 *Federal Register* (87 FR 85723), we issued a notice that provided a 3-month extension of the timeline for publication of the final rule.²⁵ We explained that we were unable to meet the November 1, 2022, timeline for publication of the previously referenced RADV-audit related provisions. We explained that we continued to have ongoing delays resulting from the agency's focus on the COVID-19 public health emergency, and we determined that additional time continued to be needed to address the complex policy and operational issues that were raised. As such, we extended the timeline to publish the final rule from November 1, 2022, to February 1, 2023.

We received approximately 154 timely pieces of correspondence in response to the 2018 proposed rule and the subsequent notices and data releases. Summaries of the public comments that respond to the RADV provisions, and our responses to those public comments, are set forth in the discussion that follows. Additional public comments outside of the scope of the RADV proposed provisions were not considered and are not addressed in this final rule.

III. Provisions of the RADV Final Rule

A. Extrapolation of RADV Audit Findings

1. Use of Extrapolation in the Medicare Program

Extrapolation, or the act of estimating a value (such as an overpayment amount for a Medicare provider) based on a statistically valid sample of units (such as Medicare claims), has historically been a standard part of auditing practice at CMS. There is significant guidance, including case law and best practices from HHS and other Federal agencies, stating that extrapolation may be utilized as a valid part of calculating improper payments. In particular, courts have held that sampling and extrapolation are a valid method of calculating improper Medicare payments, so long as statistically valid methods are used. See *United States v. Lahey Clinic Hosp., Inc.*, 399 F.3d 1, 18 n.19 (1st Cir. 2005) (noting that "sampling of similar claims and extrapolation from the sample is a recognized method of proof" for the

United States in an affirmative case seeking recovery under a common-law theory). See also *Ratanasen v. California Dep't of Health Serv.*, 11 F.3d 1467, 1469–71 (9th Cir. 1993) (collecting cases in which sampling and extrapolation have been approved in the Medicaid context, and "join[ing] other circuits in approving the use of sampling and extrapolation as part of audits in connection with Medicare and other similar programs"); *Chaves Cnty. Home Health Serv. v. Sullivan*, 931 F.2d 914, 917–23 (D.C. Cir. 1991). The authority to use sampling and extrapolation in Medicare audits is grounded in our statutory and regulatory authority to audit providers and recoup improper payments. See *Chaves*, 931 F.2d at 919 (interpreting the Medicare statute to allow for a "sample adjudication procedure" followed by extrapolation from that sample, which "is reasonable given the logistical imperatives recognized by courts in other comparable circumstances").

Sampling and extrapolation have been used to calculate improper payments in Medicare FFS (Part A and Part B) for decades. CMS formally approved of this technique in 1986 (HCFA Ruling 86–1), but Medicare Administrative Contractors (MACs), which are responsible for determining medical necessity and paying Medicare FFS claims, have been using it "at least since 1972." *Chaves*, 931 F.2d at 921; see *id.* at 913 (explaining that "sample adjudication has been used in previous instances involving post-payment review of 'coverage determinations' under Part A," and that HCFA Ruling 86–1 "simply reiterated [the agency's] belief that it had the latitude to employ sample audits on post-payment review to efficiently recoup overpayments for non-covered services"). In 1991, the United States Court of Appeals for the District of Columbia Circuit, in *Chaves*, upheld the use of this audit methodology against arguments that the Medicare statute required individualized review of claims submitted by providers (*id.* at 922).

The MMA imposed limits on the use of sampling and extrapolation in Medicare payment decisions in the context of Part A and Part B, when a settlement to resolve improper payments is not reached. Since 2003, Medicare Part A and Part B extrapolation under section 1893(f)(3) of the Act has been limited to instances in which the Secretary determines either that "there is a sustained or high level of payment error" or that "documented educational intervention has failed to correct the payment error." No similar limitation applies to the MA program,

²³ <https://www.federalregister.gov/documents/2021/10/21/2021-22908/medicare-and-medicare-programs-policy-and-technical-changes-to-the-medicare-advantage-medicare>.

²⁴ Section 1871(a)(3)(A) of the Act requires the Secretary to "establish and publish a regular timeline for the publication of final regulations based on the previous publication of a proposed regulation or an interim final regulation." Section 1871(a)(3)(B) of the Act provides that "[e]ach timeline . . . shall not be longer than 3 years except under exceptional circumstances." The Secretary therefore may not "establish" a "regular timeline" for the finalization of a proposal or interim final rule that exceeds three years, absent exceptional circumstances. Section 1871(a)(3)(B) of the Act authorizes the Secretary to "vary such timeline"—that is, to alter the "regular timeline" initially "established" for finalization—by publishing a timely notice in the *Federal Register* with "a brief explanation of the justification for such variation." As we have said, "[i]f the Secretary may extend the initial targeted publication date of the final regulation, if the Secretary provides public notice including a brief explanation of the justification for the variation no later than the regulation's previously established proposed publication date." 69 FR 78443.

Under the plain text of the Act, no "exceptional circumstances" are required for the Secretary to extend the initial targeted publication date of the final regulation, but only "a brief explanation of the justification" for doing so. The Secretary has often extended such timelines without any reference to "exceptional circumstances." (See 66 FR 50363; 85 FR 55385; 85 FR 52940; 85 FR 7; 79 FR 62356; 74 FR 8867; 72 FR 16794; 72 FR 18710.) But the Secretary has also said that the Act "permits an extension of a published timeline under exceptional circumstances," 69 FR 78442, and has invoked "exceptional circumstances" in extending such timelines, including in the notices published in this rulemaking. For the reasons explained in this notice, the Act has never required exceptional circumstances for such extensions—though exceptional circumstances have often been present, as they were here, when such timelines have been extended.

²⁵ <https://www.federalregister.gov/documents/2022/11/01/2022-23563/medicare-and-medicare-programs-policy-and-technical-changes-to-the-medicare-advantage-medicare>.

As previously discussed, sampling and extrapolation is a generally accepted audit technique in the Medicare context, and the Act does not apply any limits to the use of extrapolation in the MA program. Therefore, we believe that CMS has the authority to implement this audit methodology in RADV audits for any case in which a RADV audit identifies improper risk-adjusted payments. We also believe that this is a reasonable approach to our RADV audits, given the sustained and high level of risk adjustment payment error, as previously described.

2. Summary of Proposed Rule

In the 2018 proposed rule, CMS proposed to extrapolate contract-level RADV audit findings using statistically valid random sampling techniques. CMS proposed to extrapolate findings in PY 2011 and all subsequent payment years, but specifically sought comment on how to treat the audits for PYs 2011, 2012, and 2013. In the proposed rule, we explained that we had conducted RADV audits for PYs 2011–2013 according to the sampling and extrapolation methodology described in the 2012 methodology but that these audits were not yet finalized because we had not yet issued the audit findings to the MAOs.²⁶ For PYs 2011 through 2013, we estimated that audited MA contracts received \$650 million in improper payments.

In the 2018 proposed rule, we stated that, given the amount of improper payments identified under the MA program, interest in determining an accurate recovery amount for each audited MA plan, and importance of protecting the overall integrity of the program, we believed that it was in the public interest for CMS to apply the RADV payment error methodology(ies) adopted through this rulemaking to PY 2011 and all subsequent years. We stated that CMS would be acting in compliance with the improper payment obligations under the Act (most recently updated as part of the Payment Integrity Information Act of 2019 (PIIA)), as well as our fiduciary responsibility to recover funds due to the Medicare Trust Funds. We also noted that our February 2012 publication put MAOs on notice that CMS expected to calculate a contract-level payment error for PY 2011 and subsequent payment years by extrapolating from its review of a statistically valid sample of enrollees, and that MAOs have never been entitled to receive or retain payments associated

with HCCs that cannot be validated by medical records.

We also proposed that MAOs would be required to remit extrapolated recovery amounts from RADV audit findings through CMS' payment system, the Medicare Advantage and Prescription Drug system (MARx), as offsets to MA plans' monthly capitation payments. In the event that the recovery amount exceeds the payment in one month, we proposed that the recovery would be spread across adjustments for multiple months until the full amount is recovered. We also proposed that CMS might likewise require MAOs to remit such recovery amounts based upon audit findings by the HHS-OIG.

We explained in the 2018 proposed rule that CMS is not required to set forth the methodology for calculating an extrapolated payment error through regulatory provisions. However, we explained that, in the interest of transparency, we were choosing to inform MAOs about our plans to use various sampling and extrapolation methodologies in RADV audits, as CMS deems appropriate, through rulemaking.

In addition to codifying in regulation our existing authority to use extrapolation techniques in the RADV context, we also used the 2018 proposed rule as a means to gather public feedback on sampling methodologies that could be employed for purposes of extrapolation. We explained that, in addition to the contract-level approach described in the 2012 RADV Methodology, we have identified other potential methodologies for sampling and extrapolation that are based on a particular sub-cohort or sub-cohorts in a given payment year. For example, a sub-cohort could be the enrollees for whom a particular HCC or one of a related set of HCCs (such as the three diabetes HCCs) was reported.

TABLE 1—DIABETES HCCs

HCC category description	HCC
Diabetes with acute complications ...	17
Diabetes with chronic complications	18
Diabetes without complication	19

After choosing an MA contract and a sub-cohort or sub-cohorts to audit, we would select a statistically significant sample of enrollees in the sub-cohort or sub-cohorts. After reviewing these enrollees' medical records that are submitted by the MAO, we would use statistical extrapolation to calculate and recoup the improper payments made to the audited MA contract for all enrollees in the sub-cohort or sub-cohorts in that payment year.

We noted in the 2018 proposed rule that using a sub-cohort methodology, such as one focused on enrollees with high-risk HCCs, could allow us to use a much smaller sample size to calculate a statistically valid extrapolated improper payment amount. This is possible because, when selecting a sample from a smaller population (that is, a sub-cohort of enrollees), one can still achieve an acceptable level of statistical confidence with that smaller sample size. This sub-cohort-based audit methodology would also allow us to spread our audit resources across a wider range of MA contracts and focus on cohorts of enrollees that raise programmatic concerns, while also reducing operational burden on both CMS and the MAOs due to the reduced sample size needed to calculate improper payments.

In the 2018 proposed rule, we invited comment on both the contract-level audit methodology published in February 2012 and our proposal for an extrapolated audit methodology based on sub-cohorts of enrollees. We also sought comment on whether there are particular situations in which one methodology may be preferable to the other. We emphasized that neither proposed methodology was meant to displace our longstanding authority to audit the medical records of particular enrollees who we believe may be associated with improper payments or to use any statistically valid audit methodology. We also stated that, if we finalize one or more sampling and extrapolation methodologies through this rulemaking, we would announce any future changes to that methodology (or those methodologies) through the Health Plan Management System (HPMS).

In addition, we stated that we may begin to conduct RADV audits for PYs 2014 and 2015 before finalizing the policies in the proposed rule, pursuant to our longstanding authority to review the medical records of any MA enrollee and recoup improper payments identified. We also sought comment on whether the use of sampling and extrapolation for certain payment years would require the exercise of our statutory authority to engage in retroactive rulemaking, as set out in section 1871(e)(1)(A) of the Act, which authorizes retroactive application of rules where "failure to apply the change would be contrary to the public interest."

We also discussed proposed changes to our RADV dispute and appeals regulations in 42 CFR 422.311 to conform with the finalized RADV provisions. Specifically, consistent with

²⁶ See 83 FR 55038.

our other proposed policies, we proposed to amend § 422.311 by adding language to clarify that recovery of improper payments from MAOs will be conducted according to the Secretary's payment error extrapolation and recovery methodologies, and that CMS will apply extrapolation to RADV audits beginning with PY 2011. We also requested comment on whether to explicitly expand the MAOs' RADV appeal rights, such as by permitting appeal of the RADV payment error calculation methodology used in a RADV audit, similar to practices in Medicare FFS. A summary of the comments received and our responses follow.

3. Summary of Public Comments

Comment: Several commenters supported CMS' proposal to use extrapolation in RADV audits, as well as our proposal to begin extrapolation for PY 2011 audits. Commenters indicated that this is the most effective way to address improper payments in MA.

Response: We thank commenters for their support. While we plan to finalize our proposal to apply extrapolation to RADV audits, we are making a change to the years in which to apply extrapolation to achieve what we believe is an appropriate final policy that still takes into consideration our obligation to address potentially significant improper payments in the MA program. Extrapolation will now begin with the PY 2018 RADV audits rather than PY 2011, as proposed. This change, as further described in this section of this rule, is being made due to our fiduciary duty to protect taxpayer dollars from overpayments, certain operational considerations, and public comments on the timeliness of RADV audits.

Comment: Several commenters opposed the use of extrapolation in RADV audits. Some commenters questioned whether we had the statutory authority to use sampling and extrapolation in RADV audits. These commenters suggested that, because section 1893(f)(3) of the Act grants CMS the authority to use sampling and extrapolation in certain circumstances when conducting audits in Medicare Part A and Part B, CMS cannot use those techniques in Part C audits without an equivalent grant of statutory authority.

Several commenters challenged the statistical and methodological validity of both the contract-level sampling and extrapolation techniques described in the 2012 methodology, as well as an approach based on sub-cohorts of enrollees. A commenter stated that it is more difficult for plans to determine

results from extrapolation in MA than in Medicare FFS because RADV audits can include the review of multiple medical records to validate one diagnosis from various providers with "disparate methods of documentation."

Some comments focused on the application of extrapolation beginning in PY 2011. Several commenters asserted that increased liabilities of MAOs from retroactive application of an extrapolated payment error recovery would deter future participation by MAOs in the MA program and reduce benefits to beneficiaries. Several commenters expressed concern that extrapolation for past payment years will destabilize physician care. Specifically, the concern is that providers participating in risk-sharing contracts with MAOs that have not yet completed a final settlement may be at risk for losses. The same commenters believe that recovering improper payments when the audit methodology has been revised several times is inequitable to the MAOs.

Response: We appreciate these comments and considered them when finalizing the timing and content of these extrapolation policies. As discussed previously, CMS has the authority to use sampling and extrapolation in its RADV audits. Federal courts have held that sampling and extrapolation are a valid method of calculating improper Medicare payments, so long as statistically valid methods are used. The MMA added section 1893(f)(3) of the Act, which specifically applies to Medicare Part A and Part B and limits the use of extrapolation to determine overpayment amounts for recoupment under certain circumstances. This provision did not confer new authority to use extrapolation, but limited our preexisting audit authority in Medicare Part A and Part B. No similar limitation has been applied to audits in Medicare Part C. However, CMS will continue to focus its RADV efforts on MAOs identified as being at higher risk of improper payments.

In the implementation of this authority to use sampling and extrapolation in RADV, CMS will employ statistical methods to determine statistically valid sample sizes, accurately identify payment error, and extrapolate to the universe of enrollees from which the sample is selected. These statistically valid methods may include applying one or more RADV audit methodologies for any given RADV audit. In addition, while CMS views extrapolation as a statistically valid methodology for RADV audits, the agency may, at times, use its discretion

to not utilize extrapolation in a particular instance. For example, there may be unforeseen circumstances in which the statistical validity of the sample is disturbed (such as the need to exclude a large number of cases from the sample due to the loss of medical records in a natural disaster) and extrapolation is no longer possible, despite the initial intent to do so. There may be other limited instances in which CMS seeks to collect overpayments associated only with enrollees in a given sample, or wishes to perform only a probe sample of RADV reviews without the use of a statistically valid sample and yet will seek to recover any identified, non-extrapolated overpayments. The OIG may also independently decide not to extrapolate for reasons outside the control of CMS, and CMS will still recover those overpayments in accordance with the provisions in this final rule. To account for this, we are finalizing § 422.311(a)(2) to read "CMS *may* (emphasis added) apply extrapolation to audits for payment year 2018 and subsequent payment years," rather than "CMS will apply extrapolation . . ." as proposed. This language is not intended to signal that it would be a frequent occurrence to not extrapolate in PY 2018 and future audits; rather, extrapolation is expected to be the standard practice for RADV audits beginning in PY 2018.

As previously stated, we believe that it is in the best interest of the Federal Government and our efforts to protect taxpayer dollars to extrapolate in our RADV audits, given the substantial amount of improper payments in MA and the fact that RADV is CMS' main corrective action used to address the submission of inaccurate diagnosis data. However, we also have decided not to extrapolate for PY 2011 through 2017 audits, as originally proposed, due to certain operational considerations and public comments on the timeliness of RADV audits. The reasoning for this decision is discussed in greater detail later in this final rule.

In addition, we do not agree with the comment that RADV audits include the review of multiple medical records with "disparate methods of documentation." We reemphasize that the policies we are finalizing in this rule do not impose new documentation requirements on providers. The core component of a RADV audit is ensuring that all diagnoses reported to CMS are properly supported by medical record documentation. CMS' existing regulatory documentation standards, 42 CFR 422.310(d)(1); 45 CFR 162.1002(c)(2) and (c)(3), including the RADV-specific authority to validate risk

adjustment data through the review of a sample of medical records at § 422.310(e), remain unchanged under this final rule and are described in current agency policy documents, including the Medicare Managed Care Manual (with which MAOs agree, in their MA contracts, to comply). MAOs are also already required to ensure that contracted providers meet MA documentation requirements.

We respectfully disagree with commenters' assertions that liabilities will increase. We are not imposing additional liabilities, penalties or retroactive application of new requirements or policy. We only seek to recover improper payments received by MACs for HCCs that are not substantiated by enrollees' medical records. We continue to rely on existing program methods to establish auditing practices that encourage proper payment recovery consistent with established audit practices. We recognize that MAOs enter into agreements with providers, including those with a risk-sharing component, and we encourage all parties to those agreements to take steps to mitigate the submission of diagnosis codes that are not properly supported in the medical record.

We emphasize that nothing in this rule changes the longstanding principle that a diagnosis code that is not documented in a patient's medical record is not a valid basis for CMS risk adjustment payments to an MAO. Nor does this rule change the longstanding obligation of an insurer to refund payments to CMS if it learns that a diagnosis lacks support in the beneficiary's medical record.

Comment: Many comments were received on the proposed extrapolation methodologies, mainly focused on our proposed sub-cohort approach. Some commenters requested clarity on the sub-cohort methodology, while others expressed support for this methodology with various suggestions to improve it. Commenters questioned whether the proposed sub-cohort methodology will replace the existing contract-level methodology, which utilizes a general, non-targeted sampling methodology, and how CMS will determine which HCC groups will be used in the identification of sub-cohorts. A commenter requested that CMS confirm whether RADV will consist of a single audit methodology or whether MAOs will be subject to multiple audit methodologies.

Some commenters believe that applying a sub-cohort extrapolation methodology of enrollees would produce inaccurate results in RADV

audits because of differences between plans with regard to size and risk characteristics. For example, several commenters argued that plans with a higher than average risk score are at increased risk for RADV audit because high-risk enrollees are more likely to have more HCCs. Other commenters believe that a small sample size, which CMS sees as a benefit of a sub-cohort methodology, will result in inaccuracies. Others commented that an extrapolation methodology based on sub-cohorts of enrollees would violate the statutory mandate of "actuarial equivalence" between payments made under MA and Medicare FFS because it would generate recoveries based on random outcomes without regard to specific characteristics of MA plans' diagnostic mix, enrollment size, and risk scores. A commenter requested that, if CMS adopts a sub-cohort extrapolation methodology, it uses a pilot period first before implementing the program on a large scale and extrapolating results.

Other comments spoke to extrapolation methods more generally, including the appropriate confidence interval, potential for plans of certain sizes to be unduly chosen for RADV audits, and perceived inability to assess potential liability for RADV audits already performed if CMS abandons the extrapolation methodology set forth in the 2012 methodology.

Other comments on our proposed extrapolation methodologies were focused on the impact of underpayments. A commenter objected to the RADV audit sampling methodology, arguing that it results in a purported payment recovery bias against MAOs. The commenter believes the results of the RADV audit sample are "asymmetric," thus incorrectly representing the improper payment rate. More specifically, the commenter asserted that "[t]hrough there is no upper limit for how high the payment recovery amount can be, there is no balancing negative recovery amount." In other words, the commenter objected that MAOs cannot receive a payment from CMS based on a RADV audit if, overall, the risk scores should have been higher because, for instance, there were more supported diagnoses that had not been submitted (that is more under-coding) than unsupported diagnoses that had been submitted (that is over-coding). Other commenters shared these concerns, as well as voiced concern that RADV audit samples do not account for the reported bias that exists for enrollees who have no diagnosis codes submitted during the year but have existing documentation to support a diagnosis

that could have been submitted. The same commenters perceive the audit methodology as being random and indiscriminate, believing that the results will incorrectly estimate the risk profile of enrollees.

A commenter requested information related to the sampling methodology used to select enrollees for the PY 2014 RADV audit. Specifically, the commenter requested details on the development of the regression model used to predict payment error and on the sampling criteria from which the RADV audit currently extrapolates. This commenter also contended that the PY 2014 methodology appears to maximize the probability of selecting individuals with coding errors.

Response: As previously explained, extrapolation is an established auditing practice and remains a valid method for addressing audit recoveries. In this final rule, we are clarifying the scope of our authority to strengthen the integrity of the MA program by identifying improper payments. Our initiatives are designed to ensure fair and accurate recovery efforts by focusing on the areas at highest risk of improper payments. We will use statistically valid methodologies to extrapolate improper payment findings to the universe of enrollees from which a sample is selected. These statistically valid methodologies may include applying one or more RADV audit methodologies for any given RADV audit. As previously discussed, we may also determine that extrapolation will not be applied in certain limited instances. We emphasize that, in this final rule, we are not adopting either the contract-level sampling and extrapolation technique described in the 2012 methodology or a specific extrapolated audit methodology based on sub-cohorts of enrollees. Instead, for future RADV audits, CMS will rely on any statistically valid method for sampling and extrapolation that it determines to be well-suited to a particular audit. We described the sub-cohort methodology in the 2018 proposed rule to provide the industry with transparency on potential audit methodologies. In addition, while not required, CMS will continue to disclose our extrapolation methodology to MAOs through HPMS memos or other appropriate means, providing MAOs with the information sufficient to understand the means by which CMS extrapolated the improper payment determination.

Any sampling and extrapolation methodologies adopted by CMS for RADV audits will be focused on MAO contracts and enrollees' HCCs that, through statistical modeling and/or data

analytics, are identified as being at highest risk for improper payments. This is an appropriate approach to any Federal MA audit that seeks to recoup taxpayer dollars that have been inappropriately paid to MAOs for diagnoses that are not supported in the medical record. This approach was also recommended by the GAO in a 2016 report titled "Fundamental Improvements Needed in CMS's Effort to Recover Substantial Amounts of Improper Payments."²⁷ The GAO recommended that CMS "modify [its] selection of contracts for contract-level RADV audits to focus on those contracts most likely to have high rates of improper payments by taking actions such as the following: selecting more contracts with the highest coding intensity scores; excluding contracts with low coding intensity scores; selecting contracts with high rates of unsupported diagnoses in prior contract-level RADV audits; if a contract with a high rate of unsupported diagnoses is no longer in operation, selecting a contract under the same MAO that includes the service area of the prior contract; and selecting some contracts with high enrollment that also have either high rates of unsupported diagnoses in prior contract-level RADV audits or high coding intensity scores."²⁸

We also note that the purpose of RADV audits is to validate that diagnoses submitted by MAOs for risk-adjusted payment are properly supported by medical record documentation. See 42 CFR 422.310(e). RADV audits are the main corrective action used to address the submission of inaccurate diagnosis data. Occasionally, upon review of these medical records, CMS will uncover "additional" diagnoses supported by the medical records that were not submitted for payment by MAOs during the data collection period for enrollees selected in the sample. Under current contract-level RADV policy, when CMS uncovers these additional diagnoses that map to CMS-HCCs during medical record review of audited CMS-HCC(s), these newly-discovered diagnosis codes are used to recalculate risk scores in certain circumstances, which may result in an updated (reduced) improper payment calculation.

MAOs are required by CMS regulations (§§ 422.503 and 422.504) and MAO contracts to establish compliance programs and processes to ensure accurate diagnosis coding and

the submission of accurate diagnosis data. These processes should enable MAOs to identify not only instances where diagnoses submitted for risk-adjustment payment are not supported by the medical record, but also diagnoses that may not have been submitted to CMS. MAOs can submit additional diagnoses for risk-adjusted payment up until the final risk adjustment data submission deadlines described at § 422.310(g)(2)(ii). As with overpayment recoveries under the Affordable Care Act and CMS's Overpayment Rule, the purpose of RADV audits is not to reopen submission deadlines and for CMS to make additional payments.²⁹ RADV audits identify overpayments after the final risk adjustment data submission deadline.

Comment: Some comments were focused on the scope and number of plans selected for RADV audit. A commenter objected to an increase in the number of plans selected for the RADV audits. Another commenter requested an explanation of how sample sizes will be determined for Program of All-Inclusive Care for the Elderly (PACE) organizations, most of which have fewer than 500 enrollees.

Response: As previously described, any extrapolation methodology adopted by CMS for RADV audits will be focused on MAO contracts that, through statistical modeling and/or data analytics, are identified as being at highest risk for improper payments. Examples of MAO contracts that may be deemed higher risk for the purposes of RADV audit selection are discussed later in this section. This is also the best approach to ensure that MAOs that do not show indications of being at high risk of improper payments are not exposed to audit burden to the exclusion of higher-risk plans. In addition, as noted previously, such an approach was recommended by the GAO in its April 2016 report.³⁰ CMS does not currently subject PACE organizations to RADV audits and CMS' selection methodology for each year will

describe any adjustments made for PACE or other low enrollment contracts.

Comment: Several commenters noted that implementing these proposed policies would lead to more audit burden for providers because of an increase in documentation standards for treating providers. For example, commenters believe that this is a "more stringent audit expectation" that will increase administrative burden at a time in which there is already a physician shortage, thereby impacting patients. Another commenter contended that our extrapolation methodology should reflect that certain HCCs are more difficult to substantiate in medical record documentation than others.

Response: RADV audits will not impose new documentation requirements on health care providers and, therefore, we believe there will be no additional audit impact on providers that contract with MAOs to provide services to MA plan enrollees. As previously stated, nothing in this rule changes the longstanding principle that a diagnosis code that is not documented in a patient's medical record is not a valid basis for CMS risk adjustment payments to an MAO. In addition, there is a longstanding requirement under § 422.310(e), in place since the beginning of the MA program, that "[MAOs] and their providers and practitioners will be required to submit a sample of medical records for the validation of risk adjustment data, as required by CMS," which is unaffected by this final rule. This requirement is consistent with longstanding requirements applicable to Medicare Part A and Part B providers that they furnish sufficient information to support payment. 42 U.S.C. 1395(g) (Effective July 7, 2004) ("[No] . . . payments shall be made to any provider unless it has furnished such information as the Secretary may request in order to determine the amounts due such provider . . ."); *Clinic Res. Mgmt. v. Burwell*, 2015 WL 3932857, at *2 (S.D. Tex. June 26, 2015) ("The provider is responsible for maintaining and submitting adequate information to substantiate medical necessity and entitlement to payment.");³¹

²⁷ Under section 1853(a)(3) of the Act, the Secretary must require MAOs to submit data regarding inpatient hospital services and other services, as well as other information as the Secretary deems necessary to calculate MA risk adjustment payments. This authority has been implemented at § 422.310, which requires MAOs to submit "data necessary to characterize the context and purposes of such item and service provided to a Medicare enrollee by a provider, supplier, physician, or other practitioner." § 422.310(b). MAOs must submit data that conforms to CMS' requirements for data equivalent to Medicare FFS

²⁷ GAO, at 26, <https://www.gao.gov/assets/gao-16/78.pdf> (April 2016).

²⁸ *Id.*

²⁹ Section 6402 of the Affordable Care Act (Pub. L. 111-148) established section 1126(d) of the Act. Under the Part C and D Overpayment Rule (79 FR 29844), which implemented section 6402 of the Affordable Care Act, MAOs are required to correct overpayments by self-reporting and returning payments associated with MAO diagnosis codes not supported by medical record documentation. Although MAOs are required to correct identified overpayments after the final risk adjustment data submission deadline in order for CMS to conduct audits and recover the overpayments, MAOs are not permitted to submit additional diagnoses for payment after the submission deadline.

³⁰ GAO, at 26, <https://www.gao.gov/assets/gao-16/76.pdf> (April 2016).

Comment: A commenter contested CMS' proposal to recover contract-level payment adjustments through a lump-sum reduction in the plans' monthly payments through MARx. The commenter noted that, for example, CMS currently makes retroactive, beneficiary-specific adjustments related to miscellaneous corrections to beneficiaries' status (such as eligibility, State and county of residence, date of death, etc.) outside of the RADV process. The commenter requested that CMS seek only beneficiary-level recoveries through RADV audits so as not to overlap with these non-RADV recoveries.

Response: While we appreciate the commenter's consideration of the other areas in which CMS may make adjustments to MA payments, we do not believe that current and proposed RADV efforts overlap with non-RADV adjustments. RADV audits only validate diagnoses associated with a beneficiary's medical record documentation, not a beneficiary's demographic characteristics. If an HCC cannot be validated with medical records, MAOs are not entitled to the risk-adjustment payment associated with that HCC.

Comment: Several commenters opposed the application of our extrapolation methodology to past payment years claiming that, pursuant to section 1853(b)(2) of the Act, this would be considered a retroactive application of policy and CMS must disclose our RADV audit methodology changes prior to any payment year RADV audit. Some commenters also asserted that the application of this rule to past payment years would alter the actuarial soundness of payments previously received by MA contracts, as existing contracts relied on the RADV audit methodology we announced in the 2012 RADV Methodology. Other commenters also characterized this approach as contrary to the Supreme Court's holding in *Azar v. Allina Health Servs.*, 139 S. Ct. 1804, 204 L. Ed. 2d 139 (2019), which emphasized that a substantive legal standard must go through a notice-and-comment process.

Response: First, as a fundamental concept, this policy does not impose any new requirements on MAOs that

could be construed as retroactive. The 2012 RADV Methodology did not create a different "documentation standard" for MA plans than the standard that applies to traditional Medicare providers, nor did we state that an FPS Adjuster should set a permissible rate for the submission of erroneous codes. There is only one documentation standard for diagnosis coding, as discussed previously: proper medical record documentation is required for any reported diagnosis code to be valid. That is the consistent policy throughout the Medicare program (see previous discussion).

The RADV auditing methodology has not fundamentally changed the longstanding requirement that a diagnosis submitted to CMS by an MAO for payment must be properly supported by medical record documentation. See *UnitedHealthcare Ins. Co. v. Becerra*, 16 F.4th 867, 869, 877 (D.C. Cir. August 13, 2021, reissued November 1, 2021), cert. denied, 142 S. Ct. 2851 (U.S. June 21, 2022) (No. 21-1140). Rather, it only enforces the well-established regulatory requirement that MA diagnoses be validated under that longstanding documentation standard. (For additional information, see § 422.310(e); 83 FR 55037 (and authorities cited therein).)

We also noted in the 2018 proposed rule that we may begin to conduct RADV audits for additional payment years (specifically, 2014 and 2015) before this proposal is finalized, pursuant to our longstanding authority to review the medical records of any MA enrollee and recoup any improper payments identified.

Even if this methodology was determined to be a retroactive application of policy, a position with which we do not agree, it is still necessary to comply with statutory requirements and is in the public interest for CMS to apply extrapolation to past payment years, and, therefore, is authorized under the Act. CMS has the authority, in accordance with section 1871(e)(1)(A) of the Act, to apply retroactive changes in regulations, manual instructions, interpretative rules, statements of policy, or guidelines of general applicability to items and services furnished before the effective date of the change, if the Secretary determines that "such retroactive application is necessary to comply with statutory requirements or failure to apply the change would be contrary to the public interest." We believe that recovering extrapolated improper amounts is necessary to comply with statutory requirements and advances the public interest by protecting the overall integrity of the MA program. We have

a statutory mandate under the FICA to reduce improper payments and a fiduciary responsibility to recover funds due and owed to the Medicare Trust Funds.

As previously discussed, HHS and the GAO have identified a significant volume of improper payments in the MA program,⁴² and RADV audits are the main way CMS ensures payment accuracy to MAOs. As further discussed in the Regulatory Impact Analysis section of this final rule, CMS estimates extrapolated improper payment recoveries of approximately \$479 million per audit year beginning with the PY 2018 audit. We also believe that there will be an additional sentinel effect of RADV audits on the improper payment rate as MAOs improve their processes to report only those diagnoses that meet CMS requirements for risk adjustment payment.

In addition, as discussed previously, RADV audits will not impose new documentation requirements on health care providers. The core component of a RADV audit is ensuring that all diagnoses are properly supported by medical records. We only seek to recover improper payments received by MAOs for HCCs that are not substantiated by enrollees' medical records. MAOs have never been entitled to receive or retain payments associated with HCCs that cannot be validated by medical records. Therefore, applying the rule under the public interest exception in section 1871(e)(1)(A) of the Act would not upset any settled or reasonable reliance interests. This all serves the public interest by reducing the improper allocation of taxpayer dollars that can otherwise be used for other purposes within the Federal Government, including solvency of the Medicare Trust Funds. Thus, applying the rule retroactively is necessary to comply with statutory requirements and in the public interest within the meaning of section 1871(e)(1)(A) of the Act.

Comment: Several comments provided input on the potential promulgation of rules permitting administrative appeals of RADV audit methodology. A commenter opined that such procedures were unnecessary because stakeholders had an opportunity to participate in the development of our methodology through the notice-and-comment

⁴² For example, the FY 2021 HHS Agency Financial Report, pg. 211, <https://www.hhs.gov/sites/default/files/fy-2021-hhs-agency-financial-report.pdf>, states that Part C Improper Payment Measurement (IPM) estimated approximately \$15 billion in overpayments for calendar year 2019 risk-adjusted payments to MAOs.

data, when appropriate, and to all relevant national standards. The International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM) Guidelines for Coding and Reporting is the existing national standard. (See § 422.310(d)(1); 45 CFR 182.1902(c)(2) and (c)(3)). This is consistent with obligations imposed on hospitals and providers in Medicare Parts A and B, who are required to furnish proper documentation and comply with the ICD Guidelines. See, for example, 42 U.S.C. 1395g and 1395n.

Subject: 2013 CMS RAF Attestation

Cheri,

Similar to last year, we are reaching out to you to reiterate our approach to the electronic annual risk adjustment certifications. As you know, annual risk adjustment data certifications before 2014 were submitted on paper, enabling companies to add notes explaining their understanding of these certifications (including any remediation efforts). As we discussed with you last year, because the certifications are now electronic, companies are unable to include explanatory notes. As such, we informed you in writing our understanding of these certifications.

Because the certifications remain electronic with no ability to add explanatory notes, we feel it would again be helpful, and appropriate, to capture our discussion and understanding regarding the certifications.

- As with our past certifications, the 2013 certifications are based on facts reasonably available or made available to us as of the date of the certifications. As we receive additional information, we may be required to modify the date to which the certifications relate.
- The certifications use the phrase best knowledge, information, and belief, which is based on our ordinary business practices.
- The certifications only cover risk adjustment data for 2013 dates of service that were submitted to CMS and not subsequently deleted prior to the date of the certifications.
- As we have mentioned to you previously, we are engaged in an ongoing review of our risk adjustment processes and submission system. This review has identified areas for improvement and, as a result, we will be deleting all risk adjustment data for 2013 dates of service that we ultimately determine should be deleted consistent with this email.
- CMS issued a proposed rule last year that would have required MA plans to design any medical record reviews to determine the accuracy of risk adjustment diagnoses associated with those records. In May 2014, CMS withdrew the proposed rule. During our conversations last year before the proposed rule was withdrawn, CMS confirmed to us that the proposed requirements would not apply until the effective date of the rule, and that MA plans were thus not required to design their medical record reviews to determine the accuracy of risk adjustment diagnoses. As we discussed last year, we previously had a process through which we reviewed certain medical records to determine the accuracy of risk adjustment diagnoses and submitted appropriate deletes. Based on our conversations with CMS last year, CMS's withdrawal of the proposed rule, and CMS's ongoing consideration of a FFS Adjuster to address diagnoses not supported by a medical record in the context of RADV, we ended this process and informed you of that decision. That decision remains operative for 2013 dates of service. In particular, we did not use our previous process to determine whether diagnosis codes submitted through claims are unsupported in the medical record. We do have a quality assurance process that deletes codes initially identified during chart review and that are later determined to be unsupported.

The certifications we submit this year are made subject to these clarifications. Please let me know if you have any questions. As always, we appreciate your time and attention on this matter.

CMS MEETING NOTES

Meeting Date

- April 29, 2014
- Approximate start time was 12:45 eastern time

Attendees

- CMS: Sean Cavanaugh, Cynthia Tudor, Cheri Rice, Dan [Farmer], Julie Grover
- UnitedHealth Group (UHG): Dan Schumacher, Steve Nelson, Karen Erickson, Thad Johnson

Location

- UHG attendees: HHS offices in Washington DC
- CMS attendees: CMS offices in Baltimore, MD

Topic

- Medical records review requirements; Notice of Proposed Rulemaking (NPR or "proposed rule") issued in January 2014; 2012 annual risk adjustment data certification

Meeting Summary

- CMS and UHG representatives began the meeting by introducing themselves. UHG representatives explained the reason for requesting the meeting and asked whether the CMS attendees had seen the email to Marilyn Tavenner sent by Larry Renfro on April 27 requesting the meeting (see exhibit A hereto). CMS attendees acknowledged that they had read the email and inquired as to UHG's specific ask.
- UHG representatives explained their understanding that CMS' proposed rule relates to future periods and wanted to confirm any potential impact to 2012 dates of service in light of the annual risk adjustment data certification for 2012 dates of service due on April 30.
- CMS had a number of clarifying questions relating to UHG's current processes as they relate to medical records review
- UHG representatives provided a general overview of UHG's claim verification process and explained that UHC had already submitted a number of deletes for 2012 dates of services as a result of that process. (Later in the meeting, UHG representatives informed CMS that the number of new and unique diagnosis code deletes already submitted was approximately 13,000.) UHG representatives also indicated that, in light of the proposed rule and other discussions with CMS, UHC had suspended its claims verification process pending a decision by the Company of whether it was appropriate to submit additional deletes to CMS that have been identified through the Company's claims verification process; and also whether the Company should continue with, make changes to, or stop, its current process to identify any additional potential deletes relating to 2012 dates of service.
- Cheri Rice of CMS indicated that until the proposed rule relating to medical records review was finalized, MA plans do not have any proactive responsibility to confirm whether diagnoses submitted by physicians are correct. She also said, however, that if a plan has knowledge that specific codes submitted through medical claims are not supported by medical charts appropriate deletes should be submitted. She summarized this by saying that if a plan has knowledge of an overpayment it should submit appropriate deletes.

- There was then a more detailed discussion of UHG's claim verification process, including the last step of the process being a review by an external expert. Cheri Rice asked for a quantification of the number of codes at various steps in the process. UHG's representatives informed CMS of the number of new and unique codes that had previously been submitted for deletion for 2012 dates of services (approximately 13,000); the number of new and unique codes for which all steps of the claims verification process had been completed, including external review, but which had not been submitted as deletes due to the Company suspending its claims verification process in light of (1) CMS' proposed rule, (2) prior conversations with CMS and (3) the inherent FFS error rate (approximately 8,000); and the number of codes that the Company estimated might be deleted if the Company were to continue its claims verification process to conclusion, including external review, for all codes that were still under review in the claims verification process (i.e., codes for which the claims verification process had not been completed) (approximately 40,000). Cheri Rice requested clarification of the last group and was informed that these codes were at various stages of the process including not having been through external review.
- Cheri Rice then asked some follow-up questions on the general state of the submission of deletes relating to 2012 dates of service based on a call other CMS employees had with OptumInsight the week of April 21, and whether our inquiry was related to the deletes discussed on that call. UHG representatives explained that the prior call related to a number of other deletes that were still in the process of being completed, including finalization of the Q/A process relating to chart review and completion of the Company's process for obtaining attestations for medical charts that may not have included signatures. UHG further explained in response to CMS questions that the Q/A process for chart review was separate from the claims verification process and was a quality control procedure for codes added as a part of chart review. As part of this discussion, CMS representatives reiterated that, under CMS regulations, MA plans were not required to design their chart review programs for overall accuracy until the proposed rule is finalized. Sean Cavanaugh stated that, under current rules, if UHG doesn't know codes are inaccurate the Company would not have to delete them. He went on to state that if UHC does not know until the end of its claims verification process that a code is incorrect then there is no requirement to delete the code until the effective date of CMS' final rule. Cheri Rice added that there is a false claims act requirement that plans not knowingly keep overpayments so if you do not know that there is an overpayment you do not need to delete a code.
- UHC representatives then informed CMS that, due to the new electronic certification methodology and the resultant inability to footnote the certification as UHG had done previously, UHG would be submitting a letter from Steve Nelson explaining UHG's understandings regarding the certification. CMS representatives indicated they were working with other plans on similar concerns.
- UHG inquired whether CMS could provide any guidance into assumptions the Company should make about chart review requirements in preparing its bids for 2015. After conferring among themselves, CMS representatives acknowledged the issues created by the proposed rule, but stated they could not provide any guidance into assumptions UHG should make in preparing its 2015 bids.
- UHG representatives thanked CMS attendees for their time and the meeting concluded.

Subject: 2014 CMS RAF Attestation

Cheri,

As we have done the past several years, we are reaching out to you to reiterate our approach to the electronic annual risk adjustment certifications. As you know, annual risk adjustment data certifications before 2014 were submitted on paper, enabling companies to add notes explaining their understanding of these certifications (including any remediation efforts). As we discussed with you in the past, because the certifications are now electronic, companies are unable to include explanatory notes. As such, we informed you in writing regarding our understanding of these certifications.

Because the certifications remain electronic with no ability to add explanatory notes, we feel it would again be helpful, and appropriate, to capture our prior discussion and understanding regarding the certifications.

- As with our past certifications, the 2014 certifications are based on facts reasonably available or made available to us as of the date of the certifications. As we receive additional information, we may be required to modify the data to which the certifications relate
- The certifications use the phrase "best knowledge, information, and belief," which is based on our ordinary business practices
- The certifications only cover risk adjustment data for 2014 dates of service that were submitted to CMS and not subsequently deleted prior to the date of the certifications.
- As we have mentioned to you previously, we are continuously engaged in the ongoing review of our risk adjustment processes and submission system. This review has identified areas for improvement and, as a result, we will be deleting all risk adjustment data for 2014 dates of service that we ultimately determine should be deleted consistent with this email.
- CMS issued a proposed rule two years ago that would have required MA plans to design any medical record reviews to determine the accuracy of risk adjustment diagnoses associated with those records. In May 2014, CMS withdrew the proposed rule. During our conversations before the proposed rule was withdrawn, CMS confirmed to us that the proposed requirements would not apply until the effective date of the rule, and that MA plans were thus not required to design their medical record reviews to

determine the necessity of risk adjustment diagnoses. As we discussed in that time, we previously had a process through which we reviewed certain medical records to determine the accuracy of risk adjustment diagnoses and submit appropriate deletes. Based on our conversations with CMS six years ago, CMS's withdrawal of the proposed rule, and CMS's announced plans to use a ICD Adjuster to address diagnoses not supported by a medical record in the context of RVDV, we ended this process and informed you of that decision at the time. That decision remains operative for 2014 days of service. In particular, we did not use our previous process to determine whether diagnosis codes submitted through a claim are unsupported by the medical record. We do have a quality assurance process that delete codes initially identified during claim review and that are later determined to be unsupported.

The certifications we submit this year are made subject to these clarifications. Please let me know if you have any questions. And again, we appreciate your time and attention on this matter.

Subject: RE: 2014 CMS RAF Attestation

Steve,

With this email, we are acknowledging receipt of your email dated 6/7/16. However, neither the receipt of your email nor any acknowledgment of such receipt should be interpreted as acquiescence by the Government to any purported modification to the Attestations of Risk Adjustment Data submitted by United or to any of the arrangements described in or statements made in your email, or as a release of any of United's present or future liability to the Government. As you know, both regulation and the MA organizations' contracts with CMS prescribe the specific language of this Attestation, and the MA organizations' execution and submission of the Attestation as specified is a condition of payment by the Medicare Program.

With respect to your fifth point, as we noted last year in response to a similar email from you, there are laws and contractual provisions that impose standards, requirements and responsibilities on MA organizations in connection with federal payments, including risk adjustment payments, they receive from the Medicare Program. We cannot provide legal advice to United about whether its current or proposed courses of action are compliant with such laws and obligations, but we do wish to remind you that MA organizations are required to implement effective compliance programs that prevent, detect and correct non-compliance with CMS program requirements, to exercise reasonable diligence in identifying overpayments, and to report and return such overpayments to the Medicare Program within 60 days. MA organizations cannot delegate these legal obligations to others.

Cheri Rice
Director, Medicare Plan Payment Group
Centers for Medicare and Medicaid Services

Subject: 2014 CMS RAF Attestation

Cheri,

As we have done the past several years, we are reaching out to you, to reiterate our approach to the electronic annual risk adjustment certifications. As you know, annual risk adjustment data certifications before 2014 were submitted on paper, enabling companies to add notes explaining their understanding of these certifications (including any remediation efforts). As we discussed with you in the past, because the certifications are now electronic, companies are unable to include explanatory notes. As such, we informed you in writing regarding our understanding of these certifications.

Because the certifications remain electronic with no ability to add explanatory notes, we feel it would again be helpful, and appropriate, to capture our prior discussion and understanding regarding the certifications.

- As with our past certifications, the 2014 certifications are based on facts reasonably available or made available to us as of the date of the certifications. As we receive additional information, we may be required to modify the data to which the certifications relate.
- The certifications use the phrase "best knowledge, information, and belief," which is based on our ordinary business practices.
- The certifications only cover risk adjustment data for 2014 dates of service that were submitted to CMS and not subsequently deleted prior to the date of the certifications.
- As we have mentioned to you previously, we are continuously engaged in the ongoing review of our risk adjustment processes and submission system. This review has identified areas for improvement and, as a result, we will be deleting all risk adjustment data for 2014 dates of service that we ultimately determine should be deleted consistent with this email.
- CMS issued a proposed rule two years ago that would have required MA plans to design any medical record reviews to determine the accuracy of risk adjustment diagnoses associated with those records. In May 2014, CMS withdrew the proposed rule. During our conversations before the proposed rule was withdrawn, CMS confirmed to us that the proposed requirements would not apply until the effective date of the rule, and that MA plans were thus not required to design their medical record reviews to determine the accuracy of risk adjustment diagnoses. As we discussed at that time, we previously had a process through which we reviewed certain medical records to determine the accuracy of risk adjustment diagnoses and submitted appropriate deletes. Based on our conversations with CMS two years ago, CMS's withdrawal of the proposed rule, and CMS's announced plans to use a FFS Adjuster to address diagnoses not supported by a medical record in the context of RADV, we ended this process and informed you of that decision at the time. That decision remains operative for 2014 dates of service. In particular, we did not use our previous process to determine whether diagnosis codes submitted through claims are unsupported in the medical record. We do have a quality assurance process that deletes codes initially identified during chart review and that are later determined to be unsupported.

The certifications we submit this year are made subject to these clarifications. Please let me know if you have any questions. As always, we appreciate your time and attention on this matter.

Steve Nelson
Chief Executive Officer
UnitedHealthcare Medicare & Retirement

EXHIBIT D-28

**ATTESTATION OF RISK ADJUSTMENT DATA INFORMATION RELATING TO
CMS PAYMENT TO A MEDICARE ADVANTAGE ORGANIZATION**

Pursuant to the contracts between the Centers for Medicare & Medicaid Services (CMS) and the UnitedHealth Group affiliate listed in Attachment 1, hereafter referred to as the MA Organization, governing the operation of the Medicare Advantage and Medicare Advantage- Prescription Drug plans listed in Attachment 1, the MA Organization hereby requests payment under the contract and, in doing so, makes the following attestation concerning CMS payments to the MA Organization * The MA Organization acknowledges that the information described below directly affects the calculation of CMS payments to the MA Organization or additional benefit obligations of the MA Organization and that misrepresentations to CMS about the accuracy of such information may result in Federal civil action and/or criminal prosecution.

The MA Organization has reported to CMS for the period of January 1, 2009 to December 31, 2009 all risk adjustment data for 2009 dates of service available to the MA Organization as of December 31, 2009, with respect to the MA and MA-PD plans listed in Attachment 1. Based on best knowledge, information, and belief as of the date indicated below, all information submitted to CMS in such report and not subsequently deleted prior to the date hereof is accurate, complete, and truthful.

NAME: John Larsen
TITLE: Chief Financial Officer,
Public & Senior Markets Group
On behalf of the UnitedHealth Group
entities listed in Attachment 1

3/26/10
DATE

* This Certification is based on facts reasonably available or made available to the MA Organization as of the date of this Certification and is not to be construed as a representation by the entities listed in Attachment 1, their affiliates, officers, representatives, or agents that the data to which the Certification relate may not require subsequent modification should additional information become available. Best knowledge, information, and belief means based on normal business practices. In addition, the scope of this Certification does not include risk adjustment data related to "long-term institutionalized" or "community," which the MA Organization is not required to report to or otherwise verify for CMS. Such designations are made by CMS based on a CMS data source and are subject to reconciliation by CMS in accordance with Section 91.1.2 of Chapter 7 of the Medicare Managed Care Manual. As previously communicated to CMS, we believe these designations are materially inaccurate. However, we acknowledge CMS' position that such designations are generally accurate.

CC: Korinko, Anna L; Harlow, Jennifer A. (CMS:CM)
Subject: PY2016 and PY2017 RAF Attestations

Cheri,

As we have done the past several years, we are reaching out to you to reiterate our approach to the electronic annual risk adjustment certifications. As you know, annual risk adjustment data certifications before 2014 were submitted on paper, enabling companies to add notes explaining their understanding of these certifications (including any remediation efforts). As we discussed with you in the past, because the certifications are now electronic, companies are unable to include explanatory notes. As such, we informed you in writing regarding our understanding of these certifications.

Because the certifications remain electronic with no ability to add explanatory notes, we feel it would again be helpful, and appropriate, to capture our prior discussion and understanding regarding the certifications.

- As with our past certifications, the 2016 and 2017 certifications are based on facts reasonably available or made available to us as of the date of the certifications. As we receive additional information, we may modify the data to which the certifications relate.
- The certifications use the phrase "best knowledge, information, and belief," which is based on our ordinary business practices.
- The certifications only cover risk adjustment data for 2015 and 2016 dates of service that were submitted to CMS and not subsequently deleted before the date of the certifications.
- As we have mentioned to you previously, we are continuously engaged in the ongoing review of our risk adjustment processes and submission system. This review has identified areas for improvement and, as a result, we will be deleting all risk adjustment data for 2015 and 2016 dates of service that we ultimately determine should be deleted consistent with this email.
- CMS issued a proposed rule in 2014 that would have required MA plans to design any medical record reviews to determine the accuracy of risk adjustment diagnoses associated with those records. In May 2014, CMS withdrew the proposed rule. During the conversations between United and CMS before the proposed rule was withdrawn, CMS confirmed to United that the proposed requirements would not apply until the effective date of the rule, and that MA plans were thus not required to design their medical record reviews to determine the accuracy of risk adjustment diagnoses. As was discussed at that time, we previously had a process through which we reviewed certain medical records to determine the accuracy of risk adjustment diagnoses and submitted appropriate deletes. Based on the conversations with CMS in 2014, CMS's withdrawal of the proposed rule, and CMS's announced plans to use a FFS Adjuster to address diagnoses not supported by a medical record in the context of RADV, we ended this process and informed you of that decision at the time.
- As you know, United subsequently filed suit under the Administrative Procedures Act (APA) against the Department alleging that the final overpayment rule adopted by CMS in 2014 violates the Medicare Act because it purports to require MA plans to delete unsupported diagnosis codes even though CMS does not delete similar diagnosis codes from the data used to calibrate risk adjustment payments. In September 2018, the District Court granted United's motion for summary judgment.
- In 2017, the Department of Justice filed Complaints in Intervention in two False Claims Act (FCA) cases indicating that it has a broader view of the significance of this certification. The allegations in these complaints related to this certification have now been dismissed.
- Our decision to discontinue our prior process remains operative for 2015 and 2016 dates of service. In particular, we did not use our previous process to determine whether diagnosis codes submitted through claims are unsupported in the medical record. We do have a quality assurance process that deletes codes initially identified during chart review and that are later determined to be unsupported.
- Notwithstanding the Justice Department's allegations regarding the requirements related to risk adjustment data and the meaning of our certification, we are not certifying that we have validated

diagnostic codes submitted through claims so that we have deleted such codes based on our review of medical records during chart review.

The certifications we submit this year are made subject to these clarifications. Please let me know if you have any questions. As always, we appreciate your time and attention on this matter.

Subject: RE: OMB Responses (Overpayment and Part D technical changes in CMS-4159-P) - For your review - due by noon tomorrow

Jennifer:

Yes and No. I pulled some cases which use the phrase "reasonable diligence", but only one seemed to provide a standard for it. The cases were primarily ERISA and RICO cases.

A more commonly used term of art would be "due diligence" or "reasonable care". Anne and I started trying to piece something together, but I would have to agree that if we want to stay consistent with the CPI reg – we should hold on trying to create a standard on our end – especially if we want to lessen plan burden and also not create an affirmative obligation to "identify".

Is "reasonable diligence" a term of art that is commonly used in legal forums?

Subject: Re: OMB Responses (Overpayment and Part D technical changes in CMS-4159-P) - For your review - due by noon tomorrow

I like that - deliberately choosing not to define the term, consistent with CPI.

On Sep 27, 2013, at 11:41 AM, "Scott, John A. (CMS/CM)" <John.Scott@cms.hhs.gov> wrote:

Got it. Maybe that's all we need to say then:

We are developing these overpayment regulations in a manner consistent with the overpayment regulations developed by CPI, including CPI's use of "due diligence." Because CPI did not define due diligence in its regulations, we deliberately chose not to define it in our proposed regulations either.

Redacted

Just a thought.

final (I checked with them). We took this term from CPI and need to be consistent as possible. OMB is asking this question.

I don't think our response answers the question about defining reasonable diligence. We say a plan must use reasonable diligence to determine whether an overpayment exists, but we aren't saying what

Redacted

exercise reasonable diligence to do that is up them. In other words, reasonable diligence in this context may be the amount of diligence the plan deems reasonable to identify an overpayment.

Hello,

Below are draft responses to OMB questions we have received (so far...). Please send me any major edits/comments by noon tomorrow. Thanks!

Whitney

Redacted

Any person who 'knowingly conceals or knowingly and improperly avoids or decreases an obligation to pay or transmit money or property to the Government' may be found liable under the False Claims Act. (See 31 U.S.C. 3729 et seq.). Additionally, any person who knows of an overpayment [as defined in section 1128J(d)(4) of the Act] and does not report and return the overpayment in accordance with such section' may be found liable under the Civil Monetary Penalties Law (section 1128A(a)(10) of the Act) and accordingly could be excluded from participation in Federal health care programs.

A102: Reasonable Diligence: Is this defined somewhere?

As indicated in preamble, it is to determine whether an overpayment exists. Without such a proposal, some providers and suppliers might avoid performing activities to determine whether an overpayment exists.

A103: "CMS will recover the returned overpayment through routine processing according to the systems schedule established in the annual operations budget": Please provide more information on the timing of these processes.

For Parts C and D, some reconciliations are routine and some are at CMS discretion. For Part C, final reconciliations occur each year around August (risk adjustment). For Part D, final reconciliations occur around October for the previous payment year. Reopening of the reconciliation for a payment year generally occurs several years later and for Part D we are proposing once within five years after the initial final reconciliation. Running reconciliation is resource-intensive.

A104: "However, in light of the overpayment provision.....we do not believe that it is necessary to reopen a payment reconciliation after that five year period, nor do we believe it is necessary to reopen a reconsidered payment determination": Please confirm that even in the case of fraud reopening a payment reconciliation is still subject to the 5 year limitation.

That is correct. Even in the case of fraud, the reopening payment reconciliation is still subject to the 5 year limitation. If an overpayment (even an overpayment resulting from fraud) is discovered after a payment year has closed, the overpayment will be reported and returned to CMS via the overpayment process described at proposed § 423.360.

A105: "we now propose to amend 423.2320 such that.....CMS will then attempt to recover those costs from the bankrupt manufacturer by filing a proof of claim with the bankruptcy court": Are there estimated costs with this policy?

Given our experience, we do not anticipate many manufacturers failing to pay quarterly invoices as a result of bankruptcy. The more typical scenario we see is that a manufacturer, or its assets, becomes acquired by another company prior to the manufacturer declaring bankruptcy. Since 2011, only one manufacturer has declared bankruptcy, and it is too early to determine whether or not there could be costs, or the extent of those costs, based on that case.

A016: "In the event that a manufacturer becomes bankrupt, CMS is concerned that the court will either discharge or reduce the amount of the CMP....": In absence of CMS covering these costs, would these losses show up in reconciliation?

CMS reconciles based on the amounts invoiced to the manufacturers, not the amounts actually paid by the manufacturers. Therefore, if a manufacturer fails to pay a quarterly invoice, that unpaid invoiced amount will not be reflected in reconciliation.

A107: "Medical record review methodologies must be designed to identify errors in diagnoses submitted to CMS as risk adjustment data, regardless of whether the data errors would result in positive or negative payment adjustments": How will this be enforced?

We expect that RADV audits will help in evaluating whether a MA organization is effectively fulfilling this requirement.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

INTRODUCTION

INTRODUCTION

Purpose (Slide 2)

The purpose of this training is to provide participants who are new to risk adjustment the support necessary to understand risk adjustment. This information will enable new participants to collect and submit risk adjustment data in accordance with Centers for Medicare & Medicaid Services (CMS) requirements.

About This Training

This training is organized into nine modules:

- 1. Risk Adjustment Methodology**
Provides an understanding of CMS' Risk Adjustment models and payment methodologies.
- 2. Risk Adjustment Process Overview**
Identifies the systems and timeline for the risk adjustment data collection, submission, editing, and reporting processes.
- 3. Data Collection**
Describes the acceptable sources of risk adjustment data and data collection formats.
- 4. Data Submission**
Describes the acceptable formats for submitting risk adjustment data.
- 5. Edits**
Identifies data integrity logic and error codes, error resolution, and suggestions for avoiding errors.
- 6. Diagnosis Codes & Risk Adjustment**
Provides important medical record documentation and coding guidelines related to risk adjustment.
- 7. Data Validation**
Identifies the data validation approach under the CMS' Risk Adjustment models, including responding to CMS medical record requests.
- 8. Reports**
Describes risk adjustment reports, and defines their uses in monitoring data collection and submission processes.
- 9. Verifying Risk Scores**
Describes the process for calculating the risk score and its impact on risk adjusted payment.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

INTRODUCTION

This participant guide is designed as the foundation of the training program. The presentation slides complement the participant guide and both will be used extensively throughout this training. The participant binder includes the participant guide, presentation slides, a resource guide, and job aids. Collectively, these tools enhance the learning experience. Sections of the binder are described in Table A.

TABLE A – TRAINING TOOLS

SECTION	DESCRIPTION
Participant Guide	- Detailed description of relevant risk adjustment information - Case studies - Exercises - Answer keys
Slides	- Organized by module - Printed two slides per page
Resource Guide	- List of common acronyms - Risk adjustment instructions - Contact information - Other source documents

Future Use of This Participant Guide

The participant guide, slides, and resource guide are designed for use when participants return to their organizations. Additional copies of the training materials are available at www.csscooperations.com. CMS revises training materials, when required. An appropriate label will appear in the footer of the replacement pages affected by the revisions. Organizations are encouraged to register at www.csscooperations.com to receive notification for these revisions.

Audience

This training program is designed for individuals new to the risk adjustment process. The primary audiences for this training are:

- Staff of new Medicare Advantage (MA) and Medicare Advantage – Prescription Drug (MA-PD) organizations, Regional and Employer Group Health plans, demonstration projects, Program of All-Inclusive Care for the Elderly (PACE) organizations, and specialty plans.
- Existing staff unable to attend previous training sessions.
- New staff at the existing organizations mentioned above.
- Third party submitters contracted to submit data on behalf of MA Risk Adjustment organizations.

The organizations listed in Table B will be used throughout this training.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

INTRODUCTION

TABLE B – ORGANIZATION DESCRIPTION

NAME	DESCRIPTIONS
MA Organizations	Organizations, including Health Maintenance Organizations with or without Prescription Drug Programs, Employer Group Health and Medical Savings Account organizations, private fee-for-service organizations, preferred provider organizations, and provider sponsored organizations that receive capitated payments to provide comprehensive medical services to Medicare beneficiaries.
PACE	Program of All-Inclusive Care for the Elderly (PACE) that serves a community of frail and elderly individuals who are eligible for nursing home placement based on State Medicaid criteria.
MSHO/ MnDHO	Minnesota Senior Health Options (MSHO) and Minnesota Disability Health Options (MnDHO) are managed care products in a ten-county area in Minnesota, including the Twin Cities. They integrate Medicare and Medicaid financing of acute and long-term care service delivery for dually eligible and Medicaid eligible physically disabled adults and elderly. MnDHO is approved for Carver, Scott, Washington, Hennepin, Ramsey, Dakota, and Anoka counties.
S/HMO	Social Health Maintenance Organizations (SHMO) offer seniors an expanded care benefits package that may include prescription drugs and community-based services, which enables them to maintain independence and avoid nursing home placement.
WPP	Wisconsin Partnership Program (WPP) is a comprehensive program for Medicaid and Medicare beneficiaries who are elderly or disabled and meet the State's nursing home criteria. WPP integrates health and long-term support services, and includes home and community-based waiver services (HCBS), physician services, and all other medical care.
SCO	The MassHealth Senior Care Option (SCO) is a dual eligible demonstration that CMS and the Division of Medical Assistance for the Commonwealth of Massachusetts developed. The contractors provide care through managed care organizations to beneficiaries who enroll voluntarily. SCOs serve community-well, community-frail and institutionalized beneficiaries age 65 and older. SCOs are required to contract with State Aging Services Access Point providers as part of the SCO care management team, which deliver home and community-based services as part of an integrated model of care.
Capitated Demonstration Projects	Capitated demonstration projects use alternative capitated financing to allow the provider to offer comprehensive medical service.

For Medicare Advantage Organizations
Participant Guide**

INTRODUCTION

Learning Objectives (Slide 5)

At the completion of this training, participants will be able to:

- Identify Risk Adjustment and payment methodologies.
- Describe the requirements for data collection.
- Determine the process for submitting data to CMS.
- Interpret the editing rules and steps in the error resolution process.
- Name and interpret the reports available for risk adjustment monitoring.
- Demonstrate how to verify risk scores.

The roles and contact information for important resources are provided in Table C.

TABLE C – RISK ADJUSTMENT PROCESS POINTS OF CONTACT

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

MODULE 1 – RISK ADJUSTMENT METHODOLOGY

Purpose (Slide 2)

To provide information on risk adjusted data submission and payment under the risk payment models. The goal of risk adjustment is to pay applicable Parts C and D organizations accurately and fairly by adjusting payment for enrollees based on demographics and health status. Changes to risk adjustment under the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (MMA) are also provided in this module.

Learning Objectives (Slide 3)

At the completion of this module, participants will be able to:

- Define the purpose of risk adjustment.
- Identify the components of risk adjusted payments.
- Describe the Part C community model.
- Describe how to calculate the frailty adjuster.
- Describe Part C Community and Long-term institutional models.
- Describe how to calculate a risk factor.
- Recognize the components of the Part C End-Stage Renal Disease (ESRD) model.
- Describe the Part D Prescription Drug Risk Adjustment model.
- Identify the new enrollee factors.

Example

Reminder

Resource

1.1 Risk Adjustment History (Slides 4-9)

The following is a list of key dates that have occurred during the process of implementing a risk adjustment payment methodology.

- Balanced Budget Act of 1997 (BBA) (42 CFR 422).
 - Created the Medicare+Choice (M+C) program.
 - Mandated risk adjustment payment methodology to increase payment accuracy.
 - Mandated the implementation of a frailty adjuster for the Program for All-Inclusive Care for the Elderly (PACE) organizations.
- August 1998
 - Hospital inpatient encounter data collection began.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

- January 2000 – Principal Inpatient Diagnostic Cost Group (PIP-DCG) Payment Model implemented.
 - Gradual phase-in of risk adjustment based on principal inpatient diagnosis and demographic factors (age, sex, Medicaid status, original reason for Medicare entitlement).
 - Implemented at 10 percent PIP-DCG and 90 percent demographic.
 - The PIP-DCG model is based on hospital inpatient diagnoses only.
- Benefits Improvement and Protection Act of 2000 (BIPA) (December).
 - Established the current implementation schedule to achieve 100 percent risk adjusted payment in 2007.
 - Mandated the incorporation of ambulatory data.
- May 2001 – Secretary of the Department of Health and Human Services suspended collection of ambulatory data to seek burden reduction for M+C organizations.
- January 2002 – CMS announced new risk adjustment data processing system—RAPS (Risk Adjustment Processing System).
- March 2002 – Draft CMS-HCC Payment Model selected.
 - New risk adjustment model needed to accommodate other types of data (hospital outpatient and physician)
 - Included approximately 70 condition groups with reduced number of diagnostic codes.
 - Proposed for implementation in calendar year 2004.
- February 3, 2003 – CMS presented a draft CMS-HCC model discussed at national public meeting and addressed the elimination of the data lag for payment.
- March 28, 2003 – Advanced Notice of Methodological Changes (i.e., 45-Day notice) published the proposed CMS-HCC model, ESRD model, frailty adjuster, and elimination of the data lag.
- May 12, 2003 – Published final M+C rates for 2004 payment.
 - Announced final CMS-HCC model, including the institutional and community models.
 - Provided risk adjustment new enrollee factors.
 - Delayed implementation of ESRD model for M+C until 2005.
 - Described process for elimination of the data lag.

See 2004 45-Day Notice at

<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Advance2004.pdf> and May 12, 2003 Announcement of Rates for 2004 at:

<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Announcement2004.pdf>

- December 8, 2003 – Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (MMA) Enacted (P.L. 108-173).
 - Created MA program to replace M+C program.
 - Retained many M+C provisions.
 - Created Medicare drug benefit to begin in 2006.
 - Established bidding methodology for MA organizations and drug plans in 2006.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

- January 16, 2004-New ratebook for 2004 published.
 - Revised ratebook took into account changes from MMA—adding 4th prong to the "highest of" methodology for 2004 and modifying the minimum percentage increase rate for 2004 and beyond.
-  See January 16, 2004 cover letter regarding revised MA rates at:
<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Announcement2004b.pdf>
- March 26, 2004-Advanced Notice of Methodological Changes for 2005 (i.e., 45-Day notice) published.
 - Proposed revised MA payment methodology—based on MMA, ratebook transitions to "highest of 2."
 - Proposes ESRD model for implementation in 2005.
-  See 2005 45-Day Notice for additional details at:
<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Advance2005.pdf>
- May 2004-Announcement of draft diagnoses collected for drug risk adjustment model for payment beginning in 2006 and additional codes for CMS-HCC risk adjustment models.
- May 10, 2004-Announcement of rates for 2005.
 - Announced MA county capitation rates.
 - Announced final ESRD CMS-HCC risk adjustment model.
- February 18, 2005-Advanced Notice of Methodological Changes for 2006 (i.e., 45-Day notice) published.
 - Proposed changes in the MA capitation rate methodology and risk adjustment methodology under Part C.
 - Proposed the health status risk adjustment methodology for Part D [Draft Prescription Drug (RxHCC) Model].
 - Proposed payment methodologies for the direct, low income, and reinsurance subsidies, and risk sharing.
-  See 2006 45-Day Notice for additional details at:
<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Advance2006.pdf>
-  April 4, 2005-Announcement of rates for 2006.
 - Announced final Part D risk adjustment model.
 - Rolled back proposed changes to MA risk adjustment model outlined in February 18, 2005 Advance Notice.
 - April 8, 2005-Updated regional rates.
 - April 13, 2005-Updated ratebook.
-  See Final 2006 Notice for additional details at:
<http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/Downloads/Announcement2006.pdf>
- April 7, 2005- Risk Adjustment models and ICD-9/HCC crosswalks posted at

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

April 3, 2006—Announcement of 2007 Payments posted at
<http://www.cms.hhs.gov/MedicareAdvltgSpecRateStats/Downloads/Announcement2007.pdf>.

- Announced recalibrated version of the CMS-HCC model for 2007
- Announced updated normalization factor for CMS-HCC models

April 2, 2007—Announcement of 2008 Payments posted at
<http://www.cms.hhs.gov/MedicareAdvltgSpecRateStats/Downloads/Announcement2008.pdf>.

- Announced recalibrated versions of ESRD models for 2008
- Announced normalization factor for Part D risk adjustment model
- Announced updated normalization factor for Part C CMS-HCC and functioning graft models
- Announced normalization factor for ESRD dialysis and transplant models
- Announced recalibrated frailty model
- Announced new frailty payment implementation for PACE and certain demonstration organizations

1.2 Calculating Payments

1.2.1 Payments for 2004 and 2005

Traditionally, payments to MA organizations were based solely on demographic information. Risk adjustment provides more accurate payments for MA organizations. Payments are higher for less healthy enrollees and lower for more healthy enrollees. For 2004 and 2005, MA risk payment calculations involved two steps:

1. Derive the county risk rate, and
2. Multiply by the individual risk factor.

CMS derived county risk rates for Part A and Part B by multiplying the unadjusted Part A and Part B county rates (used for demographic payments) by a rescaling factor, based on the CMS-HCC risk factor of the FFS enrollees in that county. This county risk rate was then multiplied by the individual's CMS-HCC risk factor to determine the appropriate payment amount. The MA organization demographic and CMS-HCC payment rates for 2004 through 2007 and beyond are as follows:

- For 2004, MA organizations were paid using 70 percent of the demographic payments and 30 percent of the CMS-HCC payments.
- For 2005, MA organizations were paid using 50 percent of the demographic payments and 50 percent of the CMS-HCC payments.
- For 2006, MA organizations were paid using 25 percent of the demographic payments and 75 percent of the CMS-HCC payment.
- For 2007 and beyond, MA organizations are paid using 100 percent of the CMS-HCC payment.

Prior to the passage of the MMA, the 2004 MA (then M+C) rates for each county were defined as the maximum of three possible categories: the blended capitation rate, minimum "floor" amount, or minimum two percent increase rate. With the enactment of the MMA in December 2003, the original 2004 payment methodology changed and required CMS to issue revised capitation rates for CY 2004.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

The MMA mandated that a fourth rate type, 100 percent of projected fee-for-service Medicare costs (with adjustments to exclude direct medical education and include a VA/DOD adjustment) be added to the payment methodology. With the addition of this 4th prong to the MA payment methodology, the formula reconnects the link between managed care payment rates and fee-for-service spending at the county level. For 2004 only (a transition year under the MMA rate-setting rules), the county capitation rate was this highest of four rates: blended rate, floor amount, minimum increase rate, and FFS rate.

In addition, from 2004 onward, the MMA modifies the methodology for calculating the minimum percentage increase. The previous year's rate is increased by the larger of:

- 2 percent
- or
- the Medicare growth percentage, - with no adjustments to this growth trend for over/under projections for years before 2004.

For 2005 and subsequent years, the MA capitation rate for a county is the minimum percentage increase rate, except for years when CMS re-tabulates ("rebases") the FFS rates. In rebasing years, the county capitation rate is the higher of the minimum percentage increase rate or the FFS rate.

1.2.2 MA Capitation Rates for 2006 through 2008

CY 2006 was the first year that MAOs were paid based on the MMA bid-based methodology. Thus, the capitation rates are no longer the same as payment rates. Capitation rates are used to establish benchmarks, and payment rates are plan-specific per capita monthly bids (adjusted).

For 2006, the final estimate of the increase in the National Per Capita Medicare Advantage Growth Percentage for aged beneficiaries was 4.8 percent, which is greater than 2 percent. Therefore, 4.8 percent was used as the minimum update percentage in calculating the 2006 rates. For 2006, all capitation rates are the 2005 rate increased by 4.8 percent. Per the MMA, CMS is not required to rebase the county fee-for-service rate every year and did not do so for 2006. In addition, for 2006, MA organizations were paid using 25 percent of the demographic payments and 75 percent of the CMS-HCC risk payments.

For 2007, the final estimate of the National Per Capita Medicare Advantage Growth Percentage was 7.1 percent. Because fee-for-service rates were rebased (to reflect more recent county growth trends in fee-for-service expenditures), counties where the FFS rate is greater than the minimum percentage increase rate received the FFS rate. For 2007, 6 percent of the counties received the FFS rates. For 2007 and beyond, payments to MA organizations will be at 100 percent of the CMS-HCC risk rate.

For 2008, the final estimate of the National Per Capita MA Growth Percentage is 5.7%. This final estimate includes 4.3 percent for the 2008 underlying trend change and 1.3 percent due to corrections to prior years' estimates, as required by law. CMS did not re-tabulate the FFS rates for 2008, so all MA capitation rates are minimum percentage increase rates.

1.2.3 Risk Ratebook

For payments years through 2006, a rescaling factor has been used to convert the demographic capitation rates to the risk adjusted capitation rates for each county. This is referred to as a restandardizing

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

the ratebook. The rescaling factor is defined as the county rate properly standardized to the new risk adjustment factors divided by the demographic county rate. In addition to restandardizing the ratebook, a budget neutrality factor is applied to make risk adjustment budget neutral. (see below for more information)

Section 5301 of the Deficit Reduction Act (DRA) changes the way CMS develops its capitation rates, beginning in 2007. The DRA established a single risk ratebook for monthly capitation rates, because the statutory transition for MA plans from payment based on the demographic rates and demographic adjustment factors to payment based on risk adjustment rates and risk adjustment factors were completed in 2006. Effective 2007, MA capitation rates are risk rates. Capitation risk rates are used to determine the plan benchmarks for virtually all MA plans and MAOs set their bids in relation to their benchmarks.

The DRA defines the risk rates as the base ratebook, so CMS will now publish two sets of rates – risk and demographic rates. CMS will continue to publish the demographic rates because they are used in budget neutrality (BN) factor calculations. Also, the demographic rates will be used in 2007 to determine payments to certain demonstrations and PACE organizations, which lag one year in the transition blend so that 25 percent of their payments will be based on demographic rates.

In addition, the FFS normalization factor, which was applied in the rate book prior to 2007, is instead applied to the risk scores starting in 2007. The result of these two approaches is mathematically the same.

Table 1A shows the risk adjustment models and updates implemented for payments beginning with 2004. Note that all models are implemented with their associated new enrollee models.

TABLE 1A – RISK ADJUSTMENT MODEL IMPLEMENTATION FOR PAYMENT (Slides 12 & 37)

PAYMENT YEAR	RISK ADJUSTMENT MODEL IMPLEMENTED FOR PAYMENT	CALIBRATION YEARS	NORMALIZATION FACTOR
2004-2006	CMS-HCC Community & Institutional	1999-2000	1.05
2005-2007	ESRD Functioning Graft	1999-2000	1.05
	ESRD Dialysis and Transplant	1999-2000	N/A
2006-current	RxHCC	2002-2006	N/A
2007-current	Recalibrated CMS-HCC Community & Institutional	2002-2003	1.029
2008	Recalibrated ESRD Functioning Graft	2002-2003	1.04
	Recalibrated ESRD Dialysis and Transplant	2002-2003	1.010
	Recalibrated CMS-HCC Community and Institutional	2002-2003	1.04*
	RxHCC	2002-2006	1.065**

*The 2008 normalization factor for the CMS-HCC community and institutional models was updated from 2007 to include one additional year of FFS data. Note that the 2007 recalibrated model did not change for 2008 payments.

**The 2008 normalization factor for the RxHCC model will be first implemented in 2008. Note that the 2006 model did not change for 2008 payments.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.2.3.1 Adjustment for Budget Neutrality

While risk adjustment (without the implementation of budget neutrality) would reduce aggregate payments to the MA program, budget neutrality redistributes these payments as a constant percentage to organizations affected by risk adjustment (including MA organizations, PACE, and certain demonstrations). In other words, under budget neutrality, savings that would have accrued to the Medicare Trust Fund due to the application of risk adjustment are instead redistributed among MA organizations. The budget neutrality factor is calculated as the difference between payments under 100 percent of the risk adjustment method (i.e., under the CMS-HCC model) versus payment under 100 percent of the demographic only method.

The following sections discuss recent changes in the application of budget neutrality policy.

1.2.3.2 Change in the Budget Neutrality Calculation to Account for Different Payment Methodologies for Local MA Plans Versus Regional MA Plans

Because of the difference in payment methods for local MA plans versus regional MA plans beginning in 2006, CMS will modify the budget neutrality calculation. Budget neutrality is calculated as the difference between aggregate MA payments at the local MA benchmark rate that would have been made using the demographic method for 100 percent of payments and the aggregate payments that would be made using 100 percent of risk adjusted payments. Budget neutrality will be applied to both local and regional MA plans. For regional plans, this means that the budget neutrality factor will be applied to the statutory component of the benchmark.

1.2.3.3 Phase Out of Budget Neutrality

The DRA mandates the phase-out schedule for the BN factor from 2007 through 2010. The phase out schedule is shown in Table 1B. Under the budget neutrality methodology, in 2006, 100 percent of the difference between payment under the demographic method and payment under risk adjustment was added back to the risk payment rates via a rescaling factor. However, due to the payment blend for 2006 this will result in 75 percent of the budget neutrality amount being added back to the blended benchmark. For 2007, 55 percent of the BN factor was applied to every risk rate. The percentage applied will decrease each year until 2011, when it is 0 percent (see Table 1B).

TABLE 1B – PHASE-OUT SCHEDULE FOR BUDGET NEUTRAL RISK ADJUSTMENT PAYMENTS

YEAR	BUDGET NEUTRALITY PERCENTAGE
2006	100% ^{1/}
2007	55%
2008	40%
2009	25%
2010	5%
2011	0%

^{1/} 100 percent of the difference between payment under the demographic method and the payment under the risk adjusted method will be added to the risk adjusted payment rates. However, due to the payment blend for 2006 of 25 percent demographic and 75 percent risk adjustment the net effect is a 75 budget neutrality adjustment.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.2.4 Payment Blends

The schedule for implementing risk adjusted payments based on the CMS-HCC model and the blended transitional approach is shown below. In 2004, the CMS-HCC model was implemented at a 30 percent risk adjusted payment, with the remaining 70 percent represented by the demographic payment. The portion of risk adjusted payment will increase to 50 percent in 2005, to 75 percent in 2006, and finally to 100 percent in 2007. There was not blended payment transition for the Part C ESRD and Part D models. Payments under these models were implemented at 100 percent risk adjustment from the beginning. The CMS-HCC implementation schedule is shown in Table 1C. The Part C blended payment transition schedule for PACE and certain demonstration organizations is on a one year lag from the payment transition for MA organizations. Table 1D shows that CMS-HCC implementation schedule for specialty organizations.

**TABLE 1C – RISK ADJUSTMENT IMPLEMENTATION SCHEDULE FOR MA ORGANIZATIONS
AND FOR MA-PDS AND PDPS FOR DRUG BENEFIT**

PAYMENT YEAR	CMS-HCC MODEL -COMMUNITY -INSTITUTIONAL	ESRD CMS-HCC MODEL	DRUG BENEFIT MODEL
2004	70% Demographic 30% CMS-HCC Model	N/A	N/A
2005	50% Demographic 50% CMS-HCC Model	100%	N/A
2006	25% Demographic 75% CMS-HCC Model	100%	100%
2007	100% CMS-HCC Model	100%	100%

TABLE 1D – PAYMENT BLEND SCHEDULE FOR SPECIALTY ORGANIZATIONS

TYPE OF HEALTH PLAN	PART C TRANSITION BLEND*				
	2004	2005	2006	2007	2008
PACE	90/10%	70/30%	50/50%	25/75%	100%
WPP	90/10%	70/30%	50/50%	25/75%	100%
MSHO and MnDHO	90/10%	70/30%	50/50%	25/75%	100%
S/HMOs	90/10%	70/30%	50/50%	25/75%	100%
SCO	90/10%	70/30%	50/50%	25/75%	100%

*Represents percentage of original demographic payment methodology (specific to each plan type) versus CMS-HCC risk adjusted portion of payment. ESRD and Part D risk adjustment were implemented at 100 percent risk.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.2.5 Fee-for-Service Normalization Adjustment (Slide 37)

The purpose of the fee-for-service normalization adjustment is so that CMS payments are based on a population with an average risk score of 1.0. Because average predicted FFS expenditures increase after the model calibration year due to coding and population changes, CMS applies a normalization factor to adjust beneficiaries' risk scores so that the average risk score is 1.0 in subsequent years. Through 2006, CMS adjusted the restandardized ratebook to the appropriate denominator for the payment year. The denominator represented the national average predicted fee-for-service expenditures per beneficiary in that year. Every year there are shifts in the Medicare population. Specifically, fee-for-service coding across all sites of service, coding has not yet stabilized as much as inpatient hospital coding. Therefore, it has been necessary to apply a fee-for-service normalization factor to adjust for changes in coding patterns.

The DRA required CMS to apply the fee-for-service normalization factor to the risk scores. For 2007 the Part C normalization factor for the recalibrated CMS-HCC model is 1.029, and 1.05 for the ESRD functioning graft models. The functioning graft normalization factor remained unchanged from the previous year since the ESRD models were not recalibrated for 2007. There was no normalization factor applied to the dialysis and transplant risk scores for 2007. For 2008, the normalization factor is 1.04 for the CMS-HCC and ESRD functioning graft risk scores. The Part D normalization factor is 1.065.

CMS will implement a four-year normalization phase-in of the Part C - ESRD dialysis and transplant risk scores. For 2008 (Y1) through 2011 (Y4), CMS will calculate a yearly normalization factor. The calculated normalization factor for each year will be adjusted using the specified phase-in percentage for that year. The risk scores will then be divided by the resulting adjusted normalization factor for that year. For example, in 2008 (Y1), dialysis and transplant risk scores will be divided by 25% of the calculated 2008 normalization factor. The normalization factor calculated for 2008 is .039 (or 3.9%). This factor will be multiplied by 25% to get the adjusted normalization factor. Therefore, the ESRD dialysis and transplant risk score normalization formula is $[\text{risk score} / (1 + (\text{the adjusted factor}))]$, which is 1.010 (i.e., $1 + (.039 * 25\%)$) (See Table 1E).

Beneficiary risk scores are divided by a normalization factor. The fee-for-service normalized risk scores will appear on the MMRs. If plans calculate their own raw risk scores using the CMS-provided software, they will need to divide these raw risk scores by the respective normalization factors to obtain the risk scores used for payment.

**TABLE 1E – DIALYSIS AND TRANSPLANT RISK SCORE NORMALIZATION
PHASE-IN SCHEDULE**

YEAR	ADJUSTED NORMALIZATION FACTOR PHASE-IN PERCENTAGE
2008 (Y1)	$1 + (.039 * 25\%)$
2009 (Y2)	$1 + (\text{Calculated Normalization Factor} * 50\%)$
2010 (Y3)	$1 + (\text{Calculated Normalization Factor} * 75\%)$
2011 (Y4) (forward)	$1 + (\text{Calculated Normalization Factor} * 100\%)$

For a complete explanation of the derivation of the demographic and risk adjusted ratebook, see the following: <http://www.cms.hhs.gov/manuals/Downloads/mc85c07.pdf>

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.2.6 Payments for 2006 and Beyond

1.2.6.1 Bidding Background

Beginning in 2006, CMS' payments for plan enrollees are based on the plan bid relative to the plan benchmark. An MA organization's combined bid for its service area, for both local and regional organizations (or service area segment, in the case of a local organization), will have three parts:

- An amount for the provision of Medicare Parts A and B medical benefits. (This is the standardized A/B bid, and does not include beneficiary cost-sharing.)
- An amount for basic coverage of Medicare prescription drug benefits (if any).
- An amount for the provision of supplemental medical and prescription drug benefits (if any).

Benchmarks. For both local and regional MA plans, the plan A/B benchmark, when compared against the plan A/B bid, determines whether a plan will have savings and rebates to offer additional benefits, or whether the MA organization will have to charge a basic premium for the plan's coverage of Part A and B benefits.

For local plans, the plan A/B benchmark is determined according to formulas established in the MMA. For a single-county plan (or segment), the plan A/B benchmark is the capitation rate for that county, adjusted to reflect the plan's projected risk profile to allow comparison to the plan A/B bid.

For local plans serving more than one county, the plan A/B benchmark is the enrollment-weighted average of all the county capitation rates in the plan's service area (or segment), adjusted by the projected risk profile of the plan. (In determining the enrollment-weighted average, the weights are based on the plan's projected enrollment in each county of its service area.)

The standardized benchmark for each MA region is a blend of two components: a statutory component consisting of the weighted average of the county capitation rates across the region; and, a competitive component consisting of the weighted average of all of the standardized A/B bids for regional plans in the region. The weighting for the statutory component is based on MA eligible individuals in the region. "MA eligibles" refers to all Medicare beneficiaries in the FFS and MA programs. The weighting for the competitive component (which includes each regional plan's bid) is based on the projected enrollment of the regional plans competing in the region. The blend of the two components will reflect the market share of traditional Medicare (for the statutory component) and the market share of all MA organizations (for the competitive component) in the Medicare population nationally.

1.2.7 Intra-Service Area Rate (ISAR) Adjusted County Payment Rates

In 2006 and beyond, payments to MA organizations must be adjusted to account for variations in MA local payment rates among the different MA local areas included in the MA plan's service area. For each MA plan, CMS will apply an ISAR adjustment based on the variation among MA capitation rates in the counties of a MA plan's service area. The ISAR is used to convert the plan's service-area bid into plan-specific county rates.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

The ISAR factor is calculated as the ratio of a county rate to the weighted average of all county rates for the service area, using plan projected county enrollment as the weights. For example, a plan with a service area of three counties (X, Y, and Z) could have ISAR factors of 0.98 for county X, 1.12 for county Y, and 0.9 for county Z. The weighted average of all the plan's county ISAR factors for that plan's service area must equal 1.0. Thus, for each county in the plan's service area, there will be a plan-specific county rate derived from the bid and the ISAR factor.

1.2.8 Plan Payments

Plan payments Part C benefits are based on the relationship of the plan's bid with the plan benchmark.

(a) If the plan bid is less than the plan benchmark, monthly payment from CMS for an enrollee is:

$$\text{ISAR-adjusted county rate} \times \text{enrollee risk factor} + \text{rebate}$$

(b) If the plan bid is equal to the plan benchmark, monthly payment from CMS for an enrollee is:

$$\text{ISAR-adjusted county rate} \times \text{enrollee risk factor}$$

There is no rebate and no basic beneficiary premium.

(c) If the plan bid is greater than the plan benchmark, monthly payment from CMS for an individual is:

$$\text{ISAR-adjusted county rate} \times \text{enrollee risk factor} + \text{government premium adjustment.}$$

There is no rebate and the enrollee pays a basic premium. The combined payment from CMS and the enrollee will on average equal the organization's bid (based on enrollment assumed in the bid submission).

For enrollees who are out of the service area, the base payment will be the 1.0 bid (with individual-level risk adjustment for demographic and health status factors). (Note that for plans with bids above benchmarks, the base payment for out-of-area enrollees is the benchmark because the beneficiary premium is subtracted from CMS' payment.) The rebate amount is not geographically or otherwise adjusted. It is a fixed amount determined through comparison of the plan A/B bid to the plan A/B benchmark based on the plan's projected enrollment.

Example: Plan with a Rebate

- Mr. Jones' plan:
 - Standardized ("1.0") A/B bid = \$600
 - Rebate = \$54
 - His plan's county ISAR factor = .98
 - His risk factor = 1.2
- ISAR-adjusted payment rate for Mr. Jones' county for his plan: $(\$600 \times .98) = \588
- Monthly Part C payment for Mr. Jones for his plan: $(\$588 \times 1.2) + 54 = \759.60

RISK ADJUSTMENT METHODOLOGY

Figure 1A illustrates the calculation of Risk Adjusted Payment for Plans.

Figure 1A – Calculation of Risk Adjusted Payment for Plans

1.3 Risk Adjustment Payment Models for Payment (Slide 13)

In 2003, after public comment, the CMS-HCC model was finalized as the risk adjustment payment model. The goal was to select a clinically sound risk adjustment model that improved payment accuracy while minimizing the administrative burden on MA organizations.

The model is a revision of the Hierarchical Condition Category model, originally developed by Health Economics Research, Inc. The CMS-HCC model functions by categorizing *International Classification of Diseases, 9th Edition, Clinical Modification* (ICD-9-CM) codes into separate groups of clinically related codes, (e.g., diabetes, cancer, ischemic heart disease, infections, etc.) that have similar cost implications.

In order to improve payment further, CMS has developed separate models for different populations who have different cost patterns than the general Medicare population. There are four CMS-HCC models used to calculate risk scores for MA plans: a community model, a long-term institutional model, an ESRD model, and a new enrollee model. The new enrollee model is different than the other models in that it is not disease based.

CMS implemented the Prescription Drug (Rx-HCC) model in 2006 for payment under Part D. The RxHCC model is also a disease based model similar to the CMS-HCC model. However, it varies in that there is a base model and there are separate multipliers for the long term institutionalized (LTI) and low income

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

beneficiaries which are applied to payment outside the model. The RxHCC model is described in detail towards the end of this module.

CMS has updated all of its Part C models and the frailty adjustment model, which is used for Non-ESRD ≥ 55 community residents. The result of the model recalibrations also yields updated normalization factors. Application of the normalization factors is described later in this module.

In 2007, CMS implemented updated versions of the CMS-HCC community and institutional risk adjustment models. Fee-for-service (FFS) claims data for the years 2002 and 2003 were used in the recalibrated model. Diagnosis data for 2002 predict 2003 expenditures. As these data are more current than the 1999 and 2000 data used for the original CMS-HCC model, the updated models reflect newer treatment and coding patterns in Medicare FFS.

For 2008, CMS recalibrated the original Part C ESRD models, and refined the frailty adjustment factors that are applied to the Part C community model risk scores. Similar to the community and institutional recalibration efforts, the ESRD models were recalibrated using 2002 and 2003 FFS claims data for ESRD enrollees. The frailty factors are used to calculate frailty scores applied to the payments to PACE organizations and certain demonstration plans. For PACE plans, CMS will transition from using the frailty factors used in 2007 to the revised frailty factors over five years. CMS will apply the current frailty adjustment factors to MA demonstration organization's payments on a phased-out schedule (described in the frailty section).

CMS' suite of payment models share common conceptual framework in general; however, the purpose for each is distinct to the expenditure patterns for specific Medicare populations.

Table 1F describes the characteristics of the Part C (CMS-HCC) and Part D (RxHCC) models.

TABLE 1F – CHARACTERISTICS OF THE RISK ADJUSTMENT MODELS

CHARACTERISTIC	DESCRIPTION
SIMILAR MODEL CHARACTERISTICS (PART C AND PART D)	
Selected Significant Disease (SSD) Model	- Serious manifestations of a condition are considered rather than all levels of severity of a condition. - Models are additive. - Include most body systems and conditions.
Prospective Model	Uses diagnostic information from a base year to predict total costs for the following year.
Site Neutral	Models do not distinguish payment based on a site of care.
Diagnostic Sources	Models recognize diagnoses from hospital inpatient, hospital outpatient, and physician settings.
Multiple Chronic Diseases Considered	- Risk adjusted payment is based on assignment of diagnoses to disease groups, also known as HCCs. - Model is most heavily influenced by Medicare costs associated with chronic diseases.
Disease Interactions and Hierarchies Included	- Interactions allow for additive factors based on chronic conditions and disabled status to increase payment accuracy. - Hierarchies allow for payment based on the most serious conditions when less serious conditions also exist.
Demographic Variables	- Models include four demographic factors: age, sex, disabled status, and original reason for entitlement. - These factors are typically measured as of the data collection period.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

TABLE 1F – CHARACTERISTICS OF THE RISK ADJUSTMENT MODELS (CONTINUED)

CHARACTERISTIC	DESCRIPTION
PART C SPECIFIC CHARACTERISTICS	
Frailty Adjuster	Frailty add-on is used for PACE and certain demonstration plans with a frail elderly population in the community.
Medicaid Eligibility	- Medicaid status for full risk enrollees is prospective and always determined based on the data collection period. - Medicaid status for new enrollees is concurrent and based on Medicaid status during the payment year (during final payment).
Community-Based and Long-Term Institutionalized Enrollees Distinguished	- Long-term institutionalized is defined as enrollees with 90 days or greater of residence in a nursing home. - Institutional model is not based on institutional factor demographic-only model. - Separate models account for higher treatment costs of similarly-ill community residents. - Community and institutional models both include 70 disease groups.
ESRD CMS-HCC Model	- Model addresses disparate treatment costs structures related to ESRD enrollee status. - The model includes specific payments for individuals with dialysis, transplant, and functioning graft. - The ESRD model includes 67 disease groups.
PART D SPECIFIC CHARACTERISTICS	
LTI Multiplier	- Long term institutional (LTI) factor – gets assigned to the risk scores of beneficiaries with 90 days of residence or greater in a nursing home. - LTI status is determined based on the data collection period.
LIS Multiplier	- Two low income status (LIS) factors (full subsidy, and partial subsidy) – one or the other gets assigned to the risk score for enrollees based on their Part D determined LIS status. - LIS status is determined during the payment year.

1.3.1 Components of the Risk Score in the CMS-HCC Model

CMS uses diagnoses from Medicare fee-for-service and/or from RAPS for determining the HCCs for each enrollee. Medicare fee-for-service data are utilized for risk adjusted payment when an enrollee joins an MA organization (or PACE/demonstration) after opting out of traditional Medicare fee-for-service coverage. That is, if an enrollee new to an MA organization enrolls in January of a calendar year, then CMS will use up to 12-months of prior fee-for-service data within the data collection period (both Part A and Part B) to obtain diagnostic data. Where data for a person have been submitted via RAPS, those data are also used in calculating the risk score for a person.

The risk score used in calculating payments under the CMS-HCC model includes demographics as part of the risk model as well as different disease groups or HCCs. The model allows for the recognition of coexisting diseases when calculating payment by recognizing multiple chronic conditions listed for the beneficiary. Interactions (i.e., combinations) are used to account for expected costs that are higher because, for example, multiple coexisting diseases cause additional complications. Hierarchies are imposed to provide payments only for the most severe manifestation of a certain disease.

1.3.1.1 Demographic Factors (Slide 15)

The risk score uses five demographic factors in calculating the risk score under the CMS-HCC model, including age, sex, Medicaid status, disability, and original reason for Medicare entitlement (i.e., disability).

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

Age and Sex: Based upon the enrollee's age and sex, risk adjusted demographic factors are assigned for the calculation of the enrollee's risk factor.

Under the CMS-HCC model, CMS bases payments for the entire payment year upon the age an enrollee attains as of February 1st of each year with one exception, when an enrollee ages in to Medicare. (i.e., Beneficiaries are treated as age 65 for risk adjustment purposes when they attained 65 years of age in the payment year and the reason for entitlement is age.)

Disabled Status: The disabled factors for enrollees under 65 years old are labeled as "disabled" and those over 65 years old are labeled as "aged." Under the CMS-HCC model, additional payments are made for Medicaid eligible disabled individuals.

Original Reason for Medicare Entitlement (OREC): The factors labeled "originally disabled" apply to enrollees that are 65 years old or over who were originally entitled for Medicare due to disability. Under the CMS-HCC model, additional payments are made for OREC individuals with Medicaid based on age and sex,

Medicaid Status: The Medicaid factor applies to enrollees who are entitled to Medicaid under Title XIX of the Social Security Act. A Medicaid factor is applied based on the "aged", "disabled", or "originally disabled" status of the Medicaid enrollee.

1.3.1.2 Disease Groups/HCCs (Slide 16)

Disease groups contain major diseases and are broadly organized into body systems. For risk adjustment purposes, CMS refers to disease groups as HCCs. The HCC assigned to a disease is determined by the ICD-9-CM diagnosis codes submitted during a data collection period. Only selected diagnosis codes are included in the CMS-HCC model. There are 70 distinct disease groups for payment for community and long-term institutionalized residents. The ESRD model has approximately 67 disease groups, depending on the subpart of the model.

Example 1

DISEASE GROUP/HCC	DESCRIPTION
HCC92	Specified Heart Arrhythmia
HCC158	Hip Fracture/Dislocation

1.3.1.3 Disease Hierarchies (Slide 17)

Finally, the CMS-HCC model incorporates disease hierarchies. These hierarchies are used to provide payments for only the most severe manifestation of a disease, even when diagnoses for less severe manifestations of a disease are also present in the beneficiary during the data collection year. For example, an individual with diabetes that progresses over a year from having no complications (HCC19) to having acute complications (HCC17) would trigger the payments for HCC17 but not for HCC19. (Note that payments for HCC17 are higher than for HCC19.)

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

Example 4

Cancer

CMS-HCC DISEASE HIERARCHIES			
If the Disease Group is Listed in This Column...		...Then Drop the Associated Disease Group(s) Listed in This Column	
HCC	Disease Group Label	HCC	Disease Group Label
9	Lymphatic, head & neck, brain & other major cancers	10	Breast, prostate, colorectal & other cancers & tumors

1.3.1.4 Disease Interactions

Certain combinations of coexisting diagnoses for an individual can increase their medical costs. The CMS-HCC model recognizes these higher costs through incorporating payments for disease interactions.

There are six disease interactions in the community model and five in the institutional model. Examples of the disease interactions include a two-way combination of diabetes mellitus (DM) and congestive heart failure (CHF) or a three-way combination of chronic obstructive pulmonary disease (COPD), cerebrovascular disease (CVD), and coronary artery disease (CAD).

In calculating this part of the risk score for an individual, the individual score for each HCC is added and then the disease interaction score is added. In the example below, the risk adjusted payment would include an additional factor when an enrollee has both diabetes mellitus and congestive heart failure.

Example 2

Two-disease Interaction for Community-Based Enrollee

Factor 1: Diabetes Mellitus (DM), HCC15 = 0.608

Factor 2: Congestive Heart Failure (CHF), HCC80 = 0.395

Factor 3: Interaction: DM*CHF = 0.204

Risk Score = (demographics) + 0.608 + 0.395 + 0.204

In this case, the enrollee receives an additional interaction instead of only two factors for HCC15 and HCC80.

1.3.1.5 Disabled/Disease Interactions

Another type of interaction accounted for in the CMS-HCC model involves certain diseases and the disabled status for an enrollee. There are five disabled/disease interactions in the community model and four in the institutional model.

Below is an example of an individual who is disabled and has been diagnosed with rheumatoid arthritis and an opportunistic infection.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

Example 3

Disabled/Disease Interaction for Community-Based Enrollee

Factor 1: Rheumatoid Arthritis, HCC38 = 0.363

Factor 2: Opportunistic Infection, HCC5 = 0.410

Factor 2: Disabled * Opportunistic Infection = 0.941

Risk Score = (demographics) + 0.363 + 0.410 + 0.941

1.3.2 New Enrollee Factors

For purposes of risk adjustment, new enrollees are defined as newly eligible disabled or age-in beneficiaries (including "ever-disabled" age-in beneficiaries) with less than 12 months of Medicare Part B entitlement during the data collection year. Note that payments based on Medicaid eligibility will be made retroactively for all new enrollees, once enrollment can be established and verified.

As indicated in Table 1G, beneficiaries with 12 or more months of Medicare Part B enrollment during the data collection period (previous calendar year) are considered full risk enrollees. The new enrollee factors do not apply.

Beneficiaries with less than 12 months of entitlement to benefits under Part A and less than 12 months of Part B enrollment during the data collection period will be treated as new enrollees.

Previously, beneficiaries with 12 or more months of entitlement to benefits under Part A and less than 12 months of Part B enrollment during the data collection period (referred to as "Part A-only" enrollees) are considered new enrollees for the purpose of risk adjusted payments. Because of concerns expressed by some demonstrations that "Part A only" enrollees are always considered to be new enrollees, CMS has created an option for determining payments for this category of enrollees. Effective for 2006 payments, organizations may elect to have CMS determine payments for all "Part A-only" enrollees using either new enrollee factors or full risk adjustment factors. The organization's decision will be applied to **all** "Part A-only" enrollees in the plan. Plans may not elect to move some eligible "Part A-only" enrollees into risk adjustment, while retaining others as new enrollees.

This option elected by the organization will remain turned "on" until CMS is notified otherwise prior to August 31st of any successive year. CMS will apply this option during reconciliation for a payment year only (that is, it will not be applied prospectively). Plans interested in this option must contact: Henry Thomas at Henry.Thomas@cms.hhs.gov by 8/31/2007 to elect this option.

RISK ADJUSTMENT METHODOLOGY

TABLE 1G – WHICH RISK ADJUSTMENT FACTORS APPLY TO PAYMENT*

Time Period Beneficiary Has Been Enrolled in Part B Medicare**	Time Period Beneficiary Has Been Entitled to Benefits under Part A Medicare**	
	0 - 11 months	≥ 12 months
0 - 11 months	new enrollee factors	Plan's option: new enrollee or full risk adjustment factors
≥ 12 months	full risk adjustment factors	full risk adjustment factors

*Applies to Part C and D payments for MA plans, demonstrations, and PACE organizations. Note that MA enrollees must be entitled to benefits under Part A and enrolled in Part B.

** During data collection period (previous calendar year).

During the payment year, a new enrollee factor will also be assigned to any beneficiary whose risk score is not available. In this case, the beneficiary's correct risk score will be determined during the next reconciliation.

The new enrollee factors for Part C are available at:

<http://www.cms.hhs.gov/MedicareAdvgtgSpecRateStats/Downloads/Announcement2008.pdf>

1.3.3 Community and Long-Term Institutional Model Distinctions

The CMS risk adjustment approach for Part C uses separate models for non-ESRD community and long-term institutional residents. Separate models were necessary because there are significant cost differences between the traditional community-based MA beneficiary population and the long-term institutionalized beneficiary population with the same disease profile. An adjustment for place of residence improves the payment accuracy of risk adjustment.

A long-term institutionalized MA enrollee is defined as someone who resides in an institution for more than 90 days as identified using the Minimum Data Set (MDS). The costs of the short term institutionalized (less than 90 days) are recognized in the community model.

Table 1H lists the considerations for community and long-term institutionalized populations.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT METHODOLOGY

TABLE 1H – COMMUNITY VERSUS LONG-TERM INSTITUTIONALIZED POPULATIONS

CMS-HCC MODEL CONSIDERATIONS FOR COMMUNITY AND LONG-TERM INSTITUTIONALIZED POPULATIONS	
Community-Based	Long-Term Institutionalized
• Disease-related incremental payments for the community population are generally higher. • Community-based payment includes costs for the short term institutionalized (i.e., less than 90 days in an institution). • Community-based population payment would over predict costs for long-term institutionalized population, even with the same health status. • Currently, most MA organizations have a small proportion of long-term institutionalized enrollees (less than 10 organizations have more than 5% long-term institutionalized enrollees). • For 2004 and 2005, CMS paid all enrollees in most MA organizations as community based. Beginning in 2006, CMS will make prospective payments based on the beneficiaries' statuses (i.e., community or institutional). • The final reconciliation for a payment year will incorporate the correct institutional status for each enrollee for each month.	• Age and sex payment factors are generally higher for the long-term institutionalized population. • Many of the costs of the long-term institutionalized population are not paid for by Medicare. • Institutional model merges a number of disease groups to assure stable coefficients for this population. • Long-term institutional status will be recognized in the payment year. • MDS collected from nursing homes will be used to identify long-term institutionalized enrollees. • The presence of a 90-day assessment and current residence in an institution = long-term institutionalized enrollee. • No additional reporting by MA organizations is required. • Enrollees remain in long-term institutionalized status until discharged to the community for more than 14 days.

As described above in Table 1H, institutional status will be determined from information included in the MDS that is reported by Medicare certified nursing homes. Under the CMS-HCC model, MA organizations **will not report** the institutional status of their enrollees.

Example 5

Below is an example of the different HCC factors for community versus long-term institutional enrollees.

DISEASE GROUP	DESCRIPTION	COMMUNITY FACTOR	INSTITUTIONAL FACTOR
HCC1	HIV/AIDS	0.933	0.735
HCC8	Lung, Upper Digestive Tract, and Other Severe Cancers	1.648	0.568

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

Table 1I reflects the distribution of Medicare beneficiaries in the January 2005 cohort institutionalized longer than 90 days as of April 2004.

**TABLE 1I – DISTRIBUTION OF LONG-TERM INSTITUTIONALIZED BENEFICIARIES
ACROSS ORGANIZATION TYPES - 2005**

Organization Type	Total Number Beneficiaries	Number Beneficiaries Institutional	Percent of Beneficiaries Institutional	Number of Plans	Number Of Plans >5% of Beneficiaries Institutional
1876 Cost	337,869	5,435	1.61%	32	3
Dual Eligible and Other Demonstrations	7,427	2,387	32.14%	12	5
HCPP	97,210	2,512	2.58%	15	0
PACE	10,150	531	5.23%	32	19
Medicare Advantage	4,848,817	50,158	1.03%	199	12
S/HMO	133,763	840	0.63%	4	0
Total	5,435,236	61,863	1.14%	294	39

Dual Eligible and Other Demonstrations: include Wisconsin Partnership Program (WPP), Minnesota Senior Care Options (MSHO) and Disability Health Options (MnDHO), Massachusetts Senior Options (SCO)

S/HMO: Social Health Maintenance Organizations

1.3.4 Frailty Adjuster (Slides 19-20)

The frailty adjuster is included as part of risk adjusted payments for A and B services to PACE and certain demonstration organizations. The purpose of the frailty adjuster is to predict Medicare expenditures that are unexplained by the risk adjustment methodology alone. The CMS-HCC model uses diagnoses to adjust the payments to MA organizations. This model was calibrated based on the general Medicare population that has an average level of functional impairment. The frailty model further adjusts payment based on whether an organization's enrollees are more or less frail than the average.

Under frailty adjustment, the relative frailty of an organization is measured in terms of the number of functional limitations as represented by the Activities of Daily Living (ADL) scale. There are six ADLs: 1) bathing and showering; 2) dressing; 3) eating; 4) getting in or out of bed or chairs; 5) walking; and 6) using the toilet. A sample of individuals in each organization is surveyed to determine the relative frailty of the organization. Frailty adjustment lowers risk scores for individuals with 0 ADLs and increases risk scores for all of the categories of ADLs.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.3.4.1 Why is There a Frailty Adjuster?

- The Balanced Budget Act of 1997 (BBA) mandated that Medicare capitated payments to PACE organizations be based on MA payment rates, adjusted to account for the comparative frailty of PACE enrollees.
- The CMS-HCC model does not explain all of the variation in expenditures for the frail, community-based population. The frailty adjuster is used to project the Medicare expenditures of community populations age 55 and over that are unexplained by risk adjustment.

1.3.4.2 Which Organizations Are Currently Being Paid Under Frailty Adjustment?

Table 1J lists the types of health plans being paid under frailty adjustment.

TABLE 1J – PLANS RECEIVING FRAILITY ADJUSTMENT

TYPE OF HEALTH PLAN	FRAILITY ADJUSTER IS PART OF RISK ADJUSTED PAYMENT
MA	NO
PACE	YES
Wisconsin Partnership Program (WPP)	YES
Minnesota Senior Care Options (MSHO) and Disability Health Options (MnDHO)	YES
Social Health Maintenance Organizations (S/HMOs)	YES
Massachusetts Senior Options (SCO)	YES

1.3.4.3 How Does the Frailty Adjuster Work Under the CMS-HCC Model?

The frailty adjustment factors were designed to explain (or predict) the Medicare expenditures that are unexplained by risk adjustment for groups with similar functional impairments. Therefore, frailty adjustment was designed to be applied in conjunction with the CMS-HCC model. Since the CMS-HCC model adequately predicts the Medicare expenditures of the long-term institutionalized and the under-55 disabled population, frailty adjustment is only applied to non-ESRD community residents who are 55 and over.

CMS calculates an organization-level frailty score based on the difficulties in activities of daily living (ADLs) that are reported by enrollees. The organization-level frailty score is then added to the risk score for each 55 and over community resident.

1.3.4.4 Frailty Model Development (Slide 22)

The current frailty factors were calibrated using ADL limitation information from the Medicare Current Beneficiary Survey (MCBS) -- which is a face-to-face survey. Annual frailty factors were calculated using the Health Outcomes Survey – Modified (HOS-M) -- which is an anonymous mail-in survey with telephone follow-up.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

For 2008 payments, CMS has changed its source for calibrating the frailty model from the MCBS to the FFS CAHPS data. The change has the advantage of using two surveys with similar methodologies for calibrating the model and for calculating annual frailty scores — both the HOS-M and FFS CAHPS collect ADL information via mail surveys with telephone follow-up. CMS added questions regarding ADLs to the FFS CAHPS surveys collected between March 2003 and February 2004, used claims data for the beneficiaries in the sample, and recalibrated the frailty factors with these data.

The revised frailty factors are also generally lower because:

1. Through mail versus face-to-face survey, beneficiaries more accurately report their functional impairments. Researchers have recognized that written surveys capture more accurate accounts of personal reporting than surveys that are conducted face-to-face. The changes in reporting of ADL limitations resulted in more accurate accounting of the residual expenditures from the CMS-HCC model; and
2. The decrease in home health payments mandated by BBA—as frailty is highly correlated with home health expenditures in a community setting. CMS will continue to use the current frailty methodology to transition frailty payment for PACE organizations and phase-out frailty payments for certain demonstration organization. This implementation schedule is provided in Section 1.3.4.5.

The CAHPS frailty calibration sample is much larger than the MCBS sample. These data have helped to better determine the relationship between frailty and costs given Medicaid and non-Medicaid status in the general Medicare population. For this reason, CMS is able to reliably estimate separate frailty factors for Medicaid and non-Medicaid frail Medicare beneficiaries—because the Medicaid and non-Medicaid frail populations show differences in the relationships between unexplained expenditures (in the CMS-HCC model) and functional impairments. Table 1K provides the Current and Revised Frailty Factors by ADL distribution.

CMS has considered the impact of applying a program wide frailty adjuster and the effect of this on the current bidding methodology. CMS decided that the frailty adjuster will not be applied across all MA organizations. Methodologically, a program-wide adjustment does not improve payment accuracy for two reasons:

1. The HOS data used currently to determine frailty scores for payment is sampled only at the contract level, and therefore, does not allow for accurate calculation of frailty scores at the plan benefit package (PBP) level—thus, contract level frailty scores would lead to inconsistent payments across plans and beneficiaries; and
2. MA organizations would need to project frailty scores in their bids. Due to the changing nature of the marketplace and the different enrollment profiles of plans from year to year, this creates a risk that the level of frailty assumed by a plan in its bid would not reflect its actual score in the payment year.

TABLE 1K – CURRENT AND REVISED FRAILTY FACTORS

ADL LIMITATIONS	CURRENT FACTOR	REVISED MODEL FACTORS	
		NON-MEDICAID	MEDICAID
0	-0.141	-.089	-.183
1-2	+0.171	+0.110	+0.024
3-4	+0.344	+0.200	+0.132
5-6	+1.088	+0.377	+0.188

RISK ADJUSTMENT METHODOLOGY

1.3.4.5 Frailty Payment Implementation

In 2008, CMS will begin transitioning PACE organization payments to 100 percent of the revised frailty factors over a 5-year period through 2012. In each year, the monthly PACE organizations payment would be based on the A/B risk score plus the established frailty transition amount. CMS will also begin a four year phase-out of frailty payments using the current methodology through 2011 for the dual demonstration organizations-- Social Health Maintenance Organizations (S/HMOs), Minnesota Senior Health Options (MSHO)/Minnesota Disability Health Options (MnDHO), Wisconsin Partnership Program (WPP), and Massachusetts Senior Care Options (SCO). Table 1L shows the frailty payment implementation schedule for PACE and demonstration organizations. The percentage (%) represents the percent of the contract-level frailty factor (current and/or revised) that will be added to the monthly A/B risk scores for payment.

TABLE 1L – FRAILITY PAYMENT IMPLEMENTATION SCHEDULE FOR PACE AND DUAL DEMONSTRATION ORGANIZATIONS

TYPE OF CONTRACT	2008 FRAILITY PAYMENT SCHEDULE	2009 FRAILITY PAYMENT SCHEDULE	2010 FRAILITY PAYMENT SCHEDULE	2011 FRAILITY PAYMENT SCHEDULE	2012 FRAILITY PAYMENT SCHEDULE
% current frailty factor / % revised frailty factor					
PACE	90 / 10	70 / 30	50 / 50	25 / 75	0 / 100
Wisconsin Partnership Program (WPP)	75 / 0	50 / 0	25 / 0	0 / 0	
Minnesota Senior Care Options (MSHO) and Disability Health Options (MnDHO)	75 / 0	50 / 0	25 / 0	0 / 0	
Social Health Maintenance Organizations (S/HMOs)	75 / 0	50 / 0	25 / 0	0 / 0	
Massachusetts Senior Options (SCO)	75 / 0	50 / 0	25 / 0	0 / 0	

The range of frailty scores varies considerably among the organizations to which frailty adjustment applies (i.e., "frailty" plans). Table 1M shows a range of frailty scores by type of organizations for the current frailty methodology conducted using the MCBS and the new frailty calibration methodology using the FFS CAHPS data.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

TABLE 1M – RANGE OF FRAILTY SCORE BY TYPE OF ORGANIZATION

ORGANIZATION TYPE	CURRENT MODEL FRAILTY SCORE (MCBS DATA)	RECALIBRATED—MEDICAID/ NON-MEDICAID FRAILTY SCORE (FFS CAHPS DATA)
PACE	0.375 – 0.791	0.064-0.226
S/HMOs	0.057 – 0.122	0.008-0.039
WPP	0.371 – 0.574	0.091-0.162
MnDo	0.583	0.143
MSHO	0.176 – 0.263	-0.017-0.009
SCO	0.166 – 0.414	-0.033-0.053

1.3.4.6 ADL Information Collection and Frailty Adjuster Development

CMS will continue to calculate annual contract-level frailty scores using results from the HOS-M survey. The revised frailty adjuster that will be used for PACE organization payments will include eight factors (instead of four factors under the current model): Medicaid eligible ADL limitations 0, 1-2, 3-4, and 5-6; and Non-Medicaid ADL limitations 0, 1-2, 3-4, and 5-6. The weighted factors will be summed to get the contract-level frailty score for payment. Demonstration organizations stated in Section 1.3.4.4 will continue to receive frailty payments based on the single frailty factor that is calculated using the current methodology (i.e., MCBS).

1.3.4.7 Calculating the Frailty Score for Payment

The organization-level frailty score is calculated as the weighted average frailty factor across all 55 and over community survey respondents for that organization.

The first step is to determine the number of ADLs with which each respondent has difficulty or is unable to do. Then the number of respondents in each ADL category (0 ADLs, 1 to 2 ADLs, 3 to 4 ADLs and 5 to 6 ADLs) is counted. These counts are multiplied by the corresponding frailty factor for each ADL category. The resulting products are then summed for each organization. This sum is divided by the number of 55 and over community respondents, yielding a weighted average factor (or frailty score) for each organization. The same frailty score is used for all 55 and over respondents and non-respondents of a plan who reside in the community.

This frailty score is added to the risk score of each 55 and over community enrollee in the organization (including new enrollees), resulting in a risk+frailty score for each individual. Payments to these plans are the product of this combined score and the risk adjusted county rate. Figure 1B illustrates this calculation and includes the ADL-based frailty factors.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT METHODOLOGY

Figure 1B – Frailty Adjustment Calculation

Note: For new PACE organizations not yet participating in the survey, their frailty score is the weighted average factor across all community respondents of all PACE organizations.

1.3.5 Payment Methodology for ESRD Enrollees (Slides 25-27)

In order to further improve payment accuracy, CMS implemented the ESRD risk adjustment model. Effective January 2005, MA enrollees with ESRD were incorporated into diagnosis-based risk adjustment using a different version of the CMS-HCC model. This ESRD models were re-estimated for payments beginning in 2007 and ESRD risk score normalization of dialysis and transplant risk scores will be implemented in 2008. Section 605 of BIPA required CMS to adjust its approach to computing ESRD payment rates to reflect the method used in the ESRD S/HMO demonstration then in place. The three parts of the ESRD CMS-HCC model are:

Dialysis Status—A risk adjustment model that is calibrated for people on dialysis, so the payment weights are unique to these beneficiaries. The State ratebook used for dialysis payments was rebased with more recent data.

Transplant Status—Kidney or Kidney/Pancreas – CMS calculates the payment amount by calculating the cost of services during the month of the transplant and for the two succeeding months. CMS makes different payments for those who have a kidney transplant and for those who have a pancreas transplant simultaneous with the kidney transplant. However, because the initial data system used for payment will not be able to distinguish individuals with a double transplant in a timely manner, all transplants will initially be paid at the kidney transplant rate. The rarer double transplant will be taken into account in

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

reconciliation. CMS also differentiates payments for months close to the transplant period from those further out.

Functioning Graft Status—A modified version of the CMS-HCC model for people who have functioning kidney grafts, i.e., that they have received a kidney transplant or kidney/pancreas transplant at least three months ago and did not return to dialysis status since the transplant. The model has an additional term to recognize the extra costs of immunosuppressive drugs and higher intensity of care for this group.

CMS developed this three-part model in response to the findings on expenditure patterns for ESRD beneficiaries. Dialysis patients have high ongoing costs, while transplant patients incur a very high one-time cost. Functioning graft patients are much more similar to the general population than they are to dialysis patients except for the cost of immunosuppressive drugs. Using the same payment weights for all three groups would lead to over- or underpayments to MA organizations.

CMS updated the state ratebook used to make payments for enrollees in dialysis and transplant status. CMS will phase-in the revised State rates by blending payments based on the current ratebook and the ratebook using the dialysis-only trend. Over a 4-year period, CMS will apply the payment blend according to the schedule described below in Table 1N.

TABLE 1N – NEW ESRD DIALYSIS AND TRANSPLANT PAYMENT TRANSITION

YEAR	CURRENT RATEBOOK PERCENTAGE	REVISED RATEBOOK PERCENTAGE
2008	75%	25%
2009	50%	50%
2010	25%	75%
2011	0	100%

1.3.5.1 Risk Adjustment Model for Dialysis Patients

The dialysis model has the same HCC categories used for the CMS-HCC model. The exception is that the HCCs representing dialysis status and kidney failure are excluded (HCC130 to HCC131). This means that the ESRD model has only 68 HCC categories. The model is calibrated only on dialysis patients, so the disease weights used for payment recognize disease and expenditure patterns are unique to this population.

The data used for calibrating the ESRD models were 2002 (diagnostic) and 2003 (program payment) data on fee-for-service ESRD beneficiaries. For example, expenditures for a fee-for-service beneficiary on dialysis from January through August 2003 who received a transplant in September 2003 are included in the dialysis group for eight months, but then are excluded. From September through November 2003, this beneficiary's costs are included in the transplant data to determine estimated average transplant costs. As of December 2003, this beneficiary is included in the functioning graft model.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.3.5.2 Transplant Model

To accommodate the high one-time cost of a transplant, CMS will make payments over three months to cover the costs for this transplant and payments for the immediate subsequent services. CMS calibrated the payments by using fee-for-service hospital stay payments for the transplant, and physician and other services rendered for the hospital stay and the two months after discharge. The national average was converted to a relative factor by dividing by the national average payment for dialysis patients. For example, the factor for month 1 is calculated as: \$32,558 (average transplant costs in month 1) divided by \$5,039 (mean monthly dialysis costs, i.e., \$60,471/12). The relative factors for transplant reflect the costs in each month; therefore, the 1st month has a substantially higher factor (6.45) than months 2 and 3 (1.01). The transplant factor is applied to the dialysis state ratebook to provide a transplant payment. Payment will be made in practice by determining the month of transplant and paying the amount over the three-month period starting with the transplant month.

1.3.5.3 Functioning Graft Model

The model for functioning graft enrollees is based on the model for the general population, except that HCCs for kidney transplant status, dialysis status, and renal failure are excluded. For their members with functioning grafts, as for dialysis members, MA organizations will be paid in 2008 based on the diseases reported from all risk adjustment sources in the prior year. However, functioning graft status is recognized in the payment year. In the adapted general population model, almost all of the HCC disease coefficients have been held to their general population values. A few HCCs have been removed and extra terms have been added specific to being in functioning graft status.

The values for the add-on terms have been estimated with data specific to this population and recognize the Medicare coverage of immunosuppressive drugs and the added intensity of services required by this population. They are identified as "graft factors" in the functioning graft model. The graft factors include two sets of coefficients. One set is used between the fourth and the end of the ninth month after a transplant and the second set is used for tenth month and all months thereafter. The functioning graft payment automatically begins the month after the third transplant payment unless the ESRD Network reports that the member has returned to dialysis or had to have another transplant. Anytime a functioning graft patient returns to dialysis, payment is made using the dialysis model.

1.3.5.4 Model Comparison of Coefficients (Slide 28)

The ESRD dialysis model has a higher base factor (age/sex) and lower factors associated with diagnoses than does the CMS-HCC model. This is because Medicare costs for ESRD beneficiaries are much higher than they are for the average Medicare beneficiary, but they are relatively uniform. This means that the Medicare costs for ESRD beneficiaries do not vary as much as the Medicare costs for Medicare beneficiaries in general. Hence, diseases do not explain as much of the cost variation among ESRD beneficiaries and therefore, these costs are retained in the age/sex coefficient in the ESRD dialysis model.

1.3.5.5 New Enrollee Factor

The dialysis and functioning graft models have new enrollee factors for enrollees whose risk scores are not available. New enrollees with transplants receive the normal transplant model factors.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.3.5.6 Reporting of ESRD Status

In implementing the new ESRD risk adjustment method, CMS will utilize the existing systems for identification of enrollees receiving dialysis services. Currently, MA enrollees are assigned ESRD status as a result of a physician certifying their ESRD status on CMS Form 2728, the End-Stage Renal Disease Medical Evidence Report. The ESRD facility sends Form 2728 to the Renal Network, which then transmits the status to CMS systems where various databases are updated to record the ESRD status. Payments for dialysis are triggered by this system.

1.3.6 Medicare Part D

Medicare Part D Drug Benefit. In Title I, in addition to the creation of the MA program in Title II of the MMA, Congress added a voluntary prescription drug benefit to Medicare (known as Part D) to be made available for all Medicare beneficiaries through either the MA program or the prescription drug plans. To that end, MA organizations will be required to provide at least one MA plan that provides a "required drug coverage" in each of its service areas. MA plans that offer drug coverage are called MA prescription drug plans (MA-PDs). Beneficiaries receiving health care benefits through fee-for-service Medicare will have the option of accessing prescription drug coverage through sponsors of prescription drug plans (PDPs). Unlike PDPs which can offer supplemental drug coverage only when they offer a standard package in an area, MA-PDs can offer plans with supplemental coverage that qualify as "required prescription drug coverage." Similar to the MA program, CMS established regions (34) through which PDP sponsors will offer Part D drug coverage. To the extent practicable, CMS designed the PDP regions to overlap with the MA regions. Payments to PDP plans for eligible low-income Medicare beneficiaries will be subsidized at different levels depending upon the income and asset of the enrollee.

The MMA requires organizations intending to offer MA plans with original Medicare Parts A and B benefits and/or Part D benefits to submit bids in early June of each year for their basic, supplemental and/or Part D benefit packages. Each bid must reflect a plan's actual revenue requirements to provide the benefits offered in the proposed benefit packages. Benchmarks will be created for local and/or regional plans for bid-benchmark comparisons. Monthly capitated payments will be made based on each plan's bid risk adjusted for health status minus the beneficiary premium amount. The MMA mandates MA organizations and PDPs to provide basic prescription drug coverage as one of their benefit plans.

1.3.6.1 Part D Risk Adjustment Model (Slides 29-30)

The Part D model is similar to the CMS-HCC risk adjustment model. The model includes 113 coefficients: 84 disease groups, 24 age-sex adjustments, 3 interactions between age and disease, and 2 sex-age-originally disabled status interactions. The model was developed assuming an unlimited drug benefit, and was then adjusted for the plan's liability under the Medicare standard Part D benefit.

CMS announced the final Part D risk adjustment on April 4, 2005. The model is published at:
http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp

The Part D risk adjustment model shares most of the characteristics of the CMS-HCC model. That is, the model is: prospective, additive, hierarchical, and contains demographic new enrollee model.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

The key differences are:

- The Part D model is designed to predict plan liability for prescription drugs under the Medicare drug benefit rather than Medicare Part A/B costs.
- Different diseases predict drug costs than Part A/B costs.
- Incremental costs of low-income (LI) and long term institutional (LTI) beneficiaries are multipliers to the base RxHCC model score.

As in the CMS-HCC model, some of the disease groups fall into hierarchies. Drug regimens may intensify and more drugs added in cases where a disease has a higher severity. In such an instance, the highest cost category of the related diseases is triggered and the lower cost category does not increase the Part D risk score.

Like the CMS-HCC model, the Part D model uses the presence of particular demographic characteristics and diagnoses to predict costs in the following year for an individual. The model clusters a set of ICD-9-CM diagnoses within groups that are similar clinically and in terms of their expected costs. The groupings used to predict drug spending are variants of the groups used to predict Part A and B spending, and the data sources for diagnoses are the same as those used in Part C. Disease groups and draft coefficients for the Part D risk adjustment can be found on the CMS web site at:

http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp

In development of the model, drug spending in dollars is used as the dependent variable of a regression model that estimates the marginal or incremental spending related to each of the explanatory variables (demographics and conditions) in the model. The model is ultimately expressed not in dollars, but as relative factors. The incremental dollars associated with each variable in the model are divided by the mean predicted dollars to produce a "relative costliness" or risk factor. Summing the risk factors for an individual yields a total risk adjustment factor that, when multiplied by a base rate, yields an individualized capitation rate.

Recent research has found that the variation in drug expenditures that can be explained is primarily driven by chronic conditions persisting from year to year. The research suggests many of the diagnoses used by CMS for the CMS-HCC model could be used in the Part D risk adjustment model in addition to new diagnosis codes collected. For example, the findings indicated that certain chronic conditions such as congestive heart failure and schizophrenia (CMS-HCC model diagnoses) are good predictors of drug expenditures. However, this research also shows that hypertension and glaucoma, not currently in the model, are also key predictors of drug expenditures. Hence, such findings lead to the conclusion that additional diagnoses, beyond those in the current CMS-HCC model, need to be collected to properly develop a drug risk adjustment model. It is equally true that some conditions currently included in the CMS-HCC model are predictive of Medicare Part A and B medical costs, but not predictive of Part D costs. As such, these diseases could decrease drug expenditures.

Using a similar methodology to that used for the development of the CMS-HCC risk adjustment model, CMS created a list of diagnoses for the drug risk adjuster and, in April 2005, announced the final list of conditions for inclusion in the drug risk adjustment model. Some of the diagnoses overlap with the current CMS-HCC model and others do not. In particular, there are 1,540 ICD-9 codes unique to the CMS-HCC model, 1,940 ICD-9 codes unique to the Part D risk adjustment model, and 1,622 ICD-9 codes

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

included in both models. Collection of the diagnoses for the CMS drug risk adjustment model from current MA organizations began in July 2004 and will begin payment in January 2006.

Beneficiaries with less than 12 months of Part B enrollment prior to the payment year and who do not have a complete diagnostic record in the Medicare files will be classified as new enrollees. These individuals will receive the new enrollee factor for the RxHCC model.

1.3.6.2 Low Income and Long Term Institutionalization Multipliers (Slides 31-32)

Base Part D risk factors are incremented by either a LI or a LTI multiplier to account for the additional costs of beneficiaries in these categories. See Table 10 for the definition of LI multipliers for the Part D benefit.

TABLE 10 – DEFINITION OF THE LOW INCOME MULTIPLIERS FOR PART D BENEFIT

	GROUP 1	GROUP 1	GROUP 2	GROUP 2
Income test	Medicaid Dual <100% FPL	<135% FPL	<135% FPL	135-150% FPL
Asset test	<2× SSI	<3× SSI	>3× SSI & <\$10,000 single \$20,000 couple	<\$10,000 single \$20,000 couple
Deductible	\$0	\$0	\$50	\$50
Copay for generic drugs up to catastrophic threshold	\$1	\$2	—	—
Copay for brand-name drugs up to catastrophic threshold	\$3	\$5	—	—
Coinsurance up to catastrophic threshold	—	—	15%	15%
Coinsurance above catastrophic threshold	0%	0%	0%	0%
Copay for generic drugs above catastrophic threshold	\$0	\$0	\$2	\$2
Copay for brand-name drugs above catastrophic threshold	\$0	\$0	\$5	\$5
Premium subsidy	100%	100%	100%	Sliding scale

The LI multiplier is estimated to be 1.08 for Group 1 LI individuals (as defined above) and 1.05 for Group 2 individuals (as defined above). This multiplier is defined on a concurrent basis. (For example, if an individual were not defined as LI for January 2007 but was determined to be a Group 1 beneficiary for February 2007, the plan would receive the LI multiplier for February (and beyond) but not for January.)

An enhancement was also computed for the predicted spending by persons institutionalized in nursing facilities for more than 90 days. Spending for this group is expected to be higher because prices for the specific packages of drugs they receive are somewhat higher than the same drugs in the community.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

(An analysis of drug data done by IMS Health shows that the price differences in the claims were small, particularly for brand name drugs that dominate the spending.) There are also effects related to compliance in acquiring and taking drugs in the institutional environment. On the other side, often patients take fewer drugs because of more careful monitoring of interactions.

An analysis was done for the spending by the institutionalized by first using the base model to predict for this population and then comparing the actual spending and liability to the predicted. For the case of spending, there was a significant positive effect for the aged and the disabled who are in institutions. The effect for the disabled is greater than for the aged. It was also observed that average spending for both groups was in the 100 percent coinsurance range. The disabled mean was quite close to the catastrophic limit. The implications of additional demand being, to a large extent, in the range in which plans do not have incremental liability means that the effect on plan liability is much smaller than the effect on spending. The final payment adjustments for the institutionalized are smaller for the aged than for the disabled and smaller perhaps than some people expect because the final measure is plan liability rather than spending.

Figure 1C illustrates the calculation of the Part D Direct Subsidy.

Figure 1C – Calculation of Part D Direct Subsidy

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT METHODOLOGY

1.4 Parts C and D Final Submission of Risk Adjustment Data (Reconciliation)

Reconciliation is used to complete the implementation of payments, with CMS calculating final risk adjustment factors and beneficiary status based on complete data. CMS continues to allow a period (approximately 13 months after the data collection year) for submitting final RAPS data for the appropriate data collection period. Data not received or submitted by the initial submission deadline for a data collection period can be submitted by the final submission deadline (reconciliation). In addition to incorporating new RAPS and fee-for-service diagnoses, reconciliation takes into account necessary adjustments to institutional status and demographic data for enrollees.

Note: CMS reconciles risk-adjusted payments for a calendar year only one time. When submitting risk adjustment data for reconciliation, plans may submit as well as correct data that was previously submitted.

1.4.1 Parts C and D Risk Adjustment Schedule & Elimination of the Payment Lag

Risk adjusted payments were originally implemented with a 6-month payment lag from the end of the collection period to the start of revised payments, based on the data collected.

Example: 6

Data Collection Period: July 1, 2006 through June 30, 2007

Data Collection End Date: June 30, 2007

CY2007: First payment made based on this collection period = January 1, 2008

As you can see, payments began 6 months after the end of the data collection period.

Note: The purpose of eliminating the lag between the end of the data collection period and the payment based on that year's data is to use the most recent data for more accurate payment.

Data Collection Period: January 1, 2007 through December 31, 2007

Data Collection End Date: December 31, 2007

CY2007: Updated payment made based on the non-lagged data collection period = July, 2008

- CMS calculates a preliminary risk factor based on lagged data. For 2008, it will be based on data from July 2006 through June 2007. Payments from January 2008 through June 2008 will be based on this factor.
- In July 2008 CMS will use a risk factor based on non-lagged data (i.e., from calendar year 2007) for calculating payments. That factor will be used for the remainder of the year.
- By eliminating the lag, the collection period will change from July 1 through June 30 to January 1 through December 31 (or a calendar year).

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT METHODOLOGY

1.5 Updating Diagnosis Codes in the Parts C and D Risk Adjustment Models

CMS updates the risk adjustment models to reflect the annual updates to the ICD-9 diagnostic code set. After clinical review, new ICD-9 diagnosis codes are added to the appropriate diagnostic categories and included in the CMS-HCC model. A comprehensive listing of the ICD-9 codes that MA organizations are required to submit for all risk adjustment models can be found at http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage. This list will be updated annually to take into account new codes that are required for risk adjustment.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

MODULE 2 – RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

Purpose

The success of Medicare Advantage (MA) risk adjustment is dependent upon organizations understanding the process of collecting and submitting accurate risk adjustment data. The purpose of this module is to provide participants with important terms, key resources, and schedule information that will provide the foundation for this training.

Learning Objectives

At the completion of this module, participants will be able to:

- Define common risk adjustment terminology.
- Demonstrate knowledge in interpreting key components of the risk adjustment process.
- Interpret the risk adjustment schedule.
- Identify the Centers for Medicare & Medicaid Services (CMS) outreach efforts available to organizations.

ICON KEY

Example

Reminder

Resource

2.1 Common Risk Adjustment Terms (Slide 6)

Table 2A provides descriptions of common risk adjustment terminology.

TABLE 2A – RISK ADJUSTMENT COMMON TERMS

TERM	DESCRIPTION
FERAS	Risk adjustment submitters send data to Palmetto through the Front-End Risk Adjustment System .
RAPS	Risk adjustment data are processed by the Risk Adjustment Processing System .
RAS	The Risk Adjustment System calculates the risk score.
MARx	The Medicare Advantage Prescription Drug System calculates the risk payment.
Common UI	The Common UI maintains Medicare beneficiary eligibility data.
HPMS	The Health Plan Management System is a CMS MA information system that contains health plan-level data.
Relevant Diagnosis	ICD-9-CM diagnosis code in the CMS-Hierarchical Condition Category (HCC) model.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.2 Risk Adjustment Process Overview

Hospital inpatient, hospital outpatient, and physician risk adjustment data must be submitted at least quarterly. Risk adjustment data are processed through RAPS.

2.2.1 Risk Adjustment Data Requirements (Slide 7)

- The data required under the risk adjustment process include:
 - Health Insurance Claim (HIC) number.
 - Diagnosis code.
 - Service from date.
 - Service through date.
 - Provider type (hospital inpatient, hospital outpatient, physician).
- MA organizations must submit data at least quarterly to CMS.
- Each quarterly submission should represent approximately one-fourth of the data that the MA organization will submit during a data collection year. MA organizations will be monitored to ensure compliance.
- All beneficiary ICD-9-CM diagnosis codes relevant for the CMS-HCC risk adjustment model must be reported at least once per enrollee in the data collection period.

2.2.2 Risk Adjustment Data Collection (Slide 8)

- MA organizations may choose to collect data from providers in a variety of formats:
 - Standard fee-for-service claim or encounter formats
 - Uniform Billing Form (UB-04)
 - HCFA 1500
 - National Standard Format (NSF) v3.01
 - American National Standards Institute (ANSI) X12 837 v30.51 or v40.10. Health Insurance Portability and Accountability Act (HIPAA) mandated transactions must use v40.10.
 - Superbill
 - RAPS format
 - HIC number
 - Provider type
 - Diagnosis code
 - Service from date
 - Service through date

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.2.3 Risk Adjustment Data Submission (Slide 9)

- MA organizations must submit data to CMS through FERAS (Palmetto GBA) utilizing the following formats:
 - RAPS format (all types of data)
 - Direct Data Entry Screen (all types of data)

Figure 2A illustrates the risk adjustment dataflow.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.2.4 Risk Adjustment Dataflow (Slide 10)

- Hospital/physician submits data to MA organization via:
 - Full or abbreviated UB-04, HCFA 1500, NSF v3.01, ANSI x837 v30.51 or v40.10, Superbill or RAPS format.
- The MA organization submits these data at least quarterly to Palmetto GBA.
- The MA organization submits the data via Direct Data Entry or in the RAPS format.
- The data are sent to FERAS for processing where the file-level data, batch-level data, and first and last detail records are checked.
- If any data are rejected, then data are reported on the FERAS Response Report.
- After passing the FERAS checks, the file is submitted to RAPS where detail editing is performed.
- The RAPS Return File is returned daily and shows all records approved and where errors occurred.
- The RAPS Transaction Error Report displays records on which errors occurred.
- The RAPS Transaction Summary Report is sent to the MA organization daily and identifies data that have been finalized in RAPS database.
- The Duplicate Diagnosis Cluster Report identifies diagnosis clusters submitted with information that duplicates a stored cluster.
- The RAPS Monthly Plan Activity Report and Cumulative Plan Activity Report provides a summary of all diagnoses stored for a given time period.
- Distributed monthly and quarterly, the Error Frequency Report provides an overview of all errors associated with files submitted in test and production.
- RAPS database stores all finalized diagnosis clusters.
- RAS calculates the Risk Adjuster Factors by executing the CMS-HCC model.
- MARx is used in the calculation of payments and determination of plan payments. MARx replaced Medicare Managed Care System (MMCS) on November 15, 2005.

Figure 2A – Risk Adjustment Dataflow

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.2.5 Important Information About Risk Adjustment Processing

- MA organizations transmit data to FERAS at Palmetto GBA.
- FERAS performs format and face validity checks on the file- and batch- level as well as formatting verification on the first and last detail record (CCC) in the file.
- If the data fail the front-end checks, the complete file is rejected at the front end.
- The FERAS Response Report identifies whether the file is accepted or rejected up front.
- Once the file has passed front-end checks, it moves to RAPS. All validity edits on detail-level data are performed in this system.
- Processing time from beginning to end should take approximately 1 to 2 days.
- After the file has processed through RAPS, the MA organization will receive a RAPS Return File and RAPS Transaction Error Report identifying any errors.
- All ICD-9-CM diagnoses that pass validity edits are stored in the RAPS database.
- The MA organization will also receive a RAPS Transaction Summary Report reflecting all finalized data sent to the RAPS database along with all rejected data.
- The MA organization also receives two monthly risk adjustment management reports: 1) the RAPS Monthly Plan Activity Report and 2) the RAPS Cumulative Plan Activity Report.
- All data are converted to the RAPS format and returned in the RAPS Return File.
- Interim hospital inpatient bills (112, 113, and 114 bill types) must not be submitted. If a MA organization receives interim bills, the organization should submit the hospital inpatient diagnoses on receipt of the final bill (114). This means the appropriate *discharge* diagnoses will be submitted for risk adjustment, rather than the *admitting* diagnoses.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.3 Submission Schedule (Slide 11)

The elimination of the payment lag changes the submission schedule. This requires MA organizations to meet three submission deadlines—the first Friday in September, the first Friday in March of each year, and a reconciliation (final submission) deadline of January 31. The schedule is illustrated in Table 2B.

TABLE 2B – SUBMISSION TIMETABLE

CY	DATES OF SERVICE	INITIAL SUBMISSION DEADLINE	FIRST PAYMENT DATE	FINAL SUBMISSION DEADLINE
2007	July 1, 2005 through June 30, 2006	September 1, 2006	January 1, 2007	NA
2007	January 1, 2006 through December 31, 2006	March 2, 2007	July 1, 2007	January 31, 2008
2008	July 1, 2006 through June 30, 2007	September 7, 2007	January 1, 2008	NA
2008	January 1, 2007 through December 31, 2007	March 7, 2008	July 1, 2008	January 31, 2009
2009	July 1, 2007 through June 30, 2008	September 5, 2008	January 1, 2009	NA
2009	January 1, 2008 through December 31, 2008	March 6, 2009	July 1, 2009	January 31, 2010

RISK ADJUSTMENT SUBMISSION PROCESS OVERVIEW

2.4 Training and Support (Slide 12)

To ensure that participating organizations have the necessary tools and information to be successful with the risk adjustment process, CMS has planned the following outreach efforts, as described in Table 2C.

TABLE 2C – TRAINING AND SUPPORT

INITIATIVE	DESCRIPTION
Customer Service & Support Center (CSSC)	This toll free help line (1-877-534-2772) is available Monday – Friday, 9:00 a.m. to 7:00 p.m. Eastern Time (ET) (with the exception of corporate observed holidays) to provide assistance. The support center provides ongoing assistance. The FERAS system is available to submit risk adjustment data 24 hours a day, 7 days a week regardless of holidays. The only exception is from 5:00 PM EST - 10:00 PM EST on Sunday when systems and equipment undergo routine maintenance.
<u>www.csscooperations.com</u>	The CSSC website, <u>www.csscooperations.com</u> is the gateway to RAPS. Visitors to the site can access information about RAPS/FERAS, including opportunities to register for service, enroll to submit risk adjustment data, and obtain comprehensive information about data entry and report layouts. In addition, the site provides valuable links to CMS instructions and other official resources. Monthly User Group and other training information are regularly posted. Finally, the site provides up-to-date system status alerts and answers to frequently asked questions (FAQs) about risk adjustment. To register for email updates, go to <u>www.csscooperations.com</u>, click on Risk Adjustment Processing System (RAPS), and then click on "Register for Medicare Advantage". Afterwards, click on "new registrations only" and complete the registration form.
User Groups	Conducted once each month from 1:30 – 2:30 p.m. ET. The purpose of the User Group meeting is to share information among participants, distribute new information, and identify issues for future resolution. Meeting notes and Q&As are provided. To register online for User Groups, go to <u>www.medicaretraining.net</u>.
Onsite Consultation	On-site consultation visits provide MA organizations with the opportunity to gain valuable information about risk adjustment data submission and data validation processes. These consultations generally occur between April and May. Each visit includes a review of the MA organization's system.
Monthly and Regional Training Program	The program provides practical training for new and current users.
<u>www.medicaretraining.net</u>	The website, <u>www.medicaretraining.net</u> is the website for risk adjustment training and User Group information. The website includes information about trainings and user groups, training dates, locations, online registration, and training FAQs.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

MODULE 3 – DATA COLLECTION

Purpose (Slide 2)

For the purpose of risk adjustment, Medicare Advantage (MA) organizations must collect data from hospital inpatient facilities, hospital outpatient facilities, and physicians. The collection of data from the appropriate risk adjustment sources and formats is critical for accurate risk adjusted payment. This module is designed to offer participants an opportunity to apply data collection principles in accordance with Centers for Medicare & Medicaid Services (CMS) requirements.

Learning Objectives (Slide 3)

At the completion of this module, participants will be able to:

- Identify the data elements required for risk adjustment.
- List the three sources of risk adjustment data.
- Describe the data collection formats.
- Discuss factors to consider when determining the method for collection of diagnostic data.
- Apply Health Insurance Portability and Accountability Act (HIPAA) transaction standards for purposes of risk adjustment data collection.

ICON KEY

Example
Reminder
Resource

3.1 Required Risk Adjustment Data Elements (Slide 5)

MA organizations must collect certain data elements from the sources (providers/physicians) of risk adjustment data described in this module. The minimum data elements that must be collected are:

- Health Insurance Claim (HIC) Number
- ICD-9-CM Diagnosis Codes
- Service From Date
- Service Through Date
- Provider Type

3.1.1 HIC Number (Slides 6-7)

A HIC number is a Medicare beneficiary's identification number. Both CMS and the Railroad Retirement Board (RRB) issue Medicare HIC numbers. The format of a HIC number issued by CMS is a Social Security number followed by an alpha or alphanumeric Beneficiary Identification Code (BIC). RRB numbers issued before 1964 are 6-digit numbers preceded by an alpha prefix. After 1964, the RRB began using Social Security numbers as Medicare beneficiary identification numbers preceded by an alpha prefix. Table 3A shows the characteristics for each HIC type.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

TABLE 3A – STRUCTURE OF HIC NUMBERS

HIC TYPE	CHARACTERISTICS
CMS	9-Digit Social Security number - alpha suffix "A" beneficiary "B" spouse "C" children "D" divorced spouse, widow, widower - alpha-numeric suffix - indicates number of children (e.g., "C1" first child)
RRB pre-1964	- alpha prefix 6-digit random numbers
RRB post-1964	- alpha prefix 9-digit Social Security number

Note: MA organizations are not required to collect HIC numbers from physicians and providers, but must identify beneficiaries using the HIC number when submitting data to CMS.

3.1.2 ICD-9-CM Diagnosis Code (Slide 8)

International Classification of Diseases-9th Edition-Clinical Modification (ICD-9-CM) codes are 3- to 5-digit codes used to describe the clinical reason for a patient's treatment. ICD-9-CM codes do not describe the service performed, just the patient's medical condition. Diagnosis codes drive the risk scores, which drive the risk adjusted reimbursement from CMS to MA organizations.

3.1.3 Service From and Through Dates (Slide 9)

The dates of service define when a beneficiary received medical treatment from a physician or medical facility. For outpatient and physician services, the From Date and Through Date may be identical. For inpatient services, these dates are different from each other, and reflect the dates of admission to and discharge from a facility.

Date span is the number of days between the From Date and Through Date for a reported diagnosis. For risk adjustment, the date span is important to determine if the reported diagnosis cluster falls within the data reporting period.

3.1.4 Provider Type (Slide 10)

For the purpose of risk adjustment, MA organizations must collect data from the following provider types:

- Hospital inpatient facilities
- Hospital outpatient facilities
- Physicians

These are the three principal sources of data. MA organizations are responsible for determining provider type based on the source of the data.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

3.2 Data Sources

MA organizations are responsible for ensuring that the data they collect comes from acceptable sources. These sources are hospital inpatient facilities, hospital outpatient facilities, and physicians.

3.2.1 Hospital Inpatient (Slide 11)

A hospital inpatient service is one provided by a hospital during which a patient is admitted to the facility for at least one overnight stay.

Inpatient hospital data should be differentiated based on whether it is received from within or outside of the MA organization's provider network. Effective May 1, 2007, a network hospital should have a National Provider Identifier (NPI) number as a hospital inpatient facility. Table 3B identifies covered and non-covered facilities with regard to risk adjustment data collection.

TABLE 3B – HOSPITAL INPATIENT

PROVIDER TYPE	COVERED FACILITIES	NON-COVERED FACILITIES*
Hospital Inpatient	• Short-term (general and specialty) Hospitals • Religious Non-Medical Health Care Institutions (formerly Christian Science Sanatoria) • Long-term Hospitals • Rehabilitation Hospitals • Children's Hospitals • Psychiatric Hospitals • Medical Assistance Facilities/ Critical Access Hospitals	• Skilled Nursing Facilities (SNFs) • Hospital Inpatient Swing Bed Components • Intermediate Care Facilities • Respite Care • Hospice

* These are examples of non-covered facilities and not a comprehensive list.

When submitting hospital inpatient data, MA organizations must make a distinction between the principal diagnosis and other diagnoses. The details of submitting data will be covered in the Data Submission module.

3.2.2 Hospital Outpatient (Slide 12)

Hospital outpatient services are therapeutic and rehabilitative services provided for sick or injured persons who do not require inpatient hospitalization or institutionalization.

Data must be collected from hospital outpatient departments. As with hospital inpatient facilities, the MA organization must determine which facility is Medicare certified, network, or non-network. Table 3C identifies covered and non-covered hospital outpatient facilities.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

TABLE 3C – HOSPITAL OUTPATIENT

PROVIDER TYPE	COVERED FACILITIES	NON-COVERED FACILITIES*
Hospital Outpatient	• Short-term (general and specialty) Hospitals • Medical Assistance Facilities/ Critical Access Hospitals • Community Mental Health Centers 1** • Federally Qualified Health Centers 2/ Religious Non-Medical Health Care Institutions (formerly Christian Science Sanatoria) ** • Long-term Hospitals • Rehabilitation Hospitals • Children's Hospitals • Psychiatric Hospitals • Rural Health Clinic (Free-standing and Provider-Based) 3**	• Free-standing Ambulatory Surgical Centers (ASCs) • Home Health Care • Free-standing Renal Dialysis Facilities
	NON-COVERED SERVICES	
	• Laboratory Services • Ambulance • Durable Medical Equipment • Prosthetics	• Orthotics • Supplies • Radiology Services

* These are examples of non-covered facilities and are not to be considered a comprehensive list.

** Facilities use a composite bill that covers both the physician and the facility component of the services, and services rendered in these facilities do not result in an independent physician claim.

1. Community Mental Health Centers (CMHCs) provide outpatient services, including specialized outpatient services for children, the elderly, individuals who are chronically ill, and residents of the CMHC's mental health services area who have been discharged from inpatient treatment at an inpatient facility.
2. Federally Qualified Health Centers (FQHCs) are facilities located in a medically underserved area that provide Medicare beneficiaries with preventive primary medical care under the general direction of a physician.
3. Rural Health Clinics (RHCs) are Medicare certified facilities that are located in a rural, medically underserved area that provide ambulatory primary medical care under the general direction of a physician.

**3.2.2.1 Determining Whether Facilities Are Acceptable for Risk Adjustment
(Slide 13)**

MA organizations are responsible for ensuring data collected and submitted are acceptable for the risk adjustment process. In the past, the provider number has been used to assist in this. However, CMS is in the process of implementing a new provider identifier, the National Provider Identification (NPI) number. As will be discussed below, the CMS will continue to allow the use of the legacy provider number along with the new NPI for a transition time. However, the NPI does not have intelligence, so a new code called the "taxonomy code" was developed to help identify types of providers. Both the legacy provider number and the taxonomy code can be used in determining the appropriateness of the covered hospital entities for the purposes of risk adjustment data collection. Table 3D illustrates the steps MA organizations may use to identify the provider numbers or taxonomy codes for facilities.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

TABLE 3D – DETERMINING COVERED HOSPITAL ENTITY PROVIDER NUMBERS

SITUATION	ISSUE	ACTION
Situation 1	The provider number or taxonomy code is identified.	Determine if the number is in an acceptable range for risk adjustment. If in the acceptable range, submit the data.
Situation 2	An in-network provider submitted a claim but did not include the provider number or taxonomy code.	Obtain the provider number or taxonomy code and determine if the number is in an acceptable range for risk adjustment. If in the acceptable range, submit the data. NOTE: All network providers are required to have certified Medicare provider numbers or taxonomy codes; therefore, do not submit risk adjustment data for this provider until these numbers are obtained.
Situation 3	An out-of-network provider submits a claim without a provider number.	Try to obtain a provider number or taxonomy code, if possible. If not available, check the list of Veterans Administration and Department of Defense (VA/DoD) listings published on csscooperations.com . If the provider is listed there, submit the data. If the provider is not on the VA/DoD list, the organization may need to contact CMS to determine if the provider is acceptable for risk adjustment. NOTE: All network providers are required to have certified Medicare provider numbers or taxonomy codes; therefore, do not submit risk adjustment data for this provider until these numbers are obtained.

3.2.2.2 National Provider Identifier

CMS has recently issued contingency guidance for National Provider Identifier implementation. This contingency guidance provides that, for a period of 12 months after the NPI Rule compliance date of May 23, 2007, CMS will not impose civil money penalties on covered entities that deploy contingency plans, including (in order to ensure the smooth flow of payments) continuing to use and accept legacy identifiers on HIPAA transactions, if they have made reasonable and diligent efforts to become compliant and, in the case of health plans (that are not small health plans), in order to facilitate the compliance of their trading partners.

MA organizations should verify that diagnoses are collected from Medicare certified hospitals/facilities and that data from all Medicare certified network hospital/facilities include the associated Medicare provider identifiers (NPI and taxonomy code; and in the interim the legacy provider number). They should also verify that the Medicare certified hospitals/facilities providing the data are from acceptable facilities and

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

services. As stated above, plans may use either the legacy Medicare provider numbers or the taxonomy code to determine if facilities and services are acceptable for risk adjustment.

MA organizations may wish to create a system for checking if the data are from acceptable facilities and for acceptable services. They may check the legacy provider number against the provider number ranges or check the taxonomy code against the taxonomy code ranges, both of which identify what type of service has been rendered.

If using the provider number, please note that it has six characters. The first two characters are numerals and represent the state/territory as illustrated in Table 3E.

TABLE 3E – PROVIDER NUMBER STATE ASSIGNMENTS

STATE	CODE	STATE	CODE	STATE	CODE
Alabama	01	Kentucky	18	Oklahoma	37
Alaska	02	Louisiana	19	Oregon	38
American Samoa	64	Maine	20	Palau	N/A
Arizona	03	Maryland	21	Pennsylvania	39
Arkansas	04	Massachusetts	22	Puerto Rico	40
California	05	Michigan	23	Rhode Island	41
Colorado	06	Minnesota	24	South Carolina	42
Connecticut	07	Mississippi	25	South Dakota	43
Delaware	08	Missouri	26	Tennessee	44
District of Columbia	09	Montana	27	Texas	45
Florida	10	Nebraska	28	Utah	46
Georgia	11	Nevada	29	Vermont	47
Guam	65	New Hampshire	30	Virgin Islands	48
Hawaii	12	New Jersey	31	Virginia	49
Idaho	13	New Mexico	32	Washington	50
Illinois	14	New York	33	West Virginia	51
Indiana	15	North Carolina	34	Wisconsin	52
Iowa	16	North Dakota	35	Wyoming	53
Kansas	17	Ohio	36		

States and territories are included in the list of Medicare provider numbers.

The third character may be a numeral or a letter. Provider numbers with a **U, W, Y, Z, 5** or **6** in the third character indicate that the service was provided in a swing bed component of a hospital or a skilled nursing facility, which, are not covered entities. The last three characters are numerals unique to the facility.

If using the taxonomy code, the bill type will be needed to identify if the service was provided in non-covered entity such as a swing bed component of a hospital or a skilled nursing facility.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

As an additional check, refer to Tables 3F and 3G, which provide the only acceptable ranges for hospital facilities. The tables reflect the range of provider numbers for risk adjustment covered hospital entities. Risk Adjustment data are not acceptable when received from facilities with numbers outside the ranges.

Skilled nursing facilities, home health care and hospital inpatient swing bed components are not covered entities for risk adjustment data.

TABLE 3F – HOSPITAL INPATIENT COVERED ENTITIES

TYPE OF HOSPITAL INPATIENT FACILITY	PROVIDER NUMBER RANGE	TAXONOMY CODE/TYPE OF BILL(TOB)

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

The implementation of the NPI did not change the valid Hospital Inpatient and Outpatient facilities for submission of risk adjustment data nor eliminate the process for receiving and verifying information from Medicare health care providers that are in network. Institutional providers that currently bill Medicare using more than one legacy identifier in order to identify subparts of their facility are required to submit a taxonomy code on all of the claims they submit to Medicare.

The following web site serves as a reference to types of facilities and taxonomy codes.

<http://www.wpc-edi.com/codes/taxonomy>

Figure 3A is a screen shot of the wpc-edi.com website which serves as a reference tool to determine types of facilities and taxonomy codes.

Figure 3A – WPC-EDE.COM

The following website serves as a reference for hospital provider numbers:

<http://www.ahd.com/freesearch.php3>

Figure 3B is a screenshot of the search page on the American Hospital Directory website. This web-based search database allows MA organizations the opportunity to access Medicare provider number by entering key words, city, state, zip code, or area code. When using the search tool, users need to be aware of the following:

- The most effective search option is to select the state where the provider is located.
- When entering the hospital name, users should be aware that the official name of the hospital may be different than what is included in the database.
- Avoid entering abbreviations.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

Figure 3B – American Hospital Directory

See Resource Guide for more information about Medicare provider numbers.

3.2.3 Physician Data (Slide 14)

The collection of physician data relevant for risk adjustment is associated with the physician's specialty. That is, all ICD-9-CM diagnoses that are in the risk adjustment model and rendered as a result of a physician visit must be collected by the MA organization. This includes data collected from non-network as well as network physicians.

Only those physician specialties and other clinical specialists identified in Table 3H are acceptable for risk adjustment.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA COLLECTION

26	Psychiatry	67	Occupational Therapist	98	Gynecologist/Oncologist
28*	Colorectal Surgery	68	Clinical Psychologist	99	Unknown Physician Specialty

* Indicates that a number has been skipped.

Qualified physician data for risk adjustment requires a face-to-face visit with the exception of pathology services (professional component only).

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

3.2.4 Alternative Data Sources

Alternative data sources (ADS) include diagnostic data from sources other than hospital inpatient, hospital outpatient, and physician services. MA organizations may use ADS as a **check** to ensure that all required diagnoses have been submitted to CMS for risk adjustment purposes, such as pharmacy records and information provided to national or state cancer registries. The MA organization may not, however, use ADS as substitutes for diagnoses from a hospital/physician. As in all diagnoses submitted, there must be medical record documentation to support the diagnosis as having been documented as a result of a hospital inpatient stay, a hospital outpatient visit, or a physician visit during the data collection period.

For example, a prescription for an ACE inhibitor, alone, is not considered sufficient for the sole data source of "clinical evidence" of congestive heart failure (CHF); instead, the medical record needs to document an appropriate clinician's diagnosis of CHF during the data collection period (e.g., where an "appropriate clinician" is a physician/nurse practitioner/physician assistant). A laboratory test showing one reading of high blood sugar is not considered sufficient "clinical evidence" of diabetes—the medical record needs to document a clinician's diagnosis of diabetes during the data collection period.

3.2.5 Excluded Providers

Medicare will not pay for items or services rendered to beneficiaries and recipients by an excluded provider or by entities owned or managed by an excluded provider. Providers are excluded for the following reasons: a program related crime, patient abuse or neglect, health care fraud in any health care program, and convictions relating to controlled substances.

 The HHS monthly exclusion notification can be found at <http://oig.hhs.gov/fraud/exclusions.html>.

3.3 Data Collection Formats and Considerations

There are several formats that MA organizations can accept when collecting data from medical providers. Table 3I lists the formats by provider type.

3.3.1 Data Collection Formats (Slide 16)

For facility services, the standard billing format is UB-04 (Uniform Billing Form –2004 version). The HCFA 1500 form is the standard format for physician services.

TABLE 3I – DATA COLLECTION FORMATS

HOSPITAL INPATIENT/HOSPITAL OUTPATIENT	• UB-04 • ANSI X12 837 4010 • RAPS Format
PHYSICIAN	• HCFA 1500 • NSF 3.01 • ANSI X12 837 4010 • RAPS Format • Superbill

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

3.3.2 Collection Format Features

MA organizations need to carefully consider decisions regarding data collection tools, as they may impact the volume and accuracy of data received from physicians and providers. When examining the data collection options, the organization's management should consider the features of each of the approved data collection tools. Table 3J describes key features of each data collection tools.

TABLE 3J – COLLECTION FORMAT FEATURES

FORMAT	FEATURE					
	PHYSICIAN SERVICES	HOSPITAL INPATIENT/ OUTPATIENT SERVICES	MINIMUM DATA SET	FULL CLAIMS DATA	PAPER FORMAT	ELECTRONIC
HCFA 1500*	•			•	•	
UB-04*		•		•	•	
NSF*	•			•	•	•
ANSI X12 837	•	•		•		•
Superbill	•		•		•	
RAPS Format	•	•	•			•

*These data collection formats are not HIPAA compliant transactions. However, if your plan is HIPAA compliant and your trading partners are not HIPAA compliant, CMS is allowing receipt of non-HIPAA formats until such time as your trading partners are prepared to submit the HIPAA transaction sets.

The data collection options provided by CMS offer the MA organization the ability to determine which format works best for each of the plan's providers. A variety of collection formats may be used for different providers. If an organization plans to use multiple collection formats, consideration should be given to the complexity and costs associated with supporting these formats (e.g., systems, processes, staffing, etc.).

3.3.3 Collecting Data from Physicians Using a Superbill

The superbill is a data collection option for risk adjustment. The superbill is a common physician office claim form that lists standard ICD-9-CM codes, CPT (Current Procedural Terminology) codes, and beneficiary information. Typically, physicians use the superbill to record clinical information with the appropriate codes to aid in preparing claims or encounter data for submission. MA organizations may develop superbills for use by their capitated physicians for capturing diagnostic information for risk adjustment.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

If the MA organization currently utilizes a superbill that works well for its data collection needs, then it is not necessary to create a new format for risk adjustment data collection. Additionally, if a physician group has a superbill that will capture all relevant risk adjustment diagnoses, it is not necessary for the MA organization to replace that superbill with one that is specific to risk adjustment requirements.

Examples

Examples of Superbills

Two examples of superbills are provided in Figures 3C and 3D. The first example is a typical fee-for-service superbill for an internist. This superbill contains both ICD-9-CM diagnosis codes and CPT procedure codes. For illustrative purposes, the relevant risk adjustment diagnoses have been bolded.

The second example illustrates what the same superbill might look like if used specifically for collection of risk adjustment data. The ICD-9-CM code list provided by CMS is used to develop the list of common internist ICD-9-CM diagnoses codes on the superbill. These are codes that are relevant diagnoses for the risk adjustment model, related conditions that are not specific to risk adjustment, as well as other common internists' diagnoses. A space was left for the internist to enter diagnoses that are not on the list. Note that there are no CPT procedure codes on the superbill because they are not required for risk adjustment.

DATA COLLECTION

3.3.4 Factors Affecting Data Collection Method (Slide 17)

The risk adjustment model requires that MA organizations collect a subset of data from their providers/physicians. While CMS requires that only the minimum data are collected for risk adjustment, MA organizations should also consider their business needs.

- The organization may decide to collect full claims data for a variety of reasons:
 - The organization has fee-for-service contracts and pays providers and physicians based on the specific service provided to patients.
 - The organization is earning or maintaining National Committee for Quality Assurance (NCQA) accreditation and is therefore required to collect Health Employers Data Information Set (HEDIS) data used to evaluate the plan's performance in areas of customer service, access to care, and claims processing.
 - The organization has established an internal process for credentialing purposes that requires evidence of compliance with regulatory and other standards of practice such as Joint Commission on Accreditation of Health Care Organizations (JCAHO) or American College of Surgeons. The JCAHO certification requires extensive onsite review to evaluate the health organization's performance in areas that impact healthcare.
- The organization may decide to collect the minimum data set for a variety of reasons:
 - The organization has capitated payment arrangement with physicians and providers, and pays a fixed amount for services provided.
 - The organization's physicians are paid employees of the managed care plan.

3.3.4.1 Contractual Relationships and Implications for Data Collection (Slide 18)

There are several types of contractual payment relationships that MA organizations have with network physicians. These relationships include: fee-for-service, capitated, staff model, and mixed services. These contractual relationships affect how MA organizations collect data from physicians. Table 3K describes the contractual payment relationships.

TABLE 3K – CONTRACTUAL PAYMENT RELATIONSHIPS

FEE-FOR-SERVICE	In a fee-for-service contract, the physician is paid based on the specific services provided to each patient.
CAPITATED	The physician is paid a fixed amount per patient per month, regardless of the types of services provided.
STAFF MODEL	Physicians are paid employees of the managed care plan. Physicians generally provide services in a clinic setting.
MIXED SERVICES MODEL	In a mixed services model environment, managed care organizations use a combination of contractual arrangements.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

3.4 Health Information Portability and Accountability Act (HIPAA) (Slide 19)

Effective October 16, 2003, when HIPAA transaction standards became mandatory, all *electronic* claims/encounters sent from providers/physicians to MA organizations (health plans) constitute a HIPAA-covered transaction. Any MA organization that receives an electronic claim/encounter from a provider/physician must use the ANSI X12 837 v.40.10 format. This means that after the MA organization receives electronic data in HIPAA format, it cannot request that the physician resubmit the identical information (same patient, same diagnosis) in a different format (e.g., HCFA 1500) for purposes of risk adjustment data collection.

However, if needing to clarify original information or to obtain additional information, MA organizations may use an abbreviated data collection instrument for the sole purpose of collecting supplemental diagnostic information.

UB-92 and NSF are the old data collection formats and are not HIPAA compliant transactions. However, if your plan is HIPAA compliant and your trading partners are not HIPAA compliant, CMS is allowing receipt of the non-HIPAA formats until such time as your trading partners are prepared to submit the HIPAA transaction sets. This allowance is not an extension of the mandatory date of HIPAA (October 2003), and all organizations must be able to accept the HIPAA transactions. This extension simply allows plans to continue electronic commerce while their trading partners work toward compliance.

If the transaction is from a provider to an MA organization (i.e., data collection) **and** the transaction is a claim or an encounter, **then** data must be used for risk adjustment **and** the same data cannot be requested in a different format from the provider.

3.5 Provider Communication and Risk Adjustment

Communicating risk adjustment requirements to physicians and providers can help to improve the quality and quantity of the data submitted by MA organizations. It can also help physicians and providers understand the importance of accurate coding and medical record documentation, and their role in data validation. This section describes key messages to include in provider communications, characteristics of effective communication with physicians and providers, and communication methods to consider when sending messages about risk adjustment.

3.5.1 Key Messages

Physicians and providers receive many messages from MA and other managed care organizations. It is easy for a message about risk adjustment to get lost in the stream of communications sent to physicians and providers. To help ensure that messages about risk adjustment get the attention of the provider community, it is important that organizations routinely include basic information about risk adjustment in a variety of provider communications. The key messages to reinforce are:

- **What is the purpose of risk adjustment?**

Risk adjustment strengthens the Medicare program by ensuring that accurate payments are made to MA organizations based on the health status of their enrolled beneficiaries. Accurate payments to MA organizations help ensure that providers are paid appropriately for the services they provide to MA beneficiaries. Finally, risk adjustment provides MA organizations with incentives to enroll and treat less healthy individuals.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

- **Why is risk adjustment important to physicians and providers?**

The risk adjustment model relies on the ICD-9-CM diagnosis codes to prospectively reimburse MA organizations based on the health status of their enrolled beneficiaries. Physicians and providers must focus attention on complete and accurate diagnosis reporting according to the official ICD-9-CM coding guidelines.

- **What are the responsibilities of physicians and providers?**

Physicians must report the ICD-9-CM diagnosis codes to the highest level of specificity and report these codes accurately. This requires accurate and complete medical record documentation. They are required to alert the MA organization of any erroneous data submitted and to follow the MA organization's procedures for correcting erroneous data. Finally, they must report claims and encounter information in a timely manner, generally within 30 days of the date of service (or discharge for hospital inpatient facilities).

Organizations may also want to include information about the correct data collection formats available to them, as well as any information revealed through analysis of data collection trends uncovered through monitoring of the risk adjustment process.

3.5.2 Characteristics of Effective Communication

Physicians and providers tend to respond more positively to communications from MA organizations when the messages are considered reliable, accurate, timely, and helps them make their organization or practice more efficient. For this reason, it may be helpful to consider the following characteristics when developing provider communications:

- **Authoritative**

Make the "look and feel" of provider communications conservative, official, and factual. Be certain all information is accurate. Grammar, spelling, and punctuation must be perfect, or the errors will undercut the reader's level of confidence in the message.

- **Current**

Ensure that risk adjustment information is the most recent available. Update provider handbooks, websites, job aids, and training materials routinely so all information is current. Physicians and providers will not spend time reading information they know is outdated.

- **Timely**

Provide information to providers when they need to know it. For example, if MA organizations need physicians and providers to send their diagnostic data via a specific format by a certain date, send that message to them with enough lead-time to allow them to prepare for and meet the deadline for the change.

- **Consistent**

Send consistent messages about risk adjustment. MA organizations can contact the Customer Service and Support Center (CSSC) anytime to confirm that information they are about to send out to providers is correct. Physicians and providers appreciate receiving the right information the first time and every time.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA COLLECTION

- **Practical, relevant and well organized**

Delete "background noise" from your physician and provider messages. That is, identify the primary message you want to send and provide the key information necessary to make the point. That is, focus the message. Identify any specific actions that are required in clear, easy-to-read language.

- **Accessible**

Create materials for physicians and providers that are easy to access. Information that physicians and providers can locate quickly helps to ensure compliance with risk adjustment requirements, whether that information is available on the Internet, or in a paper document.

3.5.3 Communication Methods

Many MA organizations indicate that communicating to physicians and providers through a single medium, like a newsletter, is not effective. A multimodal approach is more successful at reaching the provider community because it reaches a broader audience and reinforces the message in a number of different formats.

When deciding the methods to communicate with physicians and providers, consider the following steps:

- **Identify the methods that tend to work best for the organization.** Many MA organizations indicate that the organization's provider Web page and newsletters reach audiences, but small and large group training sessions are most successful for causing a change in action.
- **Determine the goal of the message.** If the message's intent is to raise awareness about a topic, then broad-based communication methods may be appropriate. However, if the message is intended to change the way physicians and providers do something, then group meetings, followed up by emails, and provider handbook and contract updates may be excellent options.
- **Consider the physician's and provider's response.** If the message is likely to provoke a negative reaction from the provider community, then meetings with them can be helpful in addressing and clarifying issues, and discussing possible solutions to problems.

There are a number of methods MA organizations may use to communicate risk adjustment messages to the provider community. These are illustrated in Figure 3E. Understand that, once your organization establishes a communication channel, physicians and providers will rely on that channel to receive information. Any new channels MA organizations use may not be as effective as established ones.

DATA SUBMISSION

MODULE 4 – DATA SUBMISSION

Purpose (Slide 2)

Medicare Advantage (MA) organizations must submit accurate diagnostic data when submitting risk adjustment data. This module describes the file layout for risk adjustment process submissions.

Learning Objectives (Slides 3-4)

At the completion of this module, participants will be able to:

- Understand the submission process requirements, connectivity options, and Risk Adjustment Processing System (RAPS) file layout.
- Identify the data elements required to submit risk adjustment data.
- Locate and describe the diagnosis clusters in the RAPS format.
- Understand the Direct Data Entry (DDE) process.
- Describe the filtering process.
- Describe the diagnoses deletion process.

ICON KEY	
Example	
Reminder	
Resource	

4.1 Submission Process Requirements (Slide 6)

New MA organizations must complete an Electronic Data Interchange (EDI) Agreement with the Centers for Medicare & Medicaid Services (CMS) and submit that Agreement to the Customer Service and Support Center (CSSC) prior to submitting risk adjustment data. The EDI Agreement is a contract between the MA organization and CMS attesting to the accuracy of the data submitted. An officer (e.g., CEO) that represents the MA organization must sign this document. New Plans must submit the EDI Agreement within 1 month of the HPMS effective date.

MA organizations must make special arrangements to use a third party submitter. If the submitter is an entity other than an MA organization, the submitter must complete the Submitter ID Application Form, and the MA organization must complete the EDI Agreement. MA organizations must complete, sign, and return the EDI Agreement for each plan number submitting data. CMS holds the MA organization accountable for the content of submissions regardless of who submits the data.

New MA organizations must submit test data within 3 months of the HPMS effective date and a production file must be submitted within 4 months of the effective date.

If a new contract number is required, the MA organization must submit a new EDI agreement. If the submitter's system successfully submitted test data previously, CMS does not require additional testing.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

MA organizations must submit during each calendar quarter, at a minimum, approximately one-fourth of their total risk adjustment data submission for the collection period. More frequent submissions are recommended and benefit MA organizations, in identifying data collection and submission issues early.

4.2 Connectivity Options (Slide 7)

Connectivity refers to the electronic connection between the MA organization and CMS. MA organizations use the electronic connection to submit risk adjustment to CMS and receive information in return. Table 4A describes the three connectivity options.

TABLE 4A – CONNECTIVITY OPTIONS

Connect:Direct	Formerly Network Data Mover (NDM). Mainframe-to-mainframe connection. Next day receipt of FERAS response.
FTP File Transfer Protocol	Modem-to-modem (dial-up) or lease line connection. Requires password and phone line. Same day receipt of FERAS response.
Gentran	Two connectivity options: -Secure File Transfer Protocol (SFTP); standards based protocol via a vender. -Secure Hyper Text Transfer Protocol (HTTPS), secure web interface.

Small plans with less than or equal to 100,000 members may submit data using the Gentran Mailbox. For technical support questions regarding Gentran mailbox, users may contact the Customer Support for Medicare Modernization (CSMM) by calling (800) 927-8069, emailing mmahelp@cms.hhs.gov, or viewing the website at <http://www.cms.hhs.gov/mmahelp>.

4.3 Relevant Diagnosis (Slide 8)

MA organizations must submit each relevant diagnosis at least once during a reporting period for each enrolled beneficiary.

For payments beginning on January 1, 2008, the initial submission deadline is September 7, 2007 for the reporting period July 1, 2006 through June 30, 2007. For payments beginning on July 1, 2008, March 7, 2008 is the initial submission deadline for reporting data with dates of service January 1, 2007 through December 31, 2007. **Refer to the Risk Adjustment Process Overview module, Table 2B.**

A relevant (model) diagnosis must meet the following criteria:

- The diagnosis is included in the CMS-Hierarchical Condition Category (CMS-HCC), Prescription Drug (RxHCC) or End Stage Renal Disease (ESRD) risk adjustment models.
- The diagnosis must be received from one of the three provider types (hospital inpatient, hospital outpatient, and physician) covered by the risk adjustment requirements.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

- The diagnosis must be collected according to the risk adjustment data collection instructions.

MA organizations may elect to submit a diagnosis more than once during a data collection period for any given beneficiary, as long as that recorded diagnosis was from a face-to-face visit with one of the three provider types covered under risk adjustment. MA organizations may submit any diagnoses received from the three covered provider types, including diagnoses that are not in the CMS-HCC risk adjustment model. Diagnoses that are in the model but that were not collected from one of the three provider types cannot be submitted as risk adjustment data.

4.4 Submission Formats (Slide 9)

Effective October 1, 2007, MA organizations must submit data electronically using one of two formats:

- RAPS format (all provider types)
- DDE screen (all provider types)

4.5 Submission File Layout Logic (Slide 10)

Submissions are organized into three levels of data:

- File-level information—identifies the submitter
- Batch-level information—identifies the MA organization
- Detail-level information—identifies the beneficiary

Figure 4A illustrates a summary of the RAPS file structure.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

Figure 4A – RAPS File Structure Summary

RT AAA – FILE HEADER (Submitter Info)

Always the first record on the file, and must be followed by Record Type (RT) BBB.

- Record ID
- Submitter ID
- File ID
- Transaction Date
- Production/Test Indicator
- Filler

RT BBB – BATCH HEADER (MA Organization Info)

Must follow RT AAA or RT YYY and must be followed by RT CCC.

- Record ID
- Sequence Number
- Plan Number
- Filler

RT CCC – DETAIL RECORD (Beneficiary Info)

Must follow RT BBB or RT CCC and may be followed by another RT CCC.

- Record ID
- Sequence Number
- Sequence Number Error
- Patient Control Number (optional)
- HIC Number
- HIC Error Code
- Patient Date of Birth (optional)
- Date of Birth Error Code
- Diagnosis Cluster (10 Occurrences)
 - ▶ Provider Type
 - ▶ From Date
 - ▶ Through Date
 - ▶ Delete Indicator
 - ▶ Diagnosis Code
 - ▶ Diagnosis Code – Filler
 - ▶ Diagnosis Cluster – Error 1
 - ▶ Diagnosis Cluster – Error 2
- Corrected HIC Number
- Filler

RT YYY – BATCH TRAILER

Must follow RT CCC and may be followed by another RT BBB or RT ZZZ.

- Record ID
- Sequence Number
- Plan Number
- CCC Record Total
- Filler

RT ZZZ – FILE TRAILER

Must follow RT YYY, and must be the last record on the file.

- Record ID
- Submitter ID
- File ID
- BBB Record Total
- Filler

DETAIL LEVEL

BATCH LEVEL

FILE LEVEL

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

4.6 Diagnosis Cluster

The diagnosis cluster contains the core information used to calculate a risk adjustment factor. The following components are included in the cluster:

- Provider Type
- From Date
- Through Date
- Diagnosis Code

A maximum of 10 diagnosis clusters are allowed per CCC record. Each cluster must include the items identified above. If any of these attributes are submitted more than once for the same HIC number, a duplicate diagnosis cluster error will occur.

4.7 Provider Type

MA organizations must submit risk adjustment data for hospital inpatient, hospital outpatient, and physician services. MA organizations may submit all provider types in the same CCC record. The provider type must be coded accurately. There is one provider type per diagnosis cluster. Table 4B shows the provider types and their codes.

Type of Bill (TOB), which is coded on the UB-04 during the collection of hospital data, may be used to assist in translating the correct provider type. Table 4B also shows the TOB and provider type correlation.

TABLE 4B – PROVIDER TYPES

PROVIDER TYPE	CODE	TYPE OF BILL
Principal Hospital Inpatient (principal diagnosis)	01	111 or 112
Hospital Inpatient Other (other diagnosis)	02	111 or 112
Hospital Outpatient	10	131, 132, 141 or 142
Physician	20	N/A

Interim bills (112, 113, & 114 bill types) are not accepted. If an MA organization receives interim bills, do not submit the hospital inpatient diagnoses until the receipt of the final interim bill (114).

4.8 From and Through Dates

- CCYYMMDD is the correct submission format for the "From and Through" dates of service.
- The "Through Date" defines the data used in the data collection year for risk adjustment purposes.

June 30, 2006 is submitted as 20060630.

Table 4C shows the "From" and "Through Dates" for each provider type.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA SUBMISSION

TABLE 4C – FROM AND THROUGH DATES

PROVIDER TYPE	FROM DATE	THROUGH DATE
Hospital Inpatient	Admission Date	Must have a through date and must be the discharge date
Hospital Outpatient	Exact date of patient visit or the first date service began for a series of services	Exact date of patient visit or the last date of service for a series of services
Physician		

When a submitter submits a "From Date" that does not include a "Through Date" for physician or hospital outpatient services, RAPS automatically copies the "From Date" into the "Through Date" field.

4.9 Diagnosis Code

- Each relevant (model) diagnosis code must be submitted at least once during a reporting period.
- The decimal is implied in the format.

4.10 RAPS Format

Table 4D describes each field of the RAPS file layout.

- The shaded fields in the table represent where the RAPS Return File provides new information after data processes through RAPS.
- There are two diagnosis cluster error fields because MA organizations can receive up to two errors on any diagnosis cluster.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA SUBMISSION

TABLE 4D – RAPS FILE LAYOUT

RAPS RECORD AAA – FILE HEADER				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
1	1-3	Required	Record ID	File-level information that identifies the submitter. This field should always be populated with "AAA."
2	4-9	Required	Submitter ID	Identifies the submitter and should be populated with the six-digit alphanumeric SH# assigned by CSSC.
3	10-19	Required	File ID	10-digit alphanumeric character identifying the specific file submitted. This file name may not be repeated within a 12-month period.
4	20-27	Required	Transaction Date	Specifies the date that the file was submitted to Palmetto and formatted as CCYYMMDD.
5	28-31	Required	Production Test Indicator	Must be populated with "PROD" or "TEST." Submission test data proceeds through the entire process.
6	32-512	Spaces	Filler	Must be populated with 481 spaces. The "Filler" field allows for additional fields in the future.

RAPS RECORD BBB – BATCH HEADER				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
1	1-3	Required	Record ID	Batch-level information that identifies the MA organization is populated with "BBB."
2	4-10	Required	Sequence Number	This field identifies the batch submitted. The first batch in a file must begin with 0000001. All successive batch sequence numbers in the file must be incremented by one. This is a numeric field.
3	11-15	Required	Plan Number	Identifies the MA organization and should be populated with the five-digit alphanumeric contract assigned by CMS. (H#, R#, etc.)
4	16-512	Spaces	Filler	Must be populated with 497 spaces. The "Filler" field allows for additional fields in the future.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DATA SUBMISSION

TABLE 4D – RAPS FILE LAYOUT (CONTINUED)

RAPS RECORD CCC – DETAIL LEVEL				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
1	1-3	Required	Record ID	Detail-level information that identifies the beneficiary information. This field should always be populated with "CCC."
2	4-10	Required	Sequence Number	This field identifies the detail record submitted. The first detail record in a batch must begin with 0000001. All successive detail sequence numbers in the batch must be incremented by one. This is a numeric field. Limited to 1,000,000 per day.
3	11-13	RAPS RETURN	Sequence Number Error Code	This field must be submitted with spaces. Upon return, this field is populated with an error code if RAPS finds an error in the sequence number, or will remain blank if no errors were detected in the sequence number.
4	14-53	Optional	Patient Control Number	This optional field may be used by the MA organization to identify the claim submitted. The field allows up to 40 alphanumeric characters.
5	54-78	Required	HIC	The Health Insurance Claim number for the beneficiary. This is a 25-digit alphanumeric field. Enter spaces, not zeros, in unused spaces.
6	79-81	RAPS RETURN	HIC Error Code	This should be submitted with spaces. Upon return, this field is populated with an error code if RAPS finds an error in the HIC number, or remains blank if no errors were detected in the HIC number.
7	82-89	Optional	Patient DOB	This optional field may be populated with the patient's date of birth and is used to verify that the correct beneficiary identification was submitted. If the field is populated, it must be formatted as CCYYMMDD, and CMS edits this field against the information on file at the MBD. If no DOB is submitted, fill with spaces.
8	90-92	RAPS RETURN	DOB Error Code	This field must be submitted with spaces. Upon return, this field is populated with an error code if RAPS finds an error with DOB, or remains blank if no errors were detected in the DOB.

Participant Guide**

DATA SUBMISSION

TABLE 4D – RAPS FILE LAYOUT (CONTINUED)

RAPS RECORD CCC – DETAIL LEVEL (CONTINUED)				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
9	93-412	DIAGNOSIS-CLUSTER (10 occurrences)		The following 8 fields (9.0-9.7) may be repeated 10 times in the same "CCC" record with one diagnosis per cluster. Each diagnosis cluster must contain 32 characters or spaces. Plans must not skip clusters when submitting active diagnosis codes. If there are less than 10 diagnosis clusters the remaining clusters are space filled. If there are more than 10 diagnoses, a new "CCC" record must be established.
9.0		Required	Provider Type	This 2-digit alphanumeric field identifies the site of service provided (01,02,10,20).
9.1		Required	From Date	For hospital inpatient this describes the admission date. For physician and hospital outpatient this describes the date of service. Must be formatted as CCYYMMDD.
9.2		Required	Through Date	For hospital inpatient this describes the discharge date. For physician and hospital outpatient this may be left blank and the system will fill with the "From Date." Must be formatted as CCYYMMDD.
9.3		Conditional	Delete Indicator	This field allows the MA organization to delete a diagnosis, for correction purposes, that has been stored in the RAPS database. Enter a "D" or space.
9.4		Required	Diagnosis Code	This field is populated with the three-to five-digit ICD-9-CM diagnosis code. The decimal is implied and should not be included (e.g., 42732).
9.5		SPACE	Diagnosis Code Filler	This field is designed to allow space for future ICD-10-CM codes and any other growth in the diagnosis cluster. This field must be populated with spaces.
9.6		RAPS RETURN	Diagnosis Cluster Error 1	This field must be submitted with spaces. Upon return, this field is populated with one error code if RAPS finds an error in the diagnosis cluster, or remains blank if no errors were detected in the diagnosis cluster.
9.7		RAPS RETURN	Diagnosis Cluster Error 2	This field must be submitted with spaces. Upon return, this field is populated with one error code if RAPS finds an error in the diagnosis cluster, or remains blank if no errors were detected in the diagnosis cluster.
19	413-437	RAPS RETURN	Corrected HIC number	This field must be submitted with spaces. If the MA organization has submitted an outdated HIC, upon return, this field is populated with the most current HIC number and the "HIC Error" field contains an information error code.
20	438-512	Spaces	Filler	Must be populated with 75 spaces. The "Filler" field allows for additional fields in the future.

Participant Guide**

DATA SUBMISSION

TABLE 4D – RAPS FILE LAYOUT (CONTINUED)

RAPS RECORD YYY – BATCH TRAILER				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
1	1-3	Required	Record ID	Batch trailer information should be populated with "YYY."
2	4-10	Required	Sequence Number	A 7-digit numeric character identifying the batch submitted. Must match the "BBB" record.
3	11-15	Required	"H" Number	"H" number assigned by CMS to identify the MA organization. Must match the "H" number in the corresponding "BBB" record (i.e., the "BBB" record with the same sequence number).
4	16-22	Required	CCC Record Total	This field should total the number of CCC records in the batch. This field is numeric and should be filled with leading zeroes (e.g., 0000001). Limited to 1,000,000 per day.
5	23-512	Spaces	Filler	Must be populated with 490 spaces. The "Filler" field allows for additional fields in the future.

RAPS RECORD ZZZ – FILE TRAILER				
FIELD NO	POSITION	SUBMISSION STATUS	FIELD NAME	EXPLANATION
1	1-3	Required	Record ID	File Trailer Information should be populated with "ZZZ."
2	4-9	Required	Submitter ID	Identifies the submitter and must match the 6-digit alphanumeric SH# in the AAA records.
3	10-19	Required	File ID	10-digit alphanumeric character identifying the specific file submitted. Must match the File ID in the "AAA" record.
4	20-26	Required	BBB Record Total	This field should total the number of batches in the file. This field is numeric and should be filled with leading zeros (e.g., 0000001).
5	27-512	Required	Filler	Must be populated with 486 spaces. The "Filler" field allows for additional fields in the future.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

4.11 Filtering Risk Adjustment Data (Slides 13-14)

MA organizations are required to filter risk adjustment data to ensure that they submit data from only appropriate data sources (e.g., hospital inpatient, hospital outpatient, and physician provider types). A filtering process is used to identify the correct provider types in claims and encounter data. CMS further recommends the following filtering guidelines:

- Hospital inpatient data require admission and discharge dates of service from appropriate facilities. **Refer to the Data Collection module** for examples of covered facilities.
- Physician data require face-to-face visits with a professional listed on the CMS specialty list. **Refer to the Data Collection module** for the list of acceptable physician data sources.
- Hospital outpatient data require the most demanding or accurate filtering. Data requirements include diagnoses from appropriate facilities and covered services contained on the CMS covered outpatient listings. **Refer to the Data Collection module** for examples of covered facilities and non-covered services/facilities.

The following over-filtering and under-filtering examples may be useful:

- a) Hospital Inpatient:
 - Over-filtering - Failing to submit data from specialized facilities (e.g., Rehabilitation and Psychiatric Hospitals).
 - Under-filtering - Submitting data from interim bills or from non-covered institutional stays (e.g., nursing facility data).
- b) Hospital Outpatient:
 - Over-filtering - Failing to submit data from specialized facilities, particularly those that do not appear on the inpatient provider list (e.g., Rural Health Clinics, Federally Qualified Health Centers) excluding bills with both covered and non-covered procedure codes.
 - Under-filtering - Submitting data from non-covered facilities or submitting non-covered services from covered facilities (e.g., laboratory only or radiology only claims).
- c) Physicians:
 - Over-filtering - Failing to capture data from non-physician practitioners that appear on the physician specialty list (e.g., nurse practitioners, physician assistants, etc.).
 - Under-filtering - Submitting all paid claims from the claims database, including laboratory, Durable Medical Equipment (DME), ambulance, etc.

For those plans that use CPT codes to screen diagnosis codes submitted to CMS, please note that the CPT range for radiology is 7000 through 79999. The following CPT codes indicate diagnostic radiology and diagnoses on claims and should not be submitted to CMS in risk adjustment data: 70010 through 76999 and 78000 through 78999.

4.12 Modifying Risk Adjustment Data (Slide 15)

RAPS allows for the correction of risk adjustment data submitted to CMS. This correction process is based on the concept that the incorrect cluster must be deleted from the system before the correct cluster information is added. For this reason, data correction is at least a two-step process.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

4.13 Deleting Diagnosis Clusters (Slide 16)

Each diagnosis cluster ("Diagnosis Code," "From Date," "Through Date," and "Provider Type") is stored separately as a unique cluster associated with a beneficiary's HIC number. If a diagnosis was submitted in error and needs to be corrected, the original diagnosis cluster must be resubmitted with a delete indicator in the appropriate field. **Delete transactions may only be submitted using the RAPS format or the DDE function.** When a delete record is received, CMS maintains the original diagnosis cluster on file and adds a delete indicator to it and the date of the deletion.

4.14 Reasons to Delete a Diagnosis Cluster (Slide 17)

There are three reasons MA organizations may delete a diagnosis cluster:

- Diagnosis cluster submitted erroneously (e.g., data from an interim bill was submitted for hospital inpatient).
- Incorrect HIC number used for submission of a beneficiary's diagnostic information.
- An error in a diagnosis cluster field (i.e., "Provider Type," "Dates of Service," "Diagnosis Code").

MA organizations submit deletions within a file, batch, or record containing previously submitted risk adjustment data.

4.15 Steps for Deleting a Diagnosis Cluster (Slides 18-20)

Before deleting an error, verify that the diagnosis cluster appears on the RAPS Return File. Only diagnosis clusters accepted by RAPS and stored in the RAPS database may be deleted.

There are two methods for deleting diagnosis clusters:

Method 1 for Deleting Clusters

1. Submit RAPS format using normal submission process with appropriate HIC number included.
2. Enter information in the diagnosis cluster fields (9.0, 9.1, 9.2, 9.4, 9.5) exactly as it appeared in the original submission.
3. In field 9.3 enter a "D" for delete.
4. Enter the appropriate information in all other records to ensure the submission file is complete.
5. Transmit the file to FERAS. (See www.cssoperations.com for details.)

Method 2 for Deleting Clusters

1. Create a file using the DDE screens available through FERAS at Palmetto (detailed information about the DDE process is located in Section 4.20).
2. Enter information exactly as it appeared in the original submission.
3. In the DDE "CCC" record screen, hit the down arrow key and select "D."
4. Proceed with entering all appropriate information.
5. Upload the file created in DDE to FERAS at Palmetto.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DATA SUBMISSION

4.16 MA Organization Responsibilities Regarding Deletions (Slide 21)

- MA organizations must submit delete records when an erroneous diagnosis cluster has been accepted by RAPS and stored in the RAPS database.
- If a diagnosis cluster is deleted for the purpose of correcting data, the MA organization is responsible for submitting the correct diagnosis cluster. Conversely, if the MA organization submits corrected data, the MA organization must submit the appropriate deletion record. That is, if the correct diagnosis cluster is submitted, the erroneous diagnosis cluster cannot be ignored.
- If a correction applies to the same beneficiary as the deletion, the correction may be included in the same "CCC" record as the deletion. (Do not exceed 10 diagnosis clusters per "CCC" record.)
- If only one of several clusters within the CCC record requires modification, do not resubmit all other associated clusters. If clusters are resubmitted exactly the same without the delete indicator, the plans will generate a duplicate cluster error.
- If the corrected diagnosis cluster belongs to a different beneficiary than the deleted diagnosis cluster, the correct diagnosis cluster may be submitted in the same file as the deletion.

MA organizations should not delete a diagnosis code or record repeatedly on the same day and on the same record. MA organizations should implement a process to ensure that only one instance of a specific diagnosis cluster (either add or delete) is submitted on a given day.

4.17 Direct Data Entry (Slide 22)

MA organizations have the option of manually entering diagnostic information via the DDE application offered by Palmetto. DDE instructions are illustrated in the screen shots below. DDE is available in FERAS at Palmetto via the Medicare Data Communications Network (MDCN).

- DDE entries allow for deletion of records for corrections even if another submission format was used.
- The DDE screens, as shown in Figures 4B through 4G, automatically prevent the placement of incorrect data characters (e.g., alpha characters will not be accepted in the "From" or "Through Date" fields).
- After the user has entered all relevant data, the user will click on the "Create File" button in FERAS. This will create a file on the user's local PC.
- After the file is created on the local PC, the user must upload the file to FERAS in order to complete the process.
- Files created in DDE and uploaded to FERAS will receive a FERAS Response Report, which may be downloaded from the MA organization's electronic mailbox.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

MODULE 5 – EDITS

Purpose (Slide 2)

The risk adjustment process includes an editing stage to ensure the accuracy of the data prior to storing the data for risk adjustment calculation. When Medicare Advantage (MA) organizations understand common errors and steps to prevent such errors, the efficiency of the risk adjustment process is increased. This module introduces participants to the Front-End Risk Adjustment System (FERAS) and the Centers for Medicare & Medicaid Services (CMS) Risk Adjustment Processing System (RAPS) data logic and editing processes. It provides information to assist MA organizations in minimizing data errors and taking appropriate steps in correcting errors that occur.

Learning Objectives (Slide 3)

At the completion of this module, participants will be able to:

- Interpret the FERAS and the RAPS data integrity logic and error codes.
- Describe the FERAS and RAPS editing processes.
- Recognize common FERAS and RAPS errors and determine action required to avoid or correct them.

ICON KEY	
Example	
Reminder	
Resource	

5.1 Data Flow (Slide 4)

After MA organizations submit data to Palmetto, FERAS performs format and integrity checks on the file and batch levels, as well as on the first and last detail (CCC) record. After the data pass the checks, they are sent to RAPS for complete editing of all detail records before they are stored in the RAPS database.

Files submitted in Test and Production are processed through FERAS and RAPS, and all edits are performed. Test files, however, are not stored in the RAPS database. The flow of data for edit processing is illustrated in Figure 5A.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Figure 5A – Data Flow

5.1.1 FERAS System (Slide 5)

MA organizations submit data to FERAS, which performs the format and integrity checks.

- FERAS performs format and integrity checks on file- and batch-level data.
- FERAS checks the first and last detail records in each batch.
- FERAS accepts or rejects the entire file.
- FERAS ensures that all accepted transactions contain the following correct data:
 - AAA and ZZZ record.
 - At least one BBB record for each YYY record.
 - Following each BBB record, at least one CCC record with at least one diagnosis cluster populated.
 - Valid submitter ID and plan numbers.
 - Valid record and file totals.
 - The first and last CCC record will be edited to ensure that the submitted data are in the correct location on the record (i.e., spaces are where they should be located).
 - Record Type CCC must be present in the first field.
 - The first sequence number must equal 0000001.
 - The last sequence number must equal the total CCC record count in the YYY record.
 - The "HIC (Health Insurance Claim) Error Code" and "Diagnosis Code – Filler" fields contain spaces. Do not fill fields with zeros.

If all checks pass, the transaction processing continues in RAPS. If any of the data fail, the complete file is rejected.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Example: 1

Scenario: The MA organization submitted a file and entered "AA1" in record type AAA, field 1.

Results: FERAS will reject the entire file with error message 100. The field must always be populated with "AAA".

Generally, FERAS errors occur during the initial establishment of the system and risk adjustment process in MA organizations. After data are processed, automated formats are programmed, and FERAS errors occur less frequently.

5.1.2 FERAS Error Code Logic (Slide 7)

When a FERAS check fails, an associated error code is created. Table 5A describes the error code logic. If any errors occur in FERAS, the complete file is rejected and returned to the submitter after all checks are completed.

TABLE 5A – FERAS ERROR CODE LOGIC

SERIES	EXPLANATION
100	File-level errors on the AAA or ZZZ records.
200	Batch-level errors on the BBB or YYY records.
300-400	Check performed on first and last CCC records.

- The 100- and 200- series error codes are assigned based on the level of checks that are performed, as well as the location of the edit.
- The entire file is returned to the submitter.

5.1.3 FERAS Error Code Ranges (Slide 8)

Error code ranges are explained in Table 5B.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

EDITS

TABLE 5B - ERROR CODE RANGES

SERIES	EXPLANATION
100	Indicates that the system could not determine the record type; all editing stopped at that point.
101-109	Indicates a failure of a face-validity edit on the AAA record (file-level header). The last digit indicates the specific field in which the error was found. For example, the 101-error code refers to an error found in field 1 on the AAA record.
111-125	Indicates a failure of a cross-reference edit between a field on the AAA (file-level header) record and a look-up table, a field on another record, or a value calculated from another record. The last digit will indicate the specific AAA field against which the cross-check was performed. For example, the 112-error code indicates that the submitter ID in field 2 did not appear on a look-up table of valid submitter IDs.
151-159	Indicates a failure of a face-validity edit on the ZZZ record (file-level trailer). The last digit indicates the specific field in which the error was found. For example, the 151-error code refers to an error found in field 1 on the ZZZ record.
161-175	Indicates a failure of a cross-reference edit between a field on the ZZZ (file-level trailer) record and a look-up table, a field on another record, or a value calculated from another record. The last digit will indicate the specific ZZZ field against which the cross-check was performed. For example, the 162-error code indicates that the submitter ID, field 2 in ZZZ record, does not match the submitter ID on the AAA record.
201-209	Indicates a failure of a face-validity edit on the BBB (batch-level header) record. The last digit indicates the specific field in which the error was found. For example, the 201-error code refers to an error found in field 1 on the BBB record.
211-225	Indicates a failure of a cross-reference edit between a field on the BBB (batch-level header) record and a look-up table, a field on another record, or a value calculated from another record. The last digit will indicate the specific BBB field against which the cross-check was performed. For example, the 213-error code indicates that the submitter ID, field 3 in BBB record, is not authorized to submit for the plan ID.
251-259	Indicates a failure of a face-validity edit on the YYY (batch-level trailer) record. The last digit indicates the specific field in which the error was found. For example, the 251-error code refers to an error found in field 1 in the YYY record.
261- 275	Indicates a failure of a cross-reference edit between a field on the YYY (batch-level header) record and a look-up table, a field on another record, or a value calculated from another record. The last digit will indicate the specific YYY field against which the cross-check was performed. For example, the 262-error code indicates that the sequence number in the YYY record field 2 does not match the sequence number in field 2.
301-489	Indicates a format problem with the first or last CCC record. The problem is either with the face validity of the data in specific fields or the presence of data in fields that are required to be blank. In either circumstance, the basic CCC record format is assumed to be in error and the entire file is rejected.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Note: FERAS checks the validity and format of an individual field before performing checks between fields. For example, the system first checks that there is a valid submitter ID on the AAA record before it checks that the submitter ID reported in the YYY record is identical. FERAS file-level, batch-level, and detail-level error codes are described in Table 5C.

TABLE 5C – FERAS ERROR CODES

FILE-LEVEL ERROR CODES

ERROR CODE	RECORD ID	ERROR DESCRIPTION
100	AAA	INVALID RECORD TYPE
101	AAA	AAA RECORD MISSING FROM TRANSACTION
102	AAA	MISSING / INVALID SUBMITTER-ID ON AAA RECORD
103	AAA	MISSING FILE-ID ON AAA RECORD
104	AAA	MISSING / INVALID TRANSACTION DATE ON AAA RECORD
105	AAA	MISSING / INVALID PROD-TEST-INDICATOR ON AAA RECORD
112	AAA	SUBMITTER ID NOT ON FILE
113	AAA	FILE NAME DUPLICATES ANOTHER FILE ACCEPTED WITHIN LAST 12 MONTHS
114	AAA	TRANSACTION DATE IS GREATER THAN CURRENT DATE
151	ZZZ	ZZZ RECORD MISSING FROM TRANSACTION
152	ZZZ	MISSING / INVALID SUBMITTER-ID ON ZZZ RECORD

TABLE 5C – FERAS ERROR CODES (CONTINUED)
DETAIL-LEVEL ERROR CODES

ERROR CODE	RECORD ID	ERROR DESCRIPTION
301	CCC	CCC RECORD MISSING FROM TRANSACTION
302	CCC	MISSING / INVALID SEQ-NO ON CCC RECORD
303	CCC	SEQUENCE-ERROR-CODE FILLER NOT EQUAL TO SPACES
304	CCC	HIC-ERROR-CODE FILLER NOT EQUAL TO SPACES
305	CCC	DOB-ERROR-CODE FILLER NOT EQUAL TO SPACES
306	CCC	DIAGNOSIS CODE-FILLER NOT EQUAL TO SPACES
307	CCC	DIAGNOSIS-CLUSTER-ERROR-1 NOT EQUAL TO SPACES
308	CCC	DIAGNOSIS-CLUSTER-ERROR-2 NOT EQUAL TO SPACES
309	CCC	SEQUENCE-NUMBER ON CCC RECORD IS OUT OF SEQUENCE
310	CCC	MISSING / INVALID HIC-NO ON CCC RECORD
311	CCC	AT LEAST ONE DIAGNOSIS CLUSTER REQUIRED ON TRANSACTION
313	CCC	DELETE-INDICATOR MUST BE BLANK OR EQUAL TO "D"
314	CCC	INVALID DIAGNOSIS CODE FORMAT ON CCC RECORD
315	CCC	CORRECTED HIC NOT EQUAL TO SPACES
350	CCC	INVALID PATIENT-DOB ON CCC RECORD
400	CCC	MISSING / INVALID PROVIDER-TYPE ON CCC RECORD
401	CCC	INVALID FROM-DATE ON CCC RECORD
402	CCC	INVALID THRU-DATE ON CCC RECORD

Example: 2

Scenario: The MA organization submitted a file with a 2.0 in the "Diagnosis Code – Filler" field on the first CCC record.

Results: FERAS would reject the complete file due to data being placed in the "Diagnosis Code – Filler" field of the diagnosis cluster; it must be populated with spaces. FERAS would identify this error, since it occurred in the first CCC record.

FERAS errors rarely occur after MA organizations program file layouts and adequately test the formats before submission to CMS.

5.1.4 RAPS Edits (Slide 10)

After data pass the FERAS checks, the file is sent via Connect: Direct to the CMS data center for RAPS processing.

- As a precautionary measure, RAPS performs balancing checks to ensure that the complete file was received from Palmetto prior to editing data.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

- The RAPS system performs editing on the CCC transactions.
- The data elements edited include HIC Number, Provider Type, Diagnosis Code, From Date, and Through Date.
- If Date of Birth is submitted, RAPS performs an edit on that field.

5.1.5 RAPS Editing Rules

The RAPS editing process takes place in four logical stages.

Stage 1- Field Validity and Integrity Edits (Slide 11)

RAPS performs format and integrity checks on all CCC-level fields as a first level of editing. If there are data in the "HIC Error Code" or "Diagnosis Code - Filler" fields, the entire detail record is rejected with no further editing performed. If a record fails this stage of editing, it is assumed that the data are corrupt.

The dates also are checked at this stage. If the dates within a diagnosis cluster are not valid dates, then RAPS stops the editing process for that diagnosis cluster because all other data edits within a diagnosis cluster depend upon the validity of the dates.

Stage 2 - Field-to-Field Edits (Slide 12)

After RAPS checks format and integrity of the fields, the field-to-field editing takes place.

- RAPS ensures that the from date is equal or prior to the through date.
- RAPS also checks all diagnosis clusters for hospital outpatient and physician provider types to ensure compliance with the 31-day span rule.
- RAPS checks all data to make certain that MA organizations submit the reconciliation data properly. See Submission Timetable in Module 2 (Risk Adjustment Process Overview) for dates of service included in each data submission period.

Stage 3 - Eligibility Edits (Slides 13)

The next stage of editing cross-checks the appropriate fields against the common tables in MBD and MARx. MA organizations may access MBD through the common user interface, Medicare Advantage & Part D Inquiry System. For risk adjustment purposes, these common tables are the authoritative source of beneficiary information, and supports managed care enrollments to MA organizations.

In this editing stage, the HIC number, date of birth, and Medicare entitlement are checked. For example, in Stage 1 editing, the system ensured that a valid HIC number was present in field 5 of the CCC record. In Stage 3 editing, the system makes certain that the HIC number exists on the common tables.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Figure 5B illustrates the flow of data between MARx and MBD and RAPS.

Figure 5B –Flow of Data for Eligibility Checks

The HIC number is a common way to begin researching data in the common tables.

- The common tables store historical data on file, so if a beneficiary's HIC number changed, the common tables will cross-reference the old and new numbers.
- Railroad Retirement Board (RRB) beneficiary numbers are cross-referenced automatically. This allows users to research demographic and eligibility information for beneficiaries with RRB and HIC numbers.

Stage 4 – Diagnosis Code Edits (Slide 14)

After RAPS edits the integrity of the individual fields and validates the HIC number and eligibility, it edits the diagnosis code against the Diagnosis Lookup Table in RAPS. In this stage, the system first ensures that each diagnosis code is valid. Then the system checks each diagnosis code against service dates and gender. If any of these edits fail, the diagnosis cluster is not stored in the RAPS database. The edits at this stage also include an edit to check if the diagnosis code is in the risk adjustment model. If the diagnosis code is not in the model, an information error is returned. The diagnosis cluster is stored if an information-only error is returned, and no further action by the MA organization is required.

Explanations of error codes and their consequences, RAPS error codes, informational edits, and duplicate diagnosis cluster edit are presented in Tables 5D, 5E, 5F, and 5G, respectively.

EDITS

TABLE 5G – DUPLICATE DIAGNOSIS CLUSTER EDIT

ERROR CODE	RECORD ID	ERROR DESCRIPTION
502	CCC	DIAGNOSIS CLUSTER WAS ACCEPTED BUT NOT STORED. A DIAGNOSIS CLUSTER WITH THE SAME ATTRIBUTES IS ALREADY STORED IN THE RAPS DATABASE

Example: 3

Scenario: The Low Rest Insurance Company submitted a risk adjustment transaction for Susan Doe who was admitted into the hospital. The principal diagnosis submitted was 601.0 for acute prostatitis.

Results: The error code 453 would occur. The system checked that the diagnosis field was complete. Next, the system verified that the HIC number was entered. RAPS then verified that the HIC number was on the common tables and the beneficiary was eligible. The diagnosis was determined to be a valid diagnosis. However, the diagnosis was not valid for the sex. This diagnosis cluster was rejected and not stored in the RAPS database.

5.2 Resolving Error Codes

CMS began accepting risk adjustment data in FERAS and processing data through RAPS in October 2002. While the error rate is less than one percent, there are several errors that represent the majority of the common errors seen.

5.2.1 Resolution Steps (Slide 17)

It is the MA organization's responsibility to resolve errors that CMS identifies. Described below in Figure 5C are the basic steps required to resolve errors. If inaccurate data are the cause of the error, the organization must submit a new record with corrected information to resolve the error.

Figure 5C – Resolution Steps

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

System problems may occur when MA organizations submit and delete the same diagnosis cluster several times on the same day. The error code 492 will occur if the organization tries to delete the same cluster more than once.

Example: 4

Scenario: John Smart at BaseCare Health Plan deleted a diagnosis cluster. Later the same day, he mistakenly added the same cluster using Direct Data Entry (DDE). Realizing his mistake, John immediately attempted to delete this cluster using DDE.

Results: The error code 492 occurs, indicating that (1) the diagnosis cluster was not successfully deleted and (2) that the cluster is already stored as a delete and another delete is not necessary.

Effective January 3, 2006, new error code 455 was added to the RAPS Error Codes list. The message reads "Diagnosis cluster not edited due to record format error." The diagnosis cluster is not stored. A plan will receive this error if the plan leaves a cluster blank within a CCC record, and then populates the next cluster. Error code 455 clusters may occur with, or after, the first blank diagnosis cluster. Blank clusters will not receive a 455 error.

When a submitter receives a 455-error code, "Diagnosis Cluster Not Edited Due to Record Format Error", the following steps should be taken:

- Since this is a 400-level error code message, the submitter will refer to the diagnosis cluster.
- The error code series 400-489 indicates that all possible diagnosis edits were performed but the diagnosis cluster is not stored.
- The submitter should ensure that the CCC record contains valid clusters, left justified in the record, followed by blank clusters.
- Resubmit following correction.

Note: A 455 error will not occur with error codes 302 through 315. These error codes indicate the CCC record is not valid.

Example: 5

Scenario: Horizon Valley Health Plan submitted eight diagnosis clusters. However, the fifth diagnosis cluster was a blank cluster.

Results: Error code 455 occurs. All of the diagnosis clusters following the blank cluster received the error code 455. All possible diagnosis edits were performed, but the diagnosis clusters were not stored.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

5.2.2 Informational Error Messages

RAPS generates informational messages that do not stop processing of data, i.e., no immediate action is necessary. However, these messages, illustrated in Table 5H, provide MA organizations with information to improve future submissions.

TABLE 5H – INFORMATIONAL MESSAGE CODES

ERROR CODE	RECORD ID	ERROR DESCRIPTION	PROCESS IMPROVEMENT
500	CCC	BENEFICIARY HIC NUMBER HAS CHANGED ACCORDING TO CMS RECORDS; USE CORRECT HIC NUMBER FOR FUTURE SUBMISSIONS.	USE UPDATED HIC NUMBER ON ALL FUTURE SUBMISSIONS FOR THIS BENEFICIARY.
501	CCC	VALID DIAGNOSIS BUT NOT A RELEVANT DIAGNOSIS FOR RISK ADJUSTMENT DURING THIS SERVICE PERIOD.	DETERMINE IF FILTERING SHOULD BE INCORPORATED INTO SUBMISSION PROCESS TO REDUCE NUMBER OF 501 MESSAGES.

5.2.3 Duplicate Diagnosis Cluster Error and 5 Percent Benchmark

CMS has put a 5 percent benchmark requirement in place for 502 errors, "Diagnosis cluster was accepted but not stored. A diagnosis cluster with the same attributes is already stored in the RAPS database," CMS monitors plans with error rates that exceed the benchmark. CMS defines a duplicate submission as a diagnosis cluster with the same attributes (provider type, from date, through date, diagnosis code, and HIC number) that are already stored in the RAPS database.

Each duplicate cluster that receives a 502-error code counts toward the 5 percent benchmark. For example, if a record included 10 diagnosis clusters and each one was a duplicate of another cluster, there would be 10 502-error codes and all 10 would count towards the 5 percent benchmark.

CMS will look at the overall metrics per file, as this is the easiest way to measure the benchmark. CMS will look at files on a weekly basis to determine volume and the number of duplicates the plan receives to determine if a compliance letter needs to be sent.

If the submitter is a third party and the file contains records for multiple plans, the review will occur at the plan level within the file. Table 5I provides examples of how CMS reviews plan submissions against the benchmark.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

TABLE 5I – 502 BENCHMARK COMPARISON EXAMPLES

EXAMPLE NUMBER	EXAMPLE DESCRIPTION
1	If a plan submitted one file in a given week with two records and they were duplicates, the plan would have a 100% duplicate rate, but with only two records.
2	Afterwards, the plan submitted additional files that had 10,000 records and a 2% duplicate rate. In this case, CMS would not send this plan a compliance letter.
3	If, on the other hand, a plan submitted a file with 2 million records and 1 million of them were duplicates, CMS would send a compliance letter.

Submitters should consider establishing an automated system or a process that checks previously submitted files for accepted diagnosis clusters in order to minimize or eliminate the resubmission of duplicate diagnosis clusters.

While this is an informational error and does not require action in terms of correcting an error, it is critical that plans self-monitor their submissions so that they do not exceed the 5 percent benchmark requirement on 502 errors. Table 5J provides tips to ensure plans are compliant with the guidance on the 5 percent benchmark for duplicate diagnosis cluster errors.

**TABLE 5J – TIPS FOR ENSURING COMPLIANCE WITH THE 5 PERCENT BENCHMARK
FOR DUPLICATE DIAGNOSIS CLUSTER ERROR GUIDANCE**

TIP	DESCRIPTION
Tip 1: Identify a Duplicate Diagnosis Cluster	CMS defines a Duplicate Diagnosis Cluster as one that shares all of the same attributes (HIC Number, Provider Type, From and Through Dates and Diagnosis) as one previously submitted and stored in the RAPS database.
Tip 2: Review Your Reports	Review your current and previous RAPS Return Files to determine which clusters were stored. If the cluster was stored, do not resubmit.
Tip 3: Understand Error Resolution	If you are resolving an error, you do not necessarily need to resubmit all clusters included in the record. If you are resolving a 300-level error, this indicates that none of the diagnosis clusters were stored because there was a record level error. If this is the case, you will need to resubmit all clusters associated with the record. This would not create a duplicate diagnosis because none of the records were previously stored. If you are resolving a 400-level error, this indicates that a specific diagnosis cluster was not stored. You should only resubmit the specific cluster that resulted in the 400-level error message. <i>Do not</i> resubmit all clusters within the record. If there were ten clusters within the record, but you received a 400-level error message on only two of the clusters, you should only resubmit the two clusters where the error occurred.
Tip 4: Understanding Modifying Data	In the case of self-identified errors, those not reported as an error on the RAPS reports, you should be careful to only resubmit the diagnosis clusters that require a modification. If you submit a record with eight clusters, but the following week you realize that the date of service was incorrect in one of the clusters, you would submit that specific cluster with a "D" in the delete indicator field, and submit a new cluster with the correct date. Resubmitting all of the remaining seven clusters would create seven duplicates.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Use the tips above to assist your plan in reducing or eliminating the submission of duplicate diagnosis clusters to avoid implications that may result in suspension of data submission privileges and ultimately impact your payments.

Example: 6

Scenario: Blue Health Plan submitted a CCC record with five diagnosis clusters in which the third diagnosis cluster has an invalid HIC number. Blue Health Plan also submitted a CCC record with seven diagnosis clusters in which the sixth diagnosis cluster received an error indicating the diagnosis was not appropriate for the patient sex.

Results:

The CCC record with the five diagnosis clusters received a record level error, error code 310 on the third cluster. This means that the diagnosis clusters were not stored for this CCC record and all the diagnosis clusters in this record should be resubmitted.

The CCC record with the seven diagnosis clusters received a cluster level error, error code 453 on the sixth cluster. The only cluster not accepted and stored from this CCC record is the sixth cluster. Therefore, the only cluster that should be resubmitted by Blue Health Plan is the sixth cluster, the one that received the error. Resubmitting the other diagnosis clusters that were accepted and stored would result in the Blue Health Plan receiving error code 502 for submitting duplicate diagnosis clusters. This would count against the plan's 5% benchmark.

5.2.4 Common Errors (Slide 22)

In an effort to prevent common errors, the next section describes the errors and steps that MA organizations may take to minimize their occurrence.

5.2.4.1 File Name Duplicates Another File Accepted Within Last 12 Months

To identify the unique file that has been accepted, CMS requires that all files include a 10-digit alphanumeric file ID. This file ID is required when submitting test or production data. Once a file ID has been submitted and accepted in test or production, the same file ID may not be submitted on any other files within 12 months.

In addition, if a file ID was accepted in encounter data processing prior to October 2003, the file ID should not be used for Risk Adjustment processing within 12 months. FERAS performs an edit of the entire 10-digit file number, therefore submitters should make certain that those digits are unique.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Example: 7

SenCare Health Plan submitted an encounter data hospital inpatient production file in August 2002 and an encounter data physician test file in August 2002. The plan cannot submit both files with the same file ID within 12 consecutive months (between August 2002 and August 2003).

Prevention

Submitters should consider establishing an automated system to assign a file sequence number during the establishment of the data file.

Correction

When a submitter receives a 113-error code, "File name duplicates another file accepted within the last 12 months", the following steps should be taken:

- Since this is a 100-level error code message, the submitter will refer to the AAA record.
- The error code 113, describes the field within the AAA record that must be corrected.
- The submitter must enter a valid 10-digit file ID in AAA 3.
- The file must be resubmitted following correction.

Since this file was rejected by FERAS, it will not be processed in RAPS until the data are corrected.

5.2.4.2 Delete Error, Diagnosis Cluster Previously Deleted

When a plan submits a delete and RAPS accepts it, the cluster is not physically deleted from the RAPS database. The RAPS database stores a "D" in the delete indicator and enters a delete date to indicate when the diagnosis was deleted. If a plan tries to delete the exact same diagnosis cluster at a later time, the system will generate a 491-error code, informing the plan that the cluster was already deleted.

Prevention

This issue normally occurs when plans delete all clusters from a previously submitted file, and the original file included duplicate diagnosis clusters. One way to prevent the errors is to check for duplicate diagnosis clusters prior to submitting the file with the deletes on it.

Correction

There is no corrective action necessary because the 491-error code indicates that the cluster has already been deleted.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

5.2.4.3 Diagnosis Cluster Not Successfully Deleted. Another Diagnosis Cluster With the Same Attributes Was Already Deleted From the RAPS Database On This Date

When plans submit delete records, the "D" indicator and the delete date become part of the unique database key for the diagnosis cluster. Diagnosis clusters must have one unique attribute in the database key in order to be stored. The 492-error code occurs when a plan deletes, adds, and then attempts to delete the exact same cluster during a single processing day. The delete will successfully process, as will the following add transaction. The add transaction will create a new record for this diagnosis cluster. The second delete cannot process, since accepting the second delete will cause the creation of a duplicate record in the RAPS database. This error is different from the 491 in that the last record on file will be the add record; that is, the diagnosis cluster has not been successfully deleted.

Prevention

Again, this error normally occurs when plans submit large files of correction records. Plans should check when deleting records that they are not adding the exact same cluster in the same file, or on different files on the same day. If a plan detects multiple submissions of the same diagnosis cluster, the plan should determine the final status of the cluster, deleted or active, and take appropriate action.

Correction

When a submitter receives a 492-error code, "Diagnosis Cluster Not Successfully Deleted", the following steps should be taken:

- Since this is a 400-level error code message, the submitter will refer to the CCC record.
- The error code series 490-499 indicates that it is a deletion problem.
- The submitter must determine if the diagnosis cluster should be deleted or active as a final action.
- If the cluster should be active, no further action is required.
- If the diagnosis is supposed to be deleted, the plan must submit one delete record. Since any future submissions will have a different delete date than any other clusters on file, a single delete record will successfully process.

5.2.4.4 Service From Date Is Not Within MA Organization Enrollment

MA organizations can reduce the numbers of errors that are returned due to invalid eligibility by accessing the common user interface to determine eligibility and other demographic information stored on the common tables. Implementing the following procedures can reduce time spent on resolving errors.

- Develop a monthly validation protocol verifying eligibility of MA organization enrollees.
- Program internal information systems that cross check the common tables before submitting data to FERAS.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

The Beneficiary Eligibility and Beneficiary Detail screens in the common user interface provide information that supports the MA risk adjustment requirements. The information includes:

- Date of birth.
- HIC Number.
- Medicare effective date.
- Medicare termination date.

Note: MA organizations can manually research each beneficiary online or electronically research beneficiaries in batches using the Batch Eligibility Query Request File.

The beneficiary receiving services under the MA program must be enrolled in Medicare during the service period. The dates of service reported in the diagnosis clusters must be within the enrollment dates that are posted on the common tables. RAPS cross-references the common tables to verify that the beneficiary was covered during the identified from and through dates of service. Prior to March 2003, MA organizations received the 408- and 409-error codes to reflect data inconsistencies between various CMS systems.

The 408-error code occurs with all data. The 409-error code occurs only with hospital outpatient and physician data.

Prevention

Submitters should check the from and through dates of service against internal enrollment records. Remember that for hospital outpatient and physician data, both the from and through dates must be within MA enrollment periods. For hospital inpatient data, only the from dates must be within MA enrollment periods. Performing these pre-edits will minimize the number of errors received regarding enrollment information.

Correction

When a submitter receives a 408-error code "Service from date is not within MA organization enrollment period", or a 409-error code "Service through date is not within MA organization enrollment period", the following steps should be taken:

- Since this is a 400-level error code message, the submitter will refer to the diagnosis cluster.
- The submitter must ensure that the correct service from date was entered in CCC 9.1.
- The submitter must ensure that the correct service through date was entered in CCC 9.2.
- The submitter should check these dates against the plan enrollment dates in the common tables.
- If the submitter determines that there are discrepancies in the data in CMS systems, contact CSSC.
- If the CSSC determines that the common tables require updated plan enrollment data, resubmit the data after CSSC corrects the data.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

EDITS

Since this is not a format or integrity edit, this error will not be detected in FERAS; therefore, DDE users may encounter this error. When this is detected in RAPS, the problem must be corrected in order to store any diagnosis clusters associated with this record.

5.2.4.5 Beneficiary Is Not Enrolled In Plan On or After Service From Date

Beneficiaries must be enrolled in the plan on or after the date of the service provided.

Prevention

Using information from the monthly membership report and internal enrollment files, submitters should be knowledgeable regarding the enrollment and eligibility of their beneficiaries. Establishing a systematic beneficiary enrollment tracking system will reduce the number of errors associated with this edit.

The 408- and 409-error code messages indicate that the service occurred while the beneficiary was not participating in *any* MA program. The 410-error code message indicates that the service occurred while the beneficiary was not enrolled in *your* organization.

Correction

When a submitter receives a 410-error code "Beneficiary is not enrolled in plan on or after service from date", the following steps should be taken:

- Since this is a 400-level error code message, the submitter will refer to the diagnosis cluster.
- The submitter must ensure that the correct service from date was entered in CCC 9.1.
- The submitter should check the service from date against the plan enrollment dates to confirm that the beneficiary was enrolled in this plan on or after the from date.
- If the submitter determines that there are discrepancies in the data in CMS systems, contact CSSC.
- If CSSC determines that the common tables require updated plan enrollment data, resubmit after CSSC corrects the data.

Since this is not a format or integrity edit, this error will not be detected in FERAS; therefore, DDE users may encounter this error. When this is detected in RAPS, the problem must be corrected in order to store any diagnosis clusters associated with this record.

DIAGNOSIS CODES & RISK ADJUSTMENT

MODULE 6 – DIAGNOSIS CODES & RISK ADJUSTMENT

Purpose

It is neither the intention of this module nor the purpose of this training to provide diagnostic coding training. However, this module does provide Risk Adjustment organizations with an introduction to diagnosis coding and stresses the importance of accurate diagnosis documentation and coding for risk adjustment. The module first explains the structure and layout of the official Centers for Medicare & Medicaid Services (CMS) diagnosis coding set-- the International Classification of Diseases, 9th Revision, Clinical Modification (ICD-9-CM). The module also discusses the diagnosis coding guidelines that apply to the ICD-9-CM, and how following these guidelines ensures accurate risk adjustment. The module demonstrates how verification of compliance with coding guidelines depends upon accurate documentation in the medical record. Finally, the module provides information to assist MA organizations in communicating with their physicians regarding proper documentation and diagnosis coding.

Learning Objectives

At the completion of this module, participants will be able to:

- Identify the background, key terms, and organization of ICD-9-CM.
- Describe the coding update process, recent and proposed changes impacting risk adjustment, and the status of ICD-10-CM.
- Apply official coding guidelines to common Medicare diagnoses and understand the impact on associated Hierarchical Condition Category (HCC) assignment.
- Define and identify V codes and E codes in the HCC model.
- Describe the importance of ICD-9-CM and medical record documentation to risk adjustment.
- Identify resources available for additional training and policy formation regarding documentation and coding.

ICON KEY

Example

Reminder

Resource

6.1 Introduction

Medicare uses ICD-9-CM as the official diagnosis code set for all lines of business including determination of risk adjustment factors. MA organizations must:

- Implement procedures to ensure that diagnoses are coming from physician, hospital inpatient, or hospital outpatient provider types.
- Submit all relevant ICD-9-CM diagnosis codes for each beneficiary.
- Submit unique diagnoses at least once during the risk adjustment data reporting period.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

The source medical record documentation that supports each coded diagnosis must be obtainable and demonstrate adherence to official coding guidelines.

Relevant diagnoses are defined as those diagnoses collected from one of the three provider types that are used in the Risk Adjustment models (i.e., CMS-HCC, ESRD and RxHCC models).

This module emphasizes physician documentation and reporting of diagnosis codes. Historically, physician reimbursement in fee-for-service is primarily based on procedures or services rather than diagnoses, and physicians are very familiar with documentation guidelines for procedures and services. Physicians generally are not as familiar with diagnosis codes and their associated documentation guidelines as they are with procedure coding rules. The Risk Adjustment models depend upon accurate diagnosis coding, which means that physicians must fully understand and comply with documentation and coding guidelines for reporting diagnoses.

6.1.1 Benefit to the MA Organization and Physician

Benefits to the MA organization and physician are illustrated in Table 6A.

TABLE 6A – BENEFITS TO MA ORGANIZATIONS AND PHYSICIANS

A basic understanding of ICD-9-CM process and guidelines assists MA organizations in:
• Interpreting and designing management reports. • Determining possible causes of ICD-9-CM errors. • Communicating diagnosis-related collection issues to the provider staff. • Developing and maintaining information systems that meet the clinical data collection needs of the organization. • Understanding clinical issues important to beneficiaries. • Planning for future MA organization services.
Medical record documentation and coding impact several issues important to the physician and MA organization including:
• Accurate reimbursement. – ICD-9-CM codes are the basis of the Risk Adjustment models. – Accurate diagnosis codes are a result of clear, consistent, and complete documentation. – CMS may verify the accuracy of the diagnoses submitted relative to the medical record documentation. • Communication among all members of the health care team. • Evaluation of the care provided. • Research and education. • Practice patterns.

6.2 Structure and Terminology of ICD-9-CM

ICD-9-CM diagnosis codes are 3- to 5-digit codes used to describe the clinical reason for a patient's treatment. They do not describe the service performed, just the patient's medical condition. For any classification system to be reliable, the application of the codes must be consistent across users.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

Therefore, CMS, the American Hospital Association (AHA), the American Health Information Management Association (AHIMA), and the National Center for Health Statistics (NCHS) together have developed official coding guidelines. These guidelines are available on: www.cdc.gov/nchs/data/icd9/icdguide.pdf. The diagnosis portion of ICD-9-CM consists of two volumes: the Disease Tabular and the Disease Index.

- **The Disease Tabular (Numeric)** is also known as Volume I of ICD-9-CM. It is a numeric listing of codes organized primarily by body system. The Disease Tabular provides much more detail than the Alphabetic Index on conditions included and excluded in the code selected. Another code in the same category may represent the diagnostic description better than the one indicated in the Disease Index.
- **The Disease Index (Alphabetic)** is also known as Volume II of ICD-9-CM. It is an index of all diseases and injuries categorized in ICD-9-CM. When a code is listed after the description, it means the reader should look up that code in the Disease Tabular section to determine if that is the most specific code to describe the diagnosis. The index is organized by main terms and subterms that further describes or specifies the main term. In general, the main term is the condition, disease, symptom, or eponym (i.e., disease named after a person), not the organ or body system involved.

6.2.1 Special Notes and Abbreviations

Throughout ICD-9-CM, there are notes and cross references to assist the coder in arriving at the most accurate code according to official coding guidelines. Examples include:

Excludes notes: Informs the coder which diagnosis codes are not included in the code selected.

Use Additional Code note: Informs the coder that more than one code is needed to fully describe the condition and gives examples of common associated conditions.

Not otherwise specified (NOS): Basically means "unspecified." The documentation does not provide additional information to assign a more specific code in the particular category. In many (but not all) code categories, the fourth digit "9" signifies an unspecified code.

Not elsewhere classified (NEC) also is present in ICD-9-CM. It is used when the medical record documents a condition to a level of specificity not identified by a specific ICD-9-CM code. In some cases the fifth digit "8" represents an NEC code.

6.2.2 Supplemental Classifications and Tables

Included in Volumes I and II are supplemental classifications and special tables that provide additional guidance in determining the most accurate code.

- **V codes** are a section of ICD-9-CM diagnosis codes that represent factors that influence health status or describe contact with health services. They are used to describe those circumstances or reasons for encounter other than for disease or injury. Selected V codes are included in the Risk Adjustment models and are described later in this module.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DIAGNOSIS CODES & RISK ADJUSTMENT

- **E codes** are a supplemental classification included in ICD-9-CM and are used for reporting external causes of injuries and poisonings. The Risk Adjustment models include codes E950-E959, describing suicide or self-inflicted injuries.
- **Neoplasm Table** located in the Alphabetic Index (see *Neoplasm*) lists all cancer codes by site and nature of the disease (e.g. malignant primary or secondary, benign, or unspecified behavior).
- **Table of Drugs and Chemicals** is located at the end of the Alphabetic Index. It lists drug classifications; as well as specific names of drugs; identifies the code for poisoning by that drug; and the associated E code to specify if the poisoning was accidental, an adverse effect (therapeutic use), suicide attempt, assault, or undetermined.

6.3 ICD-9-CM Updates

To assist users of ICD-9-CM in interpreting and clarifying the guidelines, as well as publishing updated codes and applications, the AHA Central Office on ICD-9-CM publishes quarterly official code advice in *Coding Clinic for ICD-9-CM*. The *Coding Clinic for ICD-9-CM* is the approved resource to update and clarify the use of ICD-9-CM. The small volumes (typically about 20 pages) include clarifications of previous advice and guidelines, or new information on a specific diagnosis coding practice by means of articles and a question and answer section.

The ICD-9-CM diagnosis code listing is updated on October 1 and April 1 (beginning April 2005). The ICD-9-CM Coordination and Maintenance Committee holds a public forum for requested updates and publishes a transcript of their recommendations on the CMS website and in the *Federal Register*. Revisions discussed at the April and December meetings generally become effective in October the following year. A complete listing and description of annual updates are available in *Coding Clinic for ICD-9-CM* during the fourth quarter of each year. More information on the process for updating ICD-9 codes may be found at http://www.cms.hhs.gov/ICD9ProviderDiagnosticCodes/01_overview.asp.

Note: There were no new ICD-9 codes implemented in April 2006. The next update to ICD-9-CM will be in October 2006. The annual ICD-9-CM diagnosis codes update may result in updates to the list of diagnosis codes used in the Risk Adjustment models. CMS posts a list of new codes in the CMS-HCC model annually, prior to the codes taking effect on October 1 and April 1.

The ICD-9-CM coding guidelines are not updated as frequently as the list of diagnosis codes. The most recent official guideline revision is published in *Coding Clinic for ICD-9-CM*, December 2005.

6.3.1 Diagnosis Codes Phase-in Schedule

As described in Table 6B below, starting with 2008 payment, the list of acceptable ICD-9-CM codes for the CMS-HCC, ESRD and RxHCC risk adjustment models for risk adjustment for any given payment year will comprise the list of published NCHS/CMS codes that are valid for the payment year.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

TABLE 6B – RISK ADJUSTMENT PHASE IN SCHEDULE FOR NEW LISTS OF DIAGNOSIS CODES

Year of Payment	Date Collection Period	Description/Source of Codes
2007	1/06 – 12/06	The list of codes is published on our website at: http://www.cms.hhs.gov/MedicareAdvgtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage , which lists acceptable codes by years.
2008	1/07 – 12/07	The list of codes is published on our website at: http://www.cms.hhs.gov/MedicareAdvgtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage
2009	1/08 – 12/08	Valid diagnoses in Fiscal Years 2007, 2008
2010	1/09 – 12/09	Valid diagnoses in Fiscal Years 2008, 2009
2011	1/10 – 12/10	Valid diagnoses in Fiscal Years 2009, 2010

6.3.2 International Classification of Diseases 10th Revision, Clinical Modification (ICD-10-CM)

ICD-10-CM is the clinical modification of ICD-10, which was adopted by the World Health Organization in July 2000. In 1994, the NCHS began a comprehensive evaluation of ICD-10-CM to determine if it is a significant improvement over ICD-9-CM and should be implemented in the United States. The new system was tested and results were favorable. In November 2003, the National Committee on Vital and Health Statistics recommended that the Secretary of the Department of Health and Human Services (HHS) approve ICD-10-CM for all lines of business. The Secretary of HHS is currently studying this recommendation. To implement this new coding system as part of the Health Insurance Portability and Accountability Act (HIPAA), the Secretary will publish a notice of proposed rule-making, and request public comment on the new policy.

6.4 Coding Guidelines Impacting the CMS-HCC Model

Standard ICD-9-CM coding practices support the CMS-HCC model. In all cases, the documentation must support the code selected and substantiate that the proper coding guidelines were followed. Data validation ensures that both are appropriate. Upcoding or changing diagnoses to obtain higher reimbursement without supporting source documents is fraudulent. However, thoroughly reviewing documentation and coding practices through internal auditing procedures ensure that data have been reported correctly and that appropriate reimbursement is received. This benefits both the MA organization and physician/provider. Several guidelines that impact physician documentation and reporting of diagnosis data are listed in the following sections.

6.4.1 Co-Existing and Related Conditions

The instructions for risk adjustment implementation refer to the official coding guidelines for ICD-9-CM, published at www.cdc.gov/nchs/icd9.htm and in the *Coding Clinic*. Physicians should “code all documented conditions that co-exist at the time of the encounter/visit, and require or affect patient care treatment or management. Do not code conditions that were previously treated and no longer exist. However, history codes (V10-V19 not in HCC model) may be used as secondary codes if the historical condition or family history has an impact on current care or influences treatment.”

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

Co-existing conditions include chronic, ongoing conditions such as diabetes (250.XX, HCCs 15-19), congestive heart failure (428.0, HCC 80), atrial fibrillation (427.31, HCC 92), chronic obstructive and pulmonary disease (496, HCC 108). These diseases are generally managed by ongoing medication and have the potential for acute exacerbations if not treated properly, particularly if the patient is experiencing other acute conditions. It is likely that these diagnoses would be part of a general overview of the patient's health when treating co-existing conditions for all but the most minor of medical encounters.

Co-existing conditions also include ongoing conditions such as multiple sclerosis (340, HCC 72), hemiplegia (342.9X, HCC 100), rheumatoid arthritis (714.0, HCC 38) and Parkinson's disease (332.0, HCC 73). Although they may not impact every minor healthcare episode, it is likely that patients having these conditions would have their general health status evaluated within a data reporting period, and these diagnoses would be documented and reportable at that time.

MA organizations must submit each relevant diagnosis at least once during a risk adjustment reporting period. Therefore, these co-existing conditions should be documented by one of the allowable provider types at least once within the data reporting period.

Another type of co-existing conditions is symptoms. Symptoms that are integral to an underlying condition should not be coded.

Example: 1

Initial myocardial infarction (410.91, HCC 81) is a specific condition that, when coded, would eliminate the need to code symptoms of that condition. For example, unstable angina (411.1, HCC 82) or angina pectoris (413.9, HCC 83) are symptoms of initial myocardial infarction and various other cardiovascular conditions and would not typically be coded in addition to the underlying problem.

6.4.1.1 Combination Codes

Often ICD-9-CM combines two or more conditions into one code when both conditions occur together or when one is a manifestation of the other. When a combination code fully describes the encounter, the combination code is reported, not the separate component codes. However, when ICD-9-CM instructions include "Code also" notes, follow the directions to fully describe the encounter.

Example: 2

Hypertension (401.9) is not in the risk adjustment model; however it may be associated with other conditions resulting in combination codes that are in the model. The documentation must specifically and directly connect the conditions using terms such as "due to" or "associated with" hypertension. The mere listing of the diseases in the same paragraph or diagnosis list does not assume the connection. For example "congestive heart failure *due to* hypertension" is coded 402.91 (hypertensive heart disease with CHF, HCC 80). Other examples include hypertensive renal disease with renal failure (403.91, HCC 131) and hypertensive heart and renal disease with heart failure and renal failure (404.93, HCC 131 & 80).

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

Code also combinations

Some codes have suggestions of related codes that might further explain the exact nature of the condition. While these codes are not required to be present, in many cases a second code is appropriate and should be utilized.

Example: 3

Some diabetes codes carry "Code also" instructions that impact directly on the Risk Adjustment models.

- If a patient has diabetic retinopathy (250.50, HCC 18), the tabular section requires a code for also the manifestation (if known). The ICD-9-CM offers several different manifestations, such as blindness (369.00-369.9, not in the CMS-HCC model) or proliferative diabetic retinopathy (362.02, HCC 119). Here, coding the correct manifestation is essential to correct HCC assignment.
- Diabetic ulcers are one of the conditions covered under diabetes with other specified manifestations (250.80, HCC 16). If ulcers are the specific manifestation, the guidelines say to code also the site of the ulcer, such as lower extremity (707.10, HCC 149). If the specific manifestation is diabetic bone changes (731.8), that code is not in the CMS-HCC model, but should be coded as instructed in the tabular section. Again, coding the correct specific manifestation ensures appropriate HCC assignment.

6.4.2 Unconfirmed Diagnoses

Physicians and hospital outpatient departments shall not code diagnoses documented as "probable," "suspected," "questionable," "rule out," or "working." Rather, the condition(s) shall be coded to the highest degree of certainty known for that encounter/visit, such as symptoms, signs, abnormal test results, or other reason for the visit. CMS recognizes that this is an area where the physician-reported diagnosis and hospital inpatient diagnosis for the same encounter may disagree, particularly since hospital inpatient rules allow for coding of suspected conditions as if they were confirmed.

It also is understood that the physician record is not a static document. Positive test results and notations regarding contact with the patient for a revised plan of treatment often are added to the record several days after the patient encounter. When these addenda are made, corrections or additions to the diagnoses reported to MA organizations may be recommended, particularly if the HCC assignment is impacted.

Example: 4

A physician removes a mole during an office visit and sends the specimen for pathology. The diagnoses documented are "suspicious skin lesion" (709.9, not in model) and "rule out melanoma." At this point, the diagnosis 709.9 may be submitted, but the diagnosis of melanoma may not. The pathology report is returned several days later and confirms malignant melanoma (172.9, HCC 10). The physician reviews the findings, initials the report, and documents in the record the results and notification to the patient. Since the removal of the mole was done during the office visit, the new code (172.9, melanoma) should be submitted with that date of service.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

6.4.3 Clinical Specificity in Documentation

Clinical specificity involves having a diagnosis fully documented in the source medical record instead of routinely defaulting to a general term for the diagnosis. It is important to understand medical terminology in order to identify terms in the medical record that may be a more specific description of a general term. Communication with the physician is key to improving documentation skills that allow for more specific coding. The following examples are guidelines and specific conditions selected from various chapters of ICD-9-CM (e.g., Circulatory, Respiratory, Neoplasm, etc.) that are representative of documentation and coding decisions that impact HCCs.

The first three examples involve situations in which a physician may use the most common code for all forms of a disease and conditions. Remember, this practice has had no impact in the past on physician reimbursement. With the Risk Adjustment models, physicians must be careful to code the correct forms and manifestations of diseases and conditions.

Example: 5

Anemia (285.9) is the most commonly coded form of anemia in physician offices. However, there are many types of anemia. Some are in the models and some are not. If the term "neutropenia" is used to describe the anemia, it must be coded to the more specific diagnosis code 288.0 (agranulocytosis), which groups to HCC 45. "Refractory" anemia is coded 238.7 (HCC 44). It is important that physicians code these types of anemia accurately.

Example: 6

Pneumonia (486) unspecified is not in the model. If the organism responsible for the pneumonia (HCC 111-112) is known or if the physician documents that the patient aspirated prior to developing pneumonia (507.0 HCC 111), the more specific code should be reported.

Example: 7

Mental disorders in the HCC models require particular attention to specific wording in documentation and coding. Episodic mood disorders (296.XX, HCC 55) are mental diseases that include mood disturbances such as major depression (296.2X-296.3X). Physicians are encouraged to carefully document the characteristics of the mood disturbance (e.g., mania, depression, single episode, recurrent episode, circular) and use specific mental disorder terminology in the final diagnosis. The coder is cautioned to exactly code only the narrative provided by the physician in the final diagnosis and not make any further assumptions based on the patient work-up. For example, in coding depression, careful use of the ICD-9-CM index directs the coder to the correct type documented. If the physician does not document specific descriptor terms such as "major" or "recurrent", then code 311 (depression, not otherwise specified, not in the model) is used.

Use of "history of." In ICD-9-CM, "history of" means the patient no longer has the condition and the diagnosis often indexes to a V code not in the HCC models. A physician can make errors in one of two ways with respect to these codes. One error is to code a past condition as active. The opposite error is to code as "history of" a condition when that condition is still active. Both of these errors can impact risk adjustment.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

Example: 8

The diagnosis statement "history of hip fracture" is not coded as a current hip fracture (820.8, HCC 158), but with a V code for orthopedic aftercare (V54.XX) or history of injury (V15.5), if appropriate. Neither "history of" code is in the HCC models. If a patient has a current acute condition, then the "history of" wording should not be used to describe the recent occurrence.

Example: 9

The physician may actually intend to communicate that a condition is ongoing, but note the "history of" a condition. An example of this is "history of Hepatitis C" (V12.09 personal history of other infectious disease). Hepatitis C generally presents as a chronic condition (070.54, HCC 27) that is rarely fully eradicated. While assigning V12.09 is not necessarily an example of incorrect coding, it may indicate that the physician office is not coding correctly. Again, communication and clear documentation are essential to make the appropriate determination.

Correct use of associated terms. Some conditions are described by more than one term depending on the clinical presentation and medical terminology practices of the physician. Coders must be careful not to assign a diagnosis to conditions that are not specified by the physician and cannot be validated by the medical record.

Example: 10

Cancer coding requires detailed specificity. Several different HCCs exist for cancer, and assigning the appropriate HCC requires closely following the cancer coding guidelines. The HCC varies depending on whether the cancer is a primary site or a secondary site. Coding guidelines state that if the malignant status is not specified, then code to the primary site, except for the following: bone, brain, diaphragm, heart, liver, lymph nodes, mediastinum, meninges, peritoneum, pleura, retro peritoneum, and spinal cord. Applying this rule assures that the correct HCC for secondary malignant neoplasm is assigned rather than an HCC for primary malignant neoplasms. [For example, bone cancer (primary) (170.9, HCC 9) vs. bone cancer (secondary) (198.5, HCC 7). Since the cancer is not specified as primary or secondary, and bone is one of the sites listed above, the correct HCC is 7.]

Cancer codes are part of a multi-category HCC hierarchy. It is not unusual for a patient to have more than one type of cancer. However, only the most severe and costly form of cancer is recognized in the HCC models. Even if the type of cancer included in HCC 7 is of a different site or origin than any other cancer the patient has and is included in HCCs 8, 9, and 10, the HCC models drop it.

Complete Neoplasm guidelines are included in the Resource Guide.

6.4.4 Coding to the Highest Specificity-Fourth and Fifth Digits

ICD-9-CM codes have three, four, or five digits. Diagnoses should be reported to the highest level of code available for that category. In selected cases, the fifth digit may impact whether the code is in the models, but at a different HCC level, which may impact reimbursement.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

DIAGNOSIS CODES & RISK ADJUSTMENT

Example: 11

Myocardial infarction (MI) (heart attack, 410.XX) is unspecified or subsequent episode fifth digits 0 and 2 are in HCC 82. All initial care for a new MI (from physician office to emergency room to hospital) should have the fifth digit of "1" and group to HCC 81.

Example: 12

Diabetes (250.XX) codes group into HCCs 15, 16, 17, 18, or 19 depending on the fourth digit applied. The fourth digit designates manifestations or complications of diabetes such as neurological conditions, eye disorders, or diabetic ulcers.

At a minimum, the submitted ICD-9-CM codes must be sufficiently specific to allow appropriate grouping of the diagnoses in the risk adjustment model. CMS encourages MA organizations to use the full level of specificity in submitting data to provide the most accurate coding and grouping of codes in the model.

6.4.5 V Codes

Health status situations that should be described by V codes are common in physician documentation. Those that impact risk adjustment include HIV status, transplant status, artificial opening status or maintenance, dialysis status or encounter, and amputation status. These V codes are used in several HCCs.

6.4.6 E Codes

The HCC models include codes E950-E959 describing suicide or self inflicted injuries (HCC 55, Major Depressive Disorders). The injury or poisoning diagnosis codes that would be reported with these E codes are not included as relevant diagnoses. Therefore, it is important that the physician documents and codes the appropriate external cause of all self-inflicted injuries and poisonings so the MA organization can report them as relevant diagnoses.

The complete list of V codes and E codes in the model is provided in the Resource Guide.

6.5 Supporting Documentation Summary

Accurate coding begins with complete documentation. Characteristics of effective documentation include quality documentation as a team effort that may require some intervention by the MA organization. Table 6C lists documentation considerations.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DIAGNOSIS CODES & RISK ADJUSTMENT

TABLE 6C – DOCUMENTATION CONSIDERATIONS

Documentation Guidelines • Reported diagnoses must be supported with medical record documentation. • Medical records and codes are subject to CMS validation. • Characteristics of acceptable documentation include: – Clear. – Concise. – Consistent. – Complete. – Legible.
Physician Documentation and Communication Tips • Document and report co-existing diagnoses. • Communicate issues regarding inadequate documentation. • Adhere to proper methods for appending (late entries) or correcting inaccurate data entries. – Lab/Radiology results. – Strike through, initial, and date. Do not obliterate. • Use only standard abbreviations. • Identify patient and date on each page of the record.
SOAP Notes • SOAP note format assists both the physician and record reviewer/coder in identifying key documentation elements. SOAP stands for: – Subjective: How the patients describe their problem or illness. – Objective: Data obtained from examinations, lab results, vital signs, etc. – Assessment: Listing of the patient's current condition and status of all chronic conditions. How the objective data relate to the patient's acute problem. – Plan: Next steps in diagnosing problem further, prescriptions, consultation referrals, patient education, and recommended time to return for followup.

6.6 Provider and Staff Training

Remaining current on medical record documentation and coding guidelines is important to ensure accurate risk adjustment payment. Table 6D provides examples of resources available for medical record documentation and coding guidelines.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

DIAGNOSIS CODES & RISK ADJUSTMENT

TABLE 6D – DOCUMENTATION AND CODING RESOURCES

TRAINING SOURCES	DESCRIPTION
Official Coding Guidelines on CDC Website Available at www.cdc.gov/nchs/icd9.htm	The Official ICD-9-CM Coding Guidelines are available as an Adobe .pdf file, or as a CD-ROM. The CDC site has the .pdf file for download, as well as information to order the CD-ROM from the Government Printing Office.
Coding Clinic for ICD-9-CM Available through AHA.	Published quarterly by the AHA. It is the official publication for ICD-9-CM coding guidelines and advice as designated by the AHA, AHIMA, CMS, and the NCHS.
American Health Information Management Association (AHIMA) www.ahima.org	AHIMA is a professional association for health information management professionals. Members make information accessible to healthcare providers and work in the healthcare industry and in the public sector by managing, analyzing, and using data that are critical to patient care. The AHIMA Catalog online offers tools for coders such as audio seminars, books, and continuing education courses.
American Academy of Professional Coders (AAPC) www.aapc.com	AAPC provides education and certification for professional medical coders. Certifications focus on physician practice (CPC) and hospital outpatient facility (CPC-H) coding. Students learn Current Procedural Terminology (CPT) Codes, diagnosis codes (ICD-9-CM), and Healthcare Common Procedure Coding System (HCPCS) while focusing on HIPAA, Office of Inspector General (OIG), and Medicare compliance.
American Medical Association (AMA) www.ama-assn.org	AMA is an advocate of physician and patient rights. Coders may access the AMA Press Online Catalog to find current resources on medical record documentation and the medical record review process.
American Hospital Association (AHA) www.aha.org	AHA is a national organization that serves and represents hospitals, healthcare networks, and their patients. The AHA Online Store offers coders online reference materials including ICD-9-CM, HCPCS, and testing and certification for HIPAA.
Local Colleges Check local community and 4-year colleges for courses.	These provide online courses in clinical coding and guidelines.

RISK ADJUSTMENT DATA VALIDATION

MODULE 7 – RISK ADJUSTMENT DATA VALIDATION

Purpose (Slide 2)

To provide participants with an understanding of the risk adjustment data validation process.

Objectives (Slide 3)

- Identify
 - The purpose and goals of risk adjustment data validation
 - The stages of risk adjustment data validation
 - Risk adjustment data discrepancies
- Understand
 - The components of a medical record request
 - Requirements for acceptable medical record documentation
 - Payment adjustments and appeals
- Provide
 - Recommendations and lessons learned.

ICON KEY

Example

Reminder

Resource

7.1 Risk Adjustment Data Validation

7.1.1 Purpose of Risk Adjustment Data Validation (Slide 4)

Data validation occurs after risk adjustment data are collected and submitted, and payments are made to the Medicare Advantage (MA) organizations. CMS uses medical record review to validate the accuracy of risk adjustment diagnoses submitted by MA organizations for payment. Future data validation activities may include other data monitoring activities.

Risk adjustment data validation is the process of verifying that diagnosis codes submitted for payment by the MA organization are supported by medical record documentation for an enrollee.

Purpose: To ensure risk adjusted payment integrity and accuracy

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT DATA VALIDATION

7.1.2 Objectives of Risk Adjustment Data Validation (Slide 5)

The primary objectives of risk adjustment data validation are to:

- Identify:
 - Confirmed risk adjustment discrepancies
 - Contracts in need of technical assistance to improve the quality of risk adjustment data
- Measure:
 - Accuracy of risk adjustment data
 - Impact of discrepancies on payment
- Improve/Inform:
 - Quality of risk adjustment data
 - The CMS-Hierarchical Condition Category (HCC) model.

7.1.3 Good Documentation = Accurate Payment (Slide 6)

Good documentation begins at the time of the patient's face-to-face encounter with the physician. The physician documents the clinical findings in the medical record. The medical record is used to determine ICD-9-CM codes. The pertinent information from the patient encounter is submitted to the MA organization for payment.

7.1.4 Guidelines for Risk Adjustment Data Validation (Slide 7)

The guidelines for risk adjustment data validation reflect the purpose and goals described above. Beginning with the CY2004 payments, validation activities incorporated the review of hospital inpatient, hospital outpatient, and physician medical records. This process reflects the implementation of the CMS-HCC model that began with CY2004 payment. Beginning with CY2006 payments, validation activities incorporated RxHCC data. This process reflects the implementation of the CMS RxHCC model that began with CY2006 payment.

Guiding Principle: The risk adjustment diagnosis must be based on clinical medical record documentation from a face-to-face encounter, coded according to the *ICD-9-CM Guidelines for Coding and Reporting*, assigned based on dates of service within the data collection period, and submitted to the MA organization from an appropriate risk adjustment provider type and an appropriate risk adjustment physician data source.

In addition to the Guiding Principle, risk adjustment data validation guidelines include the following:

- The medical record documentation must support an assigned HCC.
- Beneficiary HCCs and risk adjustment records are selected based on risk adjustment diagnoses (ICD-9 codes), provider type, and the Health Insurance Claim (HIC) number that are submitted to the Risk Adjustment Processing System (RAPS).

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

- Given the flexibility of the Guiding Principle, contracts must select **"one best medical record"** to support each beneficiary HCC identified for validation. This means the contract decides whether to submit a hospital inpatient, hospital outpatient, or physician medical record when more than one option is available.
- Since CMS does not collect provider identifiers for risk adjustment, MA organizations must be able to track and locate supporting medical record documentation.
- Once a MA organization selects the "one best medical record," the organization must identify the date of service to be reviewed to facilitate the medical record review process. The coders that are hired to review the medical records on behalf of CMS will not search beyond the date of service identified by the MA organization for the review.
- Payment adjustments are based on confirmed risk adjustment discrepancies.
- An appeals process is in place to address disagreement with a confirmed risk adjustment discrepancy.

7.1.5 Medical Record Documentation (Slide 8)

As stated in the *1997 Documentation Guidelines for Evaluation and Management Services*, "Medical record documentation is required to record pertinent facts, findings, and observations about an individual's health history, including past and present illnesses, examinations, tests, treatments, and outcomes."

7.1.6 Overview of Risk Adjustment Data Validation (Slides 9-10)

Risk adjustment data validation is the process of verifying that diagnosis codes submitted by the MA organization for payment are supported by medical record documentation for an enrollee. It involves the review of hospital inpatient, hospital outpatient, and physician medical records. Since contracts must select the "one best medical record" to validate the HCC from hospital inpatient, hospital outpatient, and physician medical records, the approach is flexible. Additionally, the data validation approach is based on the CMS risk adjustment models:

- CMS-HCC—CY 2004 and beyond for Part C
- CMS RxHCC—CY 2006 and beyond for Part D.

Hereafter for purposes of this module only, the term "HCC" refers to both CMS-HCCs and RxHCCs.

CMS contracts with two independent review contractors to conduct medical record reviews. The initial validation contractor (IVC) conducts facilitates the process and conducts the initial review of medical records. The second validation contractor (SVC) receives the discrepant medical records from the IVC, confirms risk adjustment discrepancies that are identified by the IVC, and implements the appeals process. Both IVC and SVC use certified coders to abstract diagnosis codes and validation provider type, physician data source, and date(s) of service.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

7.1.7 Risk Adjustment Discrepancies (Slide 11)

Risk adjustment discrepancies are identified when the HCC assigned based on risk adjustment data submitted by the MA organization differs from the HCC assigned after validation. Risk adjustment discrepancies affect the beneficiary risk score because of the change in HCC.

7.1.8 Data Validation Activities (Current and Future) (Slide 12)

CMS has several data validation activities on which it is or will be working. They are as follows:

- CY 2004
 - July 12, 2007: Disseminated plan-specific findings to MA organizations in the targeted sample.
 - August 29, 2007: Conducted teleconference to communicate the CY 2004 pre-reconciled medical record review national results.
 - Mid-October 2007: Anticipate mailing pre-reconciled findings to MA organizations with enrollees selected for the national sample.
- CY 2005
 - Quality checking the IVC and SVC results.
 - Anticipate releasing findings in the late fall.
- CY 2006
 - Selected contracts notified in May 2007.
- CY 2007
 - CMS to sample after final data submission deadline (January 31, 2008).

7.1.9 Risk Adjustment Data Validation Process (Slide 13)

Risk adjustment data validation occurs every year. Figure 7A illustrates the overall data validation process. This process involves the coordination of multiple entities such as CMS, MA organizations, and CMS contractors. The data validation process begins with selecting MA organizations, then beneficiaries and their respective HCCs. This occurs after the risk adjustment data submission deadline for calendar year payment. The stages of the risk adjustment data validation process are briefly described below:

- ➔ **STAGE 1 Contract Selection:** CMS designs a sampling plan to select MA organizations for risk adjustment data validation. Once the MA organizations are selected, individual beneficiaries and their HCCs are selected on the basis of the sample framework. The sample is based on payment year risk adjustment data. Every MA organization has a chance of being selected for validation.
- ➔ **STAGE 2 Medical Record Request Process:** Stage 2 is defined by three distinct segments: 1) medical record request; 2) medical record submission (contract response); and 3) medical record receipt. After the sample has been drawn, medical records are requested from the selected MA organizations. All correspondence with MA organizations related to Stage 1 is facilitated by the IVC.
- ➔ **STAGE 3 Medical Record Review:** After medical records are received by the IVC, certified ICD-9 coders review the medical records to validate the selected beneficiary HCC(s). During this stage, data discrepancies are identified. Data discrepancies occur when beneficiary medical record documentation does not match the risk adjustment data submitted for payment. A data discrepancy that results in an HCC assignment change is known as a risk adjustment

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

discrepancy. All identified risk adjustment discrepancies undergo a second, independent medical record review to confirm the discrepancy. The second medical record review is conducted by the SVC. This activity is transparent to MA organizations. There is no correspondence between the SVC and contracts during this stage.

- ➔ **STAGE 4** **Contract-Level Findings:** At this point in the data validation process, CMS communicates contract-level findings from Stage 3 to the selected MA organizations. Data discrepancies determined by medical record review are described. Additional feedback such as national and contract-level response rates and discrepancy rates are provided. Contract patterns, systemic problems, and contracts in need of additional technical assistance may also be identified during this stage.
- ➔ **STAGE 5** **Payment Adjustment:** The CMS CBC Director makes all decisions with regard to payment adjustment based on validation findings. A payment adjustment is based on a confirmed risk adjustment discrepancy. If the CMS CBC Director decides to make the adjustment, then the change in the risk adjustment payment is applied. Payment adjustments are typically reflected in the Monthly Membership Report (MMR).
- ➔ **STAGE 6** **Appeals:** After payment adjustments are made, MA organizations have the option of appealing the change. In the event that a contract chooses to appeal, then the organization has 60 days from the date of the payment adjustment to respond. This process is fully described in the *Appeals* section of this module.
- ➔ **STAGE 7** **Correct Payment:** The conclusion of the appeals process determines the correct risk adjusted payment for an MA organization. The original payment adjustment decision may stand (unchanged) or be reversed. All appeal decisions are final.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

Figure 7A – Data Validation Process

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

7.2 Components of the Risk Adjustment Data Validation Process

The key components of the data validation process include: 1) sampling; 2) the medical record request process and the receipt of medical record documentation by the IVC; and 3) the medical record review.

7.2.1 Contract Selection **STAGE 1** (Slide 14)

Sampling

Sampling for data validation is conducted on an annual basis. Sampling involves the selection of contracts, beneficiaries, and the beneficiary HCC(s). The sample is drawn from risk adjustment data submitted for the payment year (data collection period, January 1 through December 31). The sampling approach includes both random and targeted components. Some contracts may be selected randomly, while others may be targeted.

Under the CMS-HCC model, CMS expects to select a national sample for each payment year. The purpose of the national sample is to derive national net payment error and risk adjustment discrepancy estimates for the payment year. In addition to the national random sample, some targeted sampling will be employed. The targeting criteria may include:

- Patterns in the risk adjustment data that are suggestive of potential problems.
 - A contract may be targeted for data validation because the risk adjustment data for that contract showed a disproportionately high number of HCCs.
- Past performance from previous data validation years.
 - A contract may be selected for medical record review as a result of a high error rates from prior validation activities.

In addition, CMS may sample based on random selection of specific contract types(s). The medical records reviewed for a beneficiary could reflect either the entire HCC profile (all HCCs) or a subset of one or more HCCs. Every MA organization has equal opportunity of being selected.

7.2.2 Medical Record Request Process **STAGE 2** (Slides 15)

During Stage 2 CMS works with the IVC to implement the process for requesting and receiving medical records from MA organizations. Stage 2 is defined by three distinct segments: 1) medical record request; 2) medical record submission (contract response); and 3) medical record receipt.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

7.2.2.1 Medical Record Request - Initial Contact Letter (Slide 16)

On behalf of CMS, the IVC sends an initial contact letter to the Medicare compliance officer for each MA organization selected for validation. The purpose of the initial contact letter is to: 1) inform the compliance officer that the organization was selected for data validation; and 2) request a primary point of contact (either the compliance officer or a designee) to be responsible for facilitating the medical record request process for the organization.

7.2.2.2 Medical Record Request - Beneficiary List (Slide 16)

A list of contract-specific selected beneficiaries for each selected MA organization is sent to the confirmed primary contact person for the MA organization. The beneficiary list is generated based on risk adjustment data submitted for the enrollee sample. The list may be provided to MA organizations either in advance of or in conjunction with the medical record request instructions package. The purpose of the list is to provide MA organizations with ample opportunity to easily identify the selected enrollees in their systems, and establish contact with the specific provider(s) of services for those enrollees. As previously mentioned, CMS does not require or store provider identification numbers as part of risk adjustment data. Therefore, the MA organization must use data systems that can:

- Track and locate the requested medical records.
- Link a specific diagnosis to a specific provider.

The beneficiary list is provided in an electronic spreadsheet format, which displays:

- MA organization's name,
- Current Contract ID (H-number), and
- Previous Contract ID (H-number)—this information is furnished if the contract ID used during the data collection period differs from the current contract ID.

For each selected enrollee the following information is included in the beneficiary list:

- Coversheet ID number (A masked ID tracking number that can be found on the bottom left of each HCC coversheet)
- Enrollee Last Name
- Enrollee First Name
- Enrollee Date of Birth
- Enrollee HIC Number
- Validation HCC
- ICD-9-CM code(s) related to the validation HCC—you must submit a medical record to support the enrollee HCC.

Note that the beneficiary list will contain a line for each enrollee's unique HCC. This means that if an enrollee has multiple different HCCs, each line for the enrollee will comprise a unique HCC and all associated risk adjustment diagnoses that were submitted by your organization for that HCC. Therefore, a complete enrollee HCC profile could comprise multiple lines on the beneficiary list. Table 7A displays a sample beneficiary list. The information shown on the line with each beneficiary HCC reflects all ICD-9 codes submitted by the MA organizations for that HCC.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

Example 1

For beneficiary Joe K. Smith – HCCs 38, 80 and 16 will be validated. For HCC 38, the MA organization may rely on one of the five ICD-9 codes associated with that HCC to identify the date of service and provider, and **"one best medical record"** for review. The organization could also opt to identify a provider that rendered a diagnosis that is not on the list, but will map to HCC 38. Contracts should take advantage of whichever approach yields the most efficient results.

TABLE 7A – BENEFICIARY LIST

H1111-10007-HCC79						HCC 79	42741	51883			

7.2.2.3 Medical Record Request - Comprehensive Instructions and Coversheets (Slide 16)

A comprehensive instructions package is sent to MA organizations to facilitate the request for submitting medical records. This package will at a minimum include the following:

- Detailed instructions for requesting records from providers and submitting to the IVC;
- Guidance and best practices to further assist organizations with the request process;
- A list of the beneficiaries (as previously described) and their HCCs;
- CMS letters addressed to providers describing the overall risk adjustment data validation approach;
- HIPAA fact sheet to discuss HIPAA privacy;
- CMS sample request letters to providers; and
- Coversheets for each enrollee HCC.

The organizations must request records from hospital inpatient, hospital outpatient, or physician providers. When requesting medical records from your providers, be sure to attach the HIPAA fact sheet and include your MA organization contact information. This will facilitate the provider's contacting you in the event the provider has questions with regard to the medical record request.

2007 Risk Adjustment Data Training For Medicare Advantage Organizations Participant Guide

RISK ADJUSTMENT DATA VALIDATION

When requesting medical records from providers, the organization must make every effort to limit disclosure of beneficiary health information to the minimum necessary as it pertains to the specific diagnosis (es) as rendered by the provider. This means that if the organization finds a date of service for which one provider rendered a diagnosis then the organization should only request from that provider medical record documentation for the respective diagnosis.

7.2.3 Medical Record Submission (Slide 17)

MA organizations must submit medical records and all corresponding coversheets for each enrollee HCC to the IVC. In responding to the medical record request, MA organizations must select the "one best medical record" to support the enrollee HCC.

7.2.3.1 Medical Record Submission and Coversheets (Slide 17)

Under the CMS-HCC model, beneficiaries could have more than one HCC. Therefore, one coversheet will be generated and provided for every HCC being validated for each selected beneficiary. Each coversheet shows every risk adjustment diagnosis that was submitted to RAPS and generated the same HCC. Attachment A provides a sample beneficiary HCC coversheet with directions for completion.

Note that if one enrollee has two different HCCs, the contract will receive two separate HCC coversheets for that enrollee. In addition, one medical record could be used to support multiple HCCs. If you identify a medical record that supports more than one HCC selected for validation, then complete each HCC coversheet, and attach them to that the one medical record.

The coversheet is where the concept of the "one best medical record" is applied. The coversheet will at a minimum provide enrollee demographic information, stored risk adjustment data (HCC and ICD-9 codes). The MA organization must select and submit the best medical record and indicate on the coversheet the provider type and date(s) of service to be reviewed for the HCC. The date(s) of service could include a range of consecutive dates if the record is from a hospital inpatient provider or one date if the record is from a hospital outpatient or physician provider.

All coversheets must be returned regardless of whether a medical record is submitted to support the HCC. MA organizations must complete the coversheets to identify the information being submitted. Complete medical record coversheets are essential to timely medical record review.

If an MA organization is unable to submit the required medical record(s) to support the enrollee HCC(s), it must complete the coversheet as per the instructions package prior to submitting the coversheet to the IVC. This will inform the IVC that no medical record could be obtained to support the HCC.

CMS reimburses MA organizations for each medical record submitted per beneficiary HCC; however, only one medical record per beneficiary HCC will be accepted for reimbursement. If one record supports more than one beneficiary HCC, then the contract will receive reimbursement for one record. Reimbursement checks are sent by the IVC after completion of data validation activities.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT DATA VALIDATION

Guidance for Submitting Medical Records to the IVC

1. Do not submit medical records for date(s) of service that occurred outside of the data collection period.
2. If you select an inpatient discharge to substantiate the HCC(s), submit the entire inpatient medical record. Do not just submit parts of the record that may state the diagnosis as inpatient coding guidelines may differ from those for outpatient settings depending on the diagnosis.
3. Several organizations choose to submit medical record documentation that reflects only the physician face-to-face portion of an inpatient record when the entire inpatient record is not available. When this is the case complete the coversheet to reflect a "physician" provider type and the date of service in the medical record for which the physician visit occurred during the inpatient stay. Only submit the medical record page(s) for the selected physician face-to-face.

If the entire inpatient medical record is available, the contract should opt to submit the entire record and complete the coversheet as appropriate to reflect the date range for the stay. It is likely that this approach would not limit the amount of diagnoses to be abstracted for the stay.

4. In order to prevent medical record information from inadvertently being attached to the wrong coversheet(s), be sure that all coversheets are stapled to the record whenever possible. We understand that this may be difficult to do with large inpatient medical records. If necessary, consider the use of rubber bands to attach coversheets with the records. Do not submit loose documentation or documentation with only paper clips.
5. If you are submitting for multiple organizations (i.e., those with different "H" numbers), separate the records for the different organizations.
6. Unless instructed by the IVC, submit only one coversheet per enrollee HCC. Only one coversheet—the first—will be accepted. If you are unsure whether a record substantiates an HCC, you must determine whether to submit it or wait for another record.
7. Do not clip together medical records for multiple different enrollees.
8. When in doubt about the clinical documentation in a medical record and you have no viable substitute, send the medical record even if you do not believe the record supports the HCC. We may find that the record does support the HCC and/or could contain clinical information that result in risk adjustment ICD-9 codes that were not previously submitted CMS.
9. **SUBMIT ALL MEDICAL RECORDS AND COVERSHEETS BY THE OFFICIAL DEADLINE.** In the event that you are unable to submit a medical record(s), you must complete as per the instructions package and return the coversheets to the IVC.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT DATA VALIDATION

7.2.4 Medical Record Receipt by the IVC and Reimbursement (Slide 18)

Once medical records are selected by the MA organization, the organization must submit them to the IVC for data validation. Upon receipt, the IVC will log medical records into a chart-tracking database on the basis of the barcode on each medical record coversheet. This method identifies the date the medical record was received for a given HCC. To protect patient confidentiality, all records are stored in a secure, designated area accessible only to those having direct responsibility for risk adjustment data validation activities.

When the coversheet and medical record are received by the IVC, the following intake process is initiated:

- Administrative check—confirms beneficiary demographic information, including name, HIC number, and service date within or outside of the collection period.
- Clinical check—determines whether the:
 - Record is from an appropriate provider type.
 - Pertinent components needed for coding are included in the record.
 - Record is dated and signed.

Based on the administrative and clinical checks, the IVC may elect to contact (telephone call or email message) the MA organization to request clarification or additional information. This step is provided as a service to the organization and normally is performed only if the records are received in a timely manner.

After intake, the medical record (with coversheet) is assigned to a category. The possible categories include:

- Identified as "okay" for review;
- Problem; or
- Missing medical record.

Throughout the data validation process, CMS and its contractors will make a reasonable effort to alert MA organizations of medical record documentation issues and allow contracts the opportunity to correct problems.

7.2.4.1 Medical Record Documentation **STAGE 3** **(Slide 19)**

Proper medical record documentation is the key to accurate payment and successful data validation. The accurate assignment of ICD-9-CM diagnosis codes is based on thorough medical record documentation. Therefore, risk adjusted payment accuracy also relies on medical record documentation. Remember, a beneficiary HCC is assigned based on a diagnosis cluster that has been submitted to RAPS.

Below are some general guidelines for medical record documentation, based on the sources of the documentation.

**2007 Risk Adjustment Data Training
For Medicare Advantage Organizations
Participant Guide**

RISK ADJUSTMENT DATA VALIDATION

**7.2.4.2 General Guidelines for Hospital Inpatient Medical Record Documentation
(Slide 20)**

Hospital inpatient medical records are generally considered to be the most reliable source of diagnostic coding because hospitals employ certified professional coders.

Coding

According to the *ICD-9-CM Official Guidelines for Coding and Reporting*, for hospital inpatient stays a medical record reviewer should code the principal diagnosis and:

...all conditions that coexist at the time of admission, that develop subsequently, or that affect the treatment received and/or length of stay. Diagnoses that relate to an earlier episode which have no bearing on the current hospital stay are to be excluded.

The required medical record documentation should include, but is not limited to, the following:

- Face sheet
- History and physical exam
- Physician orders
- Progress notes
- Operative and pathology reports
- Consultation reports
- Diagnostic (radiology, cardiology, etc.) testing reports
- Discharge summary.

7.2.4.3 General Guidelines for Hospital Outpatient and Physician Medical Record Documentation (Slide 20)

Hospital outpatient and physician office medical records should include, but are not limited to, the following:

- Face sheet
- History and physical exam
- Physician orders
- Progress notes
- Diagnostic reports (to support documentation)
- Consultation reports

Submit all relevant medical record components needed to validate the date of service, beneficiary, the HCC, and ICD-9 code selected. When you submit medical record documentation to support only the physician face-to-face that occurred during an inpatient stay, the same medical components are needed; however, the medical record documentation will be reviewed in accordance with *Diagnostic Coding and Reporting Guidelines for Outpatient Services*.

If, however, the prosecutor believes that the court could potentially exclude or limit the RA's testimony because it borders on expert testimony, the prosecutor should alternatively notice the witness as a potential expert witness and follow the requirements of Rule 702 of the Federal Rules of Evidence. It is important for prosecutors to determine how judges in their district have typically treated RA summary testimony. In some districts, judges treat the RAs as summary expert witness and expect prosecutors to comply with the requirements for experts under Rule 702.

5. Employees of the defendant's business

If the defendant prepared her fraudulent tax returns through a business that had employees, those employees can also be valuable witnesses at trial. Employees who did not participate in preparing false tax returns could testify about the general operations of the business and how legitimate tax returns were prepared, including how tax information was obtained from clients and incorporated into tax returns. They could also testify about any training and instructions the defendant gave them about how to prepare tax returns. Employees who had a role in the preparation of false tax returns could also testify about any instructions the defendant gave them about falsifying items on those tax returns.

6. IRS Special Agent

Although calling the case agent to testify is often discouraged, as it potentially puts the entire investigation on trial and certainly makes discovery disclosure obligations more burdensome, there are certain occasions when you would want to call the IRS Special Agent who investigated the case to testify. For example, in circumstances where the Special Agent has interviewed the defendant, who has made certain favorable admissions that the prosecutor believes should be introduced at trial. If there is a second Special Agent at the interview, it would be preferable to call the non-case agent to testify instead, so long as they are able to testify concerning those statements made by the defendant.

C. Rule 404(b) evidence

In almost every fraudulent return preparer prosecution, there will be evidence of false tax returns prepared by the defendant that cannot be

excluded from sequestration. Fed. R. Evid. 615. When a witness's testimony relates only to a summary of evidence, even the rationale for the sequestration of the witness is absent. *See United States v. Charles*, 456 F.3d 249, 258 (1st Cir. 2006); *see also United States v. Strauss*, 473 F.2d 1262, 1263 (3d Cir. 1973) (purpose of excluding witnesses is "to prevent the shaping of testimony by witnesses to match that given by other witnesses") (internal citations omitted).

included in the indictment because they fall outside of the statute of limitations. The prosecutor should consider whether to offer this as “other act” evidence under Rule 404(b) of the Federal Rules of Evidence.

Rule 404(b) provides that while “evidence of any crime, wrong, or act is not admissible to prove a person’s character in order to show that on a particular occasion the person acted in accordance with the character,” evidence of any crime, wrong, or act “may be admissible for another purpose, such as proving motive, opportunity, intent, preparation, plan, knowledge, identity, absence of mistake, or lack of accident.”³⁰

In fraudulent return preparer prosecutions, the evidence of other, similarly false tax returns prepared by the defendant is typically offered to prove the defendant’s intent. In a case charged under 26 U.S.C. § 7206(1) or 7206(2) the government must prove that the defendant acted willfully, that is, that the defendant intentionally violated a known legal duty.³¹ Willfulness is rarely proved directly in any case, much less a tax case, but often is proved by circumstantial evidence of a defendant’s conduct.³² Evidence of other, similarly false tax returns prepared by the defendant is highly probative of the defendant’s intent.

The prosecutor should be cautious, however, in how much evidence to attempt to admit through Rule 404(b). While there is no bright line rule, it is prudent to make sure that the uncharged conduct is proportionate to the charged conduct. Otherwise, an objection under Rule 403 of the Federal Rules of Evidence of unfair prejudice may be sustained.³³

D. Common defenses

While, on occasion, a defendant will claim not to have prepared the false tax returns at issue in a fraudulent return preparer trial, a more typical defense is that the defendant did not act willfully because she did not know what she was doing was wrong. This commonly takes one of

³⁰ Fed. R. Evid. 404(b).

³¹ Willfulness has the same meaning in fraudulent return preparer cases as it has for other criminal tax violations: “the word ‘willfully’ in these statutes generally connotes a voluntary, intentional violation of a known legal duty.” *United States v. Bishop*, 412 U.S. 346, 360 (1973); *see also* *Cheek v. United States*, 498 U.S. 192, 200 (1991); *United States v. Ervasti*, 201 F.3d 1029, 1041 (8th Cir. 2000).

³² *See generally* *Huddleston v. United States*, 485 U.S. 681, 685 (1988) (“Extrinsic acts evidence may be critical to the establishment of the truth as to a disputed issue, especially when that issue involves the actor’s state of mind and the only means of ascertaining that mental state is by drawing inferences from conduct.”).

³³ Under Rule 403, a court may find that the probative value of an excessive number of uncharged returns is not “substantially outweighed by the danger of . . . unfair prejudice, confusing the issues, misleading the jury, undue delay, wasting time, or needlessly presenting cumulative evidence.” Fed. R. Evid. 403.

two forms: (1) the defendant did not know she reported false information on the tax returns (“blame the clients”); or (2) the defendant did not know she reported items incorrectly on the tax returns (“blame the tax law”). If the prosecutor has properly prepared the case, neither of these defenses is likely to be successful.

A “blame the clients” defense gains little traction where client-witnesses testify unequivocally that they did not provide the false information to the defendant, and where the tax returns of multiple client witnesses all contain the same, or similar falsities. This testimony is even stronger when it is corroborated by prior or subsequent tax returns of the client witnesses that were not prepared by the defendant, and that did not include similar falsities. This evidence supports the argument that the false items on the tax returns had to have come from the defendant.

A “blame the law” defense can be trickier to rebut. Often, an appeal to the jurors’ common sense is the best approach. A defendant’s scheme may be so egregious (for example, reporting wholly fake Schedule C businesses for clients) that an argument that the defendant did not know it was wrong lacks all credibility.

To support either defense, a defendant may seek to admit evidence of uncharged, non-fraudulent tax returns to support a willfulness defense. As a general rule, evidence of non-criminal conduct is irrelevant, and the fact that a defendant prepared other, accurate tax returns has no bearing on whether the tax returns charged in the indictment are false.³⁴ Accordingly, if applicable, the prosecutor should consider moving *in limine* to exclude any such evidence before trial.

E. Jury instructions

In addition to any applicable Circuit pattern jury instructions, the prosecutor can find model jury instructions for fraudulent return preparer cases in the Tax Division’s Criminal Tax Manual. Several instructions warrant particular consideration. First, a unanimity instruction can be important in a fraudulent return preparer case. That is, where a particular count in the indictment alleges that a tax return is false in more than one way, the prosecutor should consider an instruction that the jury need not find that *all* items alleged as false in the count are false, but the jury must unanimously agree on what item alleged as false is false.³⁵

³⁴ See, e.g., *United States v. Daulton*, 266 F.App’x. 381, 386 (6th Cir. 2008) (“[e]vidence of noncriminal conduct to negate the inference of criminal conduct is generally irrelevant”); *United States v. Ellisor*, 522 F.3d 1255, 1270 (11th Cir. 2008) (evidence of good conduct is not admissible to negate criminal intent); *United States v. Scarpa*, 897 F.2d 63, 70 (2d Cir. 1990).

³⁵ See, e.g., *United States v. Helmsley*, 941 F.2d 71, 93 (2d Cir. 1991).

Second, given that in some fraudulent return preparation cases the defendant's clients were knowing and willing participants in the fraud, an instruction that the culpability of the client is irrelevant to the culpability of the preparer should be used. The defense is likely to attempt to blame the clients for the falsities on their tax returns, but it is not a defense that the client also knew that the return was false.

IV. Sentencing

The defendant has been convicted at trial, and it is now time for sentencing. There are several issues the prosecutor should be prepared to address at sentencing.

A. Tax loss

1. Two-level enhancement for return preparers

First, the prosecutor should always argue that a two-level increase in the defendant's offense level is appropriate because the defendant "was in the business of preparing or assisting in the preparation of tax returns."³⁶

2. Aggravating Role Enhancement

Second, the prosecutor should consider whether the facts of the return preparer case merit an aggravating role enhancement. Aggravating role enhancements apply if the defendant was an organizer, leader, manager, or supervisor in the criminal activity and range from a two-level increase to a four-level increase.³⁷ The enhancement may be appropriate in cases where the return preparer's employees were knowingly filing false returns. It may also be appropriate if the false return scheme involved other participants responsible for creating false documents to support the fraudulently filed tax returns.

3. Relevant conduct

Third, the prosecutor should seek to include as many uncharged, but false, tax returns in the applicable tax loss calculations as possible.

In determining the base offense level for sentencing, a court must include all relevant conduct.³⁸ The U.S. Sentencing Guidelines specify that relevant conduct includes "all acts and omissions . . . that were part of the same course of conduct or common scheme or plan as the offense of conviction," but only for "offenses of a character for which § 3D1.2(d)

³⁶ U.S.S.G. § 2T1.4(b)(1)(B).

³⁷ U.S.S.G. § 3B1.1.

³⁸ U.S.S.G. § 1B1.3(a).

would require grouping of multiple counts”—which includes tax offenses sentenced under Part T of Chapter Two of the Guidelines.³⁹ The commentary to section 2T1.1 further explains that “all conduct violating the tax laws should be considered as part of the same course of conduct or common scheme or plan unless the evidence demonstrates that the conduct is clearly unrelated.”⁴⁰ Thus, other fraudulently prepared tax returns, because they are part of the same course of conduct or common scheme or plan as the offense of conviction, should be accounted for as relevant conduct in calculating tax loss.⁴¹

Relevant conduct is important in fraudulent return preparer prosecutions because the counts charged in the indictment rarely capture the full extent of the defendant’s crimes. Thus, the prosecutor should argue that the proper tax loss includes all other known false tax returns prepared by the defendant. Any tax returns that can be shown, by a preponderance of the evidence, to be false should be treated as relevant conduct, including other false tax returns prepared for the clients who testified at trial and false returns prepared on behalf of clients whose returns were not included in the indictment. It is proper to include tax returns that were confirmed to be false during IRS interviews with taxpayers, even if there was no opportunity for the defendant to cross-examine the taxpayers.⁴² The relevant conduct can include tax loss from years barred by the statute of limitations, and it can also include acquitted conduct.⁴³

Given that much of this type of evidence is unlikely to have been admitted at trial, it will need to be introduced at sentencing. Typically, an IRS RA can testify about these additional tax loss figures and the methodology used to calculate them.

4. Extrapolation

Relevant conduct can also be established through an extrapolation method. “To extrapolate means ‘to estimate the values of . . . a function or series . . . outside a range in which some of its values are known, on

³⁹ *Id.*; U.S.S.G. § 3D1.2(d) (providing that “[o]ffenses covered by” (inter alia) “§§2T1.1, 2T1.4, 2T1.6, 2T1.7, 2T1.9, 2T2.1, [and] 2T3.1” “are to be grouped under this subsection”).

⁴⁰ U.S.S.G. § 2T1.1, n.2.

⁴¹ *See, e.g.,* *United States v. Hendrickson*, 822 F.3d 812, 829–30 (6th Cir. 2016) (court properly included tax loss from fraudulent refunds in failure to file case).

⁴² *United States v. Goosby*, 523 F.3d 632, 639 (6th Cir. 2008).

⁴³ *See, e.g.,* *United States v. Ziskind*, 491 F.3d 10, 16–17 (1st Cir. 2007); *United States v. Watts*, 519 U.S. 148, 157 (1997) (per curiam) (guidelines range may rest on uncharged conduct or conduct underlying acquitted charges, if court finds conduct proven by a preponderance of evidence).

the assumption that the trends followed inside the range continue outside it.⁴⁴ In a fraudulent return preparer case, that means taking a random sample of tax returns that are “representative of the larger group of” returns, calculating the tax loss within that sample, and then using that figure to estimate the total tax loss.⁴⁵

For an extrapolation to be unbiased, the sample returns must be randomly chosen.⁴⁶ The sample returns must be chosen from the entire universe of the defendant’s returns, not those already flagged by the IRS as suspicious. A sample used for extrapolation must also consist of enough returns to allow the estimate of the total tax loss to be made with reasonable confidence—typically, that means the sample must be at least thirty returns.⁴⁷ Practically speaking, a successful extrapolation may require a lot of legwork, especially on behalf of the case agent, who will need to interview taxpayers or obtain other evidence (such as IRS audit files) that establish which of the sample returns are false. Extrapolation can be time-consuming and complicated. A prosecutor who would like to undertake it should consult with the Tax Division to obtain guidance and assistance.

B. Restitution

Restitution is an important component of sentencing in criminal tax cases. Restitution is limited to the actual loss caused by the counts of conviction, unless the defendant agrees to pay a higher restitution amount.⁴⁸ As a result, the restitution calculations will often differ from the total tax loss calculations. As previously discussed, restitution can only be ordered as a separate part of the defendant’s sentence if the defendant agrees to pay restitution in a plea agreement. When negotiating a plea agreement, the Tax Division directs prosecutors to include the sample restitution language in the Criminal Tax Manual. If there isn’t a plea agreement, or the plea agreement does not include an agreement to restitution, then the court may only order restitution as a condition of supervised release or probation.⁴⁹ It is important that prosecutors alert the court to the appropriate manner of ordering restitution to ensure a clean record.

EXHIBIT D-39

February 22, 2008

NOTE TO: Medicare Advantage Organizations, Prescription Drug Plan Sponsors, and Other Interested Parties

SUBJECT: Advance Notice of Methodological Changes for Calendar Year (CY) 2009 for Medicare Advantage (MA) Capitation Rates and Part D Payment Policies

In accordance with Section 1853(b)(2) of the Social Security Act (the Act), we are notifying you of proposed changes in the MA capitation rate methodology and risk adjustment methodology applied under Part C of the Act for CY 2009. Preliminary estimates of the national per capita MA growth percentage and other MA payment methodology changes for CY 2009 are also discussed. For 2009, CMS will announce the MA capitation rates on the first Monday in April 2008, in accordance with the timetable established in the Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (MMA). This Advance Notice is published 45 days before that date.

Attachment I shows the preliminary estimates of the national per capita MA growth percentage component of the minimum percentage increase, which is a key factor in determining the MA capitation rates. Attachment II sets forth the changes in payment methodology for CY 2009 for original Medicare benefits. Attachment III sets forth the changes in payment methodology for CY 2009 for Part D benefits. Attachment IV presents the preliminary CMS-HCC risk adjustment factors, and Attachment V presents the annual adjustments for 2009 to the Medicare Part D benefit parameters for the defined standard benefit.

Any changes to employer/union-only group waiver plan payment for 2009 will be issued in future guidance.

Comments or questions may be submitted electronically to the following address: AdvanceNotice2009@cms.hhs.gov. Comments or questions also may be mailed to:

Anne Hornsby
Centers for Medicare & Medicaid Services
7500 Security Boulevard
S3-16-16
Baltimore, Maryland 21244

In order to receive consideration prior to the April 7, 2008 release of the Announcement of Calendar Year (CY) 2009 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies, comments must be received by 6:00 PM EST on Friday, March 7, 2008.

Attachment I. Preliminary Estimate of the National Per Capita Growth Percentage for Calendar Year 2009

Section 1853(c)(1) of the Social Security Act (the Act) provides that, for years when CMS is “rebasing” the amount representing the actuarial value of 100 percent of costs under original fee-for-service (FFS) Medicare, MA capitation rates will be based on the greater of 100 percent of FFS costs or an increase which is the greater of two percent or the national per capita MA growth percentage, with no adjustment to this percentage for over- or under-estimates for years before 2004. CMS is rebasing the FFS rates for 2009. See section J, Attachment II for a discussion of the proposed methodology for adjusting the FFS rates to reflect DOD and VA costs, per Section 1853(c)(1)(D)(iii) of the Act.

The current estimate of the change in the national per capita MA growth percentage for aged and disabled enrollees combined in CY 2009 is 4.8 percent. This estimate reflects an underlying trend change for CY 2009 in per capita costs of 3.4 percent and adjustments to the estimates for CY 2008, CY 2007, CY 2006, CY 2005, and CY 2004 aged and disabled MA growth percentages of 2.4 percent, -0.9 percent, 0.1 percent, -0.3 percent, and 0.2 percent, respectively. Our new estimates for these years are lower than the estimates actually used in calculating the CY 2008 capitation rate book for CYs 2005 and 2007 and higher for CYs 2004, 2006, and 2008 than was published April 2, 2007, and are required by Section 1853(c)(6)(C) of the Act.

The following table summarizes the estimates for the change in the national per capita MA growth percentage.

Table I-1. National Per Capita MA Growth Percentage

	Aged	Disabled	ESRD	Aged+Disabled
2009 Trend Change	3.4%	3.4%	1.6%	3.4%
Revision to CY 2008 Estimate	1.8%	5.7%	2.9%	2.4%
Revision to CY 2007 Estimate	-1.1%	0.2%	-3.2%	-0.9%
Revision to CY 2006 Estimate	0.3%	-1.3%	-5.1%	0.1%
Revision to CY 2005 Estimate	-0.2%	-1.2%	-1.8%	-0.3%
Revision to CY 2004 Estimate	0.2%	0.2%	-0.2%	0.2%
Total Change	4.5%	7.0%	-5.9%	4.8%

Notes: (1) The total percentage change is multiplicative, not additive and may not exactly match due to rounding.

(2) Starting in 2008, the trend change for ESRD reflects an estimate of the trend for dialysis-only beneficiaries.

These estimates are preliminary and could change before the final rates are announced on April 7, 2008 in the Announcement of Calendar Year (CY) 2009 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies. Further details on the derivation of the national per capita MA growth percentage will also be presented in the Announcement.

Attachment II. Changes in the Payment Methodology for Original Medicare Benefits for CY 2009

Section A. Recalibration of CMS-HCC Model

In 2009, CMS will implement an updated version of the aged-disabled CMS-HCC risk adjustment model, including community, institutional, and new enrollee segments of the model. Fee-for-service (FFS) claims data for the years 2004 and 2005 are used in the recalibration of the model. Disease groupings are the same as in past models; however, the factors are different.

When CMS recalibrates the CMS-HCC risk adjustment model with more recent data, an updated coefficient is calculated for each diagnosis group and demographic characteristic in the model (e.g., age, sex), which represents the marginal (additional) cost of that diagnosis group or demographic characteristic in predicting FFS per capita costs. These coefficients are then converted to relative cost factors by dividing each by the per capita cost predicted for a specific year. For the CY 2009 recalibration, CMS used predicted per capita costs for 2007. The relative factors are used to calculate risk scores for individual beneficiaries, which will average 1.0 in the denominator year.

The current CMS-HCC model is calibrated on 2002 and 2003 data, and recalibrating the model on more current data results in more appropriate relative weights for each HCC because they reflect more recent coding and expenditure patterns in FFS Medicare. In addition, recalibrating with more recent data adjusts the model for increases in predicted FFS expenditures between calibration years. Recalibration of the CMS-HCC model can result in changes in relative risk scores for individual beneficiaries and for average plan risk scores, depending on individual beneficiaries' combinations of diagnoses.

One change that was made to the model was to remove the constraints on two HCCs: Metastatic Cancer (HCC 7) and Severe Cancers (HCC 8). In the version of the model currently in use, the coefficients of HCC 7 (Metastatic Cancer) and HCC 8 (Severe Cancers) were constrained to be equal. In the past, these HCCs were constrained because there were concerns regarding the completeness of the coding for Metastatic Cancer, specifically that secondary (metastatic) cancers were sometimes incorrectly coded as primary cancers.

With the constraint removed, the estimated incremental cost of Metastatic Cancer (HCC 7) is now higher than that for Severe Cancers (HCC 8). CMS determined that there was significant clinical and expected treatment cost difference between metastatic and localized cancer (e.g., chemotherapy for metastatic cancer). Although current coding may be imperfect, there are specific diagnostic tests and indications for metastatic versus localized cancers, and allowing a payment differential will provide incentives for accurate coding. More importantly, a higher incremental payment for beneficiaries with metastatic cancer will provide for more accurate payment to Medicare Advantage plans that enroll such beneficiaries.

In Attachment IV of this Notice, we provide the relative cost factors for each HCC for each segment of the aged-disabled model.

Section B. Frailty Adjustment**B1. Frailty Adjustment Factors**

CMS has recalibrated the frailty factors for CY 2009. The purpose of frailty adjustment is to predict the Medicare expenditures of community populations with functional impairments that are unexplained by the CMS-HCC risk adjustment model. Whenever CMS recalibrates the CMS-HCC risk adjustment model, the amount of unexplained Medicare expenditures can change. Thus, it is necessary to simultaneously recalibrate the frailty factors. Table II-1 presents the preliminary recalibrated frailty factors for CY 2009.

Table II-1. Preliminary Recalibrated Frailty Factors for CY 2009

ADL	2008 Factors (Non-Medicaid)	2009 Recalibrated Factors (Non-Medicaid)	2008 Factors (Medicaid)	2009 Recalibrated Factors (Medicaid)
0	-0.089	-0.093	-0.183	-0.180
1-2	+0.110	+0.112	+0.024	+0.035
3-4	+0.200	+0.201	+0.132	+0.155
5-6	+0.377	+0.381	+0.188	+0.200

CMS is not proposing to change the way we calculate the contract-level frailty score; we will use the results from each contract's 2008 HOS survey to calculate each contract-level frailty score for CY 2009.

B2. Frailty Adjustment Transition for PACE organizations

Frailty adjustment factors will be applied to payment to PACE organizations using the transition schedule published in the 2008 Announcement (published April 2, 2007). PACE frailty scores for payment year 2009 will be calculated at a blend of 70% of the frailty factors in use prior to 2008 and 30% of the recalibrated frailty factors implemented in 2009. The full transition schedule is as follows:

- In 2008 (year 1): 90% of the pre-2008 frailty factors and 10% of the 2008 frailty factors.
- In 2009 (year 2): 70% of the pre-2008 frailty factors and 30% of the 2009 frailty factors.
- In 2010 (year 3): 50% of the pre-2008 frailty factors and 50% of the most recently calibrated frailty factors.
- In 2011 (year 4): 25% of the pre-2008 frailty factors and 75% of the most recently calibrated frailty factors.
- In 2012 (year 5): 100% of the most recently calibrated frailty factors.

B3. Frailty Adjustment Transition for Certain Demonstrations

Frailty adjustment factors will be applied to payment to the following MA plan types using the phase-out schedule published in the 2008 Announcement (published April 2, 2007): Social Health Maintenance Organizations (S/HMOs), Minnesota Senior Health Options (MSHO)/Minnesota Disability Health Options (MnDHO), Wisconsin Partnership Program (WPP) and Massachusetts Senior Care Options (SCO) plans.

The full phase out schedule is as follows:

- In 2008 (year 1): 75% of the pre-2008 frailty factors
- In 2009 (year 2) 50% of the pre-2008 frailty factors
- In 2010 (year 3) 25% of the pre-2008 frailty factors
- In 2011, 0% of the pre-2008 frailty factors

Section C. Normalization Factors

When we calibrate a risk adjustment model and normalize the risk scores to 1.0, we produce a fixed set of dollar expenditures and coefficients appropriate to the population and data for that calibration year. When the model with fixed coefficients is used to predict expenditures for other years, predictions for prior years are lower and predictions for succeeding years are higher than for the calibration year. Because average predicted fee-for-service (FFS) expenditures increase after the model calibration year due to coding and population changes, CMS applies a normalization factor to adjust beneficiaries' risk scores so that the average risk score is 1.0 in subsequent years.

The normalization factor is derived by first using the model to predict risk scores for the FFS population over a number of years. Next, we trend the risk scores to determine the annual percent change in the risk score. This amount is then compounded by the number of years between the model denominator year and the payment year to produce the normalization factor.

Starting in 2009, CMS will use a standard of five years of data in the normalization trend. Each year, CMS will drop the earliest year and add a new year of risk scores to the trend data to create the five-year dataset. By using a standard number of years, CMS intends to calculate risk score trends based on recent trends in coding, while maintaining stability in the year-to-year trends used. For the CY 2009 recalibration, trends calculated for the aged-disabled CMS-HCC, ESRD Dialysis, and the RxHCC models are developed on risk scores calculated for 2003-2007.

Below are the preliminary normalization factors for each model. The final normalization factors will be included in the April 7, 2008 Announcement.

C1. Normalization Factor for the CMS-HCC Model

The preliminary 2009 normalization factor for the aged-disabled model is 1.030. The 2009 factor will adjust for two years of FFS risk score growth, i.e., from the denominator year of 2007 to the payment year of 2009. This 2009 normalization factor of 1.030 is lower than the 2008 factor of 1.04 because the 2008 factor adjusted for three years of FFS risk score growth (2005-2008).

C2. Normalization Factor for the ESRD Dialysis Model

The preliminary 2009 normalization factor for the ESRD dialysis model is 1.019. The 2009 factor will adjust for six years of risk score growth, i.e., from the denominator year of 2003 to the payment year of 2009, and will be applied at a phased-in percentage of 50%. (As discussed in last year's Advance Notice, the ESRD Dialysis normalization factor is being applied on the same transition schedule as is the transition of the ESRD State ratebook; see Section G2.)

C3. Normalization Factor for the RxHCC Model

The preliminary 2009 normalization factor for the RxHCC model is 1.085. This normalization factor reflects a trend calculated on five years of risk score data (2003-2007). We calculated the RxHCC normalization factor by taking the actual 2007 average Part D risk score for all potential Part D plan enrollees and the annual trend applied for the two years between the calculation of actual average Part D risk score and the payment year (2007-2009).

C4. Normalization Factor for Functioning Graft Enrollees' Risk Scores

CMS applies the normalization factor for the aged-disabled CMS-HCC model to Functioning Graft enrollees' risk scores because all but one of the coefficients for the Functioning Graft model are constrained to equal the coefficients of the CMS-HCC model, and because CMS pays for Functioning Graft enrollees using the county ratebook. However, because CMS recalibrates the functioning graft coefficients along with the dialysis model, the functioning graft coefficients still have a denominator of 2005 (instead of the 2007 denominator that the CMS-HCC community and institutional coefficients will have in 2009). For that reason, CMS will add an additional year to the 2008 CMS-HCC normalization factor; the preliminary 2009 normalization factor to be applied to the 2009 risk scores of enrollees in functioning graft status is 1.058.

Section D. Budget Neutrality

From 2003 through 2006, CMS implemented risk adjusted payments in a budget neutral manner by applying to the risk rates 100 percent of the Budget Neutrality (BN) factor, which is calculated as the estimated difference between payments to MA organizations at 100 percent of the demographic rates and payments at 100 percent of the risk rates. As previously announced by CMS on February 17, 2006 in the Advance Notice for 2007, and as summarized below, the phase-out of budget-neutral risk adjusted payments began in 2007 and will be completed by 2011, when plans will receive no budget neutrality payment adjustment. For 2009, 25 percent of the BN factor will be applied to the risk rates.

Since CMS cannot calculate the BN factor until the final capitation rates are determined, the factor will be announced in the April 7, 2008 Rate Announcement.

Phase-out Schedule for Budget Neutral Risk Adjusted Payments:

The percentage of the budget neutrality factor that is applied to the risk rates is:

- 2007: 55%
- 2008: 40%
- 2009: 25%
- 2010: 5%
- 2011: 0%

Section E. Adjustment for MA Coding Intensity

Background

As promulgated by the Deficit Reduction Act (DRA), Section 1853(k)(2)(B)(iv)(III) requires CMS to reflect in its risk adjustment for Part C payment “differences in coding patterns between Medicare Advantage plans and providers under part A and B to the extent that the Secretary has identified such differences.” The DRA further instructs that results of the analysis will be “incorporated into the risk scores only for 2008, 2009, and 2010.” In order to comply with this section of the DRA, CMS has studied the changes in MA and FFS risk scores, the differences between those changes, and the coding patterns behind these changes.

From our research for the 2008 payment year, CMS found that MA risk scores increased approximately twice as much as FFS risk scores did for our study population between 2004 and 2006. There are a number of key reasons why risk scores in the MA and FFS sectors may rise at different rates. The composition of enrollment in each sector can have an effect on the change in the average risk score. Initially, some MA plans may have had difficulty gathering and reporting diagnosis codes as completely as FFS, so part of the differential risk score growth could be due to “catching up” to FFS. MA plans may be finding and diagnosing disease at a higher rate than FFS providers. Or, it is possible that beneficiaries enrolled in MA plans may be getting sicker faster than beneficiaries in FFS.

Our preliminary research on coding patterns, which was conducted prior to the release of the 2008 Rate Announcement, was unable to clarify enough about the coding pattern differences that result in MA and FFS risk score differences. Therefore, we did not make an adjustment for coding patterns differences in payment year 2008. We stated that we would continue to study this issue, with particular focus on the plans that have experienced significant increases in risk scores, in an effort to determine what the appropriate adjustment might be for 2009 and 2010.

CMS has continued its analysis of the coding patterns that result in differences in the MA and FFS risk scores. The findings below are based on diagnoses reported for payment years 2004-2006. CMS will update these figures by adding the (currently unavailable) 2007 risk scores to the analysis, prior to the publication of the Announcement on April 7, 2008.

Study Results

Composition effects: In order to analyze the gross difference between the change in FFS and MA risk scores, we examined the change in risk scores for three categories of enrollees: stayers, leavers, and joiners. **Stayers** were those enrollees who remained in the same sector (either FFS or MA) over the study period, **leavers** were those who left either the MA or FFS sector, either to go to the other sector or who died, and **joiners** were those who came into FFS or MA, either from the other sector or who were newly eligible to Medicare. We found that indeed some of the difference in the change in risk scores between MA and FFS was due to composition effects. Specifically, we found that:

- A significant portion of the beneficiaries who join MA are beneficiaries who are switching from FFS. In FFS, the vast majority of beneficiaries who join are newly-eligible to Medicare. The risk scores of beneficiaries who are newly eligible to Medicare

tend to be very low and these low risk scores depress FFS risk score growth relative to MA.

- Of the leavers, decedents (who have high risk scores) are a slightly larger fraction of FFS beneficiaries than of MA enrollees and, thus, the exit of high-risk score decedents restrains the year-to-year growth of average FFS risk scores by slightly more than it does MA scores.

Because most new enrollees in FFS are newly-eligible to Medicare and FFS is losing higher risk beneficiaries, overall average MA risk scores are pushed up at a faster rate than risk scores in FFS. Over the two-year period, approximately 50% of the difference between the MA and FFS sectors in the growth of risk scores is due to enrollment patterns and approximately 50% is due to the more rapid growth in risk scores for beneficiaries who stay in the same sector in consecutive years.

Focus on “stayers.” Focusing on the stayers allows us to examine differences in risk score changes that are not due to the changing composition of the enrolled population. In our analyses of the impact of coding patterns on stayers’ risk scores, we did the following:

- We focused on two cohorts of stayers: those who were stayers in 2004-2005, and those who were stayers in 2005-2006. We weren’t able to add the 2006-2007 cohort to the analysis prior to the release of the Advance Notice, but will do so before the release of the Announcement in April 2008.
- For each cohort, we defined MA stayers as those enrollees who were in the same contract in the July of each cohort year, as well as in each data collection year. For example, for the 2004-2005 stayer cohort, we include enrollees who were in the same contract in July 2004 and July 2005, and in all of 2003 and 2004. This criterion resulted in the exclusion of enrollees who would have been new enrollees in the data collection years, as well as those enrollees who switched contracts.
- We found that the overall risk scores of MA stayers increased by 0.032 more than those of FFS stayers over the two-year study period. As discussed below, we then broke down the change in aggregate risk scores into the changes in the disease component of the CMS-HCC risk score (the “disease score”) versus the demographic component.

Focus on the disease score of stayers: The disease score is the HCC component of the risk score that plans (and FFS providers) affect by their reporting of diagnosis codes. Among stayers, we found that MA disease scores increased more quickly than FFS disease scores and that change in the disease component of the risk score accounted for approximately 90% of the difference in the change in MA versus FFS risk scores.

We found that, on average, disease scores for stayers in MA plans increased 20% faster than stayers in FFS over the two years in the study period. Specifically, FFS disease scores for stayers increased by 0.145 over the two-year period between 2004 and 2006, while the average disease score among beneficiaries who remained enrolled in a single MA contract for at least two data collection years increased by 0.174 over the same time period for a two-year difference of 0.029.

Dynamics behind changes in disease scores: CMS also analyzed the reasons why the change in MA and FFS disease scores differed among stayers. A significant portion of the difference in

disease score changes is attributable to the reporting of 26 HCCs (of the 70 HCCs in the model) that fall into one of seven hierarchies: diabetes (5 HCCs), cardiovascular disease (4 HCCs), coronary artery disease (3 HCCs), cancer (4 HCCs), quadriplegia and other central nervous system disease (4 HCCs), liver disease (3 HCCs), and dialysis/renal disease (3 HCCs).

Approximately one-third of the difference in disease score change is due to increases in severity within these hierarchies, particularly within the diabetes hierarchy. The remaining difference results primarily from greater retention of reported diagnosis codes within certain hierarchies from one year to the next, especially the coronary artery disease, liver, diabetes, and renal hierarchies.

Variation among contracts: CMS research has also revealed a large amount of variation among MA contracts in the disease score change among stayers, and in the dynamics behind contracts' changing disease scores. As described above, on average, disease scores for MA stayers increased by 0.174 over the 2004-2006 study period, or 0.029 greater than the average increase of 0.145 for FFS stayers. We found that approximately 40% of the contracts in our study – those operating continuously during the 2004, 2005, and 2006 payment years – had changes in stayer disease scores that were less than the changes in FFS stayers' disease scores. Looking at enrollees, we found that 25% of the MA stayers in our analysis were enrolled in contracts where the difference between the two-year increase in stayers' disease scores and the FFS increase was at least twice the industry average.

Catch-up to FFS levels of coding: Although CMS cannot definitely determine whether “catch up” to FFS coding occurred or not, CMS recognizes that plans may have experienced some catch up, particularly during initial years of operation. In order to take any such catch up into account in our adjustment, we are proposing to:

- Adjust for MA coding only in 2009 and later (not adjust for previous year's coding patterns differences).
- Make an adjustment for contracts that have existed since at least 2005.
- Adjust risk scores for enrollees in contracts that have significant coding pattern differences from FFS.
- We are proposing to weight the impact of coding differences on disease scores in more recent years (when plans would have caught up to FFS) differently than coding patterns differences in earlier years.

More complete coding: We do not assume that the coding pattern differences that we found in our study are the result of improper coding. As discussed above, CMS understands that MA plans have made efforts to identify enrollees' conditions and may be coding more completely than FFS. However, because MA coding patterns differ from FFS coding patterns, the normalization factor (which is calculated based on FFS coding) does not currently adjust for these different coding patterns.

Impact of health status on risk score changes: As noted above, it is possible that beneficiaries enrolled in MA plans may be getting sicker faster than beneficiaries in FFS and this could be driving faster risk score growth for MA enrollees. Given the care coordination and disease management activities of MA plans, however, we do not find it reasonable to assume that MA stayers' underlying health status is getting worse at a faster rate than stayers in FFS. CMS analysis has found that MA mortality rates during the study period do not explain rising risk

scores; when applying expected mortality rates to the MA population, risk scores are expected to decrease, not increase. (In our analysis, we adjusted mortality rates for age, sex, county, Medicaid status, and institutional status.)

Calculation and Application of a Coding Intensity Measure

While our research supports the finding that MA plans have coding patterns that differ from FFS, we only have a few years to observe the differences in MA and FFS coding patterns. Therefore, for 2009 we propose to apply an MA coding adjustment factor as follows:

- Apply an adjustment to the risk scores of enrollees in those contracts for which the difference between the change in stayers' disease scores and the change in the FFS stayers' disease scores is two or more times the industry average; this threshold is approximately the same as a threshold at the plans enrolling the 25% of MA stayers with the largest change in disease score. We considered a few other options for applying an adjustment:
 - We considered applying an adjustment to those contracts above two standard deviations above the mean difference in disease score change, but the variation among plans is so great that such a threshold would eliminate most contracts.
 - We considered applying an adjustment on a contract-by-contract basis, but decided instead to apply a relatively high threshold in order to focus on the contracts that have experienced the largest changes in their stayers' disease scores, relative to FFS stayers' disease scores.

CMS is requesting comments on the criteria for determining the threshold used to determine those contracts' payment to which we would apply an adjustment factor.

- Exclude those contracts that were not in existence until after 2005 (came into existence in 2006 or later). Contracts that existed in 2005 and earlier have at least two years of experience reporting to CMS stayers' diagnosis codes that have been used to calculate risk scores.
- Exclude contracts with under an average of 1,000 enrollees during 2005-2006. CMS considers these contracts too small to provide enough data to make reliable estimates of their coding patterns.

CMS proposes to calculate the 2009 MA coding adjustment as follows:

1. *Calculate the average annual difference between the increase in MA and FFS stayers' disease scores.* The average annual change in stayers' disease scores for a contract is calculated as the change in average disease score, averaged over as many cohorts of stayers that a contract has, e.g., CMS would calculate the annual average change in disease score for contracts that have been in existence since 2003 or earlier as the average of the change in disease score for the 2004-2005, 2005-2006, and the 2006-2007 stayer cohorts. We would then subtract the FFS annual average change in stayers' disease score to obtain the differential increase in stayers' disease scores. Changes in disease scores would be adjusted for age and survivor status.

2. *Calculate this average annual difference in the change in stayers' disease scores within that group of contracts that would fall above the threshold for applying the adjustment.* For example, we would calculate the annual average difference between MA and FFS stayers' disease score increase based only on MA data from those contracts where the difference between the change in stayers' disease scores and the change in FFS stayers' disease scores was two or more times the industry average. We would calculate the average disease score change for the set of contracts by weighting each contract's disease score change by the number of beneficiaries in each contract. We would then subtract the FFS disease score change from this weighted average. Based on the two years of data that were included in our analysis to date, the difference in the change in stayers' disease score for the contracts in this group and the FFS average is 0.050.
3. *Adjust the annual average difference in disease score change for the average percent of MA plan enrollees in the payment year who were enrolled in the same plan in the data collection year.* CMS currently estimates that this percentage of enrollees is approximately 75%, but will finalize the percentage after we add 2007 risk score data to our analysis. Based on our current estimate of 75% for the proportion of MA enrollees who are stayers, the adjustment for the contracts with the top 25% of MA enrollees with the largest difference between their change in disease score and the FFS change in disease score would be 0.0375. CMS (1) will update this calculation with 2007 data, (2) proposes to convert the adjustment amount into a percent change to risk scores in the Announcement, and (3) will consider whether to apply a straight average across the year-to-year differences, or whether to give more weight the disease score change differences in the most recent years. CMS requests comment on how we calculate the adjustment factor.

The average change in MA stayers' disease score, the change in MA stayers' disease scores for the top group of contracts, the FFS average change in disease score, the difference between MA and FFS, and the proportion of stayers we project to be enrolled in MA contracts in 2009, along with other calculations, will be updated in the Announcement.

Section F. Medicare as Secondary Payer (MSP) Adjustment Factor for Aged & Disabled Enrollees

MA capitation rates are calculated as if Medicare were always the primary payer; adjustments to the rates for situations in which Medicare is secondary are made as part of actual payment. The MSP adjuster applied to aged and disabled beneficiaries is calculated as the ratio of the actual Medicare spending for all MSP months for all MSP beneficiaries to the predicted Medicare spending for all MSP months for all MSP beneficiaries. Actual spending was calculated using the 2005 claims from the same analytic files used to recalibrate the CMS-HCC model. The predicted amount was calculated using the newly recalibrated CMS-HCC model. MSP status, which was determined using the working aged/working disabled status data in 2005, was used both for determining whom to exclude from the recalibration and for determining which beneficiaries to include in the MSP adjuster calculation.

CMS has recalculated the MSP adjuster for working aged and working disabled beneficiaries. The current adjuster of 0.215 will be revised to 0.174 in the 2009 payment year. There are two reasons for the change in the adjuster. First, CMS has refined the methodology used to calculate the adjuster. Previously, we prorated each beneficiary's MSP months using their total Medicare-paid costs during all months when beneficiary was enrolled. The new methodology includes costs only from those months in which beneficiaries have MSP status. Second, the average number of actual dollars calculated in the MSP months has decreased.

We are not proposing to change the formula for calculating the contract-level working aged/working disabled factor that is applied to each contract's total monthly payment for non-hospice/non-ESRD enrollees. We would simply change the value of the adjuster in that formula from 0.215 to 0.174.

Section G. ESRD Bidding and Payment

Pursuant to Section 1853(a)(1)(H) of the Act, CMS has the authority to determine whether to apply the competitive bidding methodology to ESRD enrollees, and must establish "separate rates of payment" with respect to ESRD beneficiaries.

G1. ESRD Bidding Policy

For 2009, CMS will continue the policy of excluding costs for ESRD enrollees in the plan A/B bid. The MA Bidding Instructions for CY 2009 will provide guidance on the option of adjusting A/B mandatory supplemental premiums to reflect the costs or savings for ESRD enrollees in the basic and supplemental benefits.

G2. Transition to New ESRD Payment

As announced in last year's Advance Notice, CMS continues the phase-in of the revised State capitation rates used to determine payments for enrollees in dialysis and transplant status. For payment year 2009, CMS will pay for ESRD dialysis and transplant enrollees using a blend of 50% of the old State ratebook (in use through 2007) and 50% of the revised State ratebook (implemented in 2008). The revised ESRD State ratebook reflects the dialysis-only trend. During the transition period, we will continue to trend forward the old and the revised State rates using the same dialysis-only growth trend. CMS is not rebasing the ESRD Dialysis State rates for 2009.

The full transition schedule is as follows. CMS payments for ESRD dialysis and transplant beneficiaries enrolled in MA plans will be:

- In 2008 (year 1): a blend of 75% old ratebook-based payments and 25% revised ratebook-based payments.
- In 2009 (year 2): a blend of 50% old ratebook-based payment and 50% revised ratebook-based payments.
- In 2010 (year 3): a blend of 25% old ratebook-based payments and 75% revised ratebook-based payments.
- In 2011: 100% of the revised ratebook.

In States where the revised dialysis rates are higher than the pre-2008 State rates, we will apply the revised ESRD State rates.

G3. ESRD Functioning Graft Payments

CMS pays for Functioning Graft enrollees with risk scores calculated using the aged-disabled CMS-HCC model coefficients, with the exception of the coefficient for HCC174 (Major Organ Transplant), which is not constrained, and the Graft factors, which are additive to the functioning graft risk scores. However, because CMS recalibrates the functioning graft coefficients along with the dialysis model, for 2009 CMS will continue to use the functioning graft coefficients published in the April 7, 2007 Advance Notice for 2008, when the ESRD dialysis model was last recalibrated. See Section C4 for a discussion of the normalization factors to be used with the functioning graft risk scores.

Section H. Regional Plan Stabilization Fund

Section 221 of the MMA added Section 1858(e) to the Act to create a new MA Regional Plan Stabilization Fund. The purpose of the fund is to provide financial incentives to MA organizations to offer MA regional PPO plans in each MA region, and to retain MA regional PPO plans in regions with relatively low MA market penetration.

Section 101 of the Medicare, Medicaid, and SCHIP Extension Act of 2007 – enacted December 18, 2007 – delayed Stabilization Fund payments until January 1, 2013.

Section I. Continuation of Clinical Trial Policy

In 2009, we will continue the policy of paying on a fee-for-service basis for clinical trial items and services provided to MA plan members that are covered under the relevant National Coverage Determinations on clinical trials.

Section J. Adjustment to FFS Capitation Rates for VA-DOD Costs

Per Section 1853(c)(1)(D)(iii) of the Act, CMS proposes to adjust to the extent appropriate the 2009 FFS rates to reflect CMS' "estimate, on a per capita basis, of the amount of additional payments that would have been made in the area involved under this title if individuals entitled to benefits under this title had not received services from facilities of the Department of Defense or the Department of Veterans Affairs."

The Office of the Actuary (OACT) proposes to compare the risk-adjusted Medicare reimbursements of dual-eligible individuals — those entitled to benefits under this title and entitled to benefits from the Department of Defense (e.g., DoD TRICARE for Life, DoD US Family Health Plan) or the Department of Veterans Affairs (VA) — with individuals entitled only under this title. In cases where groupings of dual-eligible individuals (who would possibly have services provided in VA or DoD facilities not reimbursed by Medicare) have risk-adjusted Medicare reimbursements significantly different from other Medicare-eligible individuals, we propose to adjust the MA FFS rates by excluding these individuals from the calculation. This

exclusion implicitly assumes that these individuals, if they had received all their services from Medicare-covered providers, would have the same risk-adjusted Medicare reimbursements as the remaining individuals.

MA FFS rates could be higher or lower under this adjustment. This is because the MA FFS rates are risk-adjusted rates. We note that under the current payment methodology we are missing two pieces of information on beneficiaries receiving health services through the VA or DoD:

1. The amounts Medicare would have reimbursed if these individuals had received their services from Medicare-covered providers rather than from VA/DoD providers.
2. Diagnostic information identified in VA/DoD-provided services but not identified in Medicare-covered services. Lack of diagnostic information could potentially understate individuals' risk scores.

Since the MA FFS rates are calculated using risk-adjusted reimbursements, there could be cases where the risk scores are understated to a greater extent than reimbursements leading to a reduction in the MA FFS rates in some counties.

In light of the foregoing, further information and analysis is required before making a final decision on the appropriateness of adjustments.

Section K. Operational Policies

K1. Reporting of Medicaid Status for Part C Payment

In CY 2009, CMS will complete the transition to using the MMA Medicare/Medicaid Dual Eligible monthly submission file (MMA State files) as the main source of Medicaid status for Part C plan payments. At the same time, CMS will end the use of the Third Party files as a source of Medicaid status. CMS anticipates that this change in Medicaid status source will improve – and increase – the identification of dual-eligible MA enrollees. As discussed in the 2008 Announcement (published April 2, 2007), CMS has found that the MMA State files identify approximately one million more dual eligibles than both the Third Party files and plan-reported data. (Please note that the changes discussed here only affect how we assign Medicaid status for Part C risk adjustment purposes, and that we are not changing how we identify deemed individuals for purposes of Part D payment.)

Plan Reporting. For any Medicaid period open on or after January 1, 2008, organizations may no longer submit batch “01” transactions to CMS. Instead, to request changes to Medicaid status, organizations must submit retroactive “01” transactions to IntegriGuard, as indicated in Table II-2.

Table II-2. Data sources for the assignment of Medicaid status

	Payment year 2007	Payment year 2008	Payment year 2009
New enrollees	1. Third Party Buy-In file 2. Plan-reported Medicaid • Batch "01" transactions • Retroactive "01s" through IntegriGuard	1. MMA State files 2. Plan-reported • Retroactive "01s" through IntegriGuard	1. MMA State files 2. Plan-reported • Retroactive "01s" through IntegriGuard
Full risk enrollees		1. MMA State files 2. Third Party Buy-In file 3. Plan-reported Medicaid • Batch "01" transactions • Retroactive "01s" through IntegriGuard	

Notes: Full risk enrollees. CMS considers full risk Medicare beneficiaries as dually-eligible if they were eligible for title XIX during any month in the year prior to the payment year. Full risk Medicare beneficiaries have 12 months of Part B in the year prior to the payment year.

New enrollees. CMS assigns Medicaid status for new enrollees on a concurrent basis, i.e., if a newly-enrolled Medicare beneficiary is eligible for title XIX during any month during the payment year, they are considered Medicaid for that year.

K2. Standard Set of ICD-9 Diagnosis Codes for Risk Adjustment

As discussed in the 2008 Announcement (released April 2, 2007), CMS is implementing the use of a standard set of valid codes to determine which plan-submitted diagnosis codes are acceptable for use in CMS's Risk Adjustment Processing System (RAPS). The goal is for RAPS to accept and store only those diagnoses codes that are valid. RAPS has historically accepted and stored old ICD-9 codes that had been superseded by more recent National Center for Health Statistics (NCHS) codes, i.e., invalid codes, without sending error messages to the plans. Having a standard set of valid codes for each year will make it more efficient for CMS and plans to manage risk adjustment processing, editing, and error reporting.

Starting with payment year 2009, RAPS will only accept valid ICD-9-CM codes for two fiscal years -- the fiscal year that begins prior to the payment year and the fiscal year that begins during the payment year -- for the CMS-HCC, ESRD, and RxHCC risk adjustment models. For example, for diagnoses codes to be used in 2009 final payment, i.e., for diagnoses from service dates between January 1, 2008 and December 31, 2008, RAPS will only accept codes that are valid for Fiscal Year 2008 and Fiscal Year 2009. (Please note that for the initial risk score run for payment year 2009, CMS will use valid diagnosis codes from FY 2007 and FY 2008 -- services dates between July 1, 2007 and June 30, 2008.)

Refer to Table II-3 for the implementation schedule of the new rules regarding the acceptance of diagnosis codes. Please note that Table II-3 of this Notice supersedes the table published in the April 2, 2007 Rate Announcement for 2008.

CMS is in the process of updating the "future diagnoses file" to eliminate invalid codes from that list. However, whether submitting diagnosis codes from the list of current model diagnoses or the list of future diagnoses, plans should resubmit an updated valid diagnosis code whenever they receive a RAPS error code specifying that a submitted diagnosis code is invalid. Both lists of current diagnosis codes and future diagnosis codes can be found in a zipped file on the CMS Web site at

http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage. Please refer to the HPMS memo released November 26, 2007 for a discussion of this policy and of the related RAPS error codes.

Table II-3. Acceptable diagnoses codes

Year of Payment	Date of Service	Source of codes
2007	1/06 – 12/06	The list of codes published on our website at http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage (which lists acceptable codes by year)
2008	1/07 – 12/07	The list of codes published on our website at http://www.cms.hhs.gov/MedicareAdvtgSpecRateStats/06_Risk_adjustment.asp#TopOfPage (which lists acceptable codes by year)
2009	1/08 – 12/08	Valid diagnoses in Fiscal Years 2008, 2009
2010	1/09 – 12/09	Valid diagnoses in Fiscal Years 2009, 2010
2011	1/10 – 12/10	Valid diagnoses in Fiscal Years 2010, 2011

Attachment III. Changes in the Payment Methodology for Medicare Part D for CY 2009

Section A. Benefit Design

A1. Medicare Part D Benefit Parameters: Annual Adjustments for Defined Standard Benefit in 2009

In accordance with section 1860D-2(b) of the Social Security Act (the Act), CMS must update the statutory parameters for the defined standard Part D prescription drug benefit each year. These parameters include the annual deductible, initial coverage limit, annual out-of-pocket threshold, and minimum copayments for costs above the annual out-of-pocket threshold. As required by statute, the parameters for the defined standard benefit are indexed to the percentage increase in average per capita total Part D drug expenses for Medicare beneficiaries. Accordingly, the actuarial value of the drug benefit increases along with any increase in Part D drug expenses, and the defined standard Part D benefit continues to cover a constant share of Part D drug expenses from year to year. The Part D benefit parameters are updated using two indexing methods specified by statute: (i) the annual percentage increase in average expenditures for Part D drugs per eligible beneficiary or the "annual percentage increase", and (ii) the annual percentage increase in the Consumer Price Index (CPI) (all items, U.S. city average).

As required by statute, the first indexing method, the "annual percentage increase," is used to update the following Part D benefit parameters:

- (i) the deductible, initial coverage limit, and out-of-pocket threshold for the defined standard benefit;
- (ii) minimum copayments for costs above the annual out-of-pocket threshold;
- (iii) maximum copayments below the out-of-pocket threshold for certain low-income full subsidy eligible enrollees;
- (iv) the deductible for partial low-income subsidy (LIS) eligible enrollees; and
- (v) maximum copayments above the out-of-pocket threshold for partial LIS eligible enrollees.

The benefit parameters listed above will be increased by 7.54% for 2009 as summarized by Table III-1 below. This increase reflects the 2008 annual percentage trend of 5.97% as well as a multiplicative update of 1.48% for prior year revisions. Please see Attachment V for additional information on the calculation of the annual percentage increase.

Per 42 CFR 423.886(b)(3), the cost threshold and cost limit for qualified retiree prescription drug plans are updated after 2006 in the same manner as the deductible and out-of-pocket threshold for the defined standard benefit. Thus, the "annual percentage increase" will be used to update these parameters as well. The cost threshold and cost limit for qualified retiree prescription drug plans will be increased by 7.54% from their 2008 values.

The statute requires CMS to use the second indexing method, the annual percentage increase in the CPI, to update the maximum copayments below the out-of-pocket threshold for full benefit dual eligible enrollees with incomes that do not exceed 100% of the Federal poverty line. These maximum copayments will be increased by 3.18% for 2009 as summarized in Table III-1 below.

This increase reflects the 2008 annual percentage trend in CPI of 2.60%, as well as a multiplicative update of 0.57% for prior year revisions. Please see Attachment V for additional information on the calculation of the annual percentage increase in the CPI.

Table III-1. Updated Part D Benefit Parameters for Defined Standard Benefit, Low-Income Subsidy, and Retiree Drug Subsidy

Annual Percentage Increases			
	Annual percentage trend for 2008	Prior year revisions	Annual percentage increase for 2008
Applied to all parameters but (1)	5.97%	1.48%	7.54%
CPI (all items, U.S. city average): Applied to (1)	2.60%	0.57%	3.18%
Part D Benefit Parameters		2008	2009
Standard Benefit Design Parameters			
Deductible		\$275	\$295
Initial Coverage Limit		\$2,510	\$2,700
Out-of-Pocket Threshold		\$4,050	\$4,350
Total Covered Part D Drug Spend at OOP Threshold (2)		\$5,726.25	\$6,153.75
Minimum Cost-sharing in Catastrophic Coverage Portion of Benefit			
Generic/Preferred Multi-Source Drug		\$2.25	\$2.40
Other		\$5.60	\$6.00
Part D Full Benefit Dual Eligible Parameters			
Copayments for Institutionalized Beneficiaries		\$0.00	\$0.00
Maximum Copayments for Non-Institutionalized Beneficiaries			
Up to or at 100% FPL			
Up to Out-of-Pocket Threshold (1)			
Generic/Preferred Multi-Source Drug (3)		\$1.05	\$1.10
Other (3)		\$3.10	\$3.20
Above Out-of-Pocket Threshold		\$0.00	\$0.00
Over 100% FPL			
Up to Out-of-Pocket Threshold			
Generic/Preferred Multi-Source Drug		\$2.25	\$2.40
Other		\$5.60	\$6.00
Above Out-of-Pocket Threshold		\$0.00	\$0.00
Part D Non-Full Benefit Dual Eligible Full Subsidy Parameters			
Resources ≤ \$6,290 (individuals) or ≤ \$9,440 (couples) (4)			
Maximum Copayments up to Out-of-Pocket Threshold			
Generic/Preferred Multi-Source Drug		\$2.25	\$2.40
Other		\$5.60	\$6.00
Maximum Copayments above Out-of-Pocket Threshold		\$0.00	\$0.00
Resources bet \$6,290-\$10,490 (ind) or \$9,440-\$20,970 (couples) (4)			
Deductible (3)		\$56.00	\$60.00
Coinsurance up to Out-of-Pocket Threshold		15%	15%
Maximum Copayments above Out-of-Pocket Threshold			
Generic/Preferred Multi-Source Drug		\$2.25	\$2.40
Other		\$5.60	\$6.00
Part D Non-Full Benefit Dual Eligible Partial Subsidy Parameters			
Deductible (3)		\$56.00	\$60.00
Coinsurance up to Out-of-Pocket Threshold		15%	15%
Maximum Copayments above Out-of-Pocket Threshold			
Generic/Preferred Multi-Source Drug		\$2.25	\$2.40
Other		\$5.60	\$6.00
Retiree Drug Subsidy Amounts			
Cost Threshold		\$275	\$295
Cost Limit		\$5,600	\$6,000

(1) CPI adjustment applies to copayments for non-institutionalized beneficiaries up to or at 100% FPL.

(2) Amount of total drug spending required to attain out-of-pocket threshold in the defined standard benefit if beneficiary does not have prescription drug coverage through a group health plan, insurance, government-funded health program or similar third party arrangement.

(3) The increases to the LIS deductible, generic/preferred multi-source drugs and other drugs copayments are applied to the unrounded 2008 values of \$55.91, \$1.04, and \$3.13 respectively.

(4) The actual amount of resources allowable will be updated for contract year 2009.

Office of the Actuary

A2. Reporting Drug Costs When Contracting with a Pharmacy Benefit Manager (PBM)

In the 2008 Part D Payment Notification issued on April 2, 2007, we stated our intent to issue a Notice of Proposed Rulemaking proposing that the pass through amount (the amount received by the pharmacy or other dispensing provider) be the only acceptable price for determining beneficiary cost-sharing and reporting drug costs to CMS in 2009 and beyond. This Notice of Proposed Rulemaking was released in the Federal Register on May 25, 2007. CMS has reviewed the comments received and expects to issue the final rule in Spring 2008. This will allow sufficient time for Part D sponsors to prepare their 2009 Part D bids in accordance with the policies established in the final rule.

Section B. Bidding**B1. Calculation of the National Average Monthly Bid Amount**

CMS will complete the transition to an enrollment-weighted average for the calculation of the national average monthly bid amount in 2009. Section 1860D-13(a)(4)(B) of the Act directs CMS to calculate the national average monthly bid amount each year as a weighted average of the standardized bid amounts for each prescription drug plan (PDP) and Medicare Advantage Prescription Drug Plan (MA-PD) described in section 1851(a)(2)(A)(i) of the Act starting in 2007. When calculating the national average monthly bid amount for contract year 2006, CMS assigned equal weighting to PDP sponsors, under section 1860D-13(a)(4)(B)(ii), because CMS did not have prior enrollment for these Part D plans. MA-PD plans were assigned a weight based on their prior MA enrollments and new MA-PD plans were assigned zero weight.

In 2007, CMS implemented the Medicare Part D demonstration entitled, "Medicare Demonstration to Limit Annual Changes in Part D Premiums Due to Beneficiary Choice of Low-Cost Plans," and began a transition from the 2006 method of calculating the national average monthly bid amount to the weighted average method based on actual plan enrollments. Under this demonstration, the national average monthly bid amounts for contract years 2007 and 2008 were calculated as a composite of (i) a weighted average calculated using the 2006 weighting methodology and (ii) a weighted average calculated based on actual plan enrollments. In 2007, 80% of the national average monthly bid amount was based on the 2006 averaging methodology and 20% was based on the enrollment-weighted average. In 2008, 40% of the national average monthly bid amount is based on the 2006 averaging methodology and 60% is based on the enrollment-weighted average. Please find the weighting methodologies for contract years 2006-2009 below.

Table III-2. Weighting Blends for the National Average Monthly Bid Amount

Contract Year	2006 Weighting	Enrollment Weighting
2006	100%	0%
2007	80%	20%
2008	40%	60%
2009	0%	100%

CMS will complete the transition to the weighted average method based on actual plan enrollments in 2009. Thus for contract year 2009, 100% of the national average monthly bid amount will be based on the enrollment-weighted average. The "Medicare Demonstration to

Limit Annual Changes in Part D Premiums Due to Beneficiary Choice of Low-Cost Plans" will not be extended for contract year 2009. The 2009 national average monthly bid amount and the reference month for the plan enrollment used to determine the enrollment-weighted average will be provided in future guidance after the June bid submission deadline.

B2. Calculation of the Low-Income Benchmark Premium Amount

The Medicare Prescription Drug Improvement, and Modernization Act of 2003 (MMA) directs CMS to use a weighted average to calculate the regional low-income benchmark premium amount used in the determination of the low-income premium subsidy amount. In determining the 2006 low-income benchmark premium amounts, PDPs were weighted equally, MA-PD plans were assigned a weight based on prior enrollment as of March 31, 2005, and new MA-PD plans were assigned a zero weight. In 2007, under the "Medicare Demonstration to Transition Enrollment of Low Income Subsidy Beneficiaries," CMS calculated the regional low-income benchmark premium amounts using the same weighting methodology applied in 2006, i.e., all PDP bids were weighted equally, and MA-PD bids received weights based on plan enrollments in the reference month (June 2006).

For contract year 2008, CMS implemented a transition to the statutorily required weighting such that the regional low-income benchmark premiums would experience a smaller decrease. CMS calculated the 2008 regional benchmarks using a composite of the 2006 weighting approach (simple average) and the statutory weighting formula (weighted average).

- The first component, the simple average, was the same as the 2006 weighting methodology for the regional low-income benchmark premium amount. The PDP organization premium amounts for basic prescription drug coverage in each region would be weighted equally and the MA-PD plan premiums, after the application of Part A/B rebates, would be weighted based upon prior enrollment.
- The second component was a weighted average of the premium amounts for each PDP and MA-PD with a weighting based on each plan's prior enrollment as a percentage of all beneficiaries enrolled in those plans.

In 2008, 50% of the regional low-income benchmark amount was based on the first component, the simple average, and 50% was based on the second component, the enrollment weighted average.

CMS proposes to calculate the 2009 regional benchmarks using a composite of the 2006 weighting approach (simple average) and the statutory weighting formula (weighted average) again. However, in 2009, 25% of the regional low-income benchmark amount will be based on the first component, the simple average, and 75% will be based on the second component, the enrollment weighted average. This proposal would continue the transition to the statutorily required weighting that was started in 2008, such that the regional low-income benchmark premiums would experience a smooth glide path to the statutory weighting approach.

Under the demonstration in 2007 and 2008, CMS also implemented a policy whereby Part D plans were required to charge full-subsidy eligible beneficiaries a monthly beneficiary premium equal to the low-income premium subsidy amount, if the plan's premium exceeded the low-

income premium subsidy amount by a certain "de minimis" amount. We do not propose to extend the "de minimis" component of this demonstration to 2009. On January 8, 2008, CMS published a proposed rule titled "Option for Prescription Drug Plans to Lower Their Premiums for Low-Income Subsidy Beneficiaries." It is our intent that the policy in the final version of this rule will replace the current "de minimis" policy.

B3. Coordination of Benefits (COB) User Fees

CMS is authorized to impose user fees on Part D sponsors for the transmittal of information necessary for benefit coordination between sponsors and other entities providing prescription drug coverage. CMS may review and update this user fee annually to reflect the costs associated with COB activities. For contract year 2008, the Part D COB user fee was \$1.36 per enrollee per year. Upon review of the anticipated costs of COB activities in 2009, the Part D COB user fee will increase to \$2.52 per enrollee per year for contract year 2009. This COB user fee will be collected at a rate of \$0.28 per enrollee per month from January to September (for an annual rate of \$0.21 per enrollee per month) for a total user fee of \$2.52 per enrollee per year. Part D sponsors should account for this COB user fee when developing their 2009 bids.

B4. Budget Neutrality Offsets for Reinsurance Payment Demonstration Plans in 2009

The budget neutrality offsets applied to the capitated reinsurance payments for flexible capitated, fixed capitated, and Medicare Advantage rebate option plans will remain at \$10.00 per member per year for contract year 2009. The Part D Reinsurance Payment Demonstration is a budget neutral alternative payment approach that provides an incentive for Part D sponsors to offer supplemental drug coverage to Medicare beneficiaries. Under this demonstration, Medicare pays participating Part D plans a capitated reinsurance payment that is actuarially equivalent to the federal reinsurance payments that they would otherwise receive when a beneficiary reaches the catastrophic phase of the Part D benefit (\$4,050 in True Out-of-pocket costs for 2008).

This demonstration must be budget neutral as stated in the Instructions for Part D Payment Demonstration released on May 10, 2005 such that the expected Medicare costs under the demonstration are no more than the expected costs to the Medicare program in the absence of the demonstration. In order to ensure budget neutrality, the capitated reinsurance payments for all plans offered under the Part D Reinsurance Payment Demonstration were offset by \$10.00 per member per year in 2008.

As stated in the Federal Register Notice published on February 25, 2005 (70 FR 9360), in order to ensure budget neutrality for this payment demonstration, CMS may increase these offsets each year in order to reflect an increase in the expected costs of the demonstration. The capitated reinsurance payments for 2009 must continue to be offset by \$10.00 per member per year to ensure that the Part D Reinsurance Payment Demonstration remains budget neutral. When developing the 2009 bids for flexible capitated, fixed capitated, and Medicare Advantage rebate option plans, Part D sponsors should reflect this offset amount in the direct administrative expense line item of the Bid Pricing Tool (BPT).

Section C. Risk Adjustment

C1. Normalization Factor for the RxHCC Model

Please see Section C, item C3 in Attachment II, Changes in the Payment Methodology for Original Medicare Benefits for CY 2009.

C2. Standard Set of ICD-9 Diagnosis Codes for Risk Adjustment

Please See Section K, item K2 in Attachment II, Changes in the Payment Methodology for Original Medicare Benefits for CY 2009.

Section D. Payment Reconciliation

Pursuant to section 1860D-15(e) of the Act and the regulations at 42 CFR 423.336, the risk percentages and payment adjustments for Part D risk sharing are unchanged from contract year 2008. The risk percentages for the first and second thresholds remain at 5% and 10% of the target amount respectively for 2009. The payment adjustments for the first and second corridors are 50% and 80% respectively. Please see Figure 1 below which illustrates the risk corridors for 2008-2011.

Figure 1. Part D Risk Corridors for 2008-2011

INT4	COPD CVD CAD	0.173	0.071
INT5	RF CHF ^{2,3}	0.231	-
INT6	RF CHF DM ²	0.477	0.358

NOTES:

¹ Includes Type I or Type II Diabetes Mellitus.

² Beneficiaries with the three-way interaction RF*CHF*DM are excluded from the two-way interactions DM*CHF and RF*CHF. Thus, the three-way interaction term RF*CHF*DM is not additive to the two-way interaction terms DM*CHF and RF*CHF. Rather, it is hierarchical to, and excludes these interaction terms. A beneficiary with all three conditions is not "credited" with the two-way interactions. All other interaction terms are additive.

³ HCC or disease interaction excluded from institutional model because estimated coefficient less than 0 or t-statistic less than 1.0.

The 2007 denominator of \$7,463.14 used to calculate both the community and institutional factors is the national predicted average annual cost under the model.

DM is diabetes mellitus (HCCs 15-19).

CHF is congestive heart failure (HCC 80).

COPD is chronic obstructive pulmonary disease (HCC 108).
CVD is cerebrovascular disease (HCCs 95, 96, 100, and 101).
CAD is coronary artery disease (HCCs 81-83).
RF is renal failure (HCC 131).

SOURCE: RTI International analysis of 2004/2005 Medicare 5% sample.

SOURCE: RTI International analysis of 2004/2005 Medicare 100% institutional sample.

Exhibit IV-2. Preliminary Disease Hierarchies for the CMS-HCC Model

Hierarchical Condition Category (HCC)	If the Disease Group is Listed in This Column...	...Then Drop the Associated Disease Group(s) Listed in This Column
	Disease Group Label	
5	Opportunistic Infections	112
7	Metastatic Cancer and Acute Leukemia	8, 9, 10
8	Lung, Upper Digestive Tract, and Other Severe Cancers	9, 10
9	Lymphatic, Head and Neck, Brain and Other Major Cancers	10
15	Diabetes with Renal Manifestations or Peripheral Circulatory Manifestation	16, 17, 18, 19
16	Diabetes with Neurologic or Other Specified Manifestation	17, 18, 19
17	Diabetes with Acute Complications	18, 19
18	Diabetes with Ophthalmologic or Unspecified Manifestations	19
25	End-Stage Liver Disease	26, 27
26	Cirrhosis of Liver	27
51	Drug/Alcohol Psychosis	52
54	Schizophrenia	55
67	Quadriplegia/Other Extensive Paralysis	68, 69, 100, 101, 157
68	Paraplegia	69, 100, 101, 157
69	Spinal Cord Disorders/Injuries	157
77	Respirator Dependence/ Tracheostomy Status	78, 79
78	Respiratory Arrest	79
81	Acute Myocardial Infarction	82, 83
82	Unstable Angina and Other Acute Ischemic Heart Disease	83
95	Cerebral Hemorrhage	96
100	Hemiplegia/Hemiparesis	101
104	Vascular Disease with Complications	105, 149
107	Cystic Fibrosis	108
111	Aspiration and Specified Bacterial Pneumonias	112
130	Dialysis Status	131, 132
131	Renal Failure	132
148	Decubitus Ulcer of Skin	149
154	Severe Head Injury	75, 155
161	Traumatic Amputation	177

How Payments are Made with a Disease Hierarchy – EXAMPLE: If a beneficiary triggers HCCs 148 (Decubitus Ulcer of the Skin) and 149 (Chronic Ulcer of Skin, Except Decubitus), then HCC 149 will be dropped. In other words, payment will always be associated with the HCC in column 1 if a HCC in column 3 also occurs during the same collection period. Therefore, the MA organization's payment will be based on HCC 148 rather than HCC 149.

NOTES:

The 2007 denominator of \$7,463.14 used to calculate the new enrollee factors is the national predicted average annual cost under the model.

Three sets of interaction coefficients were constrained to be equal (Male, Age 67 & Male, Age 68; Medicaid, Male, Age 65 & Medicaid, Male, Ages 66 to 69; Originally Disabled, Female, Age 65 & Originally Disabled, Female, Ages 66 to 69). These constraints are necessary so that predicted expenditures, and risk scores for all demographic groups, vary in a reasonable way, as shown in the table of mutually exclusive demographic groups.

**Attachment V. Medicare Part D Benefit Parameters for the Defined Standard Benefit:
Annual Adjustments for 2009**

The Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (MMA) directs CMS to update the statutory parameters for the defined standard Part D drug benefit each year. These parameters include the standard deductible, initial coverage limit, and catastrophic coverage threshold, and minimum copayments for costs above the annual out-of-pocket threshold. In addition, CMS is statutorily required to update the parameters for the low income subsidy benefit and the cost threshold and cost limit for qualified retiree prescription drug plans eligible for the Retiree Drug Subsidy. Included in this notice are (i) the methodologies for updating these parameters, (ii) the updated parameter amounts for the Part D defined standard benefit and low-income subsidy benefit for 2009, and (iii) the updated cost threshold and cost limit for qualified retiree prescription drug plans.

As required by statute, the parameters for the defined standard benefit formula are indexed to the percentage increase in average per capita total Part D drug expenses for Medicare beneficiaries. Accordingly, the actuarial value of the drug benefit increases along with any increase in drug expenses, and the defined standard Part D benefit continues to cover a constant share of drug expenses from year to year.

All of the Part D benefit parameters are updated using one of two indexing methods specified by statute: (i) the annual percentage increase in average expenditures for Part D drugs per eligible beneficiary, and (ii) the annual percentage increase in the Consumer Price Index (CPI) (all items, U.S. city average).

I. Annual Percentage Increase in Average Expenditures for Part D Drugs Per Eligible Beneficiary

Section 1860D-2(b)(6) of the Social Security Act defines the “annual percentage increase” as “the annual percentage increase in average per capita aggregate expenditures for covered Part D drugs in the United States for Part D eligible individuals, as determined by the Secretary for the 12-month period ending in July of the previous year using such methods as the Secretary shall specify.” The following parameters are updated using the “annual percentage increase”:

Deductible: From \$275 in 2008 and rounded to the nearest multiple of \$5.

Initial Coverage Limit: From \$2,510 in 2008 and rounded to the nearest multiple of \$10.

Out-of-Pocket Threshold: From \$4,050 in 2008 and rounded to the nearest multiple of \$50.

Minimum Cost-Sharing in the Catastrophic Coverage Portion of the Benefit: From \$2.25 per generic or preferred drug that is a multi-source drug, and \$5.60 for all other drugs in 2008, and rounded to the nearest multiple of \$0.05.

Maximum Copayments below the Out-of-Pocket Threshold for certain Low Income Full Subsidy Eligible Enrollees: From \$2.25 per generic or preferred drug that is a multi-source drug, and \$5.60 for all other drugs in 2008, and rounded to the nearest multiple of \$0.05.

Deductible for Low Income (Partial) Subsidy Eligible Enrollees: From \$56¹ in 2008 and rounded to the nearest \$1.

Maximum Copayments above the Out-of-Pocket Threshold for Low Income (Partial) Subsidy Eligible Enrollees: From \$2.25 per generic or preferred drug that is a multi-source drug, and \$5.60 for all other drugs in 2008, and rounded to the nearest multiple of \$0.05.

II. Annual Percentage Increase in Consumer Price Index, All Urban Consumers (all items, U.S. city average)

Section 1860D-14(a)(4) of the Social Security Act specifies that the annual percentage increase in the CPI, All Urban Consumers (all items, U.S. city average) as of September of the previous year is used to update the maximum copayments below the out-of-pocket threshold for full benefit dual eligible enrollees with incomes that do not exceed 100% of the Federal poverty line. These copayments are increased from \$1.05 per generic or preferred drug that is a multi-source drug, and \$3.10 for all other drugs in 2008², and rounded to the nearest multiple of \$0.05 and \$0.10, respectively.

III. Calculation Methodology

Annual Percentage Increase

For the 2007 and 2008 contract years, the annual percentage increases, as defined in section 1860D-2(b)(6) of the Social Security Act, were based on the National Health Expenditure (NHE) prescription drug per capita estimates because sufficient Part D program data was not available. For the 2009 contract year benefit parameters, Part D program data is used to calculate the annual percentage trend as follows:

$$\frac{\text{August 2007} - \text{July 2008}}{\text{August 2006} - \text{July 2007}} = \frac{\$2,659.37}{\$2,509.48} = 1.0597$$

In the formula, the average per capita cost for August 2006 – July 2007 (\$2,509.48) is calculated from actual Part D prescription drug event (PDE) data and the average per capita cost for August 2007 – July 2008 (\$2,659.37) is calculated based on actual Part D PDE data incurred from August – December, 2007 and projected through July, 2008.

¹ Consistent with the statutory requirements of 1860D-14(a)(4)(B) of the Social Security Act, the update for the deductible for low income (partial) subsidy eligible enrollees is applied to the unrounded 2008 value of \$55.91.

² Consistent with the statutory requirements of 1860D-14(a)(4)(A) of the Social Security Act, the copayments are increased from the unrounded 2008 values of \$1.04 per generic or preferred drug that is a multi-source drug, and \$3.13 for all other drugs.

The 2009 benefit parameters reflect the 2008 annual percentage trend as well as a revision to the prior estimates for the 2006 and 2007 annual percentage increases. Based on the updated NHE prescription drug per capita costs, the 2007 and 2008 increases are now estimated to be 6.45% and 6.59%, respectively. Accordingly, the 2009 benefit parameters reflect a multiplicative update of 1.47% ($1.0645/1.0529 * 1.0659/1.0619 - 1$) for prior year revisions. In summary, the 2008 parameters outlined in section I are updated by 7.54% for 2009 as summarized by Table V-1.

Table V-1. Annual Percentage Increase

Annual percentage trend for July 2008	5.97%
Prior year revisions	1.48%
Annual percentage increase for 2008	7.54%

Note: Percentages are multiplicative, not additive.

Values are carried to additional decimal places and may not agree to the rounded values presented above.

Annual Percentage Increase in Consumer Price Index, All Urban Consumers (all items, U.S. city average)

The annual percentage increase in the CPI as of September of the previous year referenced in section 1860D-14(a)(4)(A)(ii) is interpreted to mean that, for contract year 2009, the September 2008 CPI should be used in the calculation of the index. To ensure that plan sponsors and CMS have sufficient time to incorporate the cost-sharing requirements into benefit, marketing material and systems development, the methodology to calculate this update includes an estimate of the September 2008 CPI based on the projected amount included in the President's FY2009 Budget. The September 2007 value is from the Bureau of Labor Statistics. The annual percentage trend in CPI for contract year 2009 is calculated as follows:

$$\frac{\text{Projected September 2008 CPI}}{\text{Actual September 2007 CPI}} \text{ or } \frac{213.9}{208.5} = 1.026$$

(Source: President's FY2009 Budget and Bureau of Labor Statistics, Department of Labor)

The 2009 benefit parameters reflect the 2008 annual percentage trend in the CPI, as well as a revision to the prior estimate for the 2007 annual percentage increase. The 2008 parameter update reflected an annual percentage trend in CPI of 2.17%. Based on the actual reported CPI for September 2007, the September 2007 CPI increase is now estimated to be 2.76%. Thus, the 2009 update reflects a multiplicative 0.57% ($1.0276/1.0217 - 1$) correction for prior year revisions. In summary, the cost sharing items outlined in section II are updated by 3.18% for 2009 as summarized by Table V-2.

Table V-2. Cumulative Annual Percentage Increase in CPI

Annual percentage trend for September 2008	2.60%
Prior year revisions	0.57%
Annual percentage increase for 2008	3.18%

Note: Percentages are multiplicative, not additive.
 Values are carried to additional decimal places and may not agree to the rounded values presented above.

IV. Part D Payment Demonstration Adjustment

The fixed capitated option of the Part D Payment Demonstration includes a catastrophic benefit that begins at the total drug expense corresponding to the out-of-pocket threshold in the Defined Standard Benefit. For 2009, this amount is increased from \$5,726.50 in 2008 to \$6,153.75. Specifically, this is the minimum amount of total covered Part D drug expenditures that will have occurred when the beneficiary reaches the out-of-pocket threshold of \$4,350 in 2009 in the defined standard benefit. This expense level is determined arithmetically as a function of the 2009 out-of-pocket threshold (as opposed to being indexed directly).

V. Retiree Drug Subsidy Amounts

As outlined in §423.886(b)(3) of the regulations implementing the Part D benefit, the cost threshold and cost limit for qualified retiree prescription drug plans that end in years after 2006 are adjusted in the same manner as the annual Part D deductible and out-of-pocket threshold are adjusted under §423.104(d)(1)(ii) and (d)(5)(iii)(B), respectively. Specifically, they are adjusted by the "annual percentage increase" as defined previously in this document and the cost threshold is rounded the nearest multiple of \$5 and the cost limit is rounded to the nearest multiple of \$50. The cost threshold and cost limit are defined as \$265 and \$5,350, respectively, for plans that end in 2007, and, as \$275 and \$5,600, respectively, for plans that end in 2008. For 2009, the cost threshold is increased to \$295, and the cost limit is increased to \$6,000.

EXHIBIT D-41

February 24, 2012

**Notice of Final Payment Error Calculation Methodology for
Part C Medicare Advantage Risk Adjustment Data Validation Contract-Level Audits**

Introduction

On December 21, 2010 the Centers for Medicare and Medicaid Services (CMS) posted on its website the "Medicare Advantage Risk Adjustment Data Validation (RADV) Notice of Payment Error Calculation Methodology for Part C Organizations Selected for RADV Audit – Request for Comment". CMS invited public comment on the proposed methodology, with such comments to be submitted in writing by Friday, January 21, 2011.

CMS carefully reviewed the more than 500 comments received on the draft methodology. This Notice responds to the analytic concerns raised relating to extrapolation and payment recovery and presents the final methodology for the RADV payment error calculation.

Following the background section, this Notice provides a general walkthrough of the RADV payment error calculation methodology in two sections: (A) sampling; and (B) payment error calculation.

This methodology will be applied to the next round of RADV contract-level audits, which will be conducted on payment year 2011. Payment year 2011 is the first year for which payment recovery based on extrapolated estimates will be conducted for Medicare Advantage (MA). Note that sampling for RADV audits will occur after the close of final reconciliation for the payment year being audited.

CMS' RADV audit initiative is the Agency's primary strategy to address the national payment error rate for the MA program, which is currently estimated to be 11 percent for FY 2011. In addition to recovery of overpayments through RADV audits, CMS also expects that these contract-level audits will have a sentinel effect on the quality of risk adjustment data submitted for payment by MA organizations.

Background

Section 1853(a)(3) of the Social Security Act requires that CMS risk adjust payments to Medicare Advantage (MA) organizations. In general, the current risk adjustment methodology relies on enrollee diagnoses, as specified by the International Classification of Disease, Ninth Revision Clinical Modification guidelines (ICD-9-CM), to prospectively adjust capitation payments for a given enrollee based on the health status of the enrollee. Diagnosis codes submitted by MA organizations are used to determine beneficiary risk scores, which in turn determine the risk-adjusted reimbursement.

RADV audits determine whether the diagnosis codes submitted by MA organizations can be validated by supporting medical record documentation. This medical record documentation must meet certain criteria and standards specified in RADV materials that CMS provides to audited contracts. Diagnoses that cannot be validated contribute to a payment error rate. This document describes the sampling

methodology that CMS will use for RADV audits and the methodology for calculating the payment error for each audited Medicare Advantage contract.

A. Sampling

To conduct these audits, CMS selects a set of MA contracts for each RADV audit cycle. Enrollees are sampled from each selected MA contract for the purpose of estimating payment error related to risk adjustment.

Sampling Frame

First, CMS identifies all beneficiaries under each MA contract who are "RADV-eligible" because they meet the following criteria:

1. Enrolled in an MA contract (H-number, E-number, or R-number) in January of the payment year— based on CMS' monthly member enrollment files;
2. Continuously enrolled in the same MA contract (as identified in step (1) above) from January of the data collection year through January of the payment year;
3. Non-End Stage Renal Disease (non-ESRD) status from January of the data collection year through January of the payment year;
4. Non-hospice status from January of the data collection year through January of the payment year;
5. Enrolled in Medicare Part B coverage for all 12 months during the data collection year (i.e., defined as full risk enrollees for risk adjusted payment); and
6. Had at least one risk adjustment diagnosis (ICD-9-CM code) submitted during the data collection year that led to at least one CMS-Hierarchical Condition Category (HCC) assignment for the payment year.

Sample Size and Strata

Next, CMS selects a sample of beneficiaries from each contract's cohort of RADV-eligible enrollees. Enrollee-based stratification will be used in the process of sampling enrollees. In order to derive the strata, the RADV-eligible enrollees in each contract will be ranked from lowest to highest based on their community risk score. The enrollees will then be divided into three equal groups based on the total number of eligible enrollees, where the first group will include the third of enrollees with the highest risk scores and the third group will include the third of enrollees with the lowest risk scores. The remaining enrollees will be in the middle stratum.

CMS will select up to 201 enrollees for medical record review from each contract selected for a contract-level audit. For smaller contracts, i.e., those with fewer than 1,000 RADV-eligible enrollees, CMS will individually adjust their sample sizes by using the finite population correction factor. The sample sizes for these smaller contracts will be 201 or fewer enrollees.

To achieve a sample size of 201 enrollees per contract, sixty-seven (67) enrollees will be randomly sampled from each group or stratum. The corresponding stratum-based enrollee weights will be computed as the number of RADV-eligible enrollees in the population grouping (or stratum) divided by the number of enrollees selected from that grouping for the sample, i.e., N_h/n_h , where h represents the corresponding stratum.

For example, if a contract has 3,000 RADV-eligible enrollees, the enrollees would be ranked by risk score, then divided into three equal groups of 1,000 enrollees each (to represent high, medium, and low strata). An equal number of enrollees will be randomly selected from each group. The weight for each sampled enrollee will equal 14.925 (i.e., $1,000/67$).

For small contracts with fewer than 1,000 RADV-eligible enrollees, the same enrollee-based stratification process will be applied; however, a proportionally smaller number of enrollees will be randomly sampled from each group or stratum.

The enrollee sampling weights will be used as multipliers to scale-up (or extrapolate) the sample payment error findings to the population it represents.

Once enrollees have been selected, the MA contract will be required to submit medical records to support all CMS-HCCs represented in the sampled beneficiaries' risk scores for the payment year.

Effective with the CY 2011 RADV audit, CMS will allow audited MA contracts to submit multiple medical records for each CMS-HCC being validated. All diagnoses will be abstracted from the first medical record that validates the CMS-HCC under review. The one best medical record policy will continue to apply to the RADV audit dispute and appeal processes outlined in 42 CFR §422.311. CMS will provide more detailed information in the RADV audit procedures that will be distributed to audited MA contracts.

B. Payment Error Calculation

Enrollee-level Payment Error Calculation

CMS will calculate each contract's payment error based on the validation results. For each sampled enrollee, the RADV-corrected risk score and corrected payment will be calculated based on the CMSHCCs that are supported by RADV medical record review findings for the enrollee. Enrollee-level payment errors will be defined as the difference between the original payment and the RADV-corrected payment (per member per month). The payment error for each enrollee will be either positive (representing a net overpayment), or negative (representing a net underpayment). An annual payment error amount will be calculated for each sampled enrollee based on the number of months the person was enrolled in the selected MA contract (and was not in ESRD or hospice status) during the payment year.

Payment Error Extrapolation Calculation

To derive the payment error estimate for each MA contract, the annual payment error for each sampled enrollee will be multiplied by the enrollee's sampling weight (computed for each stratum [h] during the sampling phase as N_h/n_h , where N represents the number of enrollees in the RADV-eligible population and n is the number of enrollees sampled). The weighted enrollee annual payment error will be summed across all enrollees in the sample to determine an estimated payment error for the MA contract (the "point estimate"). A 99 percent confidence interval (CI) will then be calculated for the estimated payment error for each audited MA contract.

The following formulas illustrate computation of a 99 percent CI around the payment error estimate for one contract, assuming a sample size of 201, with 67 enrollees selected from each of three strata groupings.

The lower bound of the 99 percent CI is computed as the estimated payment error for the contract (PE) minus (2.575 multiplied by the standard error), or $(PE - (2.575 * SE))$. The standard error (SE) can be calculated as follows:

1. Derive the variance, v_h , (standard deviation squared) of the unweighted enrollee payment errors across the sample enrollees within each of the three strata (h).
2. Calculate the variance of the estimated total (V_T) payment error, where N represents the number of enrollees in the RADV-eligible population of the h^{th} (1st, 2nd, 3rd) stratum:

$$= \sum_h \frac{N_h^2}{67} V_T V_h$$

3. The standard error is $SE_T = \sqrt{V_T}$

Payment Recovery Amount and the Fee-For-Service Adjuster

If the CI for the point estimate includes zero or is below zero, the contract will have the payment recovery amount constrained to zero.

If the CI for the point estimate is above zero, the payment recovery amount for the contract will be determined as follows. First, a preliminary payment recovery amount will be set at the lower bound of the 99 percent CI for the contract's point estimate. Second, to determine the final payment recovery amount, CMS will apply a Fee-for-Service Adjuster (FFS Adjuster) amount as an offset to the preliminary recovery amount. If the FFS Adjuster amount is greater than the preliminary recovery amount, the final recovery amount is equal to zero.

The FFS adjuster accounts for the fact that the documentation standard used in RADV audits to determine a contract's payment error (medical records) is different from the documentation standard

used to develop the Part C risk-adjustment model (FFS claims). The actual amount of the adjuster will be calculated by CMS based on a RADV-like review of records submitted to support FFS claims data.

EXHIBIT D-42

Risk Adjustment of Medicare Capitation Payments Using the CMS-HCC Model

Gregory C. Pope, M.S., John Kautter, Ph.D., Randall P. Ellis, Ph.D., Arlene S. Ash, Ph.D., John Z. Ayanian, M.D., M.P.P., Lisa I. Iezzoni, M.D., M.Sc., Melvin J. Ingber, Ph.D., Jesse M. Levy, Ph.D., and John Robst, Ph.D.

This article describes the CMS hierarchical condition categories (HCC) model implemented in 2004 to adjust Medicare capitation payments to private health care plans for the health expenditure risk of their enrollees. We explain the model's principles, elements, organization, calibration, and performance. Modifications to reduce plan data reporting burden and adaptations for disabled, institutionalized, newly enrolled, and secondary-payer subpopulations are discussed.

INTRODUCTION

Medicare is one of the world's largest health insurance programs, with annual expenditures exceeding \$200 billion. It provides health insurance to nearly 40 million beneficiaries entitled by elderly age, disability, or ESRD. Approximately 11 percent of Medicare beneficiaries are enrolled in private managed care health care plans, with the rest in the traditional FFS program. The 1997 BBA modified the Medicare managed care (MMC) and other capitated programs, collectively called

M+C.¹ Medicare pays private plans participating in M+C a monthly capitation rate to provide health care services to enrolled beneficiaries.

Historically, capitation payments to MMC plans were linked to FFS expenditures by geographic area, with payments set at 95 percent of an enrollee's county's adjusted average per capita cost (AAPCC). The AAPCC actuarial rate cells were defined by: age, sex, Medicaid enrollment (indicating poverty), institutional status (for nursing home residents), and working aged status (for beneficiaries with employer-based insurance where Medicare is a secondary payer). Separate county factors were calculated for the aged and non-aged disabled (under 65 years), and at the State-level only (due to small numbers), for ESRD-entitled beneficiaries.

The AAPCC payment methodology explains only about 1-percent of the variation in expenditures for Medicare beneficiaries, and does not pay more for sicker people. Thus, research showed that the managed care program was increasing total Medicare Program expenditures, because its enrollees were healthier than FFS enrollees, and the AAPCC did not account for this favorable selection (Brown et al., 1993; Riley et al., 1996; Mello et al.,

Gregory C. Pope and John Kautter are with RTI International. Randall P. Ellis and Arlene S. Ash are with Boston University. John Z. Ayanian is with Harvard Medical School and Brigham and Women's Hospital. Lisa I. Iezzoni is with Harvard Medical School and Beth Israel Deaconess Medical Center. Melvin J. Ingber, Jesse M. Levy, and John Robst are with the Centers for Medicare & Medicaid Services (CMS). The research in this article was funded by CMS to RTI International under Contract Numbers 500-95-048 and 500-00-0030. The views expressed in this article are those of the authors and do not necessarily reflect the views of RTI International, Boston University, Harvard Medical School, Brigham and Women's Hospital, Beth Israel Deaconess Medical Center, or CMS.

¹ The Medicare Prescription Drug, Improvement and Modernization Act of 2003 (MMA) renames the M+C program Medicare Advantage. However, since this renaming does not officially take place until 2006, we continue to use M+C.

2003). Also, more money was not directed to plans enrolling sicker beneficiaries, or to plans specializing in treating high-cost populations, such as beneficiaries with particular chronic diseases or high levels of functional impairment.

The M+C program fundamentally changed the MMC payment method, including a mandate for health-based Medicare capitation payments by 2000. To support this mandate, the BBA required managed care organizations (MCOs) to report inpatient encounter data (i.e., records for each inpatient admission of a plan's enrollees noting, among other things, the beneficiaries' diagnoses) beginning in 1998. In 2000 CMS, which administers the Medicare Program, implemented the PIP-DCG model as a health-based payment adjuster (Pope et al., 2000a). This model estimates beneficiary health status (expected cost next year) from AAPCC-like demographics and the worst principal inpatient diagnosis (principal reason for inpatient stay) associated with any hospital admission. PIP-DCG-based payments were introduced gradually, with only 10 percent of total Medicare capitation payments adjusted by PIP-DCG factors in 2000. The other 90 percent of payments were still adjusted using a purely demographic (AAPCC-like) model.

The PIP-DCG model was intended as a transition, a feasible way to implement risk adjustment based on the readily available, already audited inpatient diagnostic data. Relying on inpatient diagnoses is the PIP-DCG model's major shortcoming, since only illnesses that result in hospital admissions are counted; MCOs that reduce admissions (e.g., through good ambulatory care) can end up with apparently healthier patients and lower payments. Congress's BIPA (2000) addressed the PIP-DCG limitations by requiring the use of ambulatory diagnoses in Medicare risk-

adjustment, to be phased in from 2004 to 2007 at 30, 50, 75, and 100 percent of total payments. CMS began collecting encounter data from MCOs for the physician office and hospital outpatient settings (i.e., records of each enrollee visit to these providers with dates, procedures performed, diagnoses, etc.) in October 2000 and April 2001, respectively. However, following complaints from MCOs about the burden of reporting encounter data, CMS suspended data collection in May 2001, ultimately adopting a drastically streamlined data reporting strategy (discussed later).

CMS evaluated several risk-adjustment models that use both ambulatory and inpatient diagnoses, including ACGs (Weiner et al., 1996), the chronic disease and disability payment system (CDPS) (Kronick et al., 2000), clinical risk groups (CRGs) (Hughes et al., 2004), the clinically detailed risk information system for cost (CD-RISC) (Kapur et al., 2003), and DCG/HCCs (Pope et al., 2000b). CMS chose the DCG/HCC model for Medicare risk-adjustment, largely on the basis of transparency, ease of modification, and good clinical coherence. The DCG/HCC model, part of the same DCG family of models as the PIP-DCG, was developed with CMS funding by researchers at RTI International² and Boston University, with clinical input from physicians at Harvard Medical School.³

Prior to implementing Medicare risk-adjustment in 2004, the DCG/HCC model developers and CMS staff adapted the original model for consistency with CMS' simplified data collection, and for customized fit for Medicare subpopulations. The resulting CMS-HCC model reflects these

² The early development of the DCG/HCC model was done by Health Economics Research, Inc. while under contract to CMS. However, RTI International acquired Health Economics Research, Inc. in 2002.

³ The original version of the DCG/HCC model is described in Ellis et al. (1996). The DCG/HCC model has been refined as described in Pope et al., 1998 and 2000b.

Medicare-specific adaptations of the DCG/HCC model and provides a comprehensive framework for Medicare risk-adjustment.

This article describes the DCG/HCC and CMS-HCC models. The next section describes the DCG/HCC model, including the principles and elements of its diagnostic classification system and how its performance compares to earlier models. We then describe the modifications to accommodate the simplified data that lead to the CMS-HCC model. The final section describes the CMS-HCC model adaptations for subpopulations.

DCG/HCC MODEL PRINCIPLES

Diagnostic Classification System

The following ten principles guided the creation of the diagnostic classification system.

Principle 1—Diagnostic categories should be clinically meaningful. Each diagnostic category is a set of ICD-9-CM codes (Centers for Disease Control and Prevention, 2004). These codes should all relate to a reasonably well-specified disease or medical condition that defines the category. Conditions must be sufficiently clinically specific to minimize opportunities for gaming or discretionary coding. Clinical meaningfulness improves the face validity of the classification system to clinicians, its interpretability, and its utility for disease management and quality monitoring.

Principle 2—Diagnostic categories should predict medical expenditures. Diagnoses in the same HCC should be reasonably homogeneous with respect to their effect on both current (this year's) and future (next year's) costs. (In this article we present prospective models predicting future costs.)

Principle 3—Diagnostic categories that will affect payments should have adequate sample sizes to permit accurate and stable estimates of expenditures. Diagnostic categories used in establishing payments should have adequate sample sizes in available data sets. Given the extreme skewness of medical expenditure data, the data cannot reliably determine the expected cost of extremely rare diagnostic categories.

Principle 4—In creating an individual's clinical profile, hierarchies should be used to characterize the person's illness level within each disease process, while the effects of unrelated disease processes accumulate. Because each new medical problem adds to an individual's total disease burden, unrelated disease processes should increase predicted costs of care. However, the most severe manifestation of a given disease process principally defines its impact on costs. Therefore, related conditions should be treated hierarchically, with more severe manifestations of a condition dominating (and zeroing out the effect of) less serious ones.

Principle 5—The diagnostic classification should encourage specific coding. Vague diagnostic codes should be grouped with less severe and lower-paying diagnostic categories to provide incentives for more specific diagnostic coding.

Principle 6—The diagnostic classification should not reward coding proliferation. The classification should not measure greater disease burden simply because more ICD-9-CM codes are present. Hence, neither the number of times that a particular code appears, nor the presence of additional, closely related codes that indicate the same condition should increase predicted costs.

Principle 7—Providers should not be penalized for recording additional diagnoses (monotonicity). This principle has

two consequences for modeling: (1) no condition category should carry a negative payment weight, and (2) a condition that is higher-ranked in a disease hierarchy (causing lower-rank diagnoses to be ignored) should have at least as large a payment weight as lower-ranked conditions in the same hierarchy.

Principle 8—The classification system should be internally consistent (transitive). If diagnostic category A is higher-ranked than category B in a disease hierarchy, and category B is higher-ranked than category C, then category A should be higher-ranked than category C. Transitivity improves the internal consistency of the classification system, and ensures that the assignment of diagnostic categories is independent of the order in which hierarchical exclusion rules are applied.

Principle 9—The diagnostic classification should assign all ICD-9-CM codes (exhaustive classification). Since each diagnostic code potentially contains relevant clinical information, the classification should categorize all ICD-9-CM codes.

Principle 10—Discretionary diagnostic categories should be excluded from payment models. Diagnoses that are particularly subject to intentional or unintentional discretionary coding variation or inappropriate coding by health plans/providers, or that are not clinically or empirically credible as cost predictors, should not increase cost predictions. Excluding these diagnoses reduces the sensitivity of the model to coding variation, coding proliferation, gaming, and upcoding.

In designing the diagnostic classification, principles 7 (monotonicity), 8 (transitivity), and 9 (exhaustive classification) were followed absolutely. For example, if the expenditure weights for our models did not originally satisfy monotonicity, we imposed constraints to create models that did. Judgment was used to make tradeoffs

among other principles. For example, clinical meaningfulness (principle 1) is often best served by creating a very large number of detailed clinical groupings. But a large number of groupings conflicts with adequate sample sizes for each category (principle 3). Another tradeoff is encouraging specific coding (principle 5) versus predictive power (principle 2). In current coding practice, non-specific codes are common. If these codes are excluded from the classification system, substantial predictive power is sacrificed. Similarly, excluding discretionary codes (principle 10) can also lower predictive power (principle 2). We approached the inherent tradeoffs involved in designing a classification system using empirical evidence on frequencies and predictive power, clinical judgment on relatedness, specificity, and severity of diagnoses, and the judgment of the authors on incentives and likely provider responses to the classification system. The DCG/HCC models balance these competing goals to achieve a feasible health-based payment system.

Elements and Organization

As shown in Figure 1, the HCC diagnostic classification system first classifies each of over 15,000 ICD-9-CM codes into 804 diagnostic groups, or DxGroups. Each ICD-9-CM code maps to exactly one DxGroup, which represents a well-specified medical condition, such as DxGroup 28.01 Acute Liver Disease. DxGroups are further aggregated into 189 Condition Categories, or CCs.⁴ CCs describe a broader set of similar diseases, generally organized into body systems, somewhat like ICD-9-CM major diagnostic categories.

⁴ Most CCs are assigned entirely with ICD-9-CM codes. But CCs 185-189 are assigned by beneficiary utilization of selected types of DME, such as wheelchairs. CC 173, Major Organ Transplant, is defined by procedure codes only. CC 129, ESRD is defined by Medicare entitlement status. None of these CCs are included in the CMS-HCC model.

Figure 1
Hierarchical Condition Categories Aggregations of ICD-9-CM Codes

Although they are not as homogeneous as DxGroups, CCs are both clinically- and cost-similar. An example is CC 28 Acute Liver Failure/Disease that includes DxGroups 28.01 and 28.02 Viral Hepatitis, Acute or Unspecified, with Hepatic Coma.

Hierarchies are imposed among related CCs, so that a person is only coded for the most severe manifestation among related diseases. For example (Figure 2), ICD-9-CM Ischemic Heart Disease codes are organized in the Coronary Artery Disease hierarchy, consisting of 4 CCs arranged in descending order of clinical severity and cost, from CC 81 Acute Myocardial Infarction to CC 84 Coronary Atherosclerosis/Other Chronic Ischemic Heart Disease. A person with an ICD-9-CM code in CC 81 is excluded from being coded in CCs 82, 83, or 84 even if codes that group into those categories were also present. Similarly, a person with ICD-9-CM codes that group into both CC 82 Unstable Angina and Other Acute Ischemic Heart

Disease, and CC 83 Angina Pectoris/Old Myocardial Infarction is coded for CC 82, but not CC 83. After imposing hierarchies, CCs become Hierarchical Condition Categories, or HCCs.⁵

Although HCCs reflect hierarchies among related disease categories, for unrelated diseases, HCCs accumulate. For example, a male with heart disease, stroke, and cancer has (at least) three separate HCCs coded, and his predicted cost will reflect increments for all three problems. The HCC model is more than simply additive because some disease combinations interact. For example, the presence of both Diabetes and Congestive Heart Failure (CHF) could increase predicted cost by more (or less) than the sum of the separate increments for people who have diabetes or CHF alone.

We tested 35 two- and three-way interactions among six common and high-cost chronic diseases defined by HCCs or

⁵The full list of hierarchies used in the CMS-HCC model is available on request from the authors.

Figure 2
Hierarchical Condition Categories Coronary Artery Disease Hierarchy

groups of HCCs: diabetes, cerebrovascular disease, vascular disease, or chronic obstructive pulmonary disease (COPD), CHF, and coronary artery disease (Pope et al., 2000b), as well as three interactions of several of these conditions with renal failure.⁶ Simple additivity yields most of the explanatory power, in the sense that adding all 38 interactions barely increased the base DCG/HCC model's R^2 (from 11.10 to 11.13 percent). However, six interactions were substantial in magnitude, statistically significant, and clinically plausible. Hence, to improve clinical face validity and predictive accuracy for important subgroups of beneficiaries, we include them in the DCG/HCC model. For example, the simultaneous presence of CHF and COPD leads to higher expected costs than would be calculated by adding the separate increments for CHF and COPD alone.

⁶ In later work unpublished work, we also examined all two-way interactions of cancer with the other six diagnoses, but did not find any significant effects.

Because a single beneficiary may be coded for none, one, or more than one DxGroup or HCC, the DCG/HCC model can individually price tens of thousands of distinct clinical profiles using fewer than 200 parameters. The model's structure thus provides, and predicts from, a detailed comprehensive clinical profile for each individual.

HCCs are assigned using hospital and physician diagnoses from any of five sources: (1) principal hospital inpatient; (2) secondary hospital inpatient; (3) hospital outpatient; (4) physician; and (5) clinically-trained non-physician (e.g., psychologist, podiatrist). The DCG/HCC model does not distinguish among sources; in particular, it places no premium on diagnoses from inpatient care. Using Medicare 5-percent sample FFS data, we investigated adding diagnoses from other sources (Pope et al., 2000b). Adding diagnoses from home health providers raised the explanatory power of the base model from

11.15 to 11.65 percent. Further adding diagnoses from DME suppliers raised the explanatory power from 11.65 to 11.85 percent. All other sources of diagnoses either add no predictive power (SNF, ASC, or hospice) or detract from predictive power (clinical laboratory and radiology/imaging clinics). Diagnoses assigned by home health and DME providers are likely to be less reliable than those assigned by physicians or other providers with greater clinical training. Diagnoses from laboratory and imaging tests are also problematic given the significant proportion of rule-out diagnoses. In implementing the CMS-HCC model, potential gains in predictive power from using additional sources were balanced against the costs of collecting and auditing these data; the decision was to only ask MCOs to collect diagnoses from the five baseline sources previously listed.

Consistent with principle 10, we excluded discretionary diagnostic categories (HCCs) from the preliminary prospective payment model. We excluded diagnoses that were vague/non-specific (e.g., symptoms), discretionary in medical treatment or coding (e.g., osteoarthritis), not medically significant (e.g., muscle strain), or transitory or definitively treated (e.g., appendicitis). We also excluded HCCs that did not (empirically) add to costs, and finally, the five HCCs that were defined by the presence of procedures or use of DME, because, as much as possible, we wanted payments to follow what medical problems were present as opposed to what services were offered.⁷ Altogether, we excluded 88 of the 189 HCCs, leaving 101 HCCs in the preliminary prospective payment model. As discussed further, additional HCCs were excluded from the final, 70-category CMS-HCC model.

⁷ The DME HCCs were developed to predict costs associated with functional impairment not captured by diagnoses. Although they did improve prediction for the functionally impaired, substantial under-prediction remained (Pope et al., 2000b; Kantter and Pope, 2001).

The DCG/HCC model also relies on demographics. Demographic adjusters included in the model are 24 mutually exclusive age/sex cells (e.g., female, age 65-69), an indicator for at least 1-month of Medicaid enrollment in the base year (a poverty indicator), and an indicator of originally disabled status. The age cells distinguish beneficiaries currently entitled to Medicare by age (65 or over) versus disability (under 65); a separate, explicit aged versus disabled entitlement status indicator would be redundant. The originally disabled indicator distinguishes beneficiaries who are currently age 65 or over, but were first entitled to Medicare before age 65 by disability. The age/sex, Medicaid, and originally disabled categories add to each other and to the HCC diagnostic categories.⁸ The demographic variables are the same as have been used in the PIP-DCG model, and are discussed at greater length elsewhere (Pope et al., 2000a).

Figure 3 displays a hypothetical clinical vignette of a female age 79, eligible for Medicaid and diagnosed with acute myocardial infarction (AMI), angina pectoris, COPD, renal failure, chest pain, and an ankle sprain. Note that although this female receives CCs for both AMI and angina, she receives no HCC for angina because AMI is a more severe manifestation of coronary artery disease. Also note that while payment includes additive increments for females age 75-79 (demographic categories not shown in Figure 3), Medicaid, AMI, COPD, and renal failure, the HCCs for major symptoms and other injuries are excluded from the payment calculation. Chest pain is a symptom associated with a variety of medical conditions ranging from minor to serious, and sprains are transitory, with minimal implications for next year's cost.

⁸ We did not systematically investigate interactions of age and sex with HCCs (diagnoses). This is a subject for future research.

Figure 3
Clinical Vignette for Hierarchical Condition Categories Classification 79 Year Old Female with AMI, Angina Pectoris, COPD, and Renal Failure

PERFORMANCE OF DCG/HCC AND PIP-DCG MODELS

The predictive accuracy of risk-adjustment models is typically judged by the R^2 statistic (percentage of variation explained) to measure predictive accuracy for individuals and predictive ratios (ratios of mean predicted to mean actual expenditures for subgroups of beneficiaries) to measure predictive accuracy for groups. The R^2 of age/sex, PIP-DCG, and DCG/HCC models as measured on 1996-1997 Medicare's 5-

percent sample FFS data are: age/sex, 1.0 percent; PIP-DCG, 6.2 percent; and DCG/HCC, 11.2 percent.

Adding PIP-DCG to demographic predictors (age/sex) increases predictive power sixfold. Adding secondary inpatient and ambulatory diagnoses (hospital outpatient and physician), and arraying them in a multi-condition cumulative model (DCG/HCC) nearly doubles the power again. Besides the R^2 , another interesting summary statistic is the percentage of payments based on demographic variables: 100

Table 1
Predictive Ratios¹ for Alternative Risk-Adjustment Models

Category	Model		
	Age/Sex	PIP-DCG	DCG/HCC
Quintiles of Expenditures			
First (Lowest)	2.66	2.09	1.23

SOURCE: (Pope et al., 2000b.)

percent in a demographic model, 81 percent in the PIP-DCG model, but only 43 percent in the DCG/HCC model (Pope et al., 2001). With over one-half of payments determined by diagnoses, the DCG/HCC model moves decisively away from the AAPCC demographic-based payment system.

Table 1 shows predictive ratios for selected groups of Medicare beneficiaries. Ratios close to 1.0 indicate accurate prediction of costs; less than 1.0, under prediction; and, more than 1.0, over prediction. The PIP-DCG model improves substantially on age/sex, and in almost all cases, the DCG/HCC model improves significantly on the PIP-DCG model. This is true even for hospitalizations, where the PIP-DCG model distinguishes between those hospitalized or not, while the DCG/HCC model makes no distinction by source of diagnosis.⁹ Despite the DCG/HCC model's

⁹The DCG/HCC model captures multiple conditions that might be diagnosed in multiple inpatient stays, whereas the PIP-DCG model captures only the single principal inpatient diagnosis most predictive of future costs if multiple inpatient stays occur.

impressive gains over the age/sex and PIP-DCG models, it still under-predicts for the most expensive and most often hospitalized beneficiaries.

CMS-HCC MODEL

This section describes how the DCG/HCC model was modified before implementation as the M+C risk adjuster for capitation payments in 2004. We will refer to the modified model as CMS-HCC.

DCG/HCC Model Modification to Simplify Data Collection

When several MCOs withdrew from the M+C program around the year 2000, CMS sought to improve plan retention. Since some MCOs had complained of the burden of collecting encounter data for risk-adjustment, CMS sought to develop risk adjustment models that predict well and rely on ambulatory data, but with reduced data col-

Figure 4
Model Explanatory Power as a Function of Number of Hierarchical Condition Categories (HCC)

lection requirements. One measure of the data collection burden imposed by a model is its number of diagnostic categories.¹⁰

We investigated the relationship between number of diagnostic categories used in the DCG/HCC model and its predictive power (Pope et al., 2001). Figure 4 plots the relationship between number of diagnostic categories and model explanatory power measured by R^2 . Diagnostic categories (HCCs) were entered into the model in descending order of their incremental explanatory power using stepwise regression. The base model (with zero HCCs) includes 26 demographic variables, the 24 age/sex cells, and Medicaid and originally disabled status. Its R^2 is 1.69 percent.

¹⁰The relationship between number of diagnostic categories and data collection burden is controversial. Some MCOs seemed to feel that it would be less burdensome to report all diagnoses, which CMS allows.

The incremental contribution to predictive power declines rapidly with the number of diagnostic categories added to the model. The first diagnostic category entered by the stepwise regression is CHF, which more than doubles the demographic model R^2 to 4.11 percent. The second condition category entered is COPD, raising the R^2 to 4.94 percent. This is an incremental gain of 0.83 percentage points, substantial, but much less than the increment of 2.42 percentage points due to CHF. With 5 HCCs included, 61 percent of the maximum explanatory power of the full (101 HCC) model is attained; with 10 HCCs, 74 percent of the maximum is achieved; with 20, 85 percent, and with 30, 90 percent. The incremental R^2 from adding a diagnostic category is 0.48 percentage points at 5 HCCs; 0.26 percentage points at 10 HCCs; 0.08 percentage points at 20 HCCs; and 0.05 percentage points at 30 HCCs.

This analysis shows that a parsimonious risk-adjustment model with a substantially reduced number of diagnostic categories is almost as predictive as a full model. But parsimony has a cost. In limiting the number of conditions that affect payment, many serious, high-cost diagnoses—especially rare ones—will be ignored. MCOs enrolling beneficiaries with excluded diagnoses will be disadvantaged, and beneficiaries with such conditions may not be well served by MCOs.

CMS considered these results, and consulted with clinicians, on the tradeoff between number of diagnostic categories and predictive power, and also other criteria for diagnostic categories to include in risk adjustment, such as well-defined diagnostic criteria and clinical coherence and homogeneity. It was important that the HCC hierarchies not be disrupted by deletion of higher-ranked HCCs while lower-ranked HCCs were retained. After this process, CMS selected 70 HCCs to include in the CMS-HCC model. The choices reflect a balance among the competing considerations of reducing data collection burden, maximizing predictive power, including rare, high-cost conditions, and selecting only well-defined and clinically coherent conditions. Generally, the higher-cost, more severe conditions at the top of the HCC disease hierarchies were retained, while some lower-cost, more frequent and more discretionary conditions at the bottom of the hierarchies were pruned. For example, in the coronary artery disease hierarchy, AMI (heart attack), other acute IHD (e.g., unstable angina), and angina pectoris/old myocardial infarction were retained, but chronic IHD (e.g., coronary atherosclerosis) was excluded.

After the CMS-HCC model was finalized, a list of approximately 3,000 of the more than 15,000 ICD-9-CM diagnosis codes was identified that are sufficient to define the

model's 70 HCCs. In addition, because the CMS-HCC model does not give extra credit for multiple reports of the same diagnosis, MCOs need only report a single encounter during the relevant year of data collection that establishes the diagnosis. The information required for the single encounter is: (1) beneficiary identification number, (2) date (to establish that the diagnosis was made during the relevant reporting period), (3) setting (to establish that the diagnosis was made in one of the allowed hospital or physician settings), and (4) ICD-9-CM diagnosis code. In short, MCOs are required to report only the minimum.

Concern about the quality of diagnostic reporting is the greatest in physician offices, where diagnoses have not heretofore affected payment, and recording of diagnoses is less rigorously practiced than in hospitals. The auditing standard that CMS has promulgated for reporting of physician office diagnoses is that a physician has established the diagnosis in the medical record, and that medical coders have recorded it in accordance with ICD-9-CM rules. CMS will conduct coding audits, but not clinical audits. That is, CMS will require MCOs to demonstrate that a diagnosis is present in the medical record on the specified date and has been coded according to ICD-9-CM. CMS will not require clinical verification of these diagnoses, such as diagnostic test results.

CMS-HCC Model Calibration

We calibrated the CMS-HCC model to 1999-2000 Medicare 5-percent sample FFS data for beneficiaries entitled by age or disability (beneficiaries entitled by ESRD were excluded). The model is prospective, meaning that diagnoses collected in a base year (1999) are used to predict expenditures in the following year (2000). An

important operational change from the PIP-DCG model is that the data lag will be eliminated, making the application of the model consistent with its calibration. With the PIP-DCG model, the data collection period for a payment year ended 6 months before the start of the year, i.e., on June 30 of the previous year, so that final capitation rates could be published by January 1 of the payment year. With the CMS-HCC model, provisional rates will be established by January 1 based on 6-month lagged data, and final rates will be available by June 30 of the payment year based on the previous calendar year's diagnoses. A reconciliation process will adjust the first 6 months of payments to the final rates, if necessary.

A standard set of sample restrictions was employed to ensure a population of beneficiaries with complete 12-month base year diagnostic profiles and complete payment year Medicare expenditures from the FFS claims for aged and disabled beneficiaries (Pope et al., 2000b). Decedents are included in the payment year for their eligible period. Complete FFS claims are not available for months of M+C enrollment or when Medicare is a secondary payer, and M+C plans are not responsible for hospice care, so these months were excluded from our sample. The final sample size is 1,337,887 beneficiaries.

We summed all Medicare payments for a beneficiary for months in 2000 satisfying our sample restrictions, excluding (1) deductibles and copayments paid by the beneficiary; (2) hospice payments; and (3) indirect medical education payments. Hospice and indirect medical education payments are excluded because they were not included in M+C capitation rates, but were paid directly to hospices and teaching hospitals utilized by M+C enrollees. Payments were annualized by dividing them by the fraction of months in 2000 that

satisfy our sample restrictions; all analyses are weighted by this eligibility fraction. In general, annualization and weighting ensures that monthly payments are correctly estimated for all beneficiaries, including those who died (Ellis et al., 1996).¹¹

The model was calibrated using weighted least squares multiple regression. The CMS-HCC regression model estimated for the combined aged and disabled Medicare population is shown in Table 2.

The elements of the model are:

- Age/sex cells (24).
- Medicaid interacted with sex and age/disabled entitlement status.
- Originally disabled status interacted with sex.
- HCC diagnostic categories (70).
- Interactions of diagnostic categories with entitlement by disability (5).
- Disease interactions (6).

The R^2 for this model is 9.8 percent. Several coefficients are constrained because the unconstrained coefficients violate the principle that higher-ranked conditions in a hierarchy should have higher predicted costs, or for other reasons.¹²

As an example of expenditure prediction, consider our hypothetical scenario in Figure 3 of a female age 79 eligible for Medicaid diagnosed with AMI, angina pectoris, COPD, renal failure, chest pain, and an ankle sprain. The female receives the following incremental cost predictions: female, 75 to 79, \$2,562; aged, female, Medicaid, \$616; AMI (HCC 81), \$1,885; angina pectoris, \$0; COPD (HCC 108), \$1,936; renal failure (HCC 131), \$2,908;

¹¹ In our calibration, we did not make any geographic adjustments to Medicare payments. In past work, we have found that deflating payments by a geographic input price index had little effect on estimated risk-adjustment model parameters.

¹² Clinical consultants to CMS suggested that metastatic cancer is not consistently correctly coded, so HCCs 7 and 8 were constrained to have equal coefficients. HCCs 81 and 82 were constrained to have equal coefficients because the ICD-9-CM diagnostic detail CMS collects from health plans is not sufficient to distinguish them.

chest pain, \$0; and ankle sprain, \$0¹³ (Table 2). Her total cost prediction is the sum of these increments, or \$9,907.

Calibration of DCG/HCC models on several years of data reveals increasingly thorough diagnostic coding. For example, if 1999 diagnoses are used to predict expenditures with a model calibrated on 1996/1997 data, mean expenditures will be over predicted. If more complete coding over time is not accounted for, MCOs will be overpaid by the use of current diagnoses with a model calibrated on historical data. CMS makes a slight downward adjustment in HCC-predicted expenditures to account for this.

CMS-HCC Models for Subpopulations

Medicare beneficiaries differ along characteristics that are important for risk adjustment. First, they may be entitled to Medicare in one of three ways: age, disability, or ESRD. Second, some beneficiaries reside in institutions rather than in the community. Third, some enrollees are new to

Medicare and do not have complete diagnostic data. Fourth, Medicare is a secondary payer for some beneficiaries. To account for the different cost and diagnostic patterns of these disparate subgroups of beneficiaries, the CMS-HCC model was adapted for Medicare subpopulations. This section describes models for subpopulations.¹⁴

Beneficiaries Entitled by Disability

Approximately 12 percent of Medicare beneficiaries are entitled to Medicare because they are under age 65 and have a medical condition that prevents them from working (the disabled). Models calibrated on the full Medicare population (excluding ESRD eligibles), mostly reflect cost patterns among the elderly, the other 88 percent of the population. The implications of some diagnoses might differ between the elderly and disabled. For example, a diagnosis that is disabling may be more severe, and the cost of treating a disease may vary by age. We considered allowing differences in incremental expenditure weights for some diagnoses (HCCs) for the disabled (Pope et al., 1998; 2000b).

¹³ The female receives no incremental cost prediction for angina pectoris because AMI is higher-ranked in the coronary artery disease hierarchy and excludes angina. No incremental prediction is made for chest pain and ankle sprain because these diagnoses are not included in the CMS-HCC model.

¹⁴ Risk-adjustment models for ESRD-entitled and functionally-limited beneficiaries are not described in this article.

Using Medicare's 5-percent sample FFS data (1996-1997), we estimated the DCG/HCC model separately on aged and disabled subsamples. We evaluated differences in age versus disabled parameter estimates according to their statistical significance, magnitude, clinical plausibility, and frequency of occurrence in the disabled population (Pope et al., 2000b). Based on these considerations, we chose nine diagnostic categories to receive incremental payments when they occur among disabled beneficiaries. Five of these categories remained significantly different for the disabled when the CMS-HCC model was re-estimated on 1999-2000 data: opportunistic infections, severe hematological disorders (e.g., hemophilia, sickle cell anemia), drug/alcohol psychosis, drug/alcohol dependence, and cystic fibrosis. Incremental annual payments for these conditions among the disabled (in addition to base payments for the elderly) are substantial, ranging from \$2,160 to \$9,691.

Other than for these five conditions, disease risk-adjustment weights are the same for the aged and disabled populations. The CMS-HCC model is estimated on a combined sample of aged and disabled beneficiaries, with disabled interactions for these five diagnostic categories. The combined aged/disabled model is shown in Table 2.

Community and Institutional Residents

Using the newly available Medicare MDS, we identified long-term nursing home residents in the current (i.e., payment) year. Long-term nursing home residence was defined as continuously residing in a nursing home for at least 90 days, as indicated by a 90-day clinical assessment reported by the nursing facility through the MDS. In our prospective risk-adjustment modeling sample of 1,337,887

beneficiaries, 65,593 beneficiaries, or 5 percent, had at least 1 month of long-term nursing facility residence in 2000.¹⁵

Table 3 compares sample sizes and mean expenditures by demographic categories for community and institutional residents, and shows predictive ratios from the CMS-HCC model calibrated on the combined community/institutional sample (Table 2). Nearly one-half (49 percent) of long-term nursing facility residents are age 85 or over. Facility residents are only 2 percent of the combined community plus institutional population for females age 70 to 74, but fully 37 percent of the combined population for females age 95 or over.

Overall, institutional residents are 71 percent more expensive than community residents, \$8,937 in mean annualized expenditures compared to \$5,213. The age profiles of expenditures are quite different. Among community residents, mean expenditures rise steadily with age in the under 65 disabled population and then again in the elderly population, except for a slight decline for the oldest females. In contrast, among the institutionalized, mean expenditures are fairly constant across all ages until they decline significantly among the oldest old. For all age/sex cells except the oldest old, mean expenditures for the institutionalized are substantially higher than for community-dwelling beneficiaries.

However, although not shown in Table 3, among beneficiaries diagnosed with particular HCCs, mean expenditures for the institutionalized are often similar to those of community residents. For example, among all beneficiaries with CHF (HCC 80), expenditures for the institutionalized are \$11,719, which is \$255 less than for community residents. More generally, when classifying people by the presence of

¹⁵ Beneficiaries with both community and long-term institutional months in the same year are included in both samples, weighted by the fraction of their total months alive in the year in each status.

¹ Ratio of mean expenditures predicted by the Centers for Medicare & Medicaid Services - Hierarchical Condition Categories (CMS-HCC) model for combined community/institutional samples to mean actual expenditures.

SOURCE: Pope, G.C. and Kautter, J., RTI International, Ellis, R.P. and Ash, A.S., Boston University, Ayanian, J.Z., Harvard Medical School and Brigham and Women's Hospital, Iezzoni, L.I., Harvard Medical School and Beth Israel Deaconess Medical Center, Ingber, M.J., Levy, J.M., and Robst, J., Centers for Medicare & Medicaid Services, Analysis of 1999-2000 Medicare 5% Standard Analytic File (SAF).

a single diagnosis, expenditures for the institutionalized may be higher, lower, or about the same.

Thus, the main reason that people in facilities cost more is that they have more medical problems, a distinction that is fully accounted for by the HCCs. In fact, the predictive ratios from the combined CMS-HCC model for community and institutional beneficiaries are, respectively, 0.99 and 1.12 (Table 3). This means that the combined model, on average, under predicts expenditures for community residents by 1 percent, and over predicts expenditures for

long-term nursing home residents by 12 percent. Lower expenditures among facility residents adjusting for disease burden could result from substituting non-Medicare for Medicare-reimbursed services; since most nursing home service are not reimbursed by Medicare. Also, greater monitoring of nursing home than community residents may identify and prevent problems leading to hospitalization. The under-prediction for community residents and over-prediction for facility residents is most severe for the oldest age groups, most likely due to decisions to limit

aggressive care for very old residents in nursing homes. The over-prediction of the costs of the institutionalized, together with their different cost patterns by age and diagnosis, led us to consider differentiating the CMS-HCC model for community and institutional populations.

Within a multiple regression model estimation framework, we investigated alternative approaches to allowing differences in the model between community and institutional residents, ultimately choosing to estimate separate models. This properly calibrates the prediction of each group's costs, while allowing all demographic and disease coefficients to differ between community and institutional populations.

In addition to the combined model, Table 2 shows the CMS-HCC community and institutional models. Not surprisingly, the community model R^2 and most of the demographic and disease coefficients are very similar to the combined model, because community residents comprise 95 percent of the combined sample. A few coefficients show greater differences. The community coefficients for the oldest age cells are significantly larger than the combined model coefficients because the lower-cost very old institutionalized have been removed from these cells. The community coefficients for the aged enrolled in Medicaid are also significantly higher, as are several HCC coefficients.

The institutional model R^2 is considerably lower than the community model. But some of the community model's predictive power comes from distinguishing beneficiaries who are healthy (no diagnoses) versus sick (with diagnoses), while the institutional model is explaining cost variations among a population comprised entirely of impaired individuals. Diagnoses help explain why someone might be institutionalized (i.e., distinguish healthy from sick), but are not as powerful in explaining

expenditure differences among the institutionalized. Disease (HCC) coefficients tend to be smaller in the institutional model than in the community model (Table 2). Diagnoses are less predictive of incremental costs among the more uniformly expensive institutional population than they are among the community population.

We constrained certain groups of demographic and diagnostic coefficients in the institutional model to be equal (Table 2), because the small available sample of institutionalized beneficiaries resulted in their low prevalence in some diagnostic categories (HCCs) and made it difficult to obtain stable estimates of each separate parameter. For the same reason, we included no disabled interaction terms, and only two of the disease interaction terms in the institutional model. Also, HCC 158 Hip Fracture/Dislocation was excluded because its coefficient was negative.

The age/sex coefficients for the institutionalized are much higher than for community residents except for the oldest ages. This implies that institutionalized beneficiaries are predicted to be expensive regardless of their diagnostic profile (e.g., even lacking any of the diagnoses included in the CMS-HCC model), whereas community residents are predicted to be expensive only if diagnosed with at least one of the serious diseases included in the CMS-HCC model. This makes sense since institutionalization itself is a marker of poor health, aside from diagnostic profile, but the institutionalized age/sex coefficients decline for the oldest ages, and fall below the community coefficients. Medical treatment may be less aggressive for old, frail beneficiaries who are institutionalized.

Among the institutional population, the coefficient for Medicaid was negative and the coefficients for originally disabled was statistically insignificant. These variables

were excluded from the institutional model. Beneficiaries often qualify for Medicaid after spending down their personal assets to pay for a lengthy nursing home stay. Thus, Medicaid may be a proxy for beneficiaries in the later portion of their stays, when they are less expensive than in the earlier, post-acute phase of their nursing home tenure.

New Medicare Enrollees

The CMS-HCC model requires a complete 12-month base year diagnostic profile to predict the next year's expenditures. Beneficiaries without 12 months base year Medicare enrollment, but at least 1 month of prediction year enrollment, are defined as new enrollees. About two-thirds of new enrollees are age 65.¹⁶ New enrollees may be under age 65 if they become eligible for Medicare by disability; they may be over age 65 if they delay Medicare enrollment or are not originally enrolled in both Parts A and B.¹⁷ We developed a demographic model to predict expenditures for new enrollees who lack the data needed to apply the CMS-HCC model.

Table 4 presents frequencies and mean annualized expenditures from the 5-percent FFS sample data for new enrollees and continuing enrollees. Continuing enrollees are defined as beneficiaries having 12 months of Parts A and B Medicare enrollment in the base year and at least 1 month in the prediction year. For female and male new enrollees age 65, mean annualized expenditures are \$2,729 and \$2,900, respectively, less than one-half of costs of

continuing enrollees (\$6,952 for female and \$6,055 for male). For almost all new enrollees age 65, the original reason for Medicare entitlement is age.¹⁸ In contrast, continuing enrollees age 65 were originally entitled to Medicare by disability, and hence are much more expensive. For other ages, mean expenditures of new and continuing enrollees are much more similar. To achieve sufficient sample sizes in all age ranges to calibrate the new enrollees model, we merged the new and continuing enrollees samples, which resulted in a sample size of 1,495,225 with mean expenditures of \$5,184. For age 65, actual new enrollees dominate the combined sample, and the cost weight reflects their (low) relative costs. Continuing enrollees age 65 are included in the sample to calibrate the originally disabled coefficient for age 65. For other than age 65, the sample is dominated by continuing enrollees, but their costs appear to proxy actual new enrollee costs reasonably well for younger or older ages.

Beneficiaries for Whom Medicare is a Secondary Payer

Working aged beneficiaries are Medicare beneficiaries, age 65 or over, with private group health insurance coverage from their or their spouse's employer. By law, Medicare is a secondary payer for these beneficiaries. The primary private health plan must pay for medical expenses to the extent of its defined benefits. Only if Medicare covers services not covered by the private plan, or has more generous coverage (e.g., lower deductibles or copayments) for Medicare-covered services, is Medicare responsible for payment, and then only to the extent of the difference in

¹⁶ To simplify the new enrollees model, we recoded new enrollees age 64 on February 1 with an original reason for Medicare entitlement of aged to age 65. Thus, the age 65 cell in the new enrollees model combines new enrollees ages 64 and 65 on February 1 of the prediction year whose original reason for entitlement is aged.

¹⁷ For example, a beneficiary might be entitled to Part A (hospital insurance) by age at age 65 or over, but might not pay Part B (physician insurance) premium until an older age.

¹⁸ Some age 65 new enrollees might have originally been entitled to Medicare by disability when under age 65, but then have rejoined the work force and lost their Medicare eligibility, only to re-enroll at age 65.

Table 4
Descriptive Statistics for New and Continuing Medicare Enrollees¹

Age/Sex Category	New Enrollees ²		Continuing Enrollees ³	
	Observations	Mean Annualized Expenditures	Observations	Mean Annualized Expenditures
Female				
0-34 Years	2,540	3,532	7,037	3,653
35-44 Years	3,885	4,341	15,717	4,385
45-54 Years	5,891	4,814	22,431	4,767

RTI International, Ellis, R.P. and Ash, A.S., Boston University, Ayanian, J.Z., Harvard Medical School and Brigham and Women's Hospital, Iezzoni, L.I., Harvard Medical School and Beth Israel Deaconess Medical Center, Ingber, M.J., Levy, J.M., and Robst, J., Centers for Medicare & Medicaid Services, Analysis of 1999-2000 Medicare 5% Standard Analytic File (SAF).

coverage. Medicare expenditures for working aged beneficiaries are lower for this reason, as well as because working may be a proxy for better health.¹⁹ Estimation of a separate model for the working aged is not feasible with the sample sizes available from the Medicare's 5-percent FFS sample. A simple adjustment to CMS-HCC model predictions is a multiplier that scales cost predictions to be lower for these beneficiaries.

¹⁹ Throughout this section, we use the terms working and working aged to include both those who are actually working, and the spouses of those who are working.

We defined the working aged as beneficiaries otherwise satisfying the requirements of our 1999-2000 aged/disabled prospective modeling sample who had at least 1 month of working aged status in the prediction year (2000). There are 19,057 beneficiaries in our working aged sample, or about 1.4 percent as many individuals as in our aged/disabled sample. The mean annualized expenditures of the working aged are \$966, less than one-fifth as much as for the aged/disabled community sample (\$5,213). The CMS-HCC community

model over-predicts mean working aged expenditures by a factor of 3.66. Essentially, we define the working aged multiplier as the ratio of mean actual to mean predicted expenditures for the working aged sample, where expenditures are predicted by the CMS-HCC community model. With an adjustment for beneficiaries who have a mixture of working aged and non-working-aged months in the payment year, the working aged multiplier is 0.215.

CONCLUSIONS

CMS' adaptation of the DCG/HCC model makes substantially more accurate predictions of medical costs for M+C enrollees than has previously been possible. Its use is intended to redirect money away from MCOs that cherry-pick the healthy, while providing the MCOs that care for the sickest patients the resources to do so. The ultimate purpose of the CMS-HCC payment model is to promote fair payments to MCOs that reward efficiency and encourage excellent care for the chronically ill. The CMS-HCC model will continue to evolve. Additional diagnoses may be needed to predict drug expenditures incurred under the drug benefit enacted by MMA (2003). The model may need to be recalibrated to reflect new treatment patterns and disease prevalence. Diagnosis-based risk adjustment may need to be coordinated with disease management programs and incentives for quality of care.

The model has evolved over two decades of research,²⁰ with careful attention to clinical credibility, real-world incentives and feasibility tradeoffs. Continuous feedback between government technical staff and policymakers at CMS on the one hand, and

research organization and academic researchers on the other, has shaped the CMS-HCC model. Much of the recent research reported in this article has related to adapting the model for Medicare sub-populations. The use of a single modeling framework—the CMS-HCC model—provides unity and organization to the subgroup models with the unique features specific to certain types of beneficiaries. Comprehensive risk adjustment, based on ambulatory as well as inpatient diagnoses, is just beginning to be implemented. Thus, it is too early to tell whether it will achieve its goals. As risk adjustment continues to be incorporated in Medicare payments to MCOs, it will be important to evaluate its impact on these organizations and the beneficiaries they serve, especially organizations that care for the chronically ill and their enrollees. This will tell us a great deal about the feasibility and consequences of matching health care resources to needs.

ACKNOWLEDGMENT

Measuring Diagnoses: ICD Code Accuracy

Kimberly J. O'Malley, Karon F. Cook, Matt D. Price, Kimberly Raiford Wildes, John F. Hurdle, and Carol M. Ashton

Objective. To examine potential sources of errors at each step of the described inpatient International Classification of Diseases (ICD) coding process.

Data Sources/Study Setting. The use of disease codes from the ICD has expanded from classifying morbidity and mortality information for statistical purposes to diverse sets of applications in research, health care policy, and health care finance. By describing a brief history of ICD coding, detailing the process for assigning codes, identifying where errors can be introduced into the process, and reviewing methods for examining code accuracy, we help code users more systematically evaluate code accuracy for their particular applications.

Study Design/Methods. We summarize the inpatient ICD diagnostic coding process from patient admission to diagnostic code assignment. We examine potential sources of errors at each step and offer code users a tool for systematically evaluating code accuracy.

Principle Findings. Main error sources along the “patient trajectory” include amount and quality of information at admission, communication among patients and providers, the clinician’s knowledge and experience with the illness, and the clinician’s attention to detail. Main error sources along the “paper trail” include variance in the electronic and written records, coder training and experience, facility quality-control efforts, and unintentional and intentional coder errors, such as misspecification, unbundling, and upcoding.

Conclusions. By clearly specifying the code assignment process and heightening their awareness of potential error sources, code users can better evaluate the applicability and limitations of codes for their particular situations. ICD codes can then be used in the most appropriate ways.

Key Words. ICD codes, accuracy, error sources

Nosology (the systematic classification of diseases) has always fascinated the sick and their would-be healers. Western societies developed an interest in nosology in the seventeenth and eighteenth centuries when they began to track the causes of sickness and death among their citizens. In the twentieth

century, when medical insurance programs made payers other than patients responsible for medical care, nosology became a matter of great interest to those public and private payers. The most commonly used nosologies include International Classification of Diseases (ICD), the American Medical Association's Current Procedural Terminology, 4th Edition (CPT-4); the Health Care Financing Administration (HCFA, now known as the Centers for Medicare and Medicaid Services) Health Care Common Procedural Coding System (HCPCS); the American Psychiatric Association's Diagnostic and Statistical Manual of Mental Disorders, 4th Revision (DSM-IV); Europe's Classification of Surgical Operations and Procedures, 4th Revision (OPCS-4); and the Agency for Healthcare Research and Quality's Clinical Classification Software (CCS).

This paper focuses on the International Classification of Diseases, now in its ninth and soon to be tenth iteration; the most widely used classification of diseases. Beginning in 1900 with the ICD-1 version, this nosology has evolved from 179 to over 120,000 total codes in ICD-10-CM (ICD-10 2003; ICD-10-CM 2003). The use of codes has expanded from classifying morbidity and mortality information for statistical purposes to diverse sets of applications, including reimbursement, administration, epidemiology, and health services research. Since October 1 1983, when Medicare's Prospective Payment System (PPS) was enacted, diagnosis-related groups (DRGs) based on ICD codes emerged as the basis for hospital reimbursement for acute-care stays of Medicare beneficiaries (U.S. Congress 1985). Today the use of ICD coding for reimbursement is a vital part of health care operations. Health care facilities use ICD codes for workload and length-of-stay tracking as well as to assess quality of care. The Veterans Health Administration uses ICD codes to set capitation rates and allocate resources to medical centers caring for its 6 million beneficiaries. Medical research uses ICD codes for many purposes. By grouping patients according to their diagnoses, clinical epidemiologists use ICD codes to study patterns of disease, patterns of care, and outcomes

1622 *HSR: Health Services Research 40:5, Part II (October 2005)*

of disease. Health services researchers use the codes to study risk-adjusted, cross-sectional, and temporal variations in access to care, quality of care, costs of care, and effectiveness of care. Medical and health services researchers commonly use ICD codes as inclusion and exclusion criteria to define sampling frames, to document the comorbidities of patients, report the incidence of complications, track utilization rates, and determine the case fatality and morbidity rates (see Calle et al. 2003 for a recent example) (Steinman, Landefeld, and Gonzales 2000; Calle et al. 2003; Charbonneau et al. 2003; Jackson et al. 2003; Martin et al. 2003; Studdert and Gresenz 2003). The widespread and diverse use of ICD codes demonstrates the central role nosology plays in health care.

Increased attention to code accuracy has occurred both as a result of the application of ICD codes for purposes other than those for which the classifications were originally designed as well as because of the widespread use for making important funding, clinical, and research decisions. Code accuracy, defined as the extent to which the ICD nosologic code reflects the underlying patient's disease, directly impacts the quality of decisions that are based on codes, and therefore code accuracy is of great importance to code users. Accuracy is a complicated issue, however, as it influences each code application differently. Using the codes for reporting case fatality rates in persons hospitalized for influenza, for example, might require a different level of accuracy than using codes as the basis for reimbursing hospitals for providing expensive surgical services to insured persons. Therefore, users of disease classifications, just as users of any measure, must consider the accuracy of the classifications within their unique situations. An appreciation of the measurement context in which disease classifications take place will improve the accuracy of those classifications and will strengthen research and health care decisions based on those classifications.

Researchers studying errors in the code assignment process have reported a wide range of errors. Studies in the 1970s found substantial errors in diagnostic and procedure coding. These error rates ranged from 20 to 80 percent (Institute of Medicine 1977; Corn 1981; Doremus and Michenzi 1983; Johnson and Appel 1984; Hsia et al. 1988). Studies in the 1980s reported slightly increased accuracy with average error rates around 20 percent, and most below 50 percent (Lloyd and Rissing 1985; Fischer et al. 1992; Jolis et al. 1993). Studies in the 1990s found rates similar to those of the 1980 studies, with error rates ranging from 0 to 70 percent (Benesch et al. 1997; Faciszewski, Broste, and Fardon 1997; Goldstein 1998). The inconsistency in the error rates and wide range of reported amounts of error is due largely to

differences across study methods (i.e., different data sets, versions of the ICD classifications, conditions studied, number of digits compared, codes examined, etc.) (Bossuyt et al. 2004). However, variation in error rates is also influenced by the many different sources of errors that influence code accuracy (Green and Wintfeld 1993). By clearly specifying the code process and the types of errors and coding inconsistencies that occur in each study, researchers can begin to understand which errors are most common and most important in their situation. They can then institute steps for reducing those errors.

If we think of the assignment of ICD codes as a common measurement process, then the person's true disease and the assigned ICD code represent true and observed variables, respectively. One approach to evaluating ICD code accuracy is to examine sources of errors that lead to the assignment of a diagnostic code that is not a fair representation of the patient's actual condition. Errors that differentiate the ICD code from the true disease include both random and systematic measurement errors. By understanding these sources of error, users can evaluate the limitations of the classifications and make better decisions based on them. In this manuscript, we (1) present the history of ICD code use, (2) summarize the general inpatient ICD coding process (from patient admission to the assignment of diagnostic codes), (3) identify potential sources of errors in the process, and (4) critique methods for assessing these errors.

BACKGROUND

History of ICD Codes

In 1893, the French physician Jacques Bertillon introduced the Bertillon Classification of Causes of Death. This first edition, had 179 causes of death. It was recommended that this classification system, subsequently known as the International Classification of Causes of Death (ICD), be revised every 10 years. With each revision, the numbers of codes increased, as did the appeal of using them for other purposes.

The World Health Organization (WHO) published the ninth revision of ICD in 1978. The ICD-9 is used to code mortality data from death certificates. To make the ICD more useful for American hospitals, the U.S. Public Health Service modified ICD-9 and called it the International Classification of Diseases, Ninth Revision, Clinical Modification (ICD-9-CM). In the Clinical Modification (CM) of ICD-9, codes were intended to be more precise than those needed only for statistical groupings and trend analysis (The International Classification of Diseases, 9th Revision, Clinical Modification [ICD-9-CM], Sixth Edition 2002).

1624 *HSR: Health Services Research 40:5, Part II (October 2005)*

The modified version expanded to three volumes, and a fifth-digit subclassification was introduced. The fifth digit adds increased specificity and is required when available. When identifying burns with codes 941 through 954, for example, a fourth digit indicates the depth of the burn and a fifth digit specifies the exact location. ICD-9-CM is used in the United States to code and classify diagnoses and procedures from inpatient and outpatient records, as well as inpatient procedures. The ninth revision contains over 12,000 diagnostic and 3,500 procedure codes.

The development of a tenth revision, International Statistical Classification of Diseases and Related Health Problems (ICD-10), introduces alphanumeric codes and greater specificity than ICD-9, and includes over 21,800 total codes (ICD-10 2003). In January 1999, the United States began using ICD-10 to code and classify mortality data from death certificates; however, at the time of this writing, the clinical modification version (ICD-10-CM), was still under development by the National Center for Health Statistics (NCHS) and has not been released.

The Process for Assigning ICD Codes

In this paper, we focus on codes assigned during hospital stays, and whereas basic coding procedures are similar across ambulatory settings, the reader is cautioned that some errors may be setting-specific. The basic process for assigning ICD codes for inpatient stays, presented in Figure 1, can be conceptualized as the dynamic interplay between the patient as he or she progresses through the health care system (called the "patient trajectory") and the creation of the medical record (called the "paper trail"). The basic process shown in Figure 1 is typical, even though details of any given step at any given facility may vary. The left side of Figure 1 portrays the patient trajectory through the system, from admission to discharge. The right side of Figure 1 represents the paper trail, or medical record creation, from the recording of the admitting diagnosis to the assignment of the ICD codes after discharge.

The patient trajectory starts when the patient arrives at the hospital, at which time some type of precertification (insurance) based on the admitting diagnosis is performed by the admission clerk (at least for insured patients). After admission, based on the physician's admitting diagnosis and the information generated by the initial workup, the patient undergoes diagnostic tests and procedures and/or other treatment, as ordered by the medical staff. The patient and medical staff members continue to meet throughout the hospital stay to exchange information, and additional tests, procedures, and/or

Measuring Diagnoses 1625

Figure 1: Overview of the Inpatient Coding Process.

treatments may be ordered. Test and procedure results are added to the medical record. The results from the tests and procedures often result in

changes in the admitting diagnosis. Furthermore, complications arising from care may also add to the list of diagnoses. The staff documents the hospital stay using either handwritten or electronic reporting. Upon discharge, the physician completes a narrative discharge summary that includes a list of primary and secondary diagnoses (word labels) and describes follow-up plans.

Upon discharge, the patient's medical record and all associated documentation are transferred to the medical record or health information management department. Concurrently, technicians check to ensure that all medical record information is accurate and complete (including the face sheet, history and physical, operative reports, radiology reports, physician's orders, progress and nursing notes, consultations, discharge summary, etc.). Coders then begin the process of classifying documentation, including diagnoses and procedures, using rigid ICD coding guidelines and conventions. Some facilities outsource medical transcription and coding.

After reviewing all pertinent medical record information, medical coders assign a code for the principal diagnosis, defined by the Uniform Hospital Discharge Data Set (UHDDS) as "that condition established after study to be chiefly responsible for occasioning the admission of the patient to the hospital care" (Uniform Hospital Discharge Data Set 1985). The principal diagnosis assignment is made based on written documentation from the providers. Coders also assign a code for the principal procedure, or one performed for definitive treatment or that was necessary for treating a complication. They assign additional diagnostic codes (the code count being determined by the facility) for diagnoses that require clinical evaluation, therapeutic interventions, diagnostic procedures, extended lengths of stay (for inpatient stays), or increased nursing care and/or monitoring. Additional procedures are coded as well. The VA, for example, allows up to 10 diagnoses and five procedure codes per inpatient day (Department of Veterans Affairs 2002). Coders may also assign V-codes (codes describing conditions that coexist during a patient's stay that influence the stay, such as history of cancer or lack of housing), E-codes (supplementary classification of factors influencing the patient's health status and contact with health services), and M-Codes (supplementary classification of the morphology of neoplasms).

After the code assignments and the sequencing of the codes have been determined, a computerized software program, called a grouper, is often used to classify or group the codes for reimbursement purposes. When the coding process is complete, the codes are transmitted to the billing department for reimbursement purposes.

EXAMINING CODING ERRORS

Sources of Errors

Many sources of error are interposed between a person's disease (as it is in truth) and the word label (the diagnosis) applied to it by a clinician, and between the diagnosis and the nosologic code applied to it by a medical coder. A summary of these errors, organized according to the patient trajectory and the paper trail depicted in Figure 1.

Errors Along the Patient Trajectory

A "diagnosis" is a word label applied to the disordered anatomy and physiology (the disease) presumed to be causing a person's constellation of symptoms and signs. Several sources of error influence the diagnostic process from patient admission to discharge. "Diagnosis, is in the end, an expression of probability" (author of quotation is unknown). Hardly any diagnosis—even one made at autopsy—is certain (Ornelas-Aguirre et al. 2003; Silfvast et al. 2003). The certainty, or accuracy, of a diagnosis depends upon multiple factors such as the participants (e.g., patient, clinician, medical staff), disease type, current state of medical knowledge and technology, context within which the diagnosis is made, and translation of coding changes into practice.

The first potential sources of error along the trajectory in Figure 1 relate to communication. The quality and quantity of communication between the patient and his or her admitting clerk and treating clinicians are critical determinants of the accuracy of the admitting diagnosis. If the patient describes only a subset of symptoms or withholds important information, for example, the accuracy of the diagnosis may be compromised, leading the clinician down the wrong line of diagnostic reasoning. Clinicians can be poor communicators as well. The clinician may fail to ask the right questions, may not fully elicit the patient's history, or may misunderstand the patient, resulting in another source of error in the process.

When the clinician orders diagnostic tests and procedures, potential sources of error that may be introduced include the clinician's knowledge about the best diagnostic tests and procedures, the availability of these tests and procedures, and the clinician's ability to interpret the results. Diagnostic accuracy depends upon the state of scientific understanding regarding various presentations and etiologies of the disease. Further, the utility (sensitivity, specificity, and predictive value) of the tests and procedures available to the clinician impacts the certainty of the diagnosis. A disease for which tests have high sensitivity and specificity will result in higher diagnostic accuracy

1628 *HSR: Health Services Research 40:5, Part II (October 2005)*

compared with a disease with vague manifestations and poor diagnostic tests. The accuracy of cancer diagnoses, for example, is typically higher than of schizophrenia diagnoses, in part because tumor histopathology and serum markers are less ambiguous than the behavioral diagnostic criteria for schizophrenia. Errors also occur when the physician records the diagnosis. Variance in the clinician's description of the diagnosis—often 5–10 synonyms exist for the same clinical entity—and clarity in the recording of the diagnosis, especially if handwritten, also introduce error into the coding process. Clinicians are notorious for undecipherable handwriting.

Consider how errors in the patient trajectory may influence the diagnosis of a patient with a stroke (a disruption of blood supply to the brain). The warning symptom for stroke, a transient ischemic attack (TIA), is a set of transitory neurological symptoms (in medical parlance, symptoms are subjective and not directly observable by others) and/or signs (signs are observable by others) thought to result from a temporary interference with arterial circulation to a discrete part of the brain. Some TIAs are over in seconds; by definition, all TIAs resolve within 24 hours or they are given a different label (Johnston et al. 2003). The signs and symptoms of TIA are nonspecific; that is, they can result from several other conditions besides a temporary interruption of blood flow to a part of the brain. Because the symptoms are nonspecific, the patient at admission might choose to share only a few (e.g., the patient reports headache but not dizziness), or the patient might not notice the more subtle symptoms (e.g., subtle visual field disturbances) and therefore not share them with the clinician. During the patient–clinician interaction, the clinician might make a decision based only on the symptoms reported by the patient and only on the most obvious signs. Furthermore, no blood or imaging test at present can confirm or disconfirm the occurrence of a TIA. Therefore, the diagnosis of TIA rests on a clinician's acumen, and acumen depends on training, experience, attention, thoroughness, and the ability to elicit information from the patient and/or available informants. Consequently, the interrater reliability of the diagnosis of TIA is very low, such as κ values just over 0.40 and overall agreement of 57 percent (Dewey et al. 1999; Goldstein et al. 2001; Wilson et al. 2002). Further, new diagnostic criteria for TIA have recently been proposed (Albers et al. 2002). If adopted, these criteria will compound the difficulty in monitoring the incidence and prevalence of TIAs over time.

As criteria for the diagnosis of diseases are constantly in flux because of the evolving nature of medical knowledge, new types of errors (or coding inconsistencies) are introduced into the process, and other errors may decrease as diagnostic accuracy increases. New errors may evolve from

clinicians' delay in learning about medical advances or new diagnostic tools. This is especially true for conditions for which no laboratory or imaging tests are available. A case in point is mental illness, the diagnosis of which is based on the DSM published by the American Psychiatric Association, now in its fourth major iteration (American Psychiatric Association 1994). Consider, for example, how "homosexuality" as a diagnosis evolved from being a nondiagnosis to a mental illness diagnosis to a "life style."

Even when laboratory or imaging tests are available for confirming or ruling out a diagnosis, medical technology evolves and the tests improve. For example, the diagnosis of acute stroke no longer requires a spinal tap and direct arteriography of cerebral vessels; the diagnosis can now be made noninvasively with a magnetic resonance imaging study of the brain (Provenzale et al. 2003).

Errors Along the Paper Trail

The first three error sources, those of communication and those related to tests and procedures the patient undergoes, that are listed in Figure 1 affecting the paper trail were described in the previous section. Another potential set of errors can be found in the record itself. Clinicians do not generally assign codes; coders assign them based on the labels recorded by clinicians in charts or on death certificates. Errors in this phase have been reported to range from 17.1 to 76.9 percent (Hsia et al. 1988). The variability in the error rates is best understood by considering the measurement contexts in which the code assignments take place.

One potential set of errors can be found in the record itself. In Figure 1, these are the fourth set of errors listed. In their written or electronically entered record, clinicians often use synonyms and abbreviations to describe the same condition. For example, synonyms for "stroke" include cerebrovascular accident, cerebral occlusion, cerebral infarction, and apoplexy, among others. The variance in terms is problematic, as each diagnostic code should represent one and only one disease entity. From the clinician's recorded diagnosis label, the coder must select the ICD code that best seems to match the clinician's terminology. The use of synonyms leads to imprecision. For example, a patient who had a stroke can be described by one doctor as having had an intracerebral hemorrhage (Code 431) and by another doctor as having had a cerebrovascular accident (Code 436) and both doctors would be technically correct. Errors can also occur because of physicians' and other staff's omissions in the medical record. In 1985, a study of 1,829 medical records in the Veterans Administration indicated that over 40 percent of physician errors

1630 *HSR: Health Services Research 40:5, Part II (October 2005)*

were attributed to omissions (Lloyd and Rissing 1985). Another source of recorder error is in the transcription of the medical record. Transcription can be defined as the process of converting medical record information from voice (dictation) to hardcopy report or electronic format. Transcription or scanning errors are additional threats to code accuracy. The extent to which the chart information is complete influences the accuracy of the codes as well. Concurrent coding, coding that is performed before patient discharge, is implemented in some facilities in order to expedite the coding and billing processes. With the considerable pressure on hospitals to discharge patients these days (at least, in the U.S.), coders may have incomplete clinical information when they receive the chart. As a result, coders are required to assign codes with varying amounts of information, which impacts code accuracy.

Many potential errors originate with the coder. The fact that coders must pour through sometimes voluminous records to extract diagnoses can lead to several types of errors. One study examining coding variation found that when 11 experienced, active medical coders reviewed 471 medical records and were told they would be reevaluated, all of the coders differed in one or more data fields for more than half of the records (Lloyd and Rissing 1985). The adequacy of training the coder receives influences her or his ability to synthesize large amounts of information and assign precise codes. The American Health Information Management Association (AHIMA), the governing body for health information professionals, designates two types of certification: a 2-year certification (Registered Health Information Technician, previously Accredited Record Technician) and a 4-year certification (Registered Health Information Administrator, previously Registered Record Administrator). The existence of two levels of certification, based on length of academic programs and course content, may contribute to coding inconsistencies. In addition to these two professional credentials, AHIMA also offers multiple coder certification opportunities and credentials. Continuing education of coders, or lack thereof, also influences coding accuracy, as the codes and coding rules expand and change annually. For example, on October 1 2003, a new ICD-9 procedure code (00.15) was created to identify patients who receive high dose interleukin-2 treatment. As another example, a comparison of ICD-9-CM with ICD-10-CM indicates that the number of categories doubled from 4,000 to 8,000 and the number of death causes increased from 72 to 113 (Colorado Department of Public Health and Environment 2001). Changes in codes include reclassification of codes, such as moving of hemorrhage from the "circulatory" chapter to the "signs and symptoms" chapter, and changing of the four-digit numeric codes of ICD-9 to the four-digit alphanumeric codes of

ICD-10. Diabetes mellitus, for example, was coded 250 in ICD-9 and is coded E10-E14 in ICD-10 (ICD-10 2003). Without continuing education on code changes and additions, hospitals can lose reimbursement funds and researchers can lose data accuracy.

The coders' experience, attention, and persistence also affect the accuracy of coding. These errors are the fifth and sixth errors shown in Figure 1. When a patient is admitted with renal failure and hypertension, a novice coder may code each condition separately, whereas an experienced coder will look to see if there is a connection between the two conditions, and if so, will use the specific combination code. If coders are unsure of a diagnosis or which diagnosis constitutes the principal diagnosis, they are expected to contact the physician or gather the necessary information to record the correct diagnosis. If coders fail to recognize when they need additional information or if they are not persistent in collecting it, additional error is imposed into the coding system.

At the phase of the paper trail in which diagnostic labels are translated into ICD codes, some specific types of coder-level errors can be identified. These errors, the next to last set in Figure 1, include creep, upcoding, and unbundling, to name a few. Creep includes diagnostic assignments that deviate from the governing rules of coding. Creep errors have also been labeled as misspecification, miscoding, and resequencing errors (Hsia et al. 1988).

Misspecification occurs when the primary diagnosis or order for tests and procedures is misaligned with the evidence found in the medical record. Miscoding includes assignment of generic codes when information exists for assigning more specific codes, assignment of incorrect codes according to the governing rules, or assignment of codes without the physician attesting to their accuracy (Hsia et al. 1988). An example of miscoding for an ischemic stroke might involve using the more generic ICD-9 code of 436 (acute but ill-defined cerebrovascular disease) in place of the more specific ICD-9 codes of 433 (occlusion and stenosis of precerebral arteries) or 434 (occlusion of cerebral arteries) (Goldstein 1998).

Resequencing codes, or changing the order of them, comprises another potential error source. Take as an example the patient who had respiratory failure as a manifestation of congestive heart failure. The congestive heart failure should be the principal diagnosis and the respiratory failure the secondary diagnosis. Resequencing errors occur when these diagnoses are reversed (Osborn 1999). Most sequencing errors are not deliberate. Sequencing errors may comprise the commonest kind of errors in hospital discharge abstracts (Lloyd and Rissing 1985).

1632 *HSR: Health Services Research 40:5, Part II (October 2005)*

Upcoding, assigning codes of higher reimbursement value over codes with lesser reimbursement value, is an additional source of error at the coder level. For example, upcoding a urinary tract infection to the more serious condition of septicemia results in an increase of over \$2,000 in reimbursement. Because upcoding misrepresents the true condition of the patient, it constitutes falsification of medical records and can often be detected by comparing the medical record to the codes listed in the discharge abstract. When coders assign codes for all the separate parts of a diagnosis instead of assigning a code for the overall diagnosis, the practice is called unbundling. Whether done in error or intentionally for gain, unbundling constitutes coding error. Although we label these errors as coder-level errors, systematic coding variation may be apparent at the hospital-level, as shown by some evidence from at least one study (Romano et al. 2002).

The final potential error listed in Figure 1 occurs when the physician attests to the accuracy of the coding information. As physicians treat many patients simultaneously and support heavy workloads, the time and attention physicians dedicate to checking the accuracy of the codes varies tremendously. Errors at the point of attestation include reviewing too quickly or not reviewing the face sheet and supporting documents, poor recall of the details of the patient's conditions, and incorrect recording on the attestation sheet.

Ways to Measure Code Accuracy

Five statistics are commonly used to summarize the amount of error in ICD coding: sensitivity, specificity, positive predictive value, negative predictive value, and κ coefficient. These statistics are simple to compute; that is, it is easy to come up with the "right answer." It is more challenging to state precisely what questions are answered by each of these statistics. In the current context, it is helpful to remember that the reliability of ICD coding is with respect to some other method of obtaining a diagnostic label. Sensitivity and specificity are statistics often used when some "gold standard" is available. As discussed above, however, there is no gold standard for diagnostic labeling.

A researcher whose question is, "How accurate are the diagnoses?" might compare the diagnostic labels assigned by two or more experts (e.g., physicians) evaluating the same sample of patients. A good choice of statistic for this research design might be the κ coefficient. This statistic quantifies beyond-chance agreement among experts; therefore, it would be an appropriate estimator of the reliability of diagnoses made by experts. However, if the research question is, "In medical chart reviews, how well do medical

coders' ICD code assignments match those of physicians?" then a true gold standard exists. In such a case, the researcher might prefer to calculate specificity, sensitivity, and predictive values using the physicians' reviews as the gold standard. What must be kept clearly in mind, however, is that the values of the statistics obtained in this scenario express nothing about the reliability of medical diagnosis. They estimate, in the context of medical chart review, the corroboration between physician and medical coders' ICD classifications.

Discussion

The process of assigning ICD codes is complicated. The many steps and participants in the process introduce numerous opportunities for error. By describing a brief history of ICD coding, detailing the process for assigning codes, identifying places where errors can be introduced into the process, and reviewing methods for examining code accuracy, we hope to demystify the ICD code assignment process and help code users more systematically evaluate code accuracy for their particular applications. Consideration of code accuracy within the specific context of code use ultimately will improve measurement accuracy and, subsequently, health care decisions based on that measurement.

Although this paper focused on errors influencing code accuracy, the goal was not to disparage ICD codes in general. ICD codes have proven incredibly helpful for research, reimbursement, policymaking, etc. In fact, without ICD codes, health care research, policy, and practice could not have advanced as far as they have. However, code use and decision making on the bases of codes is improved when code accuracy is well understood and taken into account. By heightening their awareness of potential error sources, users can better evaluate the applicability and limitations of codes in their own context, and thus use ICD codes in optimal ways.

One way to heighten code users' awareness of potential error sources is to create a tool for their use when evaluating ICD codes. Based on our evaluation of the code assignment process, we created Figure 1, which summarizes the basic inpatient process for code assignment. This flowchart is designed to focus code users' attention on key aspects of the code assignment process and facilitate their critique of codes. By identifying potential code errors, users may be able to specify bias that might influence data accuracy. Instead of weakening a study, the recognition of potential sources of code bias will strengthen researchers' interpretations of data analyses using the codes.

1634 *HSR: Health Services Research 40:5, Part II (October 2005)*

A few practical recommendations can be made for code users. First, codes are likely to be most accurate under the following conditions: the disease has a clear definition with observable signs and symptoms, highly qualified physicians document information on the patient, experienced coders with full access to information assign the codes, and the codes are not new. Furthermore, codes are more likely to be accurate in calculating disease prevalence than in calculating disease incidence, as incidence requires identification of new cases, or cases without previous documentation. When the accuracy of a specified code is high, it would be appropriate to identify individuals for inclusion in patient registries or intervention studies. Codes considered less accurate are better suited for screening for potential study participants and for identifying pools of recruits. As code accuracy decreases, or becomes more questionable, researchers will want to use codes in combination with other measures. For example, codes from one occasion could be combined with test results or with codes from other occasions to improve the accuracy of disease classification. Suppose researchers wish to identify patients with stroke for an expensive intervention study. Given that past studies have found that using ICD-9 diagnostic codes of 433 through 436 from administrative databases are not very accurate for diagnosing stroke (Leibson et al. 1994; Benesch et al. 1997), researchers may decide to use codes 433 through 436 as an initial screener for including patients in the study. Then, to increase the accuracy of the diagnosis, researchers may wish to review these patients' hospitalization charts and outpatient records. Researchers can make study inclusion decisions based on the combination of ICD codes and clinical evidence, such as prior history of cerebral ischemic events, cerebrovascular risk factors, related procedures (carotid endarterectomy or angiography), and functional abilities. Although collecting the clinical evidence will take additional time and resources, it will improve the accuracy of the diagnoses and will likely lead to more appropriate study results.

Because the use of ICD codes is commonplace, and studies on code accuracy can be found in a wide variety of disease- and discipline-specific journals, code users need easy access to a resource for reviewing code accuracy studies. To meet this need, the Measurement Excellence and Training Resource Information Center (METRIC), a VA initiative for improving measurement in health care, has created a repository of abstracts from code accuracy studies. The repository is located at <http://www.measurementexperts.org/icd9ab.htm>. The METRIC started the repository, but recognizes many important study references are missing. METRIC encourages code users to visit the site, review the repository, and recommend other studies and

documents that can be added. With input from the many types of code users, this resource can become a valuable tool for evaluating ICD code accuracy. METRIC envisions this as a dynamic resource that will facilitate ICD code users' ability to access code accuracy information in an efficient and timely manner.

Although many studies have examined ICD code accuracy, knowledge in several areas is underdeveloped. Two important areas are the reliability of physician diagnoses and the factors that influence that reliability. Many ICD code accuracy studies consider the physician diagnosis as recorded in the medical record as the gold standard for measuring diagnoses (Lloyd and Rising 1985; Hsia et al. 1988; Fischer et al. 1992). In at least one study, researchers demonstrated that the medical record cannot be considered a gold standard, as measured against standardized patients, for example Peabody et al. (2000).

Little consideration is given to the process leading to the physician's diagnosis. Certainly the quality of the gold standard varies based on disease factors (type, knowledge, and progression) and physician factors (experience with the disease and knowledge of diagnostic tools for the disease). Further research examining which factors influence the quality of the physician's diagnosis and the extent to which these factors affect the gold standard is greatly needed.

As researchers, policy makers, insurers, and others strive to impose some organization on the complicated health care field, disease and procedure classification systems will receive increased attention. Although no system of classification will ever be perfect, our ability to improve taxonomies rests in our dedication to understanding the code assignment process and to sharing information about its strengths and weaknesses.

ACKNOWLEDGMENTS

The authors would like to acknowledge and thank University of Kansas Medical Center staff members Richard Sahlfeld, RHIA, director and corporate privacy officer; Theresa Jackson, RHIA, assistant director; and Vicky Koehly, RHIT, coding supervisor, medical record department, for their input during our interviews and for their time spent in reviewing our manuscript. The authors would also like to thank Sandra Johnston, MA, RHIA, clinical coordinator, health information management department, School of Allied Health, University of Kansas, Kansas City, Kansas, for her contributions to the

1636 HSR: Health Services Research 40:5, Part II (October 2005)

manuscript. The expertise of these professionals in health information management and the coding process was invaluable.

Funding for the development of this manuscript came from the Department of Veterans Affairs, Veterans Health Administration, Health Services Research and Development Service, Measurement Excellence and Training Resource Information Center (METRIC; RES 02-235).

This material is the result of work supported with resources and the use of facilities at the Houston Center for Quality of Care & Utilization Studies, Houston Veterans Affairs Medical Center.

**Issues for risk adjustment
in Medicare Advantage**

CHAPTER

4

Issues for risk adjustment in Medicare Advantage

Chapter summary

Health plans that participate in the Medicare Advantage (MA) program receive monthly capitated payments for each Medicare enrollee. Each capitated payment is the product of two general parts: a base rate, which reflects the payment if an MA enrollee has the health status of the national average beneficiary, and a risk score, which indicates how costly the enrollee is expected to be relative to the national average beneficiary. The purpose of the risk scores is to adjust MA payments so that they accurately reflect how much each MA enrollee would be expected to cost. In this chapter, we examine the performance of the risk-adjustment system in the MA program and offer alternatives for improving it.

Improving payment accuracy of the CMS-hierarchical condition category model

Currently, CMS uses the CMS-hierarchical condition category (CMS-HCC) model to risk adjust each MA payment. This model uses enrollees' demographics and medical conditions collected into 70 HCCs to predict their costliness. It has been shown to be a much better predictor of a beneficiary's costliness than the demographic-based model that preceded it. Analysis of the CMS-HCC model and the demographic model indicates that the CMS-HCC model explains about 11 percent of the variation in costliness among individual beneficiaries, whereas the demographic model explains only about 1 percent (Pope et al. 2004).

In this chapter

- Evidence that MA enrollees tend to be lower cost than FFS beneficiaries
- Improving predictive accuracy of the CMS-HCC model
- Issues related to financial neutrality between FFS Medicare and the MA program

The demographic model did not include factors that are important for predicting beneficiaries' costliness—such as conditions. Consequently, it systematically overpredicted costs for healthy beneficiaries and systematically underpredicted costs for beneficiaries in poor health. Because the CMS–HCC model includes beneficiaries' conditions as well as their demographic information, it explains more of the variation in beneficiaries' costliness and predicts costs more accurately than the demographic model. However, systematic overpredictions and underpredictions may remain under the CMS–HCC model. For example, for all beneficiaries who have the same condition, the CMS–HCC model adjusts MA payments by the same proportion. But the severity of a condition varies across beneficiaries, and those with greater severity tend to be more costly. In addition, research suggests that a minimum of 20 percent to 25 percent of the variation in beneficiaries' costliness may be predictable, so the CMS–HCC may leave half or more of the predictable variation unexplained (Newhouse et al. 1997). Therefore, for a given condition it is possible that plans can be financially advantaged or disadvantaged based on the risk profile (overall health status) of their enrollees.

To the extent that systematic prediction errors occur under the CMS–HCC model, we explored several policy options for reducing these errors:

- Add measures of income and indicators for race to the model. If beneficiaries in certain income categories or racial groups tend to have greater severity for given conditions, these additional variables could reduce prediction errors.
- Include measures for the number of conditions in the model. The cost of treating a certain condition may increase as more comorbidities are present.
- Use two years of beneficiaries' diagnoses to determine their condition categories. CMS currently uses one year of beneficiaries' diagnoses to determine their conditions, but we have found that providers often do not consistently code conditions on claims from year to year. Using two years of diagnosis data (when available) would help to fully identify beneficiaries' conditions.

Our analysis indicates that including beneficiaries' race and measures of income would not improve predictive accuracy. However, including the number of conditions would improve predictive accuracy for beneficiaries who have many conditions. Using two years of diagnoses to identify beneficiaries' conditions also would improve predictive accuracy for beneficiaries who have many conditions but to a lesser extent than adding the number of conditions. In addition, using two years of diagnoses would reduce year-to-year fluctuations in beneficiaries' risk scores, which would result in more stable revenue streams for MA plans.

Because adding the number of conditions and using two years of diagnosis data both have beneficial effects, but in different ways, we also examined the effects of adding both features to the CMS-HCC model. It resulted in more accurate predictions for high-risk beneficiaries and smaller year-to-year fluctuations in beneficiaries' risk scores.

Other issues for MA risk adjustment

On several occasions, the Commission has taken a position that payments for MA enrollees should equal what they would be expected to cost in FFS Medicare (financial neutrality) (Medicare Payment Advisory Commission 2001, Medicare Payment Advisory Commission 2002, Medicare Payment Advisory Commission 2004, Medicare Payment Advisory Commission 2005). An underlying rationale for this policy is that it encourages beneficiaries to enroll in whichever sector (MA or FFS) is more efficient in their local health care market. Two recently published papers have implications for the interaction between risk adjustment and financial neutrality. One paper shows that in FFS Medicare, regions that have high per capita service use also have high average risk scores, and areas that have low per capita service use have low average risk scores (Song et al. 2010). At least some of the regional difference in risk scores is due to differences in service use that do not reflect differences in health status; that is, risk scores are high in some regions simply because beneficiaries get more health care, not because they are sicker. If these same regional differences in service use and risk scores occur in the MA program, they drive MA payments higher in high-use regions. Adjustments could be made to eliminate these differences.

A second paper shows there are differences between FFS Medicare and a large MA plan in the relative costliness of treating conditions (Newhouse et al. 2011). If these cost differences between FFS Medicare and MA plans are widespread, risk adjustment underpredicts MA costs for some conditions and overpredicts MA costs for other conditions. An issue to consider is whether it is more appropriate for CMS to estimate the CMS-HCC model by using cost and diagnosis data from MA enrollees rather than FFS beneficiaries.

Both papers have implications for equity in the MA program: Adjusting MA risk scores to reduce the effects of regional differences in risk scores would reduce regional variations in MA payments, and using data from MA enrollees to estimate the CMS-HCC model would reduce incentives for plans to attract beneficiaries who have some conditions and avoid beneficiaries who have other conditions. However, both issues are inconsistent with the concept of financial neutrality between MA and FFS Medicare. These issues will have to be discussed in the future.

A final issue regarding risk adjustment is that analyses by CMS and the Government Accountability Office (GAO) both indicate that risk scores have increased at a faster rate in the MA program than in FFS Medicare (Centers for Medicare & Medicaid Services 2009, Government Accountability Office 2012). The higher growth rate in MA has resulted in MA enrollees having higher risk scores than they would have in FFS Medicare. In an effort to bring MA risk scores in line with those in FFS Medicare, CMS has made adjustments to MA risk scores, but GAO believes that larger adjustments should be made. ■

Health plans that participate in the Medicare Advantage (MA) program receive monthly capitated payments for each Medicare enrollee. Each capitated payment is the product of two general parts: a base rate, which reflects the payment if an MA enrollee has the health status of the national average Medicare beneficiary, and a risk score, which indicates how costly the enrollee is expected to be relative to the national average beneficiary.

Over the years, CMS has employed various methods for determining MA enrollees' risk scores. Currently, CMS uses the CMS-hierarchical condition category (CMS-HCC) risk-adjustment model, which uses enrollees' demographics and condition categories (such as diabetes and stroke) to predict their costliness. The demographic variables include age, sex, Medicaid status, institutional status, eligibility based on being disabled, and eligibility based on age but originally eligible because of disability.

All demographic variables are from the year for which beneficiaries' costs are to be predicted (the prediction year). The condition categories are based on diagnoses recorded on physician, hospital outpatient, and hospital inpatient claims in the year before beneficiaries' costs are to be predicted (the base year). This makes the CMS-HCC a prospective model, as opposed to a concurrent model, which would use conditions from the prediction year. It is logical to use a prospective model in the MA program because the express purpose of MA plans is to provide care to manage their enrollees' conditions. If concurrent risk adjustment were used, MA plans would be reimbursed as their enrollees' conditions occur, rather than being paid to manage existing chronic conditions.

An underlying feature of a prospective risk-adjustment model for beneficiaries with a given set of conditions is that it underpredicts costs for some beneficiaries, overpredicts for others, but predicts accurately on average. However, when prediction inaccuracies occur systematically with identifiable beneficiary characteristics, plans can benefit if their enrollees have characteristics predictive of lower-than-average costs (favorable selection) or be disadvantaged if their enrollees have characteristics predictive of higher-than-average costs (adverse selection). An ideal risk-adjustment system would eliminate all opportunities for favorable selection, but a risk adjuster can be less than ideal and still be effective if it makes efforts by plans to identify favorable risks prohibitively costly.

To the extent that favorable selection occurs in the MA program, it could be caused by the behavior of plans

or beneficiaries. Plans can attract favorable risks by structuring benefits that are attractive to relatively healthy beneficiaries or by marketing their products so that they attract healthy enrollees. Alternatively, relatively healthy beneficiaries may find the structure of managed care plans more attractive than do beneficiaries in poor health.

Selection problems can be reduced by improving risk adjustment to reduce the extent of systematic prediction errors. An alternative method for reducing selection problems is partial capitation, which would pay plans partly on the basis of capitated rates and partly on the actual costs of providing care. This would reduce the likelihood of plans experiencing large losses from very sick enrollees or large profits from healthy enrollees. However, it is not clear what fraction of the payments should be capitated and what fraction should be based on costs.

For each MA enrollee, CMS obtains from the enrollee's plan the condition codes from encounters with physicians, hospital outpatient departments, and hospital inpatient departments. CMS maps the condition codes into hierarchical condition categories (HCCs), which define broad condition categories, such as diabetes and congestive heart failure. All condition codes fall into one of the 189 CMS-defined HCCs. However, CMS uses only 70 HCCs in the CMS-HCC model, so many conditions have no effect on beneficiaries' risk scores.¹ Some conditions, such as diabetes and cancer, are actually represented by groups of several HCCs, which differ according to severity. CMS has determined that a beneficiary cannot have more than one HCC indicated in each of these condition groups. If CMS finds that a beneficiary has conditions that map into more than one HCC within a condition group, only the highest cost HCC is used in predicting the beneficiary's costliness. For example, the CMS-HCC model has five diabetes HCCs. If CMS finds that a beneficiary has condition codes that fit the HCC "diabetes with acute complications" and the HCC "diabetes without complications," CMS drops the HCC "diabetes without complications."

CMS calibrates the additional costliness associated with each demographic variable and each HCC in the model using cost, demographic, and diagnosis data from beneficiaries in fee-for-service (FFS) Medicare, but CMS has begun collecting data on MA beneficiaries and intends to use those data to calibrate the CMS-HCC model.² CMS applies linear regression methods to obtain coefficients on each variable in the model. If a beneficiary has a particular

variable represented in the CMS–HCC model, the coefficient on that variable indicates its marginal cost.

A model that CMS used before the CMS–HCC model included only beneficiaries’ demographic data (demographic model). The demographic model does not include important observable characteristics of beneficiaries that affect their costliness, such as medical conditions. Consequently, the demographic model explains a small fraction of the variation in beneficiaries’ Medicare costliness (about 1 percent) and, within a given demographic category, systematically overpredicts costs for relatively healthy beneficiaries and underpredicts costs for the sickest beneficiaries, leaving the potential for selection problems.

The CMS–HCC model has been shown to be a much better predictor of a beneficiary’s costliness. For example, it explains about 11 percent of the variation in beneficiaries’ costliness. Therefore, the CMS–HCC model likely mitigates selection problems in the MA program.

However, the CMS–HCC model has shortcomings such that it may not have fully eliminated systematic prediction inaccuracies:

- Research on variation in individual-level health care spending suggests that at least 20 percent to 25 percent of the variation in spending can be predicted, with the remaining being random and, hence, unpredictable (Newhouse et al. 1997). Because the CMS–HCC model explains about 11 percent of the variation in spending, it may leave half or more of the predictable variation unexplained.
- For all enrollees with a given health condition, the CMS–HCC model adjusts MA capitated payments by the same rate. For example, the CMS–HCC model increases capitated payments for all MA enrollees with acute myocardial infarction by 35.9 percent above the base rate. However, within condition categories, some beneficiaries are healthier and less costly than others, while some are sicker and more costly.

Because of these shortcomings of the CMS–HCC model, there is a potential for MA plans to benefit financially if they have a relatively healthy beneficiary profile or to be disadvantaged if they have a sicker beneficiary profile. This is especially relevant to plans that specialize in managing the care for the sickest beneficiaries, such as special needs plans (SNPs) and plans in the Program of All-Inclusive Care for the Elderly (PACE), because

payments may not be adequately adjusted to effectively provide care.

We have done an analysis that suggests that MA enrollees are healthier and less costly than their FFS counterparts, meaning that favorable selection may be occurring in the MA program. In this chapter, we discuss this analysis as well as options for modifying the CMS–HCC model to mitigate systematic prediction errors.

This chapter discusses two other issues concerning risk adjustment in the MA program:

- Research indicates that geographic differences in per capita service use in FFS Medicare lead to geographic differences in risk scores that do not reflect differences in health status among FFS beneficiaries (Song et al. 2010). If regional differences in service use also lead to regional differences in risk scores in the MA program, then plans in regions where service use is high have higher risk scores, which drive capitated payments in those regions above the level in lower use regions.
- The coefficients on the conditions in the CMS–HCC model indicate the relative costliness of treating those conditions in FFS Medicare. However, the CMS–HCC model is used to risk-adjust payments in the MA program, where the relative costs of treating conditions may differ from costs in FFS Medicare (Newhouse et al. 2011). This raises questions of whether it is more appropriate to continue to calibrate the CMS–HCC model using data on FFS beneficiaries, or to switch to data on MA enrollees.

Evidence that MA enrollees tend to be lower cost than FFS beneficiaries

Recently, there has been renewed interest in examining the extent to which favorable selection occurs in the MA program. One study found a substantial amount of favorable selection (Brown et al. 2011). Another study used cost data from a large MA plan and found little correlation between how costly a condition is to treat in FFS Medicare and the extent to which beneficiaries with that condition are profitable to that plan (Newhouse et al. 2011). This gives the plan little incentive to try to select against the sickest, highest cost beneficiaries.

Within a given HCC, the severity of the condition and hence the cost of treating it can vary. For example, we examined FFS beneficiaries who were grouped into

the HCC for congestive heart failure (CHF) in 2008 and had no other HCCs. In 2008, the beneficiary at the 95th percentile of costliness had more than \$37,000 in Medicare spending, while the beneficiary at the 5th percentile had \$115 in Medicare spending. Despite these large cost differences for beneficiaries who have the same condition, the CMS–HCC model adjusts the payment rate for each beneficiary who has CHF by the same proportion (41 percent). Therefore, it is possible that, for beneficiaries in a given HCC, some will be profitable to MA plans because they are low-severity cases while others will not be profitable because they are high-severity cases.

If beneficiaries who have the same condition are randomly selected into MA plans in sufficiently large numbers, those who are profitable will be offset by those who are unprofitable, resulting in no financial gain or loss for the plan. However, if the selection of these beneficiaries is not random, it is possible that those who enroll in MA plans are on average profitable. This could occur either through the actions of plans—perhaps through benefits that are attractive to healthier beneficiaries or marketing techniques that target those beneficiaries—or because relatively healthy beneficiaries find the structure of MA plans more attractive than do sicker beneficiaries.

We conducted a study using two measures that may suggest, but not confirm, whether MA enrollees are, on average, lower risk than FFS beneficiaries. We divided the beneficiaries who were in FFS Medicare in 2007 into two groups: those who stayed in FFS Medicare in 2008 (stayers) and those who enrolled in MA plans in 2008 (joiners). For each group, we calculated the mean FFS costliness in 2007 in each HCC and used beneficiaries' risk scores to adjust for differences in health status. We reasoned that, for each HCC, if the risk-adjusted mean cost of the joiners was below that of the stayers, it indicates that lower cost beneficiaries are more likely to enroll in the MA program. We also identified the beneficiaries who were in FFS Medicare in 2008 and divided them into two groups: those who were in FFS Medicare throughout 2007 and those who left an MA plan in 2007. For both groups, we calculated the mean FFS costliness in 2008 of the beneficiaries who had conditions in each HCC and used beneficiaries' risk scores to adjust for differences in health status. We reasoned that, for each HCC, if the risk-adjusted mean cost of the beneficiaries who left an MA plan in 2007 was above that of beneficiaries who were in FFS Medicare throughout 2007 and 2008, it indicates that beneficiaries who stay in MA plans tend to be lower cost than those who leave MA for FFS Medicare.

Our results from both analyses suggest that MA enrollees are, on average, lower cost than FFS beneficiaries. In the first analysis, for 68 of the 70 HCCs, beneficiaries who joined an MA plan in 2008 had lower FFS costs in 2007 than the beneficiaries who stayed in FFS Medicare in 2008. On average, the joiners had costs that were 15 percent lower than the stayers. In the second analysis, beneficiaries who left an MA plan in 2007 had FFS costs in 2008 that averaged 16 percent higher than beneficiaries who were in FFS Medicare throughout 2007. Moreover, for 69 of the 70 HCCs, beneficiaries who disenrolled from MA in 2007 had higher average costs in 2008 than those who were in FFS Medicare throughout 2007.

Although these results suggest that MA enrollees are lower cost than FFS beneficiaries, we emphasize that they are not conclusive. It is possible that beneficiaries with relatively low costs are more likely to enroll in an MA plan but that their costs increase after enrollment. Possible reasons this may occur include that their costs regress to the mean over time, they lacked supplemental coverage while in FFS Medicare, or they have low incomes and the more comprehensive coverage that often occurs in MA plans encourages them to increase their service use.

Improving predictive accuracy of the CMS–HCC model

We have evaluated three alternatives for improving the predictive accuracy of the CMS–HCC model so that systematic prediction errors are reduced. All three options involve using more data than are currently used in the CMS–HCC model:

- Add socioeconomic variables such as race/ethnicity and income to the model. This model includes all variables in the current CMS–HCC model plus race/ethnicity indicators (African American, Hispanic, White, other race) and income level, which we approximated by the per capita income in the beneficiary's county of residence.
- Add indicators for the number of conditions beneficiaries have. This model includes all variables in the current CMS–HCC model plus indicators of whether beneficiaries have zero, one, two, three, four, or five or more HCCs.³
- Use two years of diagnosis data (when available) to determine each beneficiary's HCCs rather than one

**TABLE
4-1****Adding indicators of race and
measure of income has little effect on
predictive accuracy of CMS-HCC model**

Category	Predictive ratio	
	Standard model	Race/income model
Specific conditions		
Diabetes	1.00	1.00
COPD	1.01	1.01
CHF	0.99	0.99
Cancer	0.99	0.99
Mental illness	1.00	1.00
Schizophrenia	1.00	1.00
AMI	1.03	1.02
Unspecified stroke	1.01	1.00
All strokes	1.01	1.00
Number of conditions		
0	0.94	0.94
1	1.02	1.02
2	1.03	1.03
3	1.03	1.02
4	1.02	1.02
5 or more	0.98	0.98
8 or more	0.95	0.94

Note: CMS-HCC (CMS-hierarchical condition category), COPD (chronic obstructive pulmonary disease), CHF (congestive heart failure), AMI (acute myocardial infarction). We determined the number of conditions by counting the number of HCCs a beneficiary maps into. Both models use one year of diagnosis data to determine beneficiaries' conditions.

Source: MedPAC analysis of 5 percent standard analytic claims files and 5 percent Medicare denominator file.

year of diagnosis data, which CMS currently uses. Obviously, two years of diagnosis data would not be available for beneficiaries in their first or second year of Medicare eligibility. For those in the first year of Medicare eligibility, the demographic model that CMS currently uses for new enrollees is a viable option. For those in the second year of eligibility, we could use the current version of the CMS-HCC model.

**Adding socioeconomic variables does not
improve predictive accuracy of CMS-HCC
model**

We calibrated a model that has all the variables of the current version of the CMS-HCC model, which has 70 HCCs (standard model). We also calibrated a version that has the same variables as the standard model plus race/

ethnicity indicators (African American, Hispanic, White, and other race) and income level, which we approximated by the per capita income in the beneficiary's county of residence (race/income model). For a description of the method we used to calibrate the models presented in this chapter, see the text box (pp. 106–107).

We evaluated the predictive accuracy of the standard and race/income versions using two measures:

- R^2 , a statistical measure of how much of the variation in costliness among individuals is explained by the model: The closer the R^2 is to 1.0, the more of the variation the model has explained.
- Predictive ratio: For a group of beneficiaries, it is the total costliness predicted by the model divided by the total actual costliness of the group. The closer the predictive ratio is to 1.0, the better the model has predicted the actual costs. Predictive ratios less than 1.0 indicate the predicted costs are below the actual costs (underprediction); predictive ratios greater than 1.0 indicate the predicted costs are above actual costs (overprediction).

The R^2 gives a general sense of how well a model accounts for variations in costs across individuals. However, strategies to attract favorable risks are typically based on characteristics such as conditions that define groups of beneficiaries, not on specific individuals. Therefore, many analysts prefer to use predictive ratios to evaluate the predictive accuracy of risk-adjustment models (Frogner et al. 2011, Pope et al. 2004, Pope et al. 2011). For beneficiaries with a given attribute, the predictive ratio indicates (on average) the extent to which a model overpredicts or underpredicts the costliness of the beneficiaries with the attribute and by how much.

The addition of race and income variables to the standard model did very little to enhance its predictive accuracy. Using the standard CMS-HCC model, we obtained an R^2 of 0.1100. Adding race and income variables had no effect on the R^2 .

We also used predictive ratios to examine how accurately these two models predict beneficiaries' costliness for nine condition categories. For most of these conditions, both models predict beneficiaries' costliness quite well, but they overpredict costs to some degree for acute myocardial infarction (AMI). Within each of these conditions—as well as all conditions represented in the CMS-HCC model—some beneficiaries are relatively healthy and have no other

conditions, while other beneficiaries are much sicker and have many other conditions. We analyzed categories of beneficiaries identified by number of conditions: zero, one, two, three, four, five or more, and eight or more. We found that both models underpredict costliness to some degree for beneficiaries who have five or more conditions and by a larger degree for those who have no conditions or eight or more conditions. Also, both models overpredict costliness to some degree for categories defined by one condition, two conditions, three conditions, and four conditions (Table 4-1).

These prediction errors can be seen when we parse the beneficiaries who have diabetes by how many other conditions they have. For diabetics who have one other condition (and would be in the two conditions group in Table 4-1), the predictive ratio is 1.03; for diabetics who have at least seven other conditions (and would be in the eight or more conditions group in Table 4-1), the predictive ratio is 0.93. However, these deviations from 1.0 are a concern only if there is systematic selection into MA plans of the beneficiaries who are in categories for which the predictive ratio is above 1.0.

The important points to take away from Table 4-1 are:

- The CMS-HCC model accurately predicts costs, on average, for most conditions that are represented in the model.
- However, among beneficiaries who have the same condition, some are relatively healthy and have no other conditions or only a few other conditions, while others are sicker and have many other conditions. For those who have only a few conditions, the CMS-HCC model slightly overpredicts costs, and for those who have many conditions, the model underpredicts costs, and the underprediction increases as the number of conditions increases. Consequently, SNPs and plans in PACE, which focus on the sickest beneficiaries, may be at a disadvantage, while plans that are able to attract the healthiest beneficiaries with a given condition may benefit.
- Adding race and income to the CMS-HCC model does little to improve the model's predictive accuracy.

Including number of conditions improves predictive accuracy

We used 2007 diagnosis data and 2008 demographic and program cost data to calibrate two versions of the CMS-

HCC model. One is the standard model that CMS uses in the MA program and is the same standard model in Table 4-1. The other is the conditions model, which adds to the standard model six indicators for how many conditions each beneficiary has, as determined by the beneficiary's diagnoses: zero, one, two, three, four, and five or more conditions. We define number of conditions as the number of HCCs that each beneficiary's conditions map into.

This standard model has an R^2 of 0.1100, indicating that it explains 11 percent of the variation in beneficiaries' Medicare costs. When we add the six measures indicating the number of conditions, the improvement in the R^2 is nearly imperceptible, 0.1105.

We also calculated predictive ratios for nine condition categories using both the standard and conditions models. For all nine conditions, the predictive ratios show little or no change between the two models. For most conditions, both predict reasonably well, with the exception being AMI, where there is some degree of overprediction under both models. As we saw in Table 4-1, the standard model underpredicts for beneficiaries who have zero conditions, five or more conditions, and eight or more conditions and overpredicts for one, two, three, and four conditions. In contrast, the conditions model predicts quite accurately for each of those groups (Table 4-2, p. 104). Because the conditions model predicts accurately for the sickest beneficiaries (those who have many conditions), it may be beneficial for SNPs and PACE plans.

Using two years of diagnosis data stabilizes risk scores and improves predictive accuracy

Previous research indicates that in FFS Medicare, a beneficiary who has a chronic condition indicated on a claim in one year often will not have that condition appear on a claim in the following year (Frogner et al. 2011, Medicare Payment Advisory Commission 1998). If this inconsistent coding of beneficiaries' chronic conditions also occurs among MA plans, beneficiaries' risk scores will often have large year-to-year changes.

We evaluated the extent to which beneficiaries who were coded for the HCCs for kidney failure, stroke, quadriplegia or paraplegia, diabetes, CHF, and chronic obstructive pulmonary disease in 2007 also were coded for those HCCs in 2008. We did this for both FFS enrollees and MA enrollees.

Our results indicate that coding for all of these conditions was not consistent from year to year. The same was true for beneficiaries in both FFS Medicare and MA plans

**TABLE
4-2****Adding number of conditions to
CMS-HCC model improves predictive
accuracy for beneficiaries
who have many conditions**

Category	Predictive ratio	
	Standard model	Conditions model
Specific conditions		
Diabetes	1.00	1.00
COPD	1.01	1.01
CHF	0.99	0.99
Cancer	0.99	0.99
Mental illness	1.00	1.00
Schizophrenia	1.00	1.00
AMI	1.03	1.03
Unspecified stroke	1.01	1.01
All strokes	1.01	1.00
Number of conditions		
0	0.94	1.00
1	1.02	1.00
2	1.03	1.00
3	1.03	1.00
4	1.02	1.00
5 or more	0.98	0.99
8 or more	0.95	1.00

Note: CMS-HCC (CMS-hierarchical condition category), COPD (chronic obstructive pulmonary disease), CHF (congestive heart failure), AMI (acute myocardial infarction). We determined the number of conditions by counting the number of HCCs a beneficiary maps into. Both models use one year of diagnosis data to determine beneficiaries' conditions.

(Table 4-3). This lack of consistent coding over time presents two problems for risk adjustment. First, in a given year, many FFS beneficiaries who have a condition will not have that condition appear on a claim. Because CMS uses conditions recorded on claims for FFS beneficiaries to calibrate the CMS-HCC model, the model may not accurately reflect the true additional cost of a particular condition. Second, inconsistent coding of conditions in MA results in greater year-to-year fluctuations in enrollees' risk scores, which leads to less stable payments and revenue streams to MA plans.

These problems related to inconsistent coding of conditions would be mitigated if CMS used two years of beneficiaries' diagnosis data rather than one year to calibrate the CMS-HCC model and determine

beneficiaries' risk scores. The Commission has recommended this position in the past (Medicare Payment Advisory Commission 2000).

We calibrated a version of the CMS-HCC model that is the same as the standard model, but we used two years of diagnosis data to assign beneficiaries to HCCs (two-year model). We found that this model produces risk scores that are more consistent over time than does the standard CMS-HCC model. For example, we found that the correlation coefficient between the 2008 and 2009 risk scores for more than 1 million beneficiaries was 0.62 using the standard model and 0.80 using the two-year model, where the correlation coefficient indicates how strongly one variable is correlated with another. The closer a correlation coefficient is to 1.0, the more closely two variables are correlated.

We also found that for specific conditions, there is little difference in predictive accuracy between the standard model and the two-year model, except for mental illness. However, the two-year model predicts more accurately for beneficiaries who have five or more conditions and for those who have eight or more conditions (Table 4-4). As we mentioned earlier, this means that for most conditions, both models pay accurately, on average, except for AMI, where there is some degree of overprediction of costs. However, for those who have five or more conditions and those who have eight or more conditions, the two-year model underpredicts by a lesser amount than does the

standard model. In summary, the two-year model offers the advantages of smaller year-to-year fluctuations in risk scores and more accurate payments for the sickest beneficiaries.

**Including number of conditions and using
two years of diagnosis data have the
benefits of both**

We also analyzed the effects of a version of the CMS-HCC model that includes indicators for number of conditions and uses two years of diagnosis data to determine beneficiaries' HCCs (combined model). The combined model has the benefits of both the conditions model and the two-year model: It improves the predictive accuracy for beneficiaries who have many conditions and it reduces year-to-year fluctuations in beneficiaries'

risk scores (Table 4-5). However, the combined model underpredicts costliness for mental illness, which also occurs under the two-year model.

**Issues related to financial neutrality
between FFS Medicare and the MA
program**

CMS estimates the CMS-HCC model using cost, demographic, and diagnosis data from FFS beneficiaries. Therefore, the coefficients for each HCC indicate the relative costliness of treating those conditions in FFS Medicare. On several occasions, the Commission has

**TABLE
4-5****Adding measures for number
of conditions and using two years
of diagnoses in CMS-HCC model improves
predictive accuracy for beneficiaries
who have many conditions**

Category	Predictive ratio	
	Standard model	Combined model
Specific conditions		
Diabetes	1.00	1.00
COPD	1.01	1.01
CHF	0.99	1.00
Cancer	0.99	0.99
Mental illness	1.00	0.95
Schizophrenia	1.00	1.00
AMI	1.03	1.02
Unspecified stroke	1.01	1.01
All strokes	1.01	1.01
Number of conditions		
0	0.94	1.01
1	1.02	1.00
2	1.03	1.00
3	1.03	1.01
4	1.02	0.99
5 or more	0.98	0.99
8 or more	0.95	1.00

Note: CMS-HCC (CMS-hierarchical condition category), COPD (chronic obstructive pulmonary disease), CHF (congestive heart failure), AMI (acute myocardial infarction). We determined the number of conditions by counting the number of HCCs a beneficiary maps into. The standard model uses one year of diagnosis data to determine beneficiaries' conditions; the combined model uses two years of diagnosis data.

Source: MedPAC analysis of 5 percent standard analytic claims files and 5 percent Medicare denominator file.

Methods used in regression analysis

For this chapter, we estimated several versions of the CMS–hierarchical condition category (CMS–HCC) risk-adjustment model. We used the same general method to produce all of the regression-based results presented. The only differences between regressions are the explanatory variables. The results in all our regressions are based on a 5 percent sample of fee-for-service (FFS) beneficiaries.

In each regression, we used data from 2007 and 2008. The 2007 data are the HCCs based on diagnoses from hospital inpatient, hospital outpatient, and physician claims that we used to determine each beneficiary's condition categories for 2008, which are defined by 70 HCCs in the CMS–HCC model. Examples of conditions defined by the HCCs include diabetes with various degrees of severity, congestive heart failure (CHF), and chronic obstructive pulmonary disease (COPD). The 2008 data include the following for each beneficiary: total costliness to the Medicare program, age, sex, Medicaid status, whether institutionalized for three consecutive months, and whether eligible for Medicare on the basis of age but originally eligible because of disability.

To be included in the analysis, beneficiaries had to meet the following requirements: in both Part A and Part B of Medicare throughout 2007, in both Part A and Part B throughout their Medicare eligibility in 2008, no

Medicare Advantage enrollment at any time in 2007 or 2008, no hospice care in 2008, not classified as having end-stage renal disease in 2008, lived within the United States for all of 2007 and 2008, no Medicare as a secondary payer in 2007 or 2008, and not long-term institutionalized in 2008. In addition, the results in Tables 4-4 and 4-5 include analyses of versions of the CMS–HCC model that use two years of diagnosis data to determine each beneficiary's HCCs. For this regression, we used diagnoses from 2006 and 2007 claims; when we used data from 2007 to exclude beneficiaries in the other regressions, we used data from 2006 and 2007 to exclude beneficiaries in the two-year regression.

In each regression, the dependent variable was each beneficiary's 2008 costliness to FFS Medicare that we annualized if the beneficiary was in FFS Medicare for only a fraction of 2008. That is, we divided each beneficiary's 2008 costliness to FFS Medicare by the fraction of the year the beneficiary was in FFS Medicare in 2008. Each regression included the following explanatory variables:

- 70 HCCs;
- 24 categories indicating age and sex;
- 4 variables indicating Medicaid status;

(continued next page)

stated that payments to MA plans should be equal to what MA enrollees would cost in FFS Medicare (financial neutrality) (Medicare Payment Advisory Commission 2001, Medicare Payment Advisory Commission 2002, Medicare Payment Advisory Commission 2004, Medicare Payment Advisory Commission 2005). The current method of using cost and diagnosis data from FFS Medicare to estimate the CMS–HCC model is consistent with the goal of financial neutrality.⁴

In light of two recently published papers, more discussion about financial neutrality between FFS Medicare and the MA program may be appropriate. One study found that large regional differences in service use among FFS

beneficiaries lead to large regional differences in risk scores (Song et al. 2010). This study indicates that these regional differences in risk scores are due, at least in part, simply to differences in service use rather than differences in health status. It is not known if these regional differences in risk scores also occur in the MA program. If they do, higher risk scores in high-use regions will drive up MA payments not because MA enrollees are less healthy but simply because service use is higher.

A second study found that the relative cost of treating specific conditions differs widely between a large MA plan and FFS Medicare. For some conditions, the relative cost is

Methods used in regression analysis (continued)

- 2 variables indicating beneficiaries who are eligible because of age but were originally eligible because of disability;
- 5 categories indicating that beneficiaries are disabled and have 1 of 5 conditions: opportunistic infections, severe hematologic disorders, drug or alcohol psychosis, drug or alcohol dependence, and cystic fibrosis; and
- 6 disease interaction terms: diabetes and CHF, diabetes and cardiovascular disease, CHF and COPD, CHF with COPD and coronary artery disease, renal failure (RF) and CHF, and RF with CHF and diabetes.

These are the same dependent and explanatory variables that CMS includes in the version of the CMS–HCC model it currently uses.

We ran six weighted regressions to produce the results in Tables 4-1, 4-2, 4-4, and 4-5, where the weight is the fraction of the year each beneficiary was in FFS Medicare in 2008, which is the same fraction we used to annualize each beneficiary's costs. For Table 4-1, we ran a standard version of the CMS–HCC model, which includes all the variables listed above, and we ran a race/income version that includes the same variables plus indicators for each beneficiary's race (African American, Hispanic, White, or other) and income,

which we approximated by the per capita income in each beneficiary's county of residence.

For Tables 4-2, 4-4, and 4-5, we ran the following regressions:

- a conditions version, which includes all the variables in the standard version plus indicators of whether each beneficiary has zero, one, two, three, four, or five or more HCCs (Table 4-2);
- a two-year version, which includes all the variables in the standard version, but HCCs for each beneficiary are based on two years of diagnosis data rather than the single year used in the standard version (Table 4-4); and
- a version that combines the conditions version and the two-year version and includes all the variables in the standard version, whether each beneficiary has zero, one, two, three, four, or five or more HCCs, and HCCs that are based on two years of diagnosis data (Table 4-5).

We developed the analytic samples for each of these regressions from 5 percent samples of all FFS beneficiaries in 2008. It resulted in analytic samples of about 1.2 million beneficiaries for the standard and conditions versions and about 1.1 million beneficiaries for the two-year version and the version that combines the conditions and two-year versions. ■

lower in the MA plan; for other conditions, the relative cost in the MA plan is higher (Newhouse et al. 2011).

Should MA risk scores be adjusted for regional differences in service use?

Risk adjustment affects payments to MA plans through two mechanisms. First, county-level benchmarks depend directly on each county's per capita FFS spending, divided by the county's average CMS–HCC risk score among FFS beneficiaries. Second, CMS uses the risk scores to adjust MA payments for each enrollee.

CMS–HCC risk scores depend heavily on beneficiaries' conditions that providers have coded on claims. Research

indicates that among FFS beneficiaries, per capita service use is higher in some areas of the country than in others. Moreover, average risk scores among FFS beneficiaries are highest in regions where service use is highest and lowest in regions where service use is lowest (Song et al. 2010).

This correlation between regional differences in service use and regional differences in risk scores could occur for two reasons. First, it could occur because those in the high-use regions are sicker. In this case, the relatively high risk scores in the high-use regions accurately reflect regional differences in health status. Second, it could occur because beneficiaries in high-use areas simply use more

medical care without being sicker than beneficiaries in lower use areas. In this case, the relatively high risk scores in high-use areas do not reflect regional differences in health status. Research indicates that at least part of the regional differences in risk scores is due to beneficiaries in high-use regions using more medical care without actually being sicker. That is, beneficiaries in high-use areas would have lower risk scores if they lived in regions where service use was lower (Song et al. 2010).

To the extent that regional differences in service use cause differences in risk scores, there may be little effect on the county-level benchmarks. For example, if a county has a high level of service use, it is likely to be reflected in both high per capita FFS spending and a high average risk score among FFS beneficiaries. The high FFS spending and high average risk score should largely offset each other, so the county benchmark should be unaffected.

Regional differences in service use are more likely to have an effect on MA payments through the risk scores of MA enrollees. In regions with relatively high service use among MA enrollees, it is possible that providers' coding of conditions is more intensive than in other regions, leading to higher risk scores and MA payments in those regions. However, it is not clear whether the regional differences in service use and risk scores that occur in the FFS program also occur in the MA program because data are not available to make that determination. But, CMS has begun collecting beneficiary-level cost and diagnosis data from MA plans; after it has collected multiple years of these data, it may be possible to replicate the analysis by Song and colleagues for the MA population.

Addressing regional differences in risk scores due to differences in service use

The study by Song and colleagues (2010) divided the country into regions and determined per capita service use in FFS Medicare in each region. The regions were sorted into quintiles of per capita service use. The authors found that regional differences in service use led to regional differences in how intensively conditions are coded on claims, which resulted in average risk scores in the highest quintile of service use that were 15 percent higher than they would have been had the beneficiaries lived in a region in the lowest quintile.

If there are similar regional differences in the MA program, adjustments could be made to MA risk scores. Using the results from Song and colleagues as a hypothetical example, these adjustments could work as

follows. Regions that are in the middle (third) quintile of service use could be used as the baseline. MA enrollees residing in a region that is in the third quintile would have no adjustment to their risk scores. Relative to the third quintile, Song and colleagues found that regional differences in service use result in risk scores that are 5.2 percent lower in the first quintile, 1.7 percent lower in the second quintile, 5.7 percent higher in the fourth quintile, and 8.8 percent higher in the fifth quintile. MA risk scores in these four regions could be adjusted by these percentages to account for differences in coding.

Adjusting risk scores for MA enrollees for the effects of regional differences in service use should be considered alongside the Commission's previously stated position on financial neutrality between the MA and FFS programs. On the one hand, making regional adjustments to MA risk scores is somewhat inconsistent with financial neutrality because one sector (FFS or MA) would have a financial advantage over another sector for treating the same patient or condition. On the other hand, to the extent that regional differences in service use that are independent of beneficiaries' health status result in regional differences in risk scores among MA enrollees, plans in high-use regions would have higher payments than plans in lower use regions simply because of regional differences in use rates. It may be appropriate to discuss the merits of each alternative.

Should CMS use FFS or MA data to estimate the CMS-HCC model?

If the large differences found by Newhouse and colleagues between the cost of treating conditions in a large MA plan and FFS Medicare also occur in most or all other MA plans, the CMS-HCC model underpredicts the costs in MA plans for some conditions and overpredicts the costs in MA plans for other conditions. Obviously, it is financially beneficial for plans to have beneficiaries who have conditions for which costs are overpredicted and avoid beneficiaries who have conditions for which costs are underpredicted.

In light of the Commission's stance on financial neutrality and the findings from Newhouse and colleagues, it may be appropriate to have a discussion about whether CMS should continue using data from FFS beneficiaries to calibrate the CMS-HCC model or switch to using data from MA enrollees. An argument for continued use of FFS data is that it is consistent with a policy of financial neutrality, and financial neutrality encourages care to be provided in the sector where it can be provided more

efficiently (MA or FFS). Under financial neutrality, when plans are able to provide care at a lower cost than FFS Medicare, they may be able to offer enhanced benefits that are more attractive to beneficiaries than FFS Medicare. Alternatively, if plans cannot provide care at a lower cost than FFS Medicare, they may not be able to offer benefits that are competitive with FFS Medicare. An argument for use of MA data is that costs incurred by MA plans may differ from costs for FFS Medicare—perhaps because of different risk profiles between sectors or because of different models of care. To the extent these cost deviations occur between sectors, MA payments that reflect the cost of efficient providers require risk adjustment calibrated on data from MA enrollees.

Differences in coding between FFS Medicare and the MA program

MA plans have an incentive for providers to code their enrollees' conditions as completely as possible because MA risk scores and payments strongly depend on each enrollee's conditions. The incentive to code conditions is present but not as strong in FFS Medicare because FFS

payments often depend on the services provided rather than beneficiaries' conditions.

This discrepancy in incentives between the MA program and FFS Medicare may be reflected in analyses by CMS and the Government Accountability Office (GAO), which found differences in diagnostic coding intensity between the two sectors (Centers for Medicare & Medicaid Services 2009, Government Accountability Office 2012). In response to its finding, CMS has reduced risk scores of MA enrollees by 3.4 percent in 2010, 2011, and 2012. However, GAO asserts that CMS has underestimated the magnitude of the greater coding intensity in the MA program by at least 1.4 percentage points and by as much as 3.7 percentage points. Statutory adjustments in the Patient Protection and Affordable Care Act of 2010 (PPACA) are consistent with the findings of the GAO. Starting in 2014, PPACA requires CMS to reduce MA enrollees' risk scores by an amount greater than 3.4 percent in each year, unless CMS begins using diagnosis and cost data from MA enrollees to estimate the CMS-HCC model. ■

Endnotes

- 1 CMS arrived at which HCCs to retain and how many to retain by balancing several competing considerations, including data collection burden, predictive power, whether to retain rare high-cost conditions, and retaining only well-defined, clinically coherent conditions (Pope et al. 2004).
- 2 It is not clear when CMS intends to begin using the data from MA enrollees to estimate the CMS–HCC model.
- 3 When we estimated the model using regression analysis, we used zero conditions as the basis of comparison, so we excluded that variable from the regression.
- 4 Financial neutrality can be obtained only if coding of conditions is the same in FFS Medicare and the MA program. Research by CMS and the Government Accountability Office (GAO) indicates that differences in coding exist between these two sectors (Centers for Medicare & Medicaid Services 2009, Government Accountability Office 2012). CMS has made adjustments to account for these differences, but GAO believes the adjustments are too small.

TOOLKIT

To Help Decrease Improper Payments in Medicare Advantage Through the Identification of High-Risk Diagnosis Codes

December 2023 | A-07-23-01213

Toolkit To Help Decrease Improper Payments in Medicare Advantage Through the Identification of High-Risk Diagnosis Codes

What Is the Toolkit?

This toolkit offers Medicare Advantage (MA) organizations information that will enable them to replicate Office of Inspector General's (OIG's) techniques to identify and evaluate high-risk diagnosis codes to ensure proper payments and provide better care for enrollees.

The Centers for Medicare & Medicaid Services (CMS) makes monthly payments to MA organizations for each of their enrollees. These payments are based, in part, on the diagnoses that their enrollees receive from their providers. Using a system of risk adjustment, CMS pays MA organizations more for providing benefits to enrollees with diagnoses

associated with more intensive use of health care resources relative to healthier enrollees, who would be expected to require fewer health care resources. Accordingly, CMS relies on MA organizations not only to collect diagnosis codes from their providers and submit the associated codes to CMS, but also to implement an effective compliance program to monitor the accuracy of these diagnosis codes. In this respect, MA organizations generally review medical records in order to detect and correct inaccurate diagnosis codes.

We have identified certain diagnosis codes which, when paired with other circumstances, are at a high risk for being miscoded. This toolkit provides additional information about the circumstances under which these diagnosis codes could be miscoded and the actual programming codes that we used in our audits to identify them.

Why Did OIG Create This Toolkit?

We have performed several audits for which our objectives were to determine whether MA organizations submitted certain diagnosis codes—ones that when coupled with other data indicated that the codes were at high risk for being miscoded—to CMS for use in CMS's risk adjustment program in accordance with Federal requirements. Thus far, we have found that overall, approximately 70 percent of those diagnosis codes were not supported in the associated medical records. Moreover, some diagnosis codes were consistently not supported over 90 percent of the time. Although the audited MA organizations usually disagreed with our reports' recommendations and with various aspects of our audit methodologies, those MA organizations generally did not disagree with our determinations regarding these diagnosis codes, and some expressed a genuine interest in submitting corrections to CMS. Other MA organizations—including ones that we have not audited—have asked us to share with them how we decided which diagnosis codes were at high risk for being miscoded.

This toolkit is meant to be a practical, hands-on device that will help MA organizations improve the accuracy of their submitted diagnoses that are at high risk for being miscoded.

The purpose of this toolkit is to provide information as to the steps that we followed as well as the data supporting the process that we followed. Our hope is that the users of this toolkit will, at a minimum, use the information to detect and correct inaccurate diagnosis codes in their own systems. To a greater extent, we hope that MA organizations use this toolkit as a starting point to identify other diagnosis codes that are at high risk for being miscoded and take appropriate measures to prevent, detect, and correct such errors. Thus, our goals are to ensure that CMS makes accurate payments to the MA organizations and that the enrollees receive the correct level of care.

What Does This Toolkit Include?

We have compiled the high-risk groups identified in our audits for incorrect diagnosis codes that were consistently submitted to CMS.¹ We have also included explanations that demonstrate why these specific diagnosis codes, when coupled with other data (including procedure codes and prescription drug events (PDEs)), are at high risk for being miscoded. This toolkit contains the Structured Query Language (SQL)—a programming language used in many software programs—that we used in our audits to query CMS's systems. To provide further information as to what we analyzed, we have included all of the codes used in our programming language. The SQL language and codes included in this toolkit relate to the 2019 payment year.²

This toolkit enables an MA organization to adapt our actual programming codes in order to query its internal data systems so that it can more accurately identify the enrollees in the various high-risk groups.

To place our work in context, the figure below summarizes the errors that our audits identified for each of high-risk groups included in this toolkit.

Figure: Errors in High-Risk Groups as of November 2023

High-Risk Group	Total	Errors	Error %
Acute stroke	945	908	96%
Acute heart attack	791	751	95%
Embolism	754	593	79%
Lung cancer	391	345	88%
Breast cancer	390	373	96%
Colon cancer	390	368	94%
Prostate cancer	360	322	89%
Potentially mis-keyed diagnosis codes	522	421	81%
Totals	4,543	4,081	90%

¹ Not every high-risk group that we audited had incorrect diagnosis codes that were consistently submitted to CMS. This toolkit includes only those high-risk groups that had high error rates.

² Our various audits have spanned the 2013 through 2019 payment years. See our discussion on the next page for an explanation of "payment years."

Detailed information on our audits of the MA program, as well as related information on the high-risk diagnoses codes discussed in this toolkit, can be found at [Managed Care | HHS-OIG](#)

Background

Medicare Advantage Program—Risk-Adjusted Payments

Under the MA program, CMS makes advance payments each month to MA organizations. Federal requirements mandate that these payments be based on the anticipated cost of providing Medicare benefits to a given enrollee and, in doing so, also account for variations in the demographic characteristics and health status of each enrollee.³

CMS uses two principal components to calculate the risk-adjusted payment that it will make to an MA organization for an enrollee: a base rate that CMS sets using bid amounts received from the MA organization and the risk score for that enrollee. These are described as follows:

- **Base rate:** Before the start of each year, each MA organization submits bids to CMS that reflect the MA organization's estimate of the monthly revenue required to cover an enrollee with an average risk profile.⁴ CMS compares each bid to a specific benchmark amount for each geographic area to determine the base rate that an MA organization is paid for each of its enrollees.
- **Risk score:** A risk score is a relative measure that reflects the additional or reduced costs that each enrollee is expected to incur compared with the costs incurred by enrollees on average. CMS calculates risk scores based on an enrollee's health status (discussed below) and demographic characteristics (such as the enrollee's age and gender). This process results in an individualized risk score for each enrollee, which CMS calculates annually.

To determine an enrollee's health status for purposes of calculating the risk score, CMS uses diagnoses that the enrollee receives from acceptable provider types, including certain physicians and hospitals.⁵ MA organizations collect the diagnosis codes from providers based on information documented in the medical records and submit these codes to CMS. CMS then maps certain diagnosis codes, on the basis of similar clinical characteristics and severity and cost implications, into Hierarchical Condition Categories (HCCs). Each HCC has a factor (which is a numerical value) assigned to it for use in each enrollee's risk score.

The risk adjustment program is prospective. Specifically, CMS uses the diagnosis codes that the enrollee received for one year (known as the service year) to determine HCCs and calculate risk scores for the following calendar year (known as the payment year). Thus, an enrollee's risk score does not change for the year in which a diagnosis is made. Instead, the risk score changes for the entirety of the year after the diagnosis has been made. Further, the risk score calculation is an additive process: As HCC factors (and, when applicable, disease interaction factors) accumulate, an enrollee's risk score increases, and the monthly risk-adjusted payment to the MA organization also increases. In this way, the risk adjustment program compensates MA

⁴ The Act § 1854(a)(6); 42 CFR § 422.254 *et seq.*

⁵ The providers code diagnoses using the International Classification of Diseases (ICD), Clinical Modification (CM), *Official Guidelines for Coding and Reporting* (ICD Coding Guidelines). The ICD is a coding system that is used by physicians and other health care providers to classify and code all diagnoses, symptoms, and procedures.

organizations for the additional risk of providing coverage to enrollees expected to require more health care resources.

CMS multiplies the risk scores by the base rates to calculate the total monthly Medicare payment that an MA organization receives for each enrollee. Thus, if the factors used to determine an enrollee's risk score are incorrect, CMS will make an improper payment to an MA organization. Specifically, if diagnosis codes are incorrect, the HCCs are unvalidated, which causes overstated enrollee risk scores and overpayments from CMS.

Identifying High-Risk Groups of Diagnoses

For each of our audits, we used data mining techniques and discussed certain circumstances with medical professionals in order to identify diagnoses that were at higher risk for being miscoded.

Data Mining Techniques

After an enrollee receives a medical service, the provider of that service generates a claim for payment to the MA organization. Although MA organizations make their own payment arrangements with providers for these services, CMS requires MA organizations to submit copies of all claims to CMS. These claims include services that can be used for risk adjustment purposes (physician, outpatient, and inpatient) as well as claims whose services are not used for risk adjustment purposes (such as home health services, skilled nursing facility services, durable medical equipment, laboratory services, and x-rays, among other services).

We have developed computerized programs to access and analyze these claims data. For example, we identify the services that contain the risk-adjusted diagnoses and how often those diagnoses were submitted throughout the service year. In this regard, we analyze the data to see which diagnoses were submitted to CMS and when. We combine our knowledge of the MA program along with what we glean from our discussions with medical professionals to identify which diagnosis codes to review.

Discussions With Medical Professionals

For our audits, we have discussed various circumstances with medical professionals to ensure that we analyzed the data correctly. For example, CMS has identified 21 diagnosis codes that map to the HCC for Acute Myocardial Infarction. Our discussions with medical professionals revealed that 17 of those 21 diagnosis codes were at higher risk for being miscoded if: (1) they occurred through a face-to-face encounter with a physician, but (2) that same diagnosis did not occur on an inpatient claim within 6 months (before or after) that encounter. For instances of this nature, the medical professionals also explained to us what was likely supported in the medical records and what should have been submitted to CMS. Continuing the example, the medical professionals told us that the medical records likely supported an old myocardial infarction diagnosis (which does not map to an HCC) instead of an acute myocardial infarction diagnosis.

For this toolkit we have compiled the high-risk groups identified in our audits for incorrect diagnosis codes that were consistently submitted to CMS. We have also included explanations that demonstrate why these specific diagnosis codes, when coupled with other data (including procedure codes and PDEs), are at high risk for being miscoded. This toolkit contains the SQL, which is a programming language used in many software programs, that we used in our audits to query CMS's systems. To provide further information as to what we analyzed, we have included all of the codes used in our programming language.

Our goal is to enable an MA organization to adapt our actual programming codes in order to query its internal data systems, so that it can more accurately identify the enrollees in the various high-risk groups.

Data Analytics for High-Risk Groups

We have compiled data on the high-risk groups identified in our audits for incorrect diagnosis codes that were consistently submitted to CMS. For each of these high-risk groups, we are providing the following information:

- We have included explanations that demonstrate why these specific diagnosis codes, when coupled with other data (including procedure codes and PDEs), are at high risk for being miscoded. For example, one high-risk group included individuals who received one lung cancer diagnosis during a service year, but the encounters and the relevant PDE data did not indicate that the individuals received certain types of care and medication.
- Based on discussions with medical professionals, we have also provided in each case the diagnosis code that typically should have been submitted to CMS instead of the incorrect diagnosis code that actually was submitted. Continuing with the lung cancer diagnosis example, a history of lung cancer diagnosis is generally what was supported in the medical records.
- As a further extension of the narrative description, we have identified all the various codes and the names of the codes that we analyzed. For the example of the lung cancer high-risk group, we are providing a list of the codes and names for:
 - the lung cancer diagnoses,
 - the surgical therapy procedures,
 - the radiation treatment procedures, and
 - the chemotherapy drug treatment procedures.
- Finally, we have included the SQL—that programming language mentioned earlier—that we used in our audits to query CMS's systems. Our goal is to enable an MA organization to adapt our SQL codes in order to query its internal data systems, so that it can also identify the enrollees in the various high-risk groups.

1. Acute Stroke High-Risk Group

For the acute stroke high-risk group, we focused on enrollees who received one acute stroke diagnosis (that mapped to the HCC for Ischemic or Unspecified Stroke (HCC 100)) on one physician claim during the service year but did not have an acute stroke diagnosis on a corresponding inpatient or outpatient hospital claim (Table 1.1). In these instances, a diagnosis of history of stroke (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 1.1 includes the 94 acute stroke diagnosis codes used in our analysis:

Table 1.1: Acute Stroke Diagnosis Codes

Diagnosis Code	Description
I6300	Cerebral infarction (CI) due to thrombosis of unspecified precerebral artery
I63011	CI due to thrombosis of right vertebral artery
I63012	CI due to thrombosis of left vertebral artery
I63013	CI due to thrombosis of bilateral vertebral arteries
I63019	CI due to thrombosis of unspecified vertebral artery
I6302	CI due to thrombosis of basilar artery
I63031	CI due to thrombosis of right carotid artery
I63032	CI due to thrombosis of left carotid artery
I63033	CI due to thrombosis of bilateral carotid arteries
I63039	CI due to thrombosis of unspecified carotid artery
I6309	CI due to thrombosis of other precerebral artery
I6310	CI due to embolism of unspecified precerebral artery
I63111	CI due to embolism of right vertebral artery
I63112	CI due to embolism of left vertebral artery
I63113	CI due to embolism of bilateral vertebral arteries
I63119	CI due to embolism of unspecified vertebral artery
I6312	CI due to embolism of basilar artery
I63131	CI due to embolism of right carotid artery
I63132	CI due to embolism of left carotid artery
I63133	CI due to embolism of bilateral carotid arteries
I63139	CI due to embolism of unspecified carotid artery
I6319	CI due to embolism of other precerebral artery
I6320	CI due to unspecified occlusion or stenosis of unspecified precerebral arteries
I63211	CI due to unspecified occlusion or stenosis of right vertebral arteries

Diagnosis Code	Description
I63212	CI due to unspecified occlusion or stenosis of left vertebral arteries
I63213	CI due to unspecified occlusion or stenosis of bilateral vertebral arteries
I63219	CI due to unspecified occlusion or stenosis of unspecified vertebral arteries
I6322	CI due to unspecified occlusion or stenosis of basilar arteries
I63231	CI due to unspecified occlusion or stenosis of right carotid arteries
I63232	CI due to unspecified occlusion or stenosis of left carotid arteries
I63233	CI due to unspecified occlusion or stenosis of bilateral carotid arteries
I63239	CI due to unspecified occlusion or stenosis of unspecified carotid arteries
I6329	CI due to unspecified occlusion or stenosis of other precerebral arteries
I6330	CI due to thrombosis of unspecified cerebral artery
I63311	CI due to thrombosis of right middle cerebral artery
I63312	CI due to thrombosis of left middle cerebral artery
I63313	CI due to thrombosis of bilateral middle cerebral arteries
I63319	CI due to thrombosis of unspecified middle cerebral artery
I63321	CI due to thrombosis of right anterior cerebral artery
I63322	CI due to thrombosis of left anterior cerebral artery
I63323	CI due to thrombosis of bilateral anterior arteries
I63329	CI due to thrombosis of unspecified anterior cerebral artery
I63331	CI due to thrombosis of right posterior cerebral artery
I63332	CI due to thrombosis of left posterior cerebral artery
I63333	CI to thrombosis of bilateral posterior arteries
I63339	CI due to thrombosis of unspecified posterior cerebral artery
I63341	CI due to thrombosis of right cerebellar artery
I63342	CI due to thrombosis of left cerebellar artery
I63343	CI to thrombosis of bilateral cerebellar arteries
I63349	CI due to thrombosis of unspecified cerebellar artery
I6339	CI due to thrombosis of other cerebral artery
I6340	CI due to embolism of unspecified cerebral artery
I63411	CI due to embolism of right middle cerebral artery
I63412	CI due to embolism of left middle cerebral artery
I63413	CI due to embolism of bilateral middle cerebral arteries
I63419	CI due to embolism of unspecified middle cerebral artery
I63421	CI due to embolism of right anterior cerebral artery
I63422	CI due to embolism of left anterior cerebral artery
I63423	CI due to embolism of bilateral anterior cerebral arteries

Diagnosis Code	Description
I63429	CI due to embolism of unspecified anterior cerebral artery
I63431	CI due to embolism of right posterior cerebral artery
I63432	CI due to embolism of left posterior cerebral artery
I63433	CI due to embolism of bilateral posterior cerebral arteries
I63439	CI due to embolism of unspecified posterior cerebral artery
I63441	CI due to embolism of right cerebellar artery
I63442	CI due to embolism of left cerebellar artery
I63443	CI due to embolism of bilateral cerebellar arteries
I63449	CI due to embolism of unspecified cerebellar artery
I6349	CI due to embolism of other cerebral artery
I6350	CI due to unspecified occlusion or stenosis of unspecified cerebral artery
I63511	CI due to unspecified occlusion or stenosis of right middle cerebral artery
I63512	CI due to unspecified occlusion or stenosis of left middle cerebral artery
I63513	CI due to unspecified occlusion or stenosis of bilateral middle arteries
I63519	CI due to unspecified occlusion or stenosis of unspecified middle cerebral artery
I63521	CI due to unspecified occlusion or stenosis of right anterior cerebral artery
I63522	CI due to unspecified occlusion or stenosis of left anterior cerebral artery
I63523	CI due to unspecified occlusion or stenosis of bilateral anterior arteries
I63529	CI due to unspecified occlusion or stenosis of unspecified anterior cerebral artery
I63531	CI due to unspecified occlusion or stenosis of right posterior cerebral artery
I63532	CI due to unspecified occlusion or stenosis of left posterior cerebral artery
I63533	CI due to unspecified occlusion or stenosis of bilateral posterior arteries
I63539	CI due to unspecified occlusion or stenosis of unspecified posterior cerebral artery
I63541	CI due to unspecified occlusion or stenosis of right cerebellar artery
I63542	CI due to unspecified occlusion or stenosis of left cerebellar artery
I63543	CI due to unspecified occlusion or stenosis of bilateral cerebellar arteries
I63549	CI due to unspecified occlusion or stenosis of unspecified cerebellar artery
I6359	CI due to unspecified occlusion or stenosis of other cerebral artery
I638	Other CI
I639	CI, unspecified
I97810	Intraoperative cerebrovascular infarction during cardiac surgery
I97811	Intraoperative cerebrovascular infarction during other surgery
I97820	Postprocedural cerebrovascular infarction during cardiac surgery
I97821	Postprocedural cerebrovascular infarction during other surgery
I636	CI due to cerebral venous thrombosis, nonpyogenic

Table 1.2 includes two additional diagnosis codes that mapped to the HCC for Ischemic or Unspecified Stroke (HCC 100)); however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received either of these diagnoses were excluded from our analysis:

Table 1.2: Excluded Diagnosis Codes for the Acute Stroke High-Risk Group

Diagnosis Code	Description
I6381	Other cerebral infarction due to occlusion or stenosis of small artery
I6389	Other cerebral infarction

SQL Programming Language

Table 1.3 details the SQL programming language used to query CMS's systems in order to identify the acute stroke high-risk diagnosis codes.

Table 1.3: SQL Programming Language for Acute Stroke High-Risk Group

Step 1

We identified enrollees who received an acute stroke diagnosis (Table 1.1) in a physician setting without a corresponding inpatient or outpatient claim.

```

SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
,COUNT(raps.BENE_SK) AS BENE_LINES /*Counts the number of acute stroke diagnosis codes in an office (physician)
setting. Limited to one instance in Step #2*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Acute Stroke Diagnosis Codes Table*/
IN (
SELECT DX_CD /*Represents the diagnosis code field in the Acute Stroke Diagnosis Codes Table*/
FROM CMS_ADM_OIG_OAS_PRD.ACTIVE_STROKE_DX_CODES) /*Acute Stroke Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_PRVDR_TYPE_CD = '20' /*RAPS Provider Type Code "20" represents "physician" claims*/
AND BENE_RAPS_DGNS_DLT_SW = 'no' /*"no" indicates the RAPS diagnosis code is not deleted*/

/*Subquery to identify and exclude enrollees with an acute stroke diagnosis code in an inpatient or outpatient setting*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
NOT IN
SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis field used to match to Acute Stroke Diagnosis Codes Table*/
IN (
SELECT DX_CD /*Represents the diagnosis code field in the Acute Stroke Diagnosis Codes Table*/
FROM CMS_ADM_OIG_OAS_PRD.ACTIVE_STROKE_DX_CODES) /*Acute Stroke Diagnosis Codes Table*/

```

```
AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/  
AND BENE_RAPS_DGNS_DLT_SW = '0' /*"0" indicates the RAPS diagnosis code is not deleted*/  
AND BENE_RAPS_PRVDR_TYPE_CD IN ('01', '02', '10') /*RAPS Provider Type Code "01" and "02" represent "inpatient"  
claims and provider type code "10" represents "outpatient" claims*/
```

```
GROUP BY raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

Step 2

Using the output from Step 1, we then limited our results to those enrollees who had only one instance of an acute stroke diagnosis during the time period of interest and those enrollees whose risk scores were confirmed in CMS's Risk Adjustment System (RAS) as including HCC 100.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/  
FROM CMS_ADM_OIG_OAS_PRD.ACUTE_STROKE_ENROLLEES_STEP_1 raps /*Output from Step #1*/  
WHERE raps.BENE_LINES < 2 /*Criteria to limit enrollees to those with a single instance of an acute stroke diagnosis code  
in an office (physician) setting*/  
AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/  
IN (  
  
SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/  
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_I_SCORE ras /*CMS RAS data*/  
  
WHERE BENE_PTC_HCC_100_SW = '1' /*Confirms HCC 100 was utilized in the payment risk score*/  
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/  
AND BENE_PTC_SCORE_MODEL_SBTYP_CD = '102' /*Used subtype code "102" since all enrollees have this subtype record,  
not required for identifying enrollees for review, helps with computing efficiency*/  
AND BENE_RISK_SEQNC_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAPS based RAS record*/  
AND (CLNDR_CY_NUM = 2019)) /*Specifies the payment year for the HCC confirmation*/
```

Downloadable Information

All of the codes used in this analysis along with the SQL programming language can be found at <https://oig.hhs.gov/oas/toolkit/Acute-Stroke-High-Risk-Group.pdf>.

2. Acute Myocardial Infarction High-Risk Group

For the acute myocardial infarction high-risk group, we focused on enrollees who received one diagnosis (that mapped to the HCC for Acute Myocardial Infarction (HCC 86)) on only one physician or outpatient claim during the service year but did not have an acute myocardial infarction diagnosis on a corresponding inpatient hospital claim (either within 60 days before or 60 days after the physician or outpatient claim) (Table 2.1). In these instances, a diagnosis indicating a history of myocardial infarction (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 2.1 includes the 17 acute myocardial diagnosis codes used in our analysis:

Table 2.1: Acute Myocardial Infarction Diagnosis Codes⁶

Diagnosis Code	Description
I2109	ST elevation myocardial infarction (STEMI) involving other coronary artery of anterior wall
I2111	STEMI involving right coronary artery
I2119	STEMI involving other coronary artery of inferior wall
I2129	STEMI involving other sites
I213	STEMI of unspecified site
I214	Non-ST elevation myocardial infarction (NSTEMI)
I2101	STEMI involving left main coronary artery
I2102	STEMI involving left anterior descending coronary artery
I2121	STEMI involving left circumflex coronary artery
I219	Acute myocardial infarction, unspecified
I220	Subsequent STEMI of anterior wall
I221	Subsequent STEMI of inferior wall
I222	Subsequent NSTEMI
I228	Subsequent STEMI of other sites
I229	Subsequent STEMI of unspecified site
I21A1	Myocardial infarction type 2
I21A9	Other myocardial infarction type

Table 2.2 on the following page includes 4 additional diagnosis codes that mapped to the HCC for Acute Myocardial Infarction (HCC 86) and all 20 diagnosis codes that mapped to the HCC for Unstable Angina and

⁶ The term "ST," used in many descriptions in this table, refers to the flat section of an echocardiogram (ECG). When an individual has the most severe type of heart attack, this segment will no longer be flat on the ECG but will appear abnormally elevated.

Other Acute Ischemic Heart Disease (HCC 87). We did not consider these codes to be at a high risk for being miscoded and therefore, enrollees who received any one of these diagnoses were excluded from our analysis:

Table 2.2: Excluded Diagnosis Codes for the Acute Myocardial Infarction High-Risk Group

Diagnosis Code	Description
I200	Unstable angina
I230	Hemopericardium as current complication following acute myocardial infarction
I231	Atrial septal defect as current complication following acute myocardial infarction
I232	Ventricular septal defect as current complication following acute myocardial infarction
I233	Rupture of cardiac wall without hemopericardium as current complication following acute myocardial infarction
I234	Rupture of chordae tendineae as current complication following acute myocardial infarction
I235	Rupture of papillary muscle as current complication following acute myocardial infarction
I236	Thrombosis of atrium, auricular appendage, and ventricle as current complications following acute myocardial infarction
I237	Postinfarction angina
I238	Other current complications following acute myocardial infarction
I240	Acute coronary thrombosis not resulting in myocardial infarction
I241	Dressler's syndrome
I248	Other forms of acute ischemic heart disease
I249	Acute ischemic heart disease, unspecified
I25110	Atherosclerotic heart disease of native coronary artery with unstable angina pectoris
I25700	Atherosclerosis of coronary artery bypass graft(s), unspecified, with unstable angina pectoris
I25710	Atherosclerosis of autologous vein coronary artery bypass graft(s) with unstable angina pectoris
I25720	Atherosclerosis of autologous artery coronary artery bypass graft(s) with unstable angina pectoris
I25730	Atherosclerosis of nonautologous biological coronary artery bypass graft(s) with unstable angina pectoris
I25750	Atherosclerosis of native coronary artery of transplanted heart with unstable angina
I25760	Atherosclerosis of bypass graft of coronary artery of transplanted heart with unstable angina
I25790	Atherosclerosis of other coronary artery bypass graft(s) with unstable angina pectoris
I511	Rupture of chordae tendineae, not elsewhere classified
I512	Rupture of papillary muscle, not elsewhere classified

SQL Programming Language

Table 2.3 details the SQL programming language used to query CMS's systems in order to identify the acute myocardial infarction high-risk diagnosis codes.

Table 2.3: SQL Programming Language for Acute Myocardial Infarction High-Risk Group

Step 1

We identified enrollees who received an acute myocardial infarction diagnosis (Table 2.1) in a physician or outpatient setting without a corresponding inpatient claim.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
, COUNT(raps.DGNS_CD) AS BENE_LINES /*Counts the number of acute myocardial infarction diagnosis codes in an office
(physician) or outpatient setting. Limited to one instance in Step #2*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Acute Myocardial Infarction Diagnosis Codes Table*/
IN ('I2109', 'I2111', 'I2119', 'I2129', 'I213', 'I214', 'I2101', 'I2102', 'I2121', 'I219', 'I220', 'I221', 'I222', 'I228', 'I229', 'I21A1',
'I21A9') /* Acute Myocardial Infarction Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*/
AND (BENE_RAPS_PRVDR_TYPE_CD = '20' /*RAPS Provider Type Code "20" represents "physician" claims*/
OR BENE_RAPS_PRVDR_TYPE_CD = '10' /*RAPS Provider Type Code "10" represents "outpatient" claims*/

/* Subquery to identify and exclude all enrollees with an acute myocardial infarction diagnosis in an inpatient setting*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN
SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Acute Myocardial Infarction Diagnosis Codes Table*/
IN ('I2109', 'I2111', 'I2119', 'I2129', 'I213', 'I214', 'I2101', 'I2102', 'I2121', 'I219', 'I220', 'I221', 'I222', 'I228', 'I229', 'I21A1',
'I21A9') /* Acute Myocardial Infarction Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND (BENE_RAPS_PRVDR_TYPE_CD = '01'
OR BENE_RAPS_PRVDR_TYPE_CD = '02' /*RAPS Provider Type Code "01" and "02" represent "inpatient" claims*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*/

GROUP BY raps.BENE_SK; /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

Step 2

Using the output from Step 1, we then limited our results to those enrollees who had only one instance of an acute myocardial infarction diagnosis during the time period of interest and those enrollees whose risk scores were confirmed in CMS's Risk Adjustment System (RAS) as including HCC 86.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.MYOCARDIAL_INFARCTION_STEP_1 raps /*Output from Step #1*/
WHERE raps.BENE_LINES < 2 /*Criteria to limit enrollees to those with a single instance of an acute myocardial infarction
diagnosis code in an office (physician) or outpatient setting*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
IN (
```

```

SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_I_SCRE ras /*CMS RAS data*/

WHERE (BENE_PTC_HCC_86_SW = '1' /*Confirms HCC 86 was utilized in the payment risk score*/
OR BENE_PTC_HCC_87_SW = '1' /*Confirms HCC 87 was utilized in the payment risk score*/
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/
AND BENE_PTC_SCRE_MODEL_SBTYP_CD = '102' /*Used subtype code "102" since all enrollees have this subtype record, not
required for identifying enrollees for review, helps with computing efficiency*/
AND BENE_RISK_SQNC_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAPS based RAS record*/
AND (CLNDR_CY_NUM = 2019)) /*Specifies the payment year for the HCC confirmation*/

```

Step 3

Using the output from Step 2, we identified and removed the enrollees who had received one or more diagnoses that also mapped to HCC 86 or 87 that we did not consider to be at a high risk for being miscoded (Table 2.2).

```

SELECT DISTINCT fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.MYOCARDIAL_INFARCTION_STEP_2 fdr /*Output from Step #2*/

/*Subquery to identify and remove all enrollees that received diagnosis which maps to HCC 86 or 87 that we did not consider
to be at a high risk for being miscoded */

WHERE fdr.BENE_SK NOT IN

SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to the Excluded Diagnosis Codes for the Acute Myocardial
infarction High-Risk Group Table*/ IN ('1200', '1230', '1231', '1232', '1233', '1234', '1235', '1236', '1237', '1238', '1240', '1241',
'1248', '1249', '125110', '125700', '125710', '125720', '125730', '125750', '125760', '125790', '1511', '1512') /* Excluded Diagnosis
Codes for the Acute Myocardial Infarction High-Risk Group Table */

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /*"-" indicates the RAPS diagnosis code is not deleted*/

```

Step 4

Using the output from Step 3, we identified the Risk Adjustment Processing System (RAPS) record that included the acute myocardial infarction diagnosis. We then created a 60-day before-and-after date window using the RAPS "service thru date" field, which identified inpatient stays that occurred in the prior or preceding service year.

```

SELECT raps.*, /*selects the detail RAPS record from the CMS RAPS table*/
ADD_MONTHS(BENE_RAPS_SRVC_THRU_DT, 2) AS IP_60_DAYS_FROM_DT, /*Creates a date 60 days after the RAPS Thru
Date*/
ADD_MONTHS(BENE_RAPS_SRVC_THRU_DT, -2) AS IP_60_DAYS_BEFORE_DT, /*Creates a date 60 days before the RAPS
Thru Date*/
SUM (1) over (rows unbounded preceding) AS AATS_CLM_ID /*Create a unique RAPS record id*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.MYOCARDIAL_INFARCTION_STEP_3 fdr /*Output Enrollee List from Step #3*/
ON fdr.BENE_SK = raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan Identifier*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Acute Myocardial Infarction Diagnosis Codes Table*/
IN ('12109', '12111', '12119', '12129', '1213', '1214', '12101', '12102', '12121', '1219', '1220', '1221', '1222', '1228', '1229', '121A1',

3. Embolism High-Risk Group

For the embolism high-risk group, we focused on enrollees who received one diagnosis that mapped to either the HCC for Vascular Disease or to the HCC for Vascular Disease With Complications (Embolism HCCs) (HCCs 107 & 108) during the service year but did not have an anticoagulant medication dispensed on their behalf (Table 3.1). An anticoagulant medication is typically used to treat an embolism. In these instances, a diagnosis of history of embolism (an indication that the provider is evaluating a prior acute embolism diagnosis, which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 3.1 includes the 63 embolism diagnosis codes used in our analysis:

Table 3.1: Embolism Diagnosis Codes

Diagnosis Code	Description
I2692	Saddle embolus of pulmonary artery without acute cor pulmonale
I2699	Other pulmonary embolism without acute cor pulmonale
I82290	Acute embolism and thrombosis of other thoracic veins
I82409	Acute embolism and thrombosis of unspecified deep veins of unspecified lower extremity
I82419	Acute embolism and thrombosis of unspecified femoral vein
I82429	Acute embolism and thrombosis of unspecified iliac vein
I82439	Acute embolism and thrombosis of unspecified popliteal vein
I82449	Acute embolism and thrombosis of unspecified tibial vein
I82499	Acute embolism and thrombosis of other specified deep vein of unspecified lower extremity
I824Y9	Acute embolism and thrombosis of unspecified deep veins of unspecified proximal lower extremity
I824Z9	Acute embolism and thrombosis of unspecified deep veins of unspecified distal lower extremity
I82629	Acute embolism and thrombosis of deep veins of unspecified upper extremity
I82A19	Acute embolism and thrombosis of unspecified axillary vein
I82B19	Acute embolism and thrombosis of unspecified subclavian vein
I82C19	Acute embolism and thrombosis of unspecified internal jugular vein
I2601	Septic pulmonary embolism with acute cor pulmonale
I2602	Saddle embolus of pulmonary artery with acute cor pulmonale
I2609	Other pulmonary embolism with acute cor pulmonale
I82401	Acute embolism and thrombosis of unspecified deep veins of right lower extremity
I82402	Acute embolism and thrombosis of unspecified deep veins of left lower extremity
I82403	Acute embolism and thrombosis of unspecified deep veins of lower extremity, bilateral
I824Y1	Acute embolism and thrombosis of unspecified deep veins of right proximal lower extremity
I824Y2	Acute embolism and thrombosis of unspecified deep veins of left proximal lower extremity
I824Y3	Acute embolism and thrombosis of unspecified deep veins of proximal lower extremity, bilateral
I824Z1	Acute embolism and thrombosis of unspecified deep veins of right distal lower extremity
I824Z2	Acute embolism and thrombosis of unspecified deep veins of left distal lower extremity
I824Z3	Acute embolism and thrombosis of unspecified deep veins of distal lower extremity, bilateral

Diagnosis Code	Description
I82411	Acute embolism and thrombosis of right femoral vein
I82412	Acute embolism and thrombosis of left femoral vein
I82413	Acute embolism and thrombosis of femoral vein, bilateral
I82421	Acute embolism and thrombosis of right iliac vein
I82422	Acute embolism and thrombosis of left iliac vein
I82423	Acute embolism and thrombosis of iliac vein, bilateral
I82431	Acute embolism and thrombosis of right popliteal vein
I82432	Acute embolism and thrombosis of left popliteal vein
I82433	Acute embolism and thrombosis of popliteal vein, bilateral
I82441	Acute embolism and thrombosis of right tibial vein
I82442	Acute embolism and thrombosis of left tibial vein
I82443	Acute embolism and thrombosis of tibial vein, bilateral
I82491	Acute embolism and thrombosis of other specified deep vein of right lower extremity
I82492	Acute embolism and thrombosis of other specified deep vein of left lower extremity
I82493	Acute embolism and thrombosis of other specified deep vein of lower extremity, bilateral
I82621	Acute embolism and thrombosis of deep veins of right upper extremity
I82622	Acute embolism and thrombosis of deep veins of left upper extremity
I82623	Acute embolism and thrombosis of deep veins of upper extremity, bilateral
I82A11	Acute embolism and thrombosis of right axillary vein
I82A12	Acute embolism and thrombosis of left axillary vein
I82A13	Acute embolism and thrombosis of axillary vein, bilateral
I82B11	Acute embolism and thrombosis of right subclavian vein
I82B12	Acute embolism and thrombosis of left subclavian vein
I82B13	Acute embolism and thrombosis of subclavian vein, bilateral
I82C11	Acute embolism and thrombosis of right internal jugular vein
I82C12	Acute embolism and thrombosis of left internal jugular vein
I82C13	Acute embolism and thrombosis of internal jugular vein, bilateral
I7410	Embolism and thrombosis of unspecified parts of aorta
I7411	Embolism and thrombosis of thoracic aorta
I7419	Embolism and thrombosis of other parts of aorta
I742	Embolism and thrombosis of arteries of the upper extremities
I743	Embolism and thrombosis of arteries of the lower extremities
I744	Embolism and thrombosis of arteries of extremities, unspecified
I745	Embolism and thrombosis of iliac artery
I748	Embolism and thrombosis of other arteries
I749	Embolism and thrombosis of unspecified artery

There were 365 additional diagnosis codes that mapped to the Embolism HCCs; however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received any one of these diagnoses were excluded from our analysis. The table of 365 diagnosis codes can be downloaded at the link included in the Downloadable Information subsection found later in this section.

There were 812 National Drug Codes (NDCs) pulled from the PDE data used in our analysis. We removed enrollees in Step 3 of the SQL Programming Language who received one or more the drugs associated with these NDCs. The table of 812 NDCs can be downloaded at the link included in the Downloadable Information subsection found later in this section.

SQL Programming Language

Table 3.2 details the SQL programming language used to query CMS's systems in order to identify the embolism high-risk diagnosis codes.

Table 3.2: SQL Programming Language for Embolism High-Risk Group

Step 1

We identified enrollees who received an embolism diagnosis (Table 3.1). Additionally, we removed any enrollees who received one or more diagnoses that also mapped to HCC 107 or 108 that we did not consider to be at a high risk for being miscoded.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
COUNT(raps.DGNS_CD) AS BENE_LINES /*Counts the number of embolism diagnosis codes. Limited to one instance in Step
#2*/

FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Embolism Diagnosis Codes Table*/ IN ('I2692', 'I2699',
'I82290', 'I82409', 'I82419', 'I82429', 'I82439', 'I82449', 'I82499', 'I824Y9', 'I824Z9', 'I82629', 'I82A19', 'I82B19', 'I82C19',

- All of the codes used in this analysis along with the SQL programming language can be found at <https://oig.hhs.gov/oas/toolkit/Embolism-High-Risk-Group.pdf>.

4. Lung Cancer High-Risk Group

For the lung cancer high-risk group, we focused on enrollees who received one lung cancer diagnosis (that mapped to the HCC for Lung and Other Severe Cancers (HCC 9)) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period either before or after the diagnosis (Table 4.1). In these instances, a diagnosis of history of lung cancer (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 4.1 includes the 17 lung cancer diagnosis codes used in our analysis:

Table 4.1: Lung Cancer Diagnosis Codes

Diagnosis Code	Description
C33	Malignant neoplasm of trachea
C3400	Malignant neoplasm of unspecified main bronchus
C3401	Malignant neoplasm of right main bronchus
C3402	Malignant neoplasm of left main bronchus
C3410	Malignant neoplasm of upper lobe, unspecified bronchus or lung
C3411	Malignant neoplasm of upper lobe, right bronchus or lung
C3412	Malignant neoplasm of upper lobe, left bronchus or lung
C342	Malignant neoplasm of middle lobe, bronchus or lung
C3430	Malignant neoplasm of lower lobe, unspecified bronchus or lung
C3431	Malignant neoplasm of lower lobe, right bronchus or lung
C3432	Malignant neoplasm of lower lobe, left bronchus or lung
C3480	Malignant neoplasm of overlapping sites of unspecified bronchus and lung
C3481	Malignant neoplasm of overlapping sites of right bronchus and lung
C3482	Malignant neoplasm of overlapping sites of left bronchus and lung
C3490	Malignant neoplasm of unspecified part of unspecified bronchus or lung
C3491	Malignant neoplasm of unspecified part of right bronchus or lung
C3492	Malignant neoplasm of unspecified part of left bronchus or lung

There were 93 additional diagnosis codes that mapped to the Lung and Other Severe Cancers HCCs; however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received any one of these diagnoses were excluded from our analysis. The table of 93 diagnosis codes can be downloaded at the link included in the Downloadable Information subsection found later in this section.

We used various Current Procedural Terminology (CPT) codes to further refine our analysis.⁷ We identified and removed enrollees who received at least one of the following:

1. Table 4.2 includes 19 chemotherapy drug treatment CPT codes that we identified as common procedure codes associated with an enrollee who received a chemotherapy drug treatment for an active cancer diagnosis.

Table 4.2: Chemotherapy Drug Treatment CPT Codes

CPT Code	Description
96420	Injection of chemotherapy using push technique into an artery
96402	Hormonal anti-neoplastic chemotherapy administration beneath the skin or into muscle
96405	Administration of chemotherapy into growth, 1 – 7
96406	Chemotherapy into a lesion, more than 7 lesions
96409	Infusion of chemotherapy into a vein using push technique
96411	Infusion of different chemotherapy drug or substance into a vein
96413	Infusion of chemotherapy into a vein up to 1 hour
96415	Infusion of chemotherapy into a vein
96401	Administration of non-hormonal anti-neoplastic chemotherapy under skin or into muscle
96417	Infusion of different chemotherapy drug or substance into a vein up to 1 hour
96549	Other chemotherapy procedure
96422	Infusion of chemotherapy into an artery up to 1 hour
96423	Infusion of chemotherapy into artery
96425	Prolonged chemotherapy infusion into artery by portable or implanted pump, more than 8 hours
96440	Chemotherapy administration into chest cavity requiring insertion of catheter
96446	Administration of chemotherapy into abdominal cavity
96450	Chemotherapy administration into spinal canal requiring spinal tap
96542	Injection of chemotherapy via reservoir under skin
96416	Prolonged chemotherapy infusion into a vein by portable or implanted pump more than 8 hours

2. Table 4.3 includes 22 radiation treatment CPT codes that we identified as common procedure codes associated with an enrollee who received radiation treatment for an active cancer diagnosis.

Table 4.3: Radiation Treatment CPT Codes

CPT Code	Description
77762	Application of organ cavity radiation source, intermediate
77402	Delivery of simple radiation treatment
77407	Delivery of intermediate radiation treatment
77412	Radiation treatment delivery, complex

⁷ The five character codes and descriptions included in this document are obtained from Current Procedural Terminology (CPT®), copyright 2023 by the American Medical Association (AMA). CPT is developed by the AMA as a listing of descriptive terms and five character identifying codes and modifiers for reporting medical services and procedures. Any use of CPT outside of this document should refer to the most current version of the Current Procedural Terminology available from AMA. Applicable FARS/DFARS apply.

CPT Code	Description
77417	Therapeutic radiology port films
77423	Radiation treatment delivery, high energy
77424	Intraoperative single X-ray radiation treatment session
77425	Intraoperative electrons radiation treatment single session
77427	Radiation treatment management, 5 treatments
77401	Radiation treatment delivery, superficial
77761	Simple body cavity radiation source application
77799	Other administration of radiation therapy
77763	Complex body cavity radiation source application
77767	High dose brachytherapy through skin surface, 1 channel or up to 2.0 cm
77768	High dose brachytherapy through skin surface, 2 channels or more than 2.0 cm
77770	High dose radiation therapy, 1 channel
77771	High dose brachytherapy, 2 – 12 channels
77772	High dose brachytherapy, more than 12 channels
77778	Complex application of radiation source
77789	Surface application of radiation
77790	Supervision, handling, loading of radiation
77750	Infusion or instillation of radioelement solution

3. Table 4.4 includes 12 surgical therapy CPT codes that we identified as common procedure codes associated with an enrollee who received surgical therapy for an active lung cancer diagnosis.

Table 4.4: Lung Cancer Surgical CPT Codes

CPT Code	Description
32501	Repair of lung airway and removal of segment of lung
32491	Removal of a lung segment to reduce lung volume
32488	Removal of remaining lung after prior lung surgery
32486	Removal portion of lung tissue and segment of lung airway
32484	Removal of a segment of lung tissue
32482	Removal of two lobes of lung
32480	Removal of lobe of lung
32445	Removal of lung and chest cavity lining
32442	Removal of lung and portion of windpipe cartilage
32440	Removal of lung
32405	Needle biopsy of lung or chest tissue, accessed through the skin
32400	Needle biopsy of lining of lung, accessed through the skin

SQL Programming Language

Table 4.5 details the SQL programming language used to query CMS's systems in order to identify the lung cancer high-risk diagnosis codes.

Table 4.5: SQL Programming Language for Lung Cancer High-Risk Group

Step 1

We identified enrollees who received a lung cancer diagnosis (Table 4.1). Additionally, we removed any enrollees who received one or more diagnoses that also mapped to HCC 9 that we did not consider to be at high risk for being miscoded.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
COUNT(raps.DGNS_CD) AS BENE_LINES /*Counts the number of lung cancer diagnosis codes. Limited to one instance in
Step #2*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/
WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Lung Cancer Diagnosis Codes Table*/ IN ( 'C33',
'C3400', 'C3401', 'C3402', 'C3410', 'C3411', 'C3412', 'C342', 'C3430', 'C3431', 'C3432', 'C3480', 'C3481', 'C3482', 'C3490',
'C3491', 'C3492') /*Lung Cancer Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = 'no' /*"no" indicates the RAPS diagnosis code is not deleted*/

/*Subquery to identify and remove all enrollees that received a diagnosis that maps to HCC 9 that we did not consider to be
at a high risk for being miscoded*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (
SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Excluded Diagnosis Codes for the Lung Cancer High-
Risk Group Table*/ IN (
SELECT DX_CD

FROM CMS_ADM_OIG_OAS_PRD.LUNG_CANCER_EXCLUDED_DX) /* Excluded Diagnosis Codes for the Lung Cancer High-
Risk Group Table*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
IN (
```

*/*Subquery to identify all enrollees from Step #1 with HCC 9 */*

```
SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_I_SCRE ras /*CMS RAS data*/

WHERE (BENE_PTC_HCC_9_SW = '1' /*Confirms HCC 9 was utilized in the payment risk score*/
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/
AND BENE_PTC_SCRE_MODEL_SBTYP_CD = 'I02' /*Used subtype code "I02" since all enrollees have this subtype record, not
required for identifying enrollees for review, helps with computing efficiency*/
AND BENE_RISK_SEQNC_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAPS based RAS record*/
AND (CLNDR_CY_NUM = 2019)) ; /*Specifies the payment year for the HCC confirmation*/
```

Step 3

Using the output from Step 2, we identified the RAPS record that included the targeted lung cancer diagnosis so that we could do an encounter claim search spanning the 6-months-before-and-after date window using the targeted diagnosis RAPS "service thru date" field in the following step.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
       raps.BENE_RAPS_SRVC_THRU_DT,
       raps.DGNS_CD
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.LUNG_CANCER_STEP_2 fdr /*Output from Step #2*/
ON RAPS.BENE_SK = fdr.BENE_SK /*Join on CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/

WHERE DGNS_CD IN ( 'C33', 'C3400', 'C3401', 'C3402', 'C3410', 'C3411', 'C3412', 'C342', 'C3430',
                  'C3431', 'C3432', 'C3480', 'C3481', 'C3482', 'C3490', 'C3491', 'C3492' ) /*Lung Cancer Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = 'N' /*"N" indicates the RAPS diagnosis code is not deleted*/
```

Step 4

Using the output from Step 3, we identified and removed the enrollees for whom there was a Part C encounter claim with one of the corresponding procedure codes related to a lung cancer treatment rendered within 6 months of submission of the targeted lung cancer diagnosis.

```
SELECT distinct fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.LUNG_CANCER_STEP_3 fdr /*Output from Step #3*/

/*Subquery to identify all enrollees to remove from the step #3 output who had a Part C encounter claim that contains a
lung cancer treatment procedure code. /

WHERE fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (

SELECT fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.LUNG_CANCER_STEP_3 fdr /*Output from Step #3*/

JOIN CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_CLM_hdr

AND hdr.CLM_FINL_ACTN_IND = 'Y'; /*Indicates a final action encounter claim*/
```

Downloadable Information

- All of the codes used in this analysis along with the SQL programming language can be found at <https://oig.hhs.gov/oas/toolkit/Lung-Cancer-High-Risk-Group.pdf>.

5. Breast Cancer High-Risk Group

For the breast cancer high-risk group, we focused on enrollees who received one breast cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors (HCC 12)) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis (Table 5.1). In these instances, a diagnosis of history of breast cancer (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 5.1 includes the 54 breast cancer diagnosis codes used in our analysis:

Table 5.1: Breast Cancer Diagnosis Codes

Diagnosis Code	Description
C50011	Malignant neoplasm of nipple and areola, right female breast
C50012	Malignant neoplasm of nipple and areola, left female breast
C50019	Malignant neoplasm of nipple and areola, unspecified female breast
C50021	Malignant neoplasm of nipple and areola, right male breast
C50022	Malignant neoplasm of nipple and areola, left male breast
C50029	Malignant neoplasm of nipple and areola, unspecified male breast
C50111	Malignant neoplasm of central portion of right female breast
C50112	Malignant neoplasm of central portion of left female breast
C50119	Malignant neoplasm of central portion of unspecified female breast
C50121	Malignant neoplasm of central portion of right male breast
C50122	Malignant neoplasm of central portion of left male breast
C50129	Malignant neoplasm of central portion of unspecified male breast
C50211	Malignant neoplasm of upper-inner quadrant of right female breast
C50212	Malignant neoplasm of upper-inner quadrant of left female breast
C50219	Malignant neoplasm of upper-inner quadrant of unspecified female breast
C50221	Malignant neoplasm of upper-inner quadrant of right male breast
C50222	Malignant neoplasm of upper-inner quadrant of left male breast
C50229	Malignant neoplasm of upper-inner quadrant of unspecified male breast
C50311	Malignant neoplasm of lower-inner quadrant of right female breast
C50312	Malignant neoplasm of lower-inner quadrant of left female breast
C50319	Malignant neoplasm of lower-inner quadrant of unspecified female breast
C50321	Malignant neoplasm of lower-inner quadrant of right male breast
C50322	Malignant neoplasm of lower-inner quadrant of left male breast
C50329	Malignant neoplasm of lower-inner quadrant of unspecified male breast
C50411	Malignant neoplasm of upper-outer quadrant of right female breast
C50412	Malignant neoplasm of upper-outer quadrant of left female breast
C50419	Malignant neoplasm of upper-outer quadrant of unspecified female breast
C50421	Malignant neoplasm of upper-outer quadrant of right male breast
C50422	Malignant neoplasm of upper-outer quadrant of left male breast

Diagnosis Code	Description
C50429	Malignant neoplasm of upper-outer quadrant of unspecified male breast
C50511	Malignant neoplasm of lower-outer quadrant of right female breast
C50512	Malignant neoplasm of lower-outer quadrant of left female breast
C50519	Malignant neoplasm of lower-outer quadrant of unspecified female breast
C50521	Malignant neoplasm of lower-outer quadrant of right male breast
C50522	Malignant neoplasm of lower-outer quadrant of left male breast
C50529	Malignant neoplasm of lower-outer quadrant of unspecified male breast
C50611	Malignant neoplasm of axillary tail of right female breast
C50612	Malignant neoplasm of axillary tail of left female breast
C50619	Malignant neoplasm of axillary tail of unspecified female breast
C50621	Malignant neoplasm of axillary tail of right male breast
C50622	Malignant neoplasm of axillary tail of left male breast
C50629	Malignant neoplasm of axillary tail of unspecified male breast
C50811	Malignant neoplasm of overlapping sites of right female breast
C50812	Malignant neoplasm of overlapping sites of left female breast
C50819	Malignant neoplasm of overlapping sites of unspecified female breast
C50821	Malignant neoplasm of overlapping sites of right male breast
C50822	Malignant neoplasm of overlapping sites of left male breast
C50829	Malignant neoplasm of overlapping sites of unspecified male breast
C50911	Malignant neoplasm of unspecified site of right female breast
C50912	Malignant neoplasm of unspecified site of left female breast
C50919	Malignant neoplasm of unspecified site of unspecified female breast
C50921	Malignant neoplasm of unspecified site of right male breast
C50922	Malignant neoplasm of unspecified site of left male breast
C50929	Malignant neoplasm of unspecified site of unspecified male breast

There were 217 additional diagnosis codes that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors; however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received any one of these diagnoses were excluded from our analysis. The table of 217 diagnosis codes can be downloaded at the link included in the Downloadable Information subsection found later in this section.

We used various CPT codes to further refine our analysis. We identified and removed enrollees who received at least one of the following:

1. 19 chemotherapy drug treatment CPT codes that we identified as common procedure codes associated with an enrollee who received a chemotherapy drug treatment for an active cancer diagnosis (Table 4.2 in the preceding section).
2. 22 radiation treatment CPT codes that we identified as common procedure codes associated with an enrollee who received radiation treatment for an active cancer diagnosis (Table 4.3 in the preceding section).

3. Table 5.2 includes seven surgical therapy CPT codes (footnote 7) that we identified as common procedure codes associated with an enrollee who received surgical therapy for an active breast cancer diagnosis.

Table 5.2: Breast Cancer Surgical CPT Codes

CPT Code	Description
19301	Partial removal of breast
19302	Partial removal of breast and underarm lymph nodes
19303	Total removal of breast
19304	Removal of tumor and breast tissue, accessed beneath the skin
19305	Removal of breast, lymph nodes, and muscle
19306	Extensive removal of breast, chest muscle, underarm lymph nodes, and breast lymph nodes
19307	Removal of breast and underarm lymph nodes

There were 181 NDCs pulled from the PDE data used in our analysis. We removed enrollees who received one or more of these NDCs on a drug claim. The table of 181 NDCs can be downloaded at the link included in the Downloadable Information subsection found later in this section.

SQL Programming Language

Table 5.3 details the SQL programming language used to query CMS's systems in order to identify the breast cancer high-risk diagnosis codes.

Table 5.3: SQL Programming Language for Breast Cancer High-Risk Group

Step 1

We identified enrollees who received a breast cancer diagnosis (Table 5.1). Additionally, we removed any enrollees who received one or more diagnoses that also mapped to HCC 12 that we did consider to be at a high risk for being miscoded.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
COUNT(raps.DGNS_CD AS BENE_LINES /*Counts the number of breast cancer diagnosis codes. Limited to one instance in
Step #2*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE DGNS_CD /* RAPS diagnosis cod field used to match to the Breast Cancer Diagnosis Codes Table*/ IN ('C50011',
'C50012', 'C50019', 'C50021', 'C50022', 'C50029', 'C50111', 'C50112', 'C50119', 'C50121', 'C50122', 'C50129', 'C50211',
'C50212', 'C50219', 'C50221', 'C50222', 'C50229', 'C50311', 'C50312', 'C50319', 'C50321', 'C50322', 'C50329', 'C50411',
'C50412', 'C50419', 'C50421', 'C50422', 'C50429', 'C50511', 'C50512', 'C50519', 'C50521', 'C50522', 'C50529', 'C50511',
'C50612', 'C50619', 'C50621', 'C50622', 'C50629', 'C50811', 'C50812', 'C50819', 'C50821', 'C50822', 'C50829', 'C50911',
'C50912', 'C50919', 'C50921', 'C50922', 'C50929') /*Breast Cancer Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = 'N' /*N indicates the RAPS diagnosis code is not deleted*/

/*Subquery to identify and remove all enrollees that received a diagnosis that maps to HCC 12 that we did consider to be at
a high risk for being miscoded*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (
```

```
SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Excluded Diagnosis Codes for the Breast Cancer High-
Risk Group Table*/ IN(
SELECT DX_CD

FROM CMS_ADM_OIG_OAS_PRD.BREAST_CANCER_EXCLUDED_DX) /* Excluded Diagnosis Codes for the Breast Cancer
High-Risk Group Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted"
)
GROUP BY raps.BENE_SK; /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

Step 2

Using the output from Step 1, we then limited our results to those enrollees who had only one instance of a breast cancer diagnosis during the time period of interest and those enrollees whose risk scores were confirmed in CMS's RAS as including HCC 12.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.BREAST_CANCER_STEP_1 raps /*Output from Step #1*/

WHERE raps.BENE_LINES < 2 /*Criteria to limit enrollees to those with a single instance of a breast cancer diagnosis code*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
IN (

/*Subquery to identify all enrollees from Step #1 with HCC 12 */

SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_I_SCORE ras /*CMS RAS data*/

WHERE (BENE_PTC_HCC_12_SW = '1' /*Confirms HCC 12 was utilized in the payment risk score*/
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/
AND BENE_PTC_SCORE_MODEL_SBTYP_CD = '102' /*Used subtype code "102" since all enrollees have this subtype record, not
required for identifying enrollees for review, helps with computing efficiency*/
AND BENE_RISK_SEQ_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAPS based RAS record*/
AND (CLNDR_CY_NUM = 2019)) ; /*Specifies the payment year for the HCC confirmation*/
```

Step 3

Using the output from Step 2, we identified the RAPS record that included the targeted breast cancer diagnosis so that we could do an encounter claim search spanning the 6-months-before-and-after date window using the targeted diagnosis RAPS "service thru date" field in the following step.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
       raps.BENE_RAPS_SRVC_THRU_DT,
       raps.DGNS_CD
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.BREAST_CANCER_STEP_2 fdr /*Output from Step #2*/
ON RAPS.BENE_SK = fdr.BENE_SK /*Join on CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

```
WHERE raps.DGNS_CD IN ( 'C50011', 'C50012', 'C50019', 'C50021', 'C50022', 'C50029', 'C50111', 'C50112', 'C50119',
'C50121', 'C50122', 'C50129', 'C50211', 'C50212', 'C50219', 'C50221', 'C50222', 'C50229', 'C50311', 'C50312', 'C50319',
'C50321', 'C50322', 'C50329', 'C50411', 'C50412', 'C50419', 'C50421', 'C50422', 'C50429', 'C50511', 'C50512', 'C50519',
'C50521', 'C50522', 'C50529', 'C50611', 'C50612', 'C50619', 'C50621', 'C50622', 'C50629', 'C50811', 'C50812', 'C50819',
'C50821', 'C50822', 'C50829', 'C50911', 'C50912', 'C50919', 'C50921', 'C50922', 'C50929') /* Breast Cancer Diagnosis Codes
Table */
```

```
AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = 'N' /*'N' indicates the RAPS diagnosis code is not deleted*/
```

Step 4

Using the output from Step 3, we identified and removed the enrollees for whom there was a Part C encounter claim with one of the corresponding procedure codes related to a breast cancer treatment rendered within 6 months of submission of the targeted breast cancer diagnosis.

```
SELECT distinct fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.BREAST_CANCER_STEP_3 fdr /*Output from Step #3*/

6. Colon Cancer High-Risk Group

For the colon cancer high-risk group, we focused on enrollees who received one colon cancer diagnosis (that mapped to the HCC for Colorectal, Bladder, and Other Cancers (HCC 11)) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis (Table 6.1). In these instances, a diagnosis of history of colon cancer (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 6.1 includes the 10 colon cancer diagnosis codes used in our analysis:

Table 6.1: Colon Cancer Diagnosis Codes

Diagnosis Code	Description
C180	Malignant neoplasm of cecum
C181	Malignant neoplasm of appendix
C182	Malignant neoplasm of ascending colon
C183	Malignant neoplasm of hepatic flexure
C184	Malignant neoplasm of transverse colon
C185	Malignant neoplasm of splenic flexure
C186	Malignant neoplasm of descending colon
C187	Malignant neoplasm of sigmoid colon
C188	Malignant neoplasm of overlapping sites of colon
C189	Malignant neoplasm of colon, unspecified

There were 123 additional diagnosis codes that mapped to the HCC for Colorectal, Bladder, and Other Cancers; however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received any one of these diagnoses were excluded from our analysis. The table of 123 diagnosis codes can be downloaded at the link included in the Downloadable Information subsection found later in this section.

We used various CPT codes to further refine our analysis. We identified and removed enrollees who received at least one of the following:

1. 19 chemotherapy drug treatment CPT codes that we identified as common procedure codes associated with an enrollee who received a chemotherapy drug treatment for an active cancer diagnosis (Table 4.2 in a preceding section).
2. 22 radiation treatment CPT codes that we identified as common procedure codes associated with an enrollee who received radiation treatment for an active cancer diagnosis (Table 4.3 in a preceding section).

3. Table 6.2 includes 31 surgical therapy CPT codes (footnote 7) that we identified as common procedure codes associated with an enrollee who received surgical therapy for an active colon cancer diagnosis.

Table 6.2: Colon Cancer Surgical CPT Codes

CPT Code	Description
44187	Creation of small bowel opening using an endoscope, non-tube
44140	Partial removal of large bowel
44141	Partial removal of large bowel with creation of opening to the skin
44143	Partial removal of large bowel with creation of opening
44144	Partial removal of large bowel with creation of small or large bowel opening
44145	Partial removal of large bowel and reattachment to rectum
44146	Partial removal of large bowel and reattachment to rectum and creation of large bowel opening
44147	Partial removal of large bowel, abdominal and transanal approach
44150	Removal of large bowel with attachment of small bowel to rectum or creation of small bowel opening
44151	Removal of large bowel with creation of small bowel opening
44155	Removal of large bowel and rectum and creation of opening from end of small bowel to skin through abdomen
44156	Removal of large bowel and rectum with creation of small bowel opening
44157	Removal of large bowel and rectum with attachment of small bowel to anus
44158	Removal of large bowel and rectum with attachment of small bowel to anus and creation of small bowel reservoir
44139	Release of large bowel from spleen and abdominal wall
44206	Partial removal of large bowel with creation of opening using an endoscope
44227	Closure of large or small bowel opening using an endoscope
44213	Partial release of large bowel and partial removal of large bowel using an endoscope
44212	Removal of large bowel and rectum with creation of small bowel opening using an endoscope
44211	Removal of large bowel and rectum with attachment of small bowel to anus and creation of small bowel opening using an endoscope
44210	Removal of large bowel with attachment of small bowel to rectum or creation of small bowel opening using an endoscope
44160	Partial removal of small and large bowel with attachment of small and large bowel
44207	Partial removal of large bowel and reattachment to rectum using an endoscope
44186	Creation of small bowel opening using an endoscope
44205	Partial removal of small and large bowel with attachment of small and large bowel using an endoscope
44204	Partial removal of large bowel using an endoscope
44203	Partial removal of small bowel using an endoscope, each additional resection and connection
44202	Partial removal and reconnection of small bowel using an endoscope
44188	Creation of large bowel opening using an endoscope
44238	Bowel procedure using an endoscope
44208	Partial removal of large bowel and reattachment to rectum and creation of opening from large bowel to skin using an endoscope

SQL Programming Language

Table 6.3 details the SQL programming language used to query CMS's systems in order to identify the colon cancer high-risk diagnosis codes.

Table 6.3: SQL Programming Language for Colon Cancer High-Risk Group

Step 1

We identified enrollees who received a colon cancer diagnosis (Table 6.1). Additionally, we removed any enrollees who received one or more diagnoses that also mapped to HCC 11 that we did not consider to be at a high risk for being miscoded.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
COUNT(raps.DGNS_CD) AS BENE_LINES /*Counts the number of colon cancer diagnosis codes. Limited to one instance in
Step #2*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Colon Cancer Diagnosis Codes Table*/ IN ( 'C180',
'C181', 'C182', 'C183', 'C184', 'C185', 'C186', 'C187', 'C188', 'C189') /*Colon Cancer Diagnosis Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*/

/*Subquery to identify and remove all enrollees that received a diagnosis that maps to HCC 11 that we did not consider to be
at a high risk for being miscoded*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (

SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Excluded Diagnosis Codes for the Colon Cancer High-
Risk Group Table*/ IN (

SELECT DX_CD
FROM CMS_ADM_OIG_OAS_PRD.COLON_CANCER_EXCLUDED_DX) /*Excluded Diagnosis Codes for the Colon Cancer High-
Risk Group Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*
)
GROUP BY raps.BENE_SK; /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

Step 2

Using the output from Step 1, we then limited our results to those enrollees who had only one instance of a colon cancer diagnosis during the time period of interest and those enrollees whose risk scores were confirmed in CMS's RAS as including HCC 11.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.COLON_CANCER_STEP_1 raps /*Output from Step #1*/

WHERE raps.BENE_LINES < 2 /*Criteria to limit enrollees to those with a single instance of a colon cancer diagnosis code*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

IN (

*/*Subquery to identify all enrollees from the Step #1 with HCC 11 */*

```
SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_I_SCRE ras /*CMS RAS data*/

WHERE (BENE_PTC_HCC_11_SW = '1' /*Confirms HCC 11 was utilized in the payment risk score*/
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/
AND BENE_PTC_SCRE_MODEL_SBTYP_CD = '102' /*Used subtype code "102" since all enrollees have this subtype record, not
required for identifying enrollees for review, helps with computing efficiency*/
AND BENE_RISK_SEQNC_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAS based RAS record*/
AND (CLNDR_CY_NUM = 2019)) ; /*Specifies the payment year for the HCC confirmation*/
```

Step 3

Using the output from Step 2, we identified the RAPS record that included the targeted colon cancer diagnosis so that we could do an encounter claim search spanning the 6-months-before-and-after date window using the targeted diagnosis RAPS "service thru date" field in the following step.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
       raps.BENE_RAPS_SRVC_THRU_DT,
       raps.DGNS_CD
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.COLON_CANCER_STEP_2 fdr /*Output from Step #2*/
ON RAPS.BENE_SK = fdr.BENE_SK /*Join on CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/

WHERE DGNS_CD IN ('C180', 'C181', 'C182', 'C183', 'C184', 'C185', 'C186', 'C187', 'C188', 'C189') /*Colon Cancer Diagnosis
Codes Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '~' ; /*"~" indicates the RAPS diagnosis code is not deleted*/
```

Step 4

Using the output from Step 3, we identified and removed the enrollees for whom there was a Part C encounter claim with one of the corresponding procedure codes related to a colon cancer treatment rendered within 6 months of submission of the targeted colon cancer diagnosis.

```
SELECT distinct fdr.BENE_SK
FROM CMS_ADM_OIG_OAS_PRD.COLON_CANCER_STEP_3 fdr /*Output from Step #3*/

/*Subquery to identify all enrollees to remove from the step #3 output who had a Part C encounter claim that contains a
colon cancer treatment procedure code. /

WHERE fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (

SELECT fdr.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.COLON_CANCER_STEP_3 fdr /*Output from Step #3*/

JOIN CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_CLM_hdr
ON hdr.BENE_SK = fdr.BENE_SK /*Join enrollees from the step #3 results to the CMS Medicare Part C encounter claims*/

JOIN CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_CLM_LINE lin
ON hdr.GEO_BENE_SK = lin.GEO_BENE_SK
AND hdr.CLN_DT_SGNTR_SK = lin.CLN_DT_SGNTR_SK
```

```
AND hdr.CLM_TYPE_CD = lin.CLM_TYPE_CD
AND hdr.CLM_NUM_SK = lin.CLM_NUM_SK
AND hdr.CLM_FROM_DT = lin.CLM_FROM_DT /*Joins CMS Medicare Part C encounter claim to the claim line table with the
individual claim lines)*/

WHERE lin.CLM_LINE_THRU_DT BETWEEN fnd.BENE_RAPS_SRVC_THRU_DT-183
AND fnd.BENE_RAPS_SRVC_THRU_DT+183 /* Identifies enrollees with encounter submissions occurring 6 months before
and 6 months after which include a colon cancer treatment procedure code */

AND lin.CLM_LINE_HCPCS_CD IN ('44139', '44140', '44141', '44143', '44144', '44145', '44146', '44147', '44150', '44151',
'44155', '44156', '44157', '44158', '44160', '44186', '44187', '44188', '44202', '44203', '44204', '44205', '44206', '44207',
'44208', '44210', '44211', '44212', '44213', '44227', '44238' /*Colon Cancer Surgical CPT Codes*/

AND hdr.CLM_TYPE_CD > 3900 /*Identifies the encounter claim type codes*/
AND hdr.CLM_FINL_ACTN_IND = 'Y'; /*Indicates a final action encounter claim*/
```

Downloadable Information

- All of the codes used in this analysis along with the SQL programming language can be found at <https://oig.hhs.gov/oas/toolkit/Colon-Cancer-High-Risk-Group.pdf>.

7. Prostate Cancer High-Risk Group

For the prostate cancer high-risk group, we focused on enrollees who were 74 years old or younger and received one prostate cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors HCC 12)) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis (Table 7.1). In these instances, a diagnosis of history of prostate cancer (which does not map to an HCC) typically should have been used.

Codes Used in Our Analysis

Table 7.1 includes the single prostate cancer diagnosis code used in our analysis:

Table 7.1: Prostate Cancer Diagnosis Code

Diagnosis Code	Description
C61	Malignant neoplasm of prostate

There were 270 additional diagnosis codes that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors; however, we did not consider these codes to be at a high risk for being miscoded. Therefore, enrollees who received any one of these diagnoses were excluded from our analysis. The table of 270 diagnosis codes can be downloaded at the link included in the Downloadable Information subsection found later in this section.

We used various CPT codes to further refine our analysis. We identified and removed enrollees who received at least one of the following:

1. 19 chemotherapy drug treatment CPT codes that we identified as common procedure codes associated with an enrollee who received a chemotherapy drug treatment for an active cancer diagnosis (Table 4.2 in a preceding section).
2. 22 radiation treatment CPT codes that we identified as common procedure codes associated with an enrollee who received radiation treatment for an active cancer diagnosis (Table 4.3 in a preceding section).
3. Table 7.2 on the following page includes 10 surgical therapy CPT codes (footnote 7) that we identified as common procedure codes associated with an enrollee who received surgical therapy for an active prostate cancer diagnosis.

Table 7.2: Prostate Cancer Surgical CPT Codes

CPT Code	Description
55866	Surgical removal of prostate and surrounding lymph nodes using an endoscope
55845	Removal of prostate gland and surrounding lymph nodes on both sides of the pelvis through abdominal incision
55842	Removal of prostate gland and lymph node biopsy through abdominal incision
55840	Removal of prostate gland
55831	Partial removal of the prostate gland
55821	Partial removal of prostate (suprapubic)
55815	Removal of prostate gland through incision between scrotum and anus and removal of surrounding lymph nodes on both sides of the pelvis
55812	Removal of prostate gland with lymph node biopsy through incision between scrotum and anus
55810	Removal of prostate gland, glands for sperm movement, and sperm duct
55801	Partial removal of prostate gland through incision between scrotum and anus

There were 119 NDCs pulled from the PDE data used in our analysis. We removed enrollees who received one or more of these NDCs on a drug claim. The table of 119 NDCs can be downloaded at the link included in the Downloadable Information subsection found later in this section.

SQL Programming Language

Table 7.3 details the SQL programming language used to query CMS's systems in order to identify the prostate cancer high-risk diagnosis codes.

Table 7.3: SQL Programming Language for Prostate Cancer High-Risk Group

Step 1

We identified enrollees who received a prostate cancer diagnosis (Table 7.1). Additionally, we removed any enrollees who received one or more diagnoses that also mapped to HCC 12 that we did not consider to be at a high risk for being miscoded.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
COUNT(raps.DGNS_CD AS BENE_LINES /*Counts the number of prostate cancer diagnosis codes. Limited to one instance in Step #2*/
```

```
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/
```

```
WHERE DGNS_CD /* RAPS diagnosis cod field used to match to Prostate Cancer Diagnosis Codes Table*/ IN (
'C61') /*Prostate Cancer Diagnosis Codes Table*/
```

```
AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*/
```

```
/*Subquery to identify and remove all enrollees that received a diagnosis that maps to HCC 12 that we did not consider to be at a high risk for being miscoded*/
```

```
AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/ NOT IN (
```

```
SELECT DISTINCT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.DGNS_CD /*RAPS diagnosis code field used to match to Excluded Diagnosis Codes for the Prostate Cancer
High-Risk Group Table*/ IN (
SELECT DX_CD

FROM CMS_ADM_OIG_OAS_PRD.PROSTATE_CANCER_EXCLUDED_DX) /* Excluded Diagnosis Codes for the Prostate Cancer
High-Risk Group Table*/

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND BENE_RAPS_DGNS_DLT_SW = '-' /* '-' indicates the RAPS diagnosis code is not deleted*/
)
GROUP BY raps.BENE_SK; /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

Step 2

Using the output from Step 1, we then limited our results to those enrollees who had only one instance of a prostate cancer diagnosis during the time period of interest and those enrollees whose risk scores were confirmed in CMS's RAS as including HCC 12.

```
SELECT raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_ADM_OIG_OAS_PRD.PROSTATE_CANCER_STEP_1 raps /*Output from Step #1*/

WHERE raps.BENE_LINES < 2 /*Criteria to limit enrollees to those with a single instance of a prostate cancer diagnosis
code*/

AND raps.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
IN (

/*Subquery to identify all enrollees from Step #1 with HCC 12 */

SELECT ras.BENE_SK /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RISK_PTC_1_SCORE ras /*CMS RAS data*/

WHERE (BENE_PTC_HCC_12_SW = '1' /*Confirms HCC 12 was utilized in the payment risk score*/
AND BENE_FINL_RISK_IND = 'F' /*"F" represents the final RAS record*/
AND BENE_PTC_SCORE_MODEL_SBTYP_CD = '102' /*Used subtype code "102" since all enrollees have this subtype record, not
required for identifying enrollees for review, helps with computing efficiency*/
AND BENE_RISK_SEQ_NUM = '1' /*Used the RAS risk sequence "1" since it represents the RAPS based RAS record*/
AND (CLNDR_CY_NUM = 2019)) /*Specifies the payment year for the HCC confirmation*/
AND BENE_PTC_SCORE_AGE_BRKT_NUM IN ('7074', '6569', '6064', '5559', '4554', '3544')) /*Specifies men
under the age of 74*/
```

Step 3

Using the output from Step 2, we identified the RAPS record that included the targeted prostate cancer diagnosis so that we could do an encounter claim search spanning the 6-months-before-and-after date window using the targeted diagnosis RAPS "service thru date" field in the following step.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
       raps.BENE_RAPS_SRVC_THRU_DT,
       raps.DGNS_CD
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.PROSTATE_CANCER_STEP_2 fdr /*Output from Step #2*/
ON RAPS.BENE_SK = fdr.BENE_SK /*Join on CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
```

```
WHERE raps.DGNS_CD IN
('C61') /* Prostate Cancer Diagnosis Codes Table */

AND BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /* Specified timeframe */
AND BENE_RAPS_DGNS_DLT_SW = '~' /* '~' indicates the RAPS diagnosis code is not deleted */
```

Step 4

Using the output from Step 3, we identified and removed the enrollees for whom there was a Part C encounter claim with one of the corresponding procedure codes related to a prostate cancer treatment rendered within 6 months of submission of the targeted prostate cancer diagnosis.

```
SELECT distinct fdr.BENE_SK
FROM CMS_ADM_OIG_OAS_PRD.PROSTATE_CANCER_STEP_3 fdr /* Output from Step #3 */

/* Subquery to identify all enrollees to remove from the step #3 output who had a Part C encounter claim that contains a
prostate cancer treatment procedure code. */

WHERE fdr.BENE_SK /* CMS enrollee unique identifier, replace with HIC, MBI or plan identifier */ NOT IN (

SELECT fdr.BENE_SK /* CMS enrollee unique identifier, replace with HIC, MBI or plan identifier */
FROM CMS_ADM_OIG_OAS_PRD.PROSTATE_CANCER_STEP_3 fdr /* Output from Step #3 */

JOIN CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_CLM_hdr
ON hdr.BENE_SK = fdr.BENE_SK /* Join enrollees from the step #3 results to the CMS Medicare Part C encounter claims */

8. Potentially Mis-Keyed Diagnosis Codes High-Risk Group

For the high-risk group involving potentially mis-keyed diagnosis codes, we focused on enrollees who received multiple diagnoses for a condition but received only one—potentially mis-keyed—diagnosis for an unrelated condition (which mapped to a possibly unvalidated HCC). For example, ICD-10 diagnosis code I720 (which maps to the HCC for Vascular Disease) could be transposed as diagnosis code I270 (which maps to the HCC for Congestive Heart Failure and in this example would be unvalidated). Using an analytical tool that we developed, we identified 3,780 scenarios in which diagnosis codes could have been mis-keyed because numbers were transposed or because other data-entry errors occurred that could have resulted in the assignment of an unvalidated HCC.

Codes Used in Our Analysis

The table of 3,780 potentially mis-keyed diagnosis code pairs can be downloaded at the link included in the Downloadable Information subsection found later in this section.

SQL Programming Language

Table 8.1 details the SQL programming language used to query CMS's systems in order to identify the potentially mis-keyed diagnosis codes.

Table 8.1: SQL Programming Language for Potentially Mis-Keyed Diagnosis Codes High-Risk Group

Step 1

We Identified non-deleted RAPS records for all enrollees with a diagnosis code listed in the payment year 2019 RAPS Version 22 (V22) HCC mapping file published by CMS.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
raps.BENE_RAPS_SRVC_FROM_DT,
raps.BENE_RAPS_SRVC_THRU_DT, /*RAPS Diagnosis Code Service Dates*/
raps.CNTRCT_NUM, /*RAPS Submitter Contract Number*/
raps.BENE_RAPS_SRVC_THRU_DT(FORMAT 'YYYY')(CHAR(4)) AS THRU_YEAR, /*Capture RAPS Service Thru Year*/
raps.DGNS_CD, /*RAPS diagnosis code field used to match to CMS Diagnosis Code Mapping Table*/
dx.V22 /*HCC from the CMS Diagnosis Code Mapping Table*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

JOIN CMS_ADM_OIG_OAS_PRD.RSK_ADJ_DX_PY19_RAPS_OP_PHYSN_HCC_MAPPING dx
on raps.DGNS_CD = dx.DX_CD /*CMS Diagnosis Code Mapping Table*/

WHERE raps.BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND raps.BENE_RAPS_DGNS_DLT_SW = '~'; /*'~' indicates the RAPS diagnosis code is not deleted*/
```

Step 2

Using the output from Step 1, we created a distinct list of potentially incorrect diagnosis codes by matching the diagnosis codes from Step 1 to the Office of Inspector General (OIG) Mis-Keyed Diagnosis Codes Table.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
raps.CNTRCT_NUM, /*RAPS Submitter Contract Number*/
raps.DGNS_CD, /*RAPS diagnosis code used to match to OIG Mis-Keyed Diagnosis Codes Table*/
fnd.FLIPPED_HCC_VAL, /*Potential Incorrect Diagnosis Code Value from OIG Mis-Keyed Diagnosis Codes Table*/
```

*COUNT (DGNS_CD) as CNT_FLIPPED_DX /*Count of occurrence of potentially incorrect diagnosis submissions from the OIG Mis-keyed Diagnosis Codes Table*/*

*FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_1 raps /*Output from Step #1*/*

JOIN CMS_ADM_OIG_OAS_PRD.DASH_PY19_FD_FLIPPED_DX_CD fnd

*ON fnd.FLIPPED_DIAG = raps.DGNS_CD /*The OIG Mis-Keyed Diagnosis Codes Table contains potential incorrect mis-keyed diagnosis codes and the HCC Value; and the corresponding correct diagnosis and HCC value*/*

*WHERE raps.BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/*
AND raps.BENE_RAPS_DGNS_DLT_SW = '~'; /~ indicates the RAPS diagnosis code is not deleted*/*

*GROUP BY BENE_SK,CNTRCT_NUM, DGNS_CD, FLIPPED_HCC_VAL; /*Group records to create distinct list of potentially mis-keyed diagnosis codes*/*

Step 3

Using the output from Step 2, we identified all enrollees with only one instance of the possible mis-keyed diagnosis code.

SELECT fnd. /* Pull the entire record from Step #2*/*

*FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_2 fnd /*Output from Step #1*/*

*WHERE CNT_FLIPPED_DX = 1; /*Limits the results to a single instance of a potentially incorrect diagnosis*/*

Step 4

Using the output from Step 1, we grouped all the RAPS records that mapped to an HCC by enrollee, contract number, and HCC. We also counted the number of diagnosis codes that mapped to an HCC.

*SELECT BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/*

*CNTRCT_NUM, /*RAPS Submitter Contract Number*/*

*V22, /*HCC from the CMS Diagnosis Code Mapping Table*/*

*COUNT (V22) AS CNT_BENE_HCC /*Represent diagnosis submission count by HCC*/*

*FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_1 /*Output from Step #1*/*

*GROUP BY BENE_SK, CNTRCT_NUM, V22; /*Group RAPS records to create distinct list enrollee HCC with a diagnosis submission count*/*

Step 5

Using the output from Step 4, we identified enrollees with only one instance of a diagnosis code that mapped to an HCC.

SELECT fnd. /* Pull the entire record from Step #4*/*

*FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_1 fnd /*Output from Step #4*/*

*WHERE CNT_BENE_HCC = 1; /*Limits the results to a single instance of a potentially incorrect diagnosis*/*

Step 6

Using the outputs from Step 3 and Step 4, we joined the two tables on the enrollee identification number and HCC to identify potentially incorrect diagnosis codes that were used to support the HCC.

*SELECT t2.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/*

*t2.CNTRCT_NUM, /*RAPS Submitter Contract Number*/*

*t1.DGNS_CD, /*RAPS potentially incorrect diagnosis*/*

*t2.V22 /*RAPS potentially incorrect diagnosis HCC (V22)*/*

*FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_3 t1 /*Output from Step #3*/*

```
JOIN CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_5 t2 /*Output from Step #5*/
ON t1.BENE_SK = t2.BENE_SK /*Join on enrollee identifier*/
and t1.FLIPPED_HCC_VAL = t2.V22 /*Join on mis-keyed diagnosis HCC and single diagnosis HCC*/
```

Step 7

Using all RAPS data, we prepared an enrollee summary by grouping the information by the enrollee, contract number, diagnosis code, and the count of diagnosis code submissions.

```
SELECT raps.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
raps.CNTRCT_NUM, /*RAPS Submitter Contract Number*/
raps.DGNS_CD, /*RAPS potentially incorrect diagnosis*/
COUNT(raps.DGNS_CD) AS BENE_DX_CNT /*Represent diagnosis submission count by enrollee*/
FROM CMS_VDM_VIEW_MDCR_PRD.V2_MDCR_BENE_RAPS_MAO_DGNS raps /*CMS RAPS data*/

WHERE raps.BENE_RAPS_SRVC_THRU_DT BETWEEN '2018-01-01' AND '2018-12-31' /*Specified timeframe*/
AND raps.BENE_RAPS_DGNS_DLT_SW = 'N'; /*'N' indicates the RAPS diagnosis code is not deleted*/

GROUP BY raps.BENE_SK, raps.CNTRCT_NUM, raps.DGNS_CD /*Group RAPS records to create distinct list of enrollees by contract and diagnosis*/
```

Step 8

Using the output from Step 7, we identified enrollees with more than one instance of a diagnosis code submission.

```
SELECT BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
CNTRCT_NUM, /*RAPS Submitter Contract Number*/
DGNS_CD, /*RAPS potentially incorrect diagnosis*/
BENE_DX_CNT /*Represent diagnosis submission count by enrollee*/
FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_7 /*Output from Step #5*/
WHERE BENE_DX_CNT > 1 /*Diagnosis submission count greater than one*/
```

Step 9

Using the outputs from Step 6 and Step 8 and the OIG Mis-Keyed Diagnosis Codes Table, we identified enrollees with multiple instances of what appeared to be the correct diagnosis and HCC and a single instance of what appeared to be the potentially incorrect diagnosis or HCC.

```
SELECT t6.BENE_SK, /*CMS enrollee unique identifier, replace with HIC, MBI or plan identifier*/
t6.CNTRCT_NUM, /*RAPS Submitter Contract Number*/
fnd.DIAG_CORRECT, /*Mis-Keyed Diagnosis Codes Table correct diagnosis match to step #8 output*/
fnd.HCC_CORRECT_DX_VAL, /* Mis-Keyed Diagnosis Codes Table correct diagnosis HCC value*/
t8.BENE_DX_CNT, /*Count of correct diagnosis from Step 8 output*/
fnd.FLIPPED_DIAG, /* Mis-Keyed Diagnosis Codes Table incorrect diagnosis match to step #6 output*/
fnd.FLIPPED_HCC_VAL, /* Mis-Keyed Diagnosis Codes Table incorrect diagnosis HCC value*/
'2019' AS PMT_YR /*Identifies payment year*/
FROM CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_6 t6 /*Output from Step #6, contains enrollee list of potentially incorrect diagnosis*/

JOIN CMS_ADM_OIG_OAS_PRD.DASH_PY18_FD_FLIPPED_DX_CD fnd /*OIG Mis-Keyed Diagnosis Codes Table*/
ON (t6.V22 = fnd.FLIPPED_HCC_VAL /*OIG Mis-Keyed Diagnosis Codes Table potentially incorrect diagnosis HCC */
AND t6.DGNS_CD = fnd.FLIPPED_DIAG) /*OIG Mis-Keyed Diagnosis Codes Table potentially incorrect diagnosis*/

JOIN CMS_ADM_OIG_OAS_PRD.FLIPPED_DGNS_STEP_8 t8 /*Output from Step 8, contains enrollee list of what appears to be the correct diagnosis*/
ON ( t6.BENE_SK = t8.BENE_SK
AND fnd.DIAG_CORRECT = t8.DGNS_CD)
```

Office of Inspector General

<https://oig.hhs.gov/>

The mission of the Office of Inspector General (OIG), as mandated by Public Law 95-452, as amended, is to protect the integrity of the Department of Health and Human Services (HHS) programs, as well as the health and welfare of beneficiaries served by those programs. This statutory mission is carried out through a nationwide network of audits, investigations, and inspections conducted by the following operating components:

Office of Audit Services

The Office of Audit Services (OAS) provides auditing services for HHS, either by conducting audits with its own audit resources or by overseeing audit work done by others. Audits examine the performance of HHS programs and/or its grantees and contractors in carrying out their respective responsibilities and are intended to provide independent assessments of HHS programs and operations. These audits help reduce waste, abuse, and mismanagement and promote economy and efficiency throughout HHS.

Office of Evaluation and Inspections

The Office of Evaluation and Inspections (OEI) conducts national evaluations to provide HHS, Congress, and the public with timely, useful, and reliable information on significant issues. These evaluations focus on preventing fraud, waste, or abuse and promoting economy, efficiency, and effectiveness of departmental programs. To promote impact, OEI reports also present practical recommendations for improving program operations.

Office of Investigations

The Office of Investigations (OI) conducts criminal, civil, and administrative investigations of fraud and misconduct related to HHS programs, operations, and beneficiaries. With investigators working in all 50 States and the District of Columbia, OI utilizes its resources by actively coordinating with the Department of Justice and other Federal, State, and local law enforcement authorities. The investigative efforts of OI often lead to criminal convictions, administrative sanctions, and/or civil monetary penalties.

Office of Counsel to the Inspector General

The Office of Counsel to the Inspector General (OCIG) provides general legal services to OIG, rendering advice and opinions on HHS programs and operations and providing all legal support for OIG's internal operations. OCIG represents OIG in all civil and administrative fraud and abuse cases involving HHS programs, including False Claims Act, program exclusion, and civil monetary penalty cases. In connection with these cases, OCIG also negotiates and monitors corporate integrity agreements. OCIG renders advisory opinions, issues compliance program guidance, publishes fraud alerts, and provides other guidance to the health care industry concerning the anti-kickback statute and other OIG enforcement authorities.

Notices

THIS REPORT IS AVAILABLE TO THE PUBLIC
at <https://oig.hhs.gov>

Section 8M of the Inspector General Act, 5 U.S.C. App., requires that OIG post its publicly available reports on the OIG website.

OFFICE OF AUDIT SERVICES FINDINGS AND OPINIONS

The designation of financial or management practices as questionable, a recommendation for the disallowance of costs incurred or claimed, and any other conclusions and recommendations in this report represent the findings and opinions of OAS. Authorized officials of the HHS operating divisions will make final determination on these matters.

Report in Brief

Date: March 2023
Report No. A-07-19-01192

U.S. DEPARTMENT OF HEALTH & HUMAN SERVICES OFFICE OF INSPECTOR GENERAL

Why OIG Did This Audit

Under the Medicare Advantage (MA) program, the Centers for Medicare & Medicaid Services (CMS) makes monthly payments to MA organizations according to a system of risk adjustment that depends on the health status of each enrollee. Accordingly, MA organizations are paid more for providing benefits to enrollees with diagnoses associated with more intensive use of health care resources than to healthier enrollees, who would be expected to require fewer health care resources.

To determine the health status of enrollees, CMS relies on MA organizations to collect diagnosis codes from their providers and submit these codes to CMS. Some diagnoses are at higher risk for being miscoded, which may result in overpayments from CMS.

For this audit, we reviewed one MA organization, Cigna-HealthSpring Life & Health Insurance Company, Inc. (Cigna), and focused on nine groups of high-risk diagnosis codes. Our objective was to determine whether selected diagnosis codes that Cigna submitted to CMS for use in CMS's risk adjustment program complied with Federal requirements.

How OIG Did This Audit

We sampled 300 unique enrollee-years with the high-risk diagnosis codes for which Cigna received higher payments for 2016 through 2017. We limited our review to the portions of the payments that were associated with these high-risk diagnosis codes, which totaled \$720,395.

Medicare Advantage Compliance Audit of Specific Diagnosis Codes That Cigna-HealthSpring Life & Health Insurance Company, Inc. (Contract H4513) Submitted to CMS

What OIG Found

With respect to the nine high-risk groups covered by our audit, most of the selected diagnosis codes that Cigna submitted to CMS for use in CMS's risk adjustment program did not comply with Federal requirements. Specifically, for 200 of the 300 sampled enrollee-years, the medical records that Cigna provided did not support the diagnosis codes and resulted in \$468,372 in overpayments. As demonstrated by the errors found in our sample, Cigna's policies and procedures to prevent, detect, and correct noncompliance with CMS's program requirements could be improved. On the basis of our sample results, we estimated that Cigna received at least \$6.24 million in overpayments for 2016 and 2017.

What OIG Recommends and Cigna Comments

We recommend that Cigna: (1) refund to the Federal Government the \$468,372 of overpayments; (2) identify, for the high-risk diagnoses included in this report, similar instances of noncompliance that occurred before or after our audit period and refund any resulting overpayments to the Federal Government; and (3) continue its examination of its existing compliance procedures to identify areas where improvements can be made to ensure that diagnosis codes that are at high risk for being miscoded comply with Federal requirements and take the necessary steps to enhance those procedures.

Cigna did not concur with our recommendations and did not concur with our findings for 6 sampled enrollee-years which, according to Cigna, were supported by the medical records. Cigna did not directly agree or disagree with our findings for the remaining enrollee-years. Cigna did not agree with our audit methodology, use of extrapolation, and standards for data accuracy, coding, and documentation requirements.

After reviewing Cigna's comments and the additional information that Cigna provided, we revised the number of enrollee-years in error from 201 to 200 for this final report. After we had issued our draft report, CMS updated regulations for audits in its risk adjustment program to specify that extrapolated overpayments could only be recouped beginning with payment year 2018. Because our audit period covered payment years 2016 and 2017, we revised our first recommendation to specify a refund of only the overpayments for the sampled enrollee-years. We made no changes to our other recommendations. We followed a reasonable audit methodology and correctly applied applicable Federal requirements underlying the MA program.

INTRODUCTION

WHY WE DID THIS AUDIT

Under the Medicare Advantage (MA) program, the Centers for Medicare & Medicaid Services (CMS) makes monthly payments to MA organizations based in part on the characteristics of the enrollees being covered. Using a system of risk adjustment, CMS pays MA organizations the anticipated cost of providing Medicare benefits to a given enrollee, depending on such risk factors as the age, gender, and health status of that individual. Accordingly, MA organizations are paid more for providing benefits to enrollees with diagnoses associated with more intensive use of health care resources relative to healthier enrollees, who would be expected to require fewer health care resources. To determine the health status of enrollees, CMS relies on MA organizations to collect diagnosis codes from their providers and submit these codes to CMS.¹ We are auditing MA organizations because some diagnoses are at higher risk for being miscoded, which may result in overpayments from CMS.

This audit is part of a series of audits in which we are reviewing the accuracy of diagnosis codes that MA organizations submitted to CMS.² Using data mining techniques and considering discussions with medical professionals, we identified diagnoses that were at higher risk for being miscoded and consolidated those diagnoses into specific groups. (For example, we consolidated 29 major depressive disorder diagnoses into 1 group.) This audit covered Cigna-HealthSpring Life & Health Insurance Company, Inc. (Cigna), for contract number H4513 and focused on nine groups of high-risk diagnosis codes for payment years 2016 and 2017.³

OBJECTIVE

Our objective was to determine whether selected diagnosis codes that Cigna submitted to CMS for use in CMS's risk adjustment program complied with Federal requirements.

¹ The providers code diagnoses using the International Classification of Diseases (ICD), Clinical Modification (CM), *Official Guidelines for Coding and Reporting* (ICD Coding Guidelines). The ICD is a coding system that is used by physicians and other health care providers to classify and code all diagnoses, symptoms, and procedures. Effective October 1, 2015, CMS transitioned from the ninth revision of the ICD Coding Guidelines (ICD-9-CM) to the tenth revision (ICD-10-CM). Each revision includes different diagnosis code sets.

² See Appendix B for a list of related Office of Inspector General reports.

³ All subsequent references to "Cigna" in this report refer solely to contract number H4513.

BACKGROUND

Medicare Advantage Program

The MA program offers beneficiaries managed care options by allowing them to enroll in private health care plans rather than having their care covered through Medicare's traditional fee-for-service program.⁴ Beneficiaries who enroll in these plans are known as enrollees. To provide benefits to enrollees, CMS contracts with MA organizations, which in turn contract with providers (including hospitals) and physicians.

Under the MA program, CMS makes advance payments each month to MA organizations for the expected costs of providing health care coverage to enrollees. These payments are not adjusted to reflect the actual costs that the organizations incurred for providing benefits and services. Thus, MA organizations will either realize profits if their actual costs of providing coverage are less than the CMS payments or incur losses if their costs exceed the CMS payments.

For 2020, CMS paid MA organizations \$317.1 billion, which represented 34 percent of all Medicare payments for that year.

Risk Adjustment Program

Federal requirements mandate that payments to MA organizations be based on the anticipated cost of providing Medicare benefits to a given enrollee and, in doing so, also account for variations in the demographic characteristics and health status of each enrollee.⁵

CMS uses two principal components to calculate the risk-adjusted payment that it will make to an MA organization for an enrollee: a base rate that CMS sets using bid amounts received from the MA organization and the risk score for that enrollee. These are described as follows:

- **Base rate:** Before the start of each year, each MA organization submits bids to CMS that reflect the MA organization's estimate of the monthly revenue required to cover an enrollee with an average risk profile.⁶ CMS compares each bid to a specific benchmark amount for each geographic area to determine the base rate that an MA organization is paid for each of its enrollees.⁷

⁴ The Balanced Budget Act of 1997, P.L. No. 105-33, as modified by section 201 of the Medicare Prescription Drug, Improvement, and Modernization Act, P.L. No. 109-173, established the MA program.

⁵ The Social Security Act (the Act) §§ 1853(a)(1)(C) and (a)(3); 42 CFR § 422.308(c).

⁶ The Act § 1854(a)(6); 42 CFR § 422.254 *et seq.*

⁷ CMS's bid-benchmark comparison also determines whether the MA organization must offer supplemental benefits or must charge a basic beneficiary premium for the benefits.

- **Risk score:** A risk score is a relative measure that reflects the additional or reduced costs that each enrollee is expected to incur compared with the costs incurred by enrollees on average. CMS calculates risk scores based on an enrollee's health status (discussed below) and demographic characteristics (such as the enrollee's age and gender). This process results in an individualized risk score for each enrollee, which CMS calculates annually.

To determine an enrollee's health status for purposes of calculating the risk score, CMS uses diagnoses that the enrollee receives from acceptable data sources, including certain physicians and hospitals. MA organizations collect the diagnosis codes from providers based on information documented in the medical records and submit these codes to CMS. CMS then maps certain diagnosis codes, on the basis of similar clinical characteristics and severity and cost implications, into Hierarchical Condition Categories (HCCs).⁸ Each HCC has a factor (which is a numerical value) assigned to it for use in each enrollee's risk score.

As a part of the risk adjustment program, CMS consolidates certain HCCs into related-disease groups. Within each of these groups, CMS assigns an HCC for only the most severe manifestation of a disease in a related-disease group. Thus, if MA organizations submit diagnosis codes for an enrollee that map to more than one of the HCCs in a related-disease group, only the most severe HCC will be used in determining the enrollee's risk score.

For enrollees who have certain combinations of HCCs, CMS assigns a separate factor that further increases the risk score. CMS refers to these combinations as disease interactions. For example, if MA organizations submit diagnosis codes for an enrollee that map to the HCCs for lung cancer and immune disorders, CMS assigns a separate factor for this disease interaction. By doing so, CMS increases the enrollee's risk score for each of the two HCC factors and by an additional factor for the disease interaction.

The risk adjustment program is prospective. Specifically, CMS uses the diagnosis codes that the enrollee received for one year (known as the service year) to determine HCCs and calculate risk scores for the following calendar year (known as the payment year). Thus, an enrollee's risk score does not change for the year in which a diagnosis is made. Instead, the risk score changes for the entirety of the year after the diagnosis has been made. Further, the risk score calculation is an additive process: As HCC factors (and, when applicable, disease interaction factors) accumulate, an enrollee's risk score increases, and the monthly risk-adjusted payment to the MA organization also increases. In this way, the risk adjustment program compensates MA organizations for the additional risk of providing coverage to enrollees expected to require more health care resources.

CMS multiplies the risk scores by the base rates to calculate the total monthly Medicare payment that an MA organization receives for each enrollee before applying the budget

⁸ During our audit period CMS calculated risk scores based on the Version 22 CMS-HCC model.

sequestration reduction.⁹ Thus, if the factors used to determine an enrollee's risk score are incorrect, CMS will make an improper payment to an MA organization. Specifically, if medical records do not support the diagnosis codes that an MA organization submitted to CMS, the HCCs are unvalidated, which causes overstated enrollee risk scores and overpayments from CMS.¹⁰ Conversely, if medical records support the diagnosis codes that an MA organization did not submit to CMS, validated HCCs may not have been included in enrollees' risk scores, which may cause those risk scores to be understated and may result in underpayments.

High-Risk Groups of Diagnoses

Using data mining techniques and discussions with medical professionals, we identified diagnoses that were at higher risk for being miscoded and consolidated those diagnoses into specific groups. For this audit, we focused on nine high-risk groups:

- *Acute stroke*: An enrollee received one acute stroke diagnosis (that mapped to the HCC for Ischemic or Unspecified Stroke) on one physician claim during the service year but did not have that diagnosis on a corresponding inpatient or outpatient hospital claim. In these instances, a diagnosis of history of stroke (which does not map to an HCC) typically should have been used.
- *Acute heart attack*: An enrollee received one diagnosis that mapped to either the HCC for Acute Myocardial Infarction or to the HCC for Unstable Angina and Other Acute Ischemic Heart Disease (Acute Heart Attack HCCs) on only one physician or outpatient claim during the service year but did not have that diagnosis on a corresponding inpatient hospital claim (either within 60 days before or 60 days after the physician or outpatient claim). In these instances, a diagnosis for a less severe manifestation of a disease in the related-disease group typically should have been used.
- *Major depressive disorder*: An enrollee received one major depressive disorder diagnosis (that mapped to the HCC for Major Depressive, Bipolar, and Paranoid Disorders) during the service year but did not have an antidepressant medication dispensed on his or her behalf. In these instances, a major depressive disorder diagnosis may not be supported in the medical records.

⁹ Budget sequestration refers to automatic spending cuts that occurred through the withdrawal of funding for certain Federal programs, including the MA program, as provided in the Budget Control Act of 2011 (BCA) (P.L. No. 112-25 (Aug. 2, 2011)). Under the BCA, the sequestration of mandatory spending began in April 2013.

¹⁰ 42 CFR § 422.310(e) requires MA organizations (when undergoing an audit conducted by the Secretary) to submit "medical records for the validation of risk adjustment data." For purposes of this report, we use the terms "supported" or "unsupported" to denote whether or not the reviewed diagnoses were evidenced in the medical records. If our audit determines that the diagnoses are supported or unsupported, we accordingly use the terms "validated" or "unvalidated" with respect to the associated HCC.

- **Embolism:** An enrollee received one diagnosis that mapped to either the HCC for Vascular Disease or to the HCC for Vascular Disease With Complications (Embolism HCCs) during the service year but did not have an anticoagulant medication dispensed on his or her behalf. An anticoagulant medication is typically used to treat an embolism. In these instances, a diagnosis of history of embolism (an indication that the provider is evaluating a prior acute embolism diagnosis, which does not map to an HCC) typically should have been used.
- **Vascular claudication:** An enrollee received one diagnosis related to vascular claudication (that mapped to the HCC for Vascular Disease) during the service year, but had not received one of these diagnoses during the 2 preceding years and had medication dispensed on his or her behalf that is frequently dispensed for a diagnosis of neurogenic claudication.¹² In these instances, the diagnosis related to vascular claudication may not be supported in the medical records.
- **Lung cancer:** An enrollee received one lung cancer diagnosis (that mapped to the HCC for Lung and Other Severe Cancers) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period either before or after the diagnosis. In these instances, a diagnosis of history of lung cancer (which does not map to an HCC) typically should have been used.
- **Breast cancer:** An enrollee received one breast cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis. In these instances, a diagnosis of history of breast cancer (which does not map to an HCC) typically should have been used.
- **Colon cancer:** An enrollee received one colon cancer diagnosis (that mapped to the HCC for Colorectal, Bladder, and Other Cancers) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis. In these instances, a diagnosis of history of colon cancer (which does not map to an HCC) typically should have been used.
- **Prostate cancer:** An enrollee 74 years old or younger received one prostate cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors) during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after

¹² Vascular claudication and neurogenic claudication are different diagnoses. Vascular claudication is a condition that can result in leg pain while walking and is caused by insufficient blood flow. Neurogenic claudication is a condition that can also result in leg pain but is caused by damage to the neurological system, namely the spinal cord and nerves.

the diagnosis. In these instances, a diagnosis of history of prostate cancer (which does not map to an HCC) typically should have been used.

In this report, we refer to the diagnosis codes associated with these groups as "high-risk diagnosis codes."

Cigna-HealthSpring Life & Health Insurance Company, Inc.

Cigna is an MA organization based in Nashville, Tennessee. As of December 2017, Cigna provided coverage under contract number H4513 to 82,539 enrollees. For the 2016 and 2017 payment years (audit period), CMS paid Cigna approximately \$2.1 billion to provide coverage to its enrollees.^{12, 13}

HOW WE CONDUCTED THIS AUDIT

Our audit included enrollees on whose behalf providers documented diagnosis codes that mapped to one of the nine high-risk groups during the 2015 and 2016 service years, for which Cigna received increased risk-adjusted payments for payment years 2016 and 2017, respectively. Because enrollees could be classified into more than one high-risk group or could have high-risk diagnosis codes documented in more than 1 year, we classified these individuals according to the condition and the payment year, which we refer to as "enrollee-years."

We identified 8,667 unique enrollee-years and limited our review to the portions of the payments that were associated with these high-risk diagnosis codes (\$19,537,407). We selected for audit a stratified sample of 300 enrollee-years as shown in Table 1 on the following page.

¹² The 2016 and 2017 payment year data were the most recent data available at the start of the audit.

¹³ All of the payment amounts that CMS made to Cigna and the overpayment amounts that we identified in this report reflect the budget sequestration reduction.

Table 1: Sampled Enrollee-Years

High-Risk Group	Number of Sampled Enrollee-Years
1. Acute stroke	30
2. Acute heart attack	30
3. Major depressive disorder	60
4. Embolism	30
5. Vascular claudication	30
6. Lung cancer	30
7. Breast cancer	30
8. Colon cancer	30
9. Prostate cancer	30
Total for All High-Risk Groups	300

Cigna provided medical records as support for the selected diagnosis codes associated with 288 of the 300 sampled enrollee-years.¹⁴ We used an independent medical review contractor to review the medical records to determine whether the HCCs associated with the sampled enrollee-years were validated. If the contractor identified a diagnosis code that should have been submitted to CMS instead of the selected diagnosis code, we included the financial impact of the resulting HCC (if any) in our calculation of overpayments.

We conducted this performance audit in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Appendix A contains the details of our audit scope and methodology, Appendix C contains our statistical sampling methodology, Appendix D contains our sample results and estimates, and Appendix E contains the Federal regulations.

FINDINGS

With respect to the nine high-risk groups covered by our audit, most of the selected diagnosis codes that Cigna submitted to CMS for use in CMS's risk adjustment program did not comply with Federal requirements. For 100 of the 300 sampled enrollee-years, the medical records

¹⁴ Cigna could not locate medical records for the remaining 12 sampled enrollee-years.

validated the reviewed HCCs.¹⁵ For the remaining 200 enrollee-years, however, either the medical records that Cigna provided did not support the diagnosis codes or Cigna could not locate the medical records to support the diagnosis codes and the associated HCCs were therefore not validated. As a result, Cigna received \$468,372 in overpayments.

As demonstrated by the errors found in our sample, Cigna's policies and procedures to prevent, detect, and correct noncompliance with CMS's program requirements, as mandated by Federal regulations, could be improved. On the basis of our sample results, we estimated that Cigna received at least \$6.24 million in overpayments for 2016 and 2017.¹⁶

FEDERAL REQUIREMENTS

Payments to MA organizations are adjusted for risk factors, including the health status of each enrollee (the Social Security Act § 1853(a)). CMS applies a risk factor based on data obtained from the MA organizations (42 CFR § 422.308).

Federal regulations state that MA organizations must follow CMS's instructions and submit to CMS the data necessary to characterize the context and purposes of each service provided to a Medicare enrollee by a provider, supplier, physician, or other practitioner (42 CFR § 422.310(b)). MA organizations must obtain risk adjustment data required by CMS from the provider, supplier, physician, or other practitioner that furnished the item or service (42 CFR § 422.310(d)(3)).

Federal regulations also state that MA organizations are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS for payment purposes and that such data must conform to all relevant national standards (42 CFR §§ 422.504(l) and 422.310(d)(1)). In addition, MA organizations must contract with CMS and agree to follow CMS's instructions, including the *Medicare Managed Care Manual* (the Manual) (42 CFR § 422.504(a)).

CMS has provided instructions to MA organizations regarding the submission of data for risk scoring purposes (the Manual, chap. 7 (last rev. Sept. 19, 2014)). Specifically, CMS requires all submitted diagnosis codes to be documented in the medical record and to be documented as a result of a face-to-face encounter (the Manual, chap. 7, § 40). The diagnosis must be coded

¹⁵ For 1 of the 100 enrollee-years, Cigna informed us that it could not locate the associated medical record because the record had been destroyed in a natural disaster. CMS provides guidance for medical records that are unavailable because of "extraordinary circumstances" (*Contract-Level Risk Adjustment Data Validation CMS Submission Instructions*). Based on our assessment of the information provided by Cigna, we determined that an extraordinary circumstance prevented Cigna from locating the medical record for this enrollee-year, and we treated the sample item as a non-error.

¹⁶ Specifically, we estimated that Cigna received at least \$6,247,399 of overpayments. To be conservative, we estimate overpayments at the lower limit of a two-sided 90-percent confidence interval. Lower limits calculated in this manner are designed to be less than the actual overpayment total 95 percent of the time.

according to the International Classification of Diseases (ICD), Clinical Modification, *Official Guidelines for Coding and Reporting* (42 CFR § 422.310(d)(1) and 45 CFR §§ 162.1002(b)(1) and (c)(2)-(3)). Further, MA organizations must implement procedures to ensure that diagnoses come only from acceptable data sources, which include hospital inpatient facilities, hospital outpatient facilities, and physicians (the Manual, chap. 7, § 40).

Federal regulations state that MA organizations must monitor the data that they receive from providers and submit to CMS. Federal regulations also state that MA organizations must “adopt and implement an effective compliance program, which must include measures that prevent, detect, and correct non-compliance with CMS’ program requirements” Further, MA organizations must establish and implement an effective system for routine monitoring and identification of compliance risks (42 CFR § 422.503(b)(4)(vi)).

MOST OF THE SELECTED HIGH-RISK DIAGNOSIS CODES THAT CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY SUBMITTED TO CMS DID NOT COMPLY WITH FEDERAL REQUIREMENTS

Most of the selected high-risk diagnosis codes that Cigna submitted to CMS for use in CMS’s risk adjustment program did not comply with Federal requirements. Specifically, as shown in the figure below, the medical records for 200 of the 300 sampled enrollee-years did not support the diagnosis codes. In these instances, Cigna should not have submitted the diagnosis codes to CMS and received the resulting overpayments.

Figure: Analysis of High-Risk Groups

Incorrectly Submitted Diagnosis Codes for Acute Stroke

Cigna incorrectly submitted diagnosis codes for acute stroke for 29 of 30 sampled enrollee-years. Specifically:

- For 23 enrollee-years, the medical records indicated in each case that the individual had previously had a stroke, but the records did not justify an acute stroke diagnosis at the time of the physician's service.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no evidence of an acute stroke or any related condition that would result in an assignment of the submitted HCC or a related HCC. There is mention of a history of a stroke [diagnosis] but no description of residuals or sequelae that should be coded."¹⁷ The history of stroke diagnosis code does not map to an HCC.

- For the remaining 6 enrollee-years, the medical records in each case did not support an acute stroke diagnosis.¹⁸

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no evidence of an acute stroke or any related condition that would result in an assignment of the submitted HCC [for Ischemic or Unspecified Stroke] or a related HCC. Although [there] is mention of a cerebral infarction [diagnosis] in the current assessment there is no indication that this condition is active."¹⁹

As a result of these errors, the HCC for Ischemic or Unspecified Stroke was not validated, and Cigna received \$62,466 in overpayments for these 29 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Acute Heart Attack

Cigna incorrectly submitted diagnosis codes for acute heart attack for 29 of 30 sampled enrollee-years. Specifically:

- For 13 enrollee-years, the medical records indicated in each case that the individual had an old myocardial infarction diagnosis, but the records did not justify one of the

¹⁷ Residuals or sequelae are the late effects of an injury that can occur only after the acute phase of the injury or illness has passed.

¹⁸ For 1 of these enrollee-years, the medical record that Cigna provided to support the reviewed HCC was a magnetic resonance imaging (MRI) report. This record was not from an acceptable data source (a face-to-face encounter with a provider, physician, or other practitioner) (42 CFR § 422.310(d)(3)); the Manual, chap. 7, §§ 40 and 120.1).

¹⁹ A cerebral infarction, or stroke, is defined as a brain lesion in which a cluster of brain cells dies due to lack of blood.

diagnoses that mapped to an Acute Heart Attack HCC at the time of the physician's service.²⁰

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Acute Myocardial Infarction]. There is documentation of a past medical history of myocardial infarction [diagnosis] that does not result in an HCC."

- For 9 enrollee-years, the medical records in each case did not support the submitted diagnosis that mapped to an Acute Heart Attack HCC. However, for each of these enrollee-years, we identified support for another diagnosis that mapped to the HCC for Angina Pectoris, which is a less severe manifestation of the related-disease group.²¹

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Unstable Angina and Other Acute Ischemic Heart Disease]. There is documentation of [an] angina pectoris [diagnosis] that results in [the] HCC [for Angina Pectoris]"

- For 6 enrollee-years, the medical records in each case did not support a diagnosis that mapped to an Acute Heart Attack HCC.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Acute Myocardial Infarction]. The discharge final diagnosis stated that the patient was ruled out for an acute myocardial infarction."

- For the remaining 1 enrollee-year, Cigna could not locate any medical records to support a diagnosis that mapped to an Acute Heart Attack HCC; therefore, an Acute Heart Attack HCC was not validated.

As a result of these errors, the Acute Heart Attack HCCs were not validated, and Cigna received \$41,309 in overpayments for these 29 sampled enrollee-years.

²⁰ An "old myocardial infarction" is a distinct diagnosis that represents a myocardial infarction that occurred more than 4 weeks previously, has no current symptoms directly associated with that myocardial infarction, and requires no current care.

²¹ Angina pectoris is defined as a disease marked by brief sudden attacks of chest pain or discomfort caused by deficient oxygenation of the heart muscles, usually due to impaired blood flow to the heart.

Incorrectly Submitted Diagnosis Codes for Major Depressive Disorder

Cigna incorrectly submitted diagnosis codes for major depressive disorder for 3 of 60 sampled enrollee-years. Specifically:

- For 2 enrollee-years, the medical records in each case did not support a major depressive disorder diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Major Depressive, Bipolar, and Paranoid Disorders]."

- For the remaining 1 enrollee-year, Cigna could not locate any medical records to support the major depressive disorder diagnosis; therefore, the HCC for Major Depressive, Bipolar, and Paranoid Disorders was not validated.

As a result of these errors, the HCC for Major Depressive, Bipolar, and Paranoid Disorders was not validated, and Cigna received \$7,247 in overpayments for these 3 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Embolism

Cigna incorrectly submitted diagnosis codes for embolism for 22 of 30 sampled enrollee-years. Specifically:

- For 13 enrollee-years, the medical records in each case did not support a diagnosis that mapped to an Embolism HCC.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Vascular Disease]. Per . . . ultrasound test results, there was no evidence of deep vein thrombosis."²²

- For 8 enrollee-years, the medical records indicated in each case that the individual had previously had an embolism, but the records did not justify a diagnosis that mapped to an Embolism HCC at the time of the physician's service.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Vascular Disease]. There is documentation of a past medical history of deep vein thrombosis [diagnosis] that does not result in an HCC."

²² Deep vein thrombosis is defined as a blood clot that forms in one or more of the deep veins in the body, usually in the legs.

- For the remaining 1 enrollee-year, Cigna could not locate any medical records to support a diagnosis that mapped to an Embolism HCC; therefore, an Embolism HCC was not validated.

As a result of these errors, the Embolism HCCs were not validated, and Cigna received \$51,125 in overpayments for these 22 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Vascular Claudication

Cigna incorrectly submitted diagnosis codes for vascular claudication for 7 of 30 sampled enrollee-years. Specifically:

- For 6 enrollee-years, the medical records in each case did not support a vascular claudication diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Vascular Disease]."

- For the remaining 1 enrollee-year, Cigna could not locate any medical records to support the vascular claudication diagnosis; therefore, the HCC for Vascular Disease was not validated.

As a result of these errors, the HCC for Vascular Disease was not validated, and Cigna received \$12,872 in overpayments for these 7 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Lung Cancer

Cigna incorrectly submitted diagnosis codes for lung cancer for 28 of 30 sampled enrollee-years. Specifically:

- For 14 enrollee-years, the medical records indicated in each case that the individual had previously had lung cancer, but the records did not justify a lung cancer diagnosis at the time of the physician's service.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC for [Lung and Other Severe Cancers]. There is documentation of a past medical history of lung cancer [diagnosis] that does not result in an HCC."

- For 10 enrollee-years, the medical records in each case did not support a lung cancer diagnosis.²³

For example, for 1 enrollee-year, the independent medical review contractor stated that “there is no documentation of any condition that will result in the assignment of [the] HCC [for Lung and Other Severe Cancers]. There was not enough documentation to support that the lung cancer was an active condition on this date of service.”

- For 2 enrollee-years, the medical records in each case did not support a lung cancer diagnosis. However, for each of these enrollee-years, we identified support for another diagnosis that mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Cigna should not have received an increased payment for the submitted lung cancer diagnosis, but it should have received a lesser increased payment for the other diagnosis identified.
- For each of the remaining 2 enrollee-years, Cigna could not locate any medical records to support the lung cancer diagnosis; therefore, the HCC for Lung and Other Severe Cancers was not validated.

As a result of these errors, the HCC for Lung and Other Severe Cancers was not validated, and Cigna received \$169,930 in overpayments for these 28 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Breast Cancer

Cigna incorrectly submitted diagnosis codes for breast cancer for 28 of 30 sampled enrollee-years. Specifically:

- For 20 enrollee-years, the medical records indicated in each case that the individual had previously had breast cancer, but the records did not justify a breast cancer diagnosis at the time of the physician’s service.

For example, for 1 enrollee-year, the independent medical review contractor stated that “there is no documentation of any condition that will result in the assignment of [the] HCC [for Breast, Prostate, and Other Cancers and Tumors]. There is documentation of a past medical history of breast cancer [diagnosis] that does not result in an HCC.”

²³ For 1 of these enrollee-years, the medical record that Cigna provided to support the reviewed HCC contained only laboratory test results. This record was not from an acceptable data source (a face-to-face encounter with a provider, physician, or other practitioner) (42 CFR § 422.310(d)(3)); the Manual, chap. 7, §§ 40 and 120.1).

- For 7 enrollee years, the medical records in each case did not support a breast cancer diagnosis.²⁴

For example, for 1 enrollee-year, the independent medical review contractor stated that “there is no documentation of any condition that will result in the assignment of [the] HCC [for Breast, Prostate, and Other Cancers and Tumors] There was not enough documentation to support that the breast cancer was an active condition on this date of service.”

- For the remaining 1 enrollee-year, Cigna could not locate any medical records to support the breast cancer diagnosis; therefore, the HCC for Breast, Prostate, and Other Cancers and Tumors was not validated.

As a result of these errors, the HCC for Breast, Prostate, and Other Cancers and Tumors was not validated, and Cigna received \$31,104 in overpayments for these 28 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Colon Cancer

Cigna incorrectly submitted diagnosis codes for colon cancer for 28 of 30 sampled enrollee-years. Specifically:

- For 18 enrollee-years, the medical records indicated in each case that the individual had previously had colon cancer, but the records did not justify a colon cancer diagnosis at the time of the physician’s service.

For example, for 1 enrollee-year, the independent medical review contractor stated that “there is no documentation of a diagnosis that results in [the] HCC [for Colorectal, Bladder, and Other Cancers]. There is documentation of a past medical history of colon cancer [diagnosis] that does not result in an HCC.”

- For 5 enrollee-years, the medical records in each case did not support a colon cancer diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor stated that “there is no documentation of any condition that will result in the assignment of [the] HCC [for Colorectal, Bladder, and Other Cancers]. The medical documentation does not indicate an active diagnosis of colon cancer.”

- For 3 enrollee-years, the medical records in each case did not support a colon cancer diagnosis. However, for each of these enrollee-years, we identified support for another

²⁴ For 1 of these enrollee-years, the medical record that Cigna provided to support the reviewed HCC was a radiology order requisition. This record was not from an acceptable data source (a face-to-face encounter with a provider, physician, or other practitioner) (42 CFR § 422.310(d)(3)); the Manual, chap. 7, §§ 40 and 120.1).

diagnosis that mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, in each case Cigna should not have received an increased payment for the submitted colon cancer diagnosis, but it should have received a lesser increased payment for the other diagnosis identified.

- For each of the remaining 2 enrollee-years, Cigna could not locate any medical records to support the colon cancer diagnosis; therefore, the HCC for Colorectal, Bladder, and Other Cancers was not validated.

As a result of these errors, the HCC for Colorectal, Bladder, and Other Cancers was not validated, and Cigna received \$56,923 in overpayments for these 28 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Prostate Cancer

Cigna incorrectly submitted diagnosis codes for prostate cancer for 26 of 30 sampled enrollee-years. Specifically:

- For 23 enrollee-years, the medical records indicated in each case that the individual had previously had prostate cancer, but the records did not justify a prostate cancer diagnosis at the time of the physician's service.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Breast, Prostate, and Other Cancers and Tumors] . . . History of prostate cancer [diagnosis] should have been assigned . . . and does not result in an HCC."

- For each of 2 enrollee-years, Cigna could not locate any medical records to support the prostate cancer diagnosis; therefore, the HCC for Breast, Prostate, and Other Cancers and Tumors was not validated.
- For the remaining 1 enrollee-year, the medical records did not support a prostate cancer diagnosis. Specifically, the independent medical review contractor stated that "there is no documentation of any condition that will result in the assignment of [the] HCC [for Breast, Prostate, and Other Cancers and Tumors]. There was not enough documentation to support that the prostate cancer was an active condition on this date of service."

As a result of these errors, the HCC for Breast, Prostate, and Other Cancers and Tumors was not validated, and Cigna received \$35,396 in overpayments for these 26 sampled enrollee-years.

Summary of Incorrectly Submitted Diagnosis Codes

In summary and with respect to the nine high-risk groups covered by our audit, Cigna received \$468,372 in overpayments for the 200 sampled enrollee-years.

THE POLICIES AND PROCEDURES THAT CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY HAD TO PREVENT, DETECT, AND CORRECT NONCOMPLIANCE WITH FEDERAL REQUIREMENTS COULD BE IMPROVED

As demonstrated by the errors found in our sample, the policies and procedures that Cigna had to prevent, detect, and correct noncompliance with CMS's program requirements, as mandated by Federal regulations at 42 CFR § 422.503(b)(4)(vi), could be improved.

During our audit period, Cigna had compliance procedures in place that were designed to prevent providers from submitting incorrect diagnosis codes. These procedures included a variety of provider-specific outreach efforts to help educate its providers on medical record documentation, including accurately differentiating between: (1) conditions that were manifesting as acute and (2) conditions that were not currently active but had been historically present, such as stroke, myocardial infarction, and cancer. In addition, Cigna routinely educated its coders on best coding practices and acceptable medical documentation guidelines, and coders were expected to identify codes with at least 95-percent accuracy.

Cigna also had compliance procedures in place that were designed to determine whether the diagnosis codes that it submitted to CMS to calculate risk-adjusted payments were correct. These procedures included the use of internal data quality reviews that selected diagnosis codes from specific claims and compared them to the diagnoses that were documented on the associated medical records. Cigna had several criteria governing its selection of these diagnosis codes, including: (1) the frequency of usage by specific physicians and (2) the presence of diagnosis codes that met certain conditions (such as diagnosis codes for acute conditions that could be inaccurate when coded in an outpatient setting). Cigna's procedures also included guidance on how its reviewers should address the coding of certain conditions, including acute stroke, myocardial infarction, cancer, and the use of "history of" diagnosis codes. If the reviewers detected a compliance problem, Cigna's policies and procedures provided guidance on how to communicate the correction of the problem to CMS.

Although Cigna had policies and procedures that addressed some incorrect high-risk diagnosis codes, Cigna did not identify these diagnosis codes as problematic unless they appeared on a specific claim that was selected for review. For this reason, we concluded that Cigna's policies and procedures to prevent, detect, and correct miscoded high-risk diagnoses during our audit period could be improved.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY RECEIVED OVERPAYMENTS

As a result of the errors we identified, the HCCs for these high-risk diagnosis codes were not validated. On the basis of our sample results, we estimated that Cigna received at least \$6,247,399 in overpayments for 2016 and 2017. (See Appendix D for sample results and estimates).

Because of Federal regulations that limit the use of extrapolation in Risk Adjustment Data Validation (RADV) audits for recovery purposes, we are reporting the estimated overpayment amount but are recommending a refund of only the \$468,372 in overpayments that Cigna received for the 200 sampled enrollee-years.²⁵

RECOMMENDATIONS

We recommend that Cigna-HealthSpring Life & Health Insurance Company, Inc.:

- refund to the Federal Government the \$468,372 of overpayments;
- identify, for the high-risk diagnoses included in this report, similar instances of noncompliance that occurred before or after our audit period and refund any resulting overpayments to the Federal Government; and
- continue its examination of its existing compliance procedures to identify areas where improvements can be made to ensure that diagnosis codes that are at high risk for being miscoded comply with Federal requirements (when submitted to CMS for use in CMS's risk adjustment program) and take the necessary steps to enhance those procedures.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY COMMENTS AND OFFICE OF INSPECTOR GENERAL RESPONSE

In written comments on our draft report, Cigna did not concur with some of our findings and did not concur with any of our recommendations. More specifically, Cigna did not concur with our findings for 6 of the 201 enrollee-years in error identified in our draft report. For these 6 enrollee-years, Cigna provided explanations as to why it believed that the medical records that it previously gave us validated the reviewed HCCs. Cigna did not directly agree or disagree with our findings for the HCCs under audit for each of the remaining 195 enrollee-years.²⁶ With respect to the estimated overpayments, Cigna stated that our audit was "skewed toward identifying 'overpayments'" and that the basic premise of our audit was inconsistent with Federal requirements.

We reviewed the entirety of Cigna's comments and the additional information that it provided and, accordingly, reduced the number of enrollee-years in error from 201 to 200 and adjusted our calculation of overpayments for this final report. After we issued our draft report, CMS updated its regulations for RADV audits to specify that extrapolated overpayments could only

²⁵ After we had issued our draft report, CMS updated Federal regulations that limit the use of extrapolation in RADV audits to payment years 2018 and forward (88 Fed. Reg. 6643 (Feb. 1, 2023)). RADV audits are conducted to verify that diagnoses submitted by MA organizations for risk-adjusted payment are supported by medical record documentation.

²⁶ For 19 of the 195 enrollee-years, Cigna provided additional information that was outside the scope of our audit; accordingly, this information did not impact our audit results.

be recouped beginning with payment year 2018 (footnote 25). Because our audit period covered payment years 2016 and 2017, we revised the amount in our first recommendation to reflect only the overpayments for the 200 sampled enrollee-years. We maintain that our second and third recommendations remain valid.

A summary of Cigna's comments and our responses follows. Cigna's comments appear as Appendix F. We excluded attachments (which Cigna identified as Exhibit A and Exhibit B in its comments) because they contained personally identifiable information. We are separately providing Cigna's comments and attachments in their entirety to CMS.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY DID NOT CONCUR WITH THE OFFICE OF INSPECTOR GENERAL'S RECOMMENDATION THAT IT REFUND OVERPAYMENTS

Cigna-HealthSpring Life & Health Insurance Company Did Not Agree With the Office of Inspector General's Findings for 6 Sampled Enrollee-Years

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna did not concur with our findings for 6 of the sampled enrollee-years (as shown in Table 2) and provided explanations as to why it believed that the medical records that it previously gave us validated the reviewed HCCs.

Table 2: Summary of Enrollee-Years for Which Cigna-HealthSpring Life & Health Insurance Company Disagreed With Our Findings

High-Risk Group	Number of Sampled Enrollee-Years
Prostate cancer	4
Vascular claudication	1
Lung cancer	1
Total	6

Office of Inspector General Response

For 1 of the 6 enrollee-years that Cigna specifically disputed, our independent medical review contractor reversed its original decision after reviewing the explanation that Cigna submitted, and determined that the HCC was validated.

Specifically, for the 1 enrollee-year from the vascular claudication high-risk group, Cigna cited the medical record's reference to a physical exam that noted "dorsalis pedis pulses . . . a follow up lower extremity arterial doppler was performed 3 weeks later . . . confirming a diagnosis of

[peripheral vascular disease] PVD.”²⁷ After reviewing Cigna’s explanation for this enrollee-year, our independent medical review contractor reversed its original decision. In so doing, the contractor stated: “[t]here is documentation of [a] lower extremity claudication [diagnosis] that results in [the] HCC [for Vascular Disease].”

Accordingly, we reduced the number of enrollee-years in error from 201 (in our draft report) to 200 for this final report. We also revised our findings and reduced the associated monetary recommendation. Our independent medical review contractor confirmed that Cigna’s written comments and additional explanations had no impact on the decisions that the contractor made for other sampled enrollee-years and stated that there were no “systemic issues identified” in its reviews.

For the remaining 5 enrollee-years for which Cigna disagreed with the results of our independent medical review contractor’s coding review, our contractor reaffirmed that the HCCs were not validated and thus upheld its original decision. For example, for 1 enrollee-year from the prostate cancer high-risk group, the contractor stated that “[t]he medical record for the date of service . . . indicates a past history of prostate cancer that was under surveillance.” Further, the contractor stated that “[t]here is no medical record evidence to support the diagnosis of prostate cancer, including no documentation of PSA [prostate-specific antigen] [test], monitoring or treatment.”²⁸

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General’s Audits Were Focused Only on Identifying Overpayments

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that our “audit methodology was so targeted that it could not equally identify overpayments and underpayments.” Furthermore, Cigna stated that our audit targeted “specific diagnosis categories that OIG [Office of Inspector General] hypothesized . . . [are] likely to have resulted in an ‘overpayment.’” Cigna also stated that we did not allow it “to demonstrate support for and receive credit for diagnosis codes that had not previously been submitted to CMS for the audited [enrollees] that were unrelated to the target diagnosis codes.” Furthermore, according to Cigna, “OIG only focused on samples that it viewed to be high-risk diagnoses so that it could only identify a potential overpayment.” Cigna added that this “biased targeting resulted in findings that do not ensure accuracy because the audit was

²⁷ The dorsalis pedis artery is the main source of blood supply to the foot. A lower extremity arterial doppler is an ultrasound test used to check the blood flow of the arteries and veins in the lower extremities (leg, ankle and foot). PVD is a systemic disorder that involves the narrowing of peripheral blood vessels (i.e., vessels situated away from the heart or the brain). Both PVD and vascular claudication map to the HCC for Vascular Disease.

²⁸ The PSA blood test measures the amount of PSA in the blood and is used primarily to screen for prostate cancer.

not designed to look at payment accuracy, which would include both overpayments and underpayments.”

For these reasons, Cigna stated that it was concerned “that the proposed overpayment figure used by OIG cannot be an adequate basis” for the audit results in this report.

Office of Inspector General Response

Our objective was to determine whether selected high-risk diagnosis codes that Cigna submitted to CMS for use in CMS’s risk adjustment program complied with Federal requirements. We identified diagnoses that were at higher risk for being miscoded and consolidated those diagnoses into nine specific high-risk groups. This process involved a carefully designed audit methodology (see Appendix A) rather than “hypothesized” categories of diagnoses. Our objective did not extend to diagnosis codes not previously submitted by Cigna or to HCCs that were beyond the scope of our audit. A valid calculation of overpayments, given the objective of our audit, does not need to take into consideration all potential HCCs or underpayments within the audit period. Although for this final report we reduced the amount in our first recommendation (as discussed above), we based our calculation of overpayments on the results of the independent medical review contractor’s review; this calculation addressed only the accuracy of the portion of payments related to the reviewed HCCs and does not extend to HCCs that were beyond the scope of this audit.

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General Did Not Follow CMS’s Established Risk Adjustment Data Validation Methodology

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that our audit methodology did not account for a payment principal known as “actuarial equivalence,” because we did not apply an adjustment called a Fee-for-Service (FFS) Adjuster. The FFS Adjuster, according to Cigna, “incorporate[s] the FFS error rate into [CMS’s] methodology for calculating recovery amounts for unsupported HCCs identified during its RADV audits.” Cigna noted that, to address the FFS error rate, CMS published a notice in 2012 that notified MA organizations that it planned to calculate and apply an FFS Adjuster to payment recoveries in RADV audits to adjust for diagnosis coding errors in claims data from traditional Medicare.²⁹ Cigna also cited recent Federal court cases that have dealt with the principle of actuarial equivalence and mentioned that a CMS final rule on this issue (that CMS proposed in 2018) is still pending. In addition, Cigna stated that because we did not apply an FFS Adjuster, we “violate[d]” requirements for notice-and-comment Federal rulemaking and departed from how we addressed the FFS adjuster in a previous report.³⁰

²⁹ Cigna’s comment in this respect cited to CMS’s *Notice of Final Payment Error Calculation Methodology for Part C Medicare Advantage Risk Adjustment Data Validation for Contract-Level Audits* (Feb. 24, 2012), pages 3-4.

³⁰ The previous report to which Cigna referred was *Risk Adjustment Data Validation of Payments Made to PacificCare of California for Calendar Year 2007 (Contract Number H0543)* (A-09-09-00045; Nov. 2012).

Cigna added that “[the] actuarial equivalence requirement extends to OIG’s estimation and extrapolation of a potential ‘overpayment’ amount in this audit,” and that because we did not apply an FFS Adjuster, “it is not possible for OIG to determine whether Cigna received an overpayment.”

Office of Inspector General Response

Our audit methodology correctly applied CMS requirements to properly identify the overpayment amount associated with the unvalidated HCCs for each sample item. Specifically, we used the results of the independent medical review contractor’s review to determine which HCCs were not validated and, in some instances, to identify HCCs that should have been used but were not used in the associated enrollees’ risk score calculations. We followed CMS’s risk adjustment program requirements to determine the payment that CMS should have made for each enrollee and to estimate overpayments. With respect to Cigna’s comment regarding actuarial equivalence in our overpayment calculations, we note that after we issued our draft report, CMS stated that it “will not apply an adjustment factor (known as an FFS Adjuster) in RADV audits.”³¹ In the context of CMS’s requirements and updated guidance, we recognize that CMS—not OIG—was responsible in 2012 and is responsible now for making operational and program payment determinations for the MA program.

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General’s Audits Were Inconsistent With CMS Standards for Data Accuracy

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that we “designed and conducted an audit that was inconsistent with RADV regulations and CMS standards for data accuracy.” According to Cigna, “[t]he perfection standard posited by [our report] reflects either a misunderstanding of CMS regulations or a rejection of the data standards set by CMS.” Specifically:

- Cigna stated that we misunderstood Federal regulations at 42 CFR § 422.504(l), “in taking the position that MA organizations ‘are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS.’” Cigna added that this regulation also states that when submitting data to CMS, an MA organization attests to the accuracy of those data according to its “best knowledge, information and belief.” In this context, Cigna said that CMS has stated that there is no requirement that MA organizations need to verify every diagnosis submitted by providers. Cigna also referred to a CMS comment that MA organizations “cannot reasonably be expected to know that every piece of data is correct.”³²

³¹ 88 Fed. Reg. 6643 (Feb. 1, 2023).

³² For this comment, Cigna cited 65 Fed. Reg. 40170, 40268 (Jun. 29, 2000).

- Additionally, Cigna commented that the “perfection standard reflected in [our report] also is inconsistent with the realities and limitations of attempting to perform a risk adjustment function.” Cigna elaborated on this position in several ways:
 - Cigna referred to the “inherently subjective” nature of diagnosis coding and stated that we did not take into account that “[a]lthough [Cigna] make[s] coding and documentation training available to . . . providers, [Cigna] ultimately cannot control their submissions.” Cigna also said that CMS generally “allows providers to use their best professional judgment.”
 - Cigna also alluded to various difficulties in obtaining medical records from providers. Cigna said that the 5 to 6 years between the encounters at issue and the audit, as well as the onset of COVID-19 during the audit and resulting staff shortages, made it difficult to obtain the necessary records from providers. Moreover, according to Cigna, this 5-to-6-year “gap creates a significant data validation issue for Cigna,” because of providers that are no longer in its network and various recordkeeping challenges.
 - Furthermore, Cigna stated that the “consolidation of hospital systems and large provider groups and the increasing number of providers who are publicly traded or private investor-backed has led to some large groups and health systems refusing to respond to records requests [from MA organizations] in a timely fashion, if at all.”

Office of Inspector General Response

We disagree with Cigna’s statement that we misunderstood regulations or rejected the data standards set by CMS. Specifically, we do not agree with Cigna’s interpretation of the Federal requirements at 42 CFR § 422.504(l). We recognize that CMS applies a “best knowledge, information and belief” standard when MA organizations certify the great volume of data that they submit to CMS for use in the risk adjustment program.³³ We recognize as well that, as Cigna said, there is no CMS requirement that MA organizations verify every diagnosis submitted by providers. We also acknowledge that Cigna cannot “reasonably be expected to know that every piece of data is correct.”

However, our audit revealed a significant error rate (200 of 300 enrollee-years) with unsupported diagnosis codes (see Appendix D)) for the high-risk areas we audited. Federal regulations require MA organizations to implement procedures for “promptly responding to compliance issues as they are raised” and to “[correct] such problems promptly and thoroughly to reduce the potential for recurrence” (42 CFR § 422.503(b)(4)(vi)(G) (see Appendix E)). Accordingly, we believe that Cigna is responsible for addressing the issues that resulted in that significant error rate. Correcting these issues will also assist Cigna in attaining better assurance

³³ 79 Fed. Reg. 29844, 29926 (May 23, 2014).

with regard to the “accuracy, completeness and truthfulness” of the risk adjustment data that it submits in the future.

With respect to Cigna’s comment about the “inherently subjective” coding process, we designed our audit methodology (see Appendix A) to be as objective as possible—that is, to minimize the effects of any potential coding subjectivities on our overpayment calculations. Our independent medical review contractor followed a specific process when reviewing the medical records that Cigna gave to us, to determine whether the diagnosis codes that Cigna submitted to CMS for risk-adjustment purposes were supported. If the first reviewer (a senior coder) found that a diagnosis was not supported on the medical records, then a second senior coder (and sometimes a third reviewer, a physician) performed a separate review of the same medical records. Two reviewers needed to agree that the diagnosis was unsupported for it to be counted as an error and be included in our overpayment calculations.

Moreover, CMS’s RADV Submission Instructions, issued to MA organizations, recognizes that “there may be extraordinary circumstances that prevent an MA Organization . . . from submitting medical records for the audited enrollee(s) and CMS-HCC(s) in accordance with . . . audit requirements.”³⁴ However, CMS also notes in these instructions that “extraordinary circumstances do not typically include ordinary issues encountered during the process of requesting medical records and attestations from providers.” These ordinary issues include, but are not limited to, (1) difficulty in communicating with the provider, (2) provider difficulty in locating the record, and (3) delay caused by health information management system issues, including issues with third-party companies or vendors.

During our audit work, we worked with Cigna officials to extend (by several months) the medical record collection timeframe to account for the collection difficulties associated with the COVID-19 pandemic. Furthermore, Cigna did not convey to us during the audit that it was confronting any other extraordinary circumstances that prevented it from obtaining and providing to us medical records that would have supported the diagnosis codes submitted to CMS and validated the HCCs under review.

Cigna-HealthSpring Life & Health Insurance Company Did Not Agree With the Office of Inspector General’s Use of Extrapolation

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna disagreed with our use of extrapolation to calculate overpayments for the following reasons:

- Cigna did not agree with the fact that we used the lower limit of a two-sided 90-percent confidence interval to calculate the extrapolated repayment amount. Cigna noted that

³⁴ Contract-Level Risk Adjustment Data Validation CMS Submission Instructions, Sep. 7, 2016.

CMS follows the “statistically valid and more robust practice” of using the lower limit of a 95-percent or 99-percent confidence interval for its RADV audits.

- Cigna also stated that it “do[es] not believe that extrapolation has been authorized by Congress. . . . Part C of the Medicare statute does not authorize extrapolated recoveries and, in the absence of explicit Congressional authorization, we believe extrapolation is not available.” In addition, Cigna stated that “[e]ven if extrapolation were permitted, the methodology used would have to adhere to the final methodology established by CMS.”

Office of Inspector General Response

As stated above, for this final report our recommendation to refund overpayments is limited to the overpayments associated with the 200 sampled enrollee-years, rather than to an estimate (footnote 25). However, we believe that the results of our sampling, as well as our estimate of overpayments (Appendix D), provide a reasonable basis for our findings and conclusions—and support our recommendation that Cigna continue to examine its existing compliance procedures to identify areas where improvements can be made.

OIG is an independent oversight agency; therefore, our estimation methodology does not need to mirror CMS’s estimation methodology. Our policy recommends recovery at the lower limit of a two-sided 90-percent confidence interval. We believe that the lower limit of a two-sided 90-percent confidence interval provides a reasonably conservative estimate of the total amount overpaid to Cigna for the enrollee-years and time period covered in our sampling frame. This approach, which is routinely used by HHS for recovery calculations,³⁵ results in a lower limit (the estimated overpayment amount) that is designed to be less than the actual overpayment total 95 percent of the time.

With respect to Cigna’s comments that we are not authorized to extrapolate, we note that neither Federal statute nor any other authority limits our ability to recommend a recovery to CMS based on extrapolation. Extrapolation has long been recognized as a permissible method of calculating overpayments in Medicare. Further, Federal courts have consistently upheld statistical sampling and extrapolation as a valid means to determine overpayment amounts in

³⁵ For example, HHS has used the two-sided 90-percent confidence interval when calculating recoveries in both the Administration for Child and Families and Medicaid programs. See e.g., *New York State Department of Social Services*, HHS Departmental Appeals Board (DAB) No. 1358, 13 (1992); *Arizona Health Care Cost Containment System*, DAB No. 2981, 4-5 (2019). In addition, HHS contractors rely on the one-sided 90-percent confidence interval, which is less conservative than the two-sided interval, for recoveries arising from Medicare FFS overpayments. See e.g., *Maxmed Healthcare, Inc. v. Burwell*, 152 F. Supp. 3d 619, 634–37 (W.D. Tex. 2016), *aff’d*, 860 F.3d 335 (5th Cir. 2017); *Anghel v. Sebelius*, 912 F. Supp. 2d 4, 17-18 (E.D.N.Y. 2012).

Medicare and Medicaid.³⁶ The legal standard for use of sampling and extrapolation is that it must be based on a statistically valid methodology, not the most precise methodology.³⁷ We properly executed our statistical sampling methodology in that we defined our sampling frame and sample unit, randomly selected our sample, applied relevant criteria in evaluating the sample, and used statistical sampling software (i.e., RAT-STATS) to apply the correct formulas for the extrapolation. Thus, we did not revise the amount in our first recommendation based on Cigna's comments; rather, we revised the amount in response to the updated regulations that CMS published after we issued our draft report.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY DID NOT AGREE WITH THE OFFICE OF INSPECTOR GENERAL'S MEDICAL RECORD CODING REVIEW PROCESS

Cigna-HealthSpring Life & Health Insurance Company Did Not Agree With the Office of Inspector General's Use of Medicare Administrative Contractors

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna disagreed with our use of a Medicare Administrative Contractor (MAC) to identify HCCs that were at a high risk for noncompliance. Cigna stated that our "sampling methodology was arbitrary and relied on a source [a MAC] that lacks sufficient MA experience," and added that furthermore, "[n]o MAC is assigned to evaluate the MA risk adjustment system." Cigna stated that we did not: explain why a MAC was consulted, disclose the MAC that was consulted, or indicate the qualifications and level of expertise of the MAC medical professionals whom we consulted. Cigna described these considerations as indicative of a "lack of transparency" that prevented it from being able to evaluate the standards to which it and its contracted providers were being held.

Office of Inspector General Response

Cigna's assertions regarding our use of a MAC are not accurate. In order to accomplish our objective, we used a reasonable approach to identify diagnoses that were at higher risk for being miscoded. The MAC medical professionals whom we consulted advised us only on information that we had previously gathered from other sources, including information on some of the high-risk groups identified in this report. We did not ask the MAC professionals to

³⁶ See *Yorktown Med. Lab., Inc. v. Perales*, 948 F.2d 84 (2d Cir. 1991); *Illinois Physicians Union v. Miller*, 675 F.2d 151 (7th Cir. 1982); *Momentum EMS, Inc. v. Sebelius*, 2013 U.S. Dist. LEXIS 183591 at *26-28 (S.D. Tex. 2013), adopted by 2014 U.S. Dist. LEXIS 4474 (S.D. Tex. 2014); *Anghel v. Sebelius*, 912 F. Supp. 2d 4 (E.D.N.Y. 2012); *Miniet v. Sebelius*, 2012 U.S. Dist. ³⁷ See *John Balko & Assoc. v. Sebelius*, 2012 U.S. Dist. LEXIS 183052 at *34-35 (W.D. Pa. 2012), *aff'd* 555 F. App'x 188 (3d Cir. 2014); *Maxmed Healthcare, Inc. v. Burwell*, 152 F. Supp. 3d 619, 634-37 (W.D. Tex. 2016), *aff'd*, 860 F.3d 335 (5th Cir. 2017); *Anghel v. Sebelius*, 912 F. Supp. 2d 4, 18 (E.D.N.Y. 2012); *Miniet v. Sebelius*, 2012 U.S. Dist. LEXIS 99517 at *17 (S.D. Fla. 2012); *Transyd Enters., LLC v. Sebelius*, 2012 U.S. Dist. LEXIS 42491 at *13 (S.D. Tex. 2012).

provide opinions related to the MA risk adjustment process or to perform a coding review for the sampled enrollee-years; rather we relied only on our independent medical review contractor to perform the coding reviews. Thus, we do not believe that identifying the MAC would provide additional information that is relevant to our findings and recommendations.

Cigna-HealthSpring Life & Health Insurance Company Stated That Coding and Documentation Standards Used During the Audit Were Not Validly Established

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that the "coding and documentation standards" applied during our audit were not validly established through the notice-and-comment rulemaking process that is required by the Administrative Procedure Act³⁸ and more broadly by Medicare statute.³⁹ Cigna argued that "[t]he Supreme Court has explained that this [notice and comment] obligation is broad and is likely to invalidate many policies found only in the Medicare manuals." In addition, Cigna stated that "[a]s applied to this audit, the coding and documentation standards are offered as the difference between valid risk adjustment payments and alleged overpayments. The audit uses sub-regulatory standards" (i.e., policies found only in Medicare manuals) to determine whether any overpayments occurred. For these reasons, Cigna stated that our "potential reliance on these standards is improper."

Office of Inspector General Response

We disagree with Cigna's assertion that our reliance on the Manual to differentiate between a valid risk adjustment payment and an overpayment was improper. We designed our audit to comply with Federal requirements. Specifically, our audit methodology required that our independent medical review contractor review medical records to determine whether the diagnosis codes that Cigna submitted to CMS for risk-adjustment purposes were supported. With regard to Cigna's comment about *Azar v. Allina Health Services*, our reliance on the Manual does not constitute the creation of new payment rules. Rather, we have designed our audit to determine whether Cigna complied with Federal requirements.

Moreover, the Manual is legally binding on an MA organization, a fact that is based not only on regulation, but also on the organization's contract with CMS. Federal regulations state that MA organizations are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS for payment purposes and that such data must conform to all relevant national standards.⁴⁰ In addition, MA organizations that contract with CMS must agree to

³⁸ 5 U.S.C. § 553.

³⁹ 42 U.S.C. § 1395hh(a)(2) as acknowledged in *Azar v. Allina Health Services*, 139 S.Ct. 1804 (2019).

⁴⁰ 42 CFR §§ 422.504(l) and 422.310(d)(1).

follow CMS's instructions, including the provisions of the Manual.⁴¹ Cigna has agreed to operate in compliance with the Manual under the terms of its contract with CMS and is bound by the requirements of that contract, including any applicable provisions of the Manual.

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General Did Not Provide Any Information Regarding the Independent Medical Review Contractor and the Coding Standards Used for This Audit

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that it had concerns regarding our independent medical review contractor's review and that the review methodology was "[n]eedlessly [o]paque." With regard to these concerns, Cigna made several related points:

- Cigna stated that we should identify our independent medical review contractor so that Cigna can assess: (1) whether there is a conflict of interest, (2) the contractor's credentials, coding policies, procedures, and training, (3) consistency between this audit and prior work, and (4) the results of each level of medical review as well as any inter-rater reliability (IRR) reviews.⁴²
- Cigna stated that we did not provide the coding or documentation standards used by the independent medical review contractor. In this context, Cigna referred to "inconsistencies and variations" in the ICD-9-CM and ICD-10-CM coding guidelines (footnote 1) and added that we should identify the specific coding and documentation standards used to evaluate the high-risk groups of diagnoses.
- Cigna cited our report's discussion of multiple levels of reviews performed by our independent medical review contractor, and stated that Cigna received only the final medical review determinations. Cigna added that "the subjective nature of coding determinations" made it important for Cigna to be able to evaluate the results of each level of review.
- In addition, Cigna stated that it believed "that OIG's contractor went beyond assessing coding and questioned the clinical validity of providers' diagnostic statements . . . [because] the audit methodology indicate[d] that a physician was required to serve as a tie-breaker when at least one coder already determined a code to be supported."

⁴¹ 42 CFR § 422.504(a).

⁴² IRR reviews verify the accuracy of medical record decisions and identify the consistency of decisions between two reviewers.

Office of Inspector General Response

We do not agree with Cigna's comments that we should provide additional information about the independent medical review contractor and results of each level of the contractor's reviews. Specifically:

- It is not our practice to name our independent medical review contractor. However, our audit process includes measures to ensure that there are no conflicts of interest among the parties involved in the audit. The name of the independent medical review contractor would not provide information about the contractor's qualifications beyond what we state in this audit report. Furthermore, during the course of our audit, we informed Cigna that our medical reviews were performed by professional coders credentialed by the American Health Information Management Association (AHIMA) and the American Academy of Professional Coders (AAPC).⁴³ These coders were experienced in coding ICD-9-CM and ICD-10-CM diagnosis codes for hospital inpatient, outpatient, and physician medical records.

The independent medical review contractor's quality review process included IRR reviews along with additional supervisory review of case determinations. The quality review process identified and made corrections, if needed. We do not believe that providing the results of those internal IRR reviews would provide additional information, as the results of the quality review process are reflected in the coding determinations that serve as the bases for our findings.

- Our independent medical review contractor used the following coding and documentation standards: (1) the CMS-published Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance,⁴⁴ (2) 2011 ICD-9-CM Official Guidelines for Coding and Reporting,⁴⁵ (3) 2015 ICD-10-CM Official Guidelines for Coding and

⁴³ Our independent medical review contractor used senior coders all of whom possessed one or more of the following qualifications and certifications: Registered Health Information Technician (RHIT), Certified Coding Specialist (CCS), Certified Coding Specialist – Physician-Based (CCS-P), Certified Professional Coder (CPC), CPC – Instructor, and Certified Risk Adjustment Coder (CRC). RHITs have completed a 2-year degree program and have passed an AHIMA certification exam. AHIMA also credentials individuals with CCS and CCS-P certifications and the AAPC credentials both CPCs and CRCs. This information also appears in a footnote in Appendix A of both our draft and final reports.

⁴⁴ CMS, *Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance As of 9/27/2017*. Available online at <https://www.cms.gov/research-statistics-data-and-systems/monitoring-programs/medicare-risk-adjustment-data-validation-program/other-content-types/radv-docs/coders-guidance.pdf>. Accessed on Nov. 18, 2022.

⁴⁵ *ICD-9-CM Official Guidelines for Coding and Reporting Effective October 1, 2011*. Available online at https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf. Accessed on Nov. 18, 2022.

Reporting,⁴⁶ (4) the American Hospital Association (AHA), Coding Clinic for ICD-9-CM, and (5) the AHA Coding Clinic for ICD-10-CM and ICD-10-PCS.⁴⁷ We provided Cigna information regarding the coding guidelines and guidance during the course of our audit.

- As explained in our audit methodology (Appendix A), the coding review followed a specific process to determine whether there was support for a diagnosis code and the associated HCC. At the conclusion of this process, we used only the final coding review determination for each sampled enrollee-year to calculate overpayments or underpayments (if any). We provided Cigna the final coding review determinations for each sampled enrollee-year.
- The independent medical review contractor used both skilled coders and physicians (when necessary) to review medical record documentation in accordance with the relevant CMS guidance,⁴⁸ which states, “reviewers should evaluate all listed conditions for consistency within the full provider documentation” (emphasis added). The coders and physicians did not make clinical judgments, but rather applied coding rules to accurately assign applicable ICD codes that translated to HCCs. Physician input was not an assessment of clinical support; rather, it constituted an assessment of documented evidence in support of the assignment of diagnosis codes. We believe that the use of a physician to serve as the final decision maker (i.e., tiebreaker), was a reasonable method for determining whether the medical records adequately supported the reported diagnosis codes.

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General Used an Arbitrary Date Range That Prohibited Cigna From Submitting Documentation That Would Substantiate a Diagnosis

Cigna stated that our “narrowly defined documentation requirements conflicted” with our sampling methodology. Specifically, Cigna stated that we developed “parameters for when a diagnosis would be considered a high risk of noncompliance” but prohibited Cigna from submitting documentation from the same time periods as were contained within those parameters. Cigna also stated that because of this conflict, “records that would substantiate a diagnosis were not accept[ed] if outside of the narrow time frame of the audit.” Cigna offered

⁴⁶ ICD-10-CM Official Guidelines for Coding and Reporting FY 2015. Available online at <https://www.cdc.gov/nchs/data/icd/10cmguidelines-2015-updated-9-26-14.pdf>. Accessed on Nov. 18, 2022.

⁴⁷ The “PCS” acronym in the ICD-10-PCS refers to the Procedure Coding System, which is a medical classification coding system that tracks various health interventions taken by medical professionals. See also footnote 1.

⁴⁸ CMS, Contract-Level Risk Adjustment Data Validation, Medical Record Reviewer Guidance, for reviews 3/20/2019. Available online at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>. Accessed on Nov. 18, 2022.

examples of cases in which enrollees received diagnoses near the end of one calendar year and treatments or prescriptions the following calendar year. Cigna argued that “[t]his disregard of documentation and support for a diagnosis code based on an arbitrary date range . . . ignores the fact that for MA [enrollees] and their plan providers, the end of a calendar year does not change how providers deliver care.”

Office of Inspector General Response

Cigna incorrectly linked the methodology we used to develop the sampling frame with CMS’s medical record documentation requirements. As explained in Appendix C, our sampling methodology identified specific diagnoses that occurred only once during the service year along with other information that we took into consideration. Although the dates associated with this other information may have spanned consecutive calendar years, they helped us determine whether the identified diagnoses were at high risk for being miscoded. Thus, our sampling methodology has no correlation to CMS’s medical record documentation requirements.

With respect to the medical record documentation, CMS uses the diagnosis codes that the enrollee received for one calendar year (known as the service year) to determine HCCs and calculate risk scores for the following calendar year (known as the payment year). Accordingly, the medical record documentation that we considered for each enrollee-year involved only the service year associated with the scope of the audit (service years 2015 and 2016).

Cigna-HealthSpring Life & Health Insurance Company Stated That the Office of Inspector General Used Problematic Standards To Determine the Validity of Diagnoses

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna stated that OIG used “problematic and arbitrary” standards “to supplant its medical knowledge years later for that of . . . treating providers.” Cigna added that it knows of “no CMS guidance suggesting that the health status of [an enrollee] . . . is disproved solely by whether a provider prescribes a certain course of treatment or whether [an enrollee] elects to follow through with such treatment.” As an example, Cigna cited a sampled enrollee-year in which the individual had been diagnosed with prostate cancer and who had elected to undergo “watchful waiting with monitoring of his PSA levels.”⁴⁹ Cigna stated that “[i]dentifying such a diagnosis as unsupported was clinically inaccurate . . . and this finding results in OIG and its MAC consultant supplanting the member’s personal choices with their own.”

In addition, Cigna stated that we “ignored information regarding [enrollees] seeking care outside of the Medicare program.” For example, Cigna cited a sampled enrollee-year in which the individual “was diagnosed with and treated for prostate cancer in 2006, and continued to

⁴⁹ “Watchful waiting” involves closely watching a patient’s condition but not giving treatment unless symptoms appear or change.

be prescribed Lupron for his prostate cancer in 2016.”⁵⁰ In addition, the enrollee was obtaining followup care through the Department of Veterans Affairs (VA). Because this individual filled the prescription using a means other than the Cigna MA plan and “was obtaining oncology follow-up care through the VA, OIG invalidated the diagnosis.”

Office of Inspector General Response

We disagree with Cigna’s characterizations of the standards used during the medical review process. We used a reasonable approach to identify diagnoses that were at higher risk for being miscoded. This approach involved, among other things, discussions with medical professionals regarding the treatment of certain conditions; and used that information to identify enrollee-years with high-risk diagnosis codes. This sampling methodology has no correlation to the CMS medical record documentation requirements that our independent medical review contractor used to determine whether or not the diagnoses were supported.

For this audit, our objective was to determine whether selected high-risk diagnosis codes that Cigna submitted to CMS for use in CMS’s risk adjustment program complied with Federal requirements. For each of the sampled enrollee-years, we asked Cigna to provide up to five medical records of its choosing to support the reviewed HCC. We asked our independent medical review contractor to review all the medical records that Cigna provided to determine whether the information documented in the medical records supported any diagnoses that mapped to the reviewed HCC. During its review, the independent medical review contractor did not make clinical judgments, but rather used applicable coding and documentation standards to accurately assign the appropriate diagnosis codes that translate to HCCs.

With respect to Cigna’s example of the individual who had been diagnosed and treated for prostate cancer through the VA, the associated enrollee-year is one for which we reviewed the additional explanations provided by Cigna for this final report. Specifically, our independent medical review contractor reviewed the additional information that Cigna provided and determined that there was no documentation that the individual was being actively treated for prostate cancer, stating that “the patient had a radical prostatectomy in the past. There is no evidence of active cancer.”⁵¹

More generally, our audit does not supplant provider decision making or enrollee choice. We acknowledge that providers have choices in prescribing courses of treatment, and that enrollees also have choices regarding treatment, some of which are outside of the Medicare program. Nevertheless, Medicare requirements are clear that in order for a diagnosis code that has been submitted to CMS to be appropriately included in the calculation of the risk score, the diagnosis needs to be documented in, and supported by, an acceptable medical record.

⁵⁰ Lupron is a type of hormone therapy that doctors typically use in combination with other treatments to treat people with prostate cancer.

⁵¹ In a radical prostatectomy operation, the surgeon removes the entire prostate gland as well as some of the tissue around it.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY DID NOT CONCUR WITH THE OFFICE OF INSPECTOR GENERAL'S RECOMMENDATION TO PERFORM ADDITIONAL REVIEWS BEFORE OR AFTER THE AUDIT PERIOD

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna did not concur with our second recommendation—that it perform additional reviews to determine whether similar instances of high-risk diagnoses occurred before or after the audit period. According to Cigna, “MA regulations do not require the sort of audits that OIG recommends and do not require data perfection.” Cigna also stated that this recommendation holds MA organizations to standards that are “unknown, vague, and nonexistent.” Further, Cigna stated that if it “undertook an audit similar to OIG’s, it could not result in ‘risk adjustment payment integrity and accuracy’” because “a payment audit designed to target errors without considering and recognizing diagnoses that are supported but not previously submitted, does not ensure payment accuracy and is improper.”

Office of Inspector General Response

We do not agree with Cigna’s interpretation of the Federal requirements. Contrary to Cigna’s assertions, we maintain that our recommendation that Cigna review whether similar instances of high-risk diagnoses occurred before or after our audit period remains valid and conforms to the requirements specified in Federal regulations (42 CFR § 422.503(b)(4)(vi) (Appendix E)).

These Federal regulations state that MA organizations must “implement an effective compliance program, which must include measures that prevent, detect, and correct non-compliance with CMS’ program requirements.” Further, these regulations specify that Cigna’s compliance plan “must, at a minimum, include [certain] core requirements,” which include “an effective system for routine monitoring and identification of compliance risks . . . [including] internal monitoring and audits and, as appropriate, external audits to evaluate . . . compliance with CMS requirements and the overall effectiveness of the compliance program.” These regulations also require MA organizations to implement procedures and a system for investigating “potential compliance problems as identified in the course of self-evaluations and audits, correcting such problems promptly and thoroughly to reduce the potential for recurrence.” Thus, CMS has, through the issuance of these Federal regulations, assigned the responsibility for dealing with potential compliance issues to the MA organizations.

With respect to Cigna’s comments stating that audits like ours do not result in payment accuracy, we note that our findings are not indicative of the overall accuracy of diagnosis codes that Cigna submitted to CMS. We limited our audit and recommendations to certain diagnosis codes that we determined to be at high risk for being miscoded. We believe that the error rate identified in our audit (200 of 300 enrollee-years (see Appendix D)) demonstrates that Cigna has compliance issues that need to be addressed. These issues may extend to periods of time beyond our scope. Accordingly, we maintain the validity of our recommendation that Cigna

identify, for the high-risk diagnoses included in this report, similar instances of noncompliance that occurred before or after our audit period.

CIGNA-HEALTHSPRING LIFE & HEALTH INSURANCE COMPANY DID NOT CONCUR WITH THE OFFICE OF INSPECTOR GENERAL'S RECOMMENDATION THAT IT ENHANCE ITS EXISTING COMPLIANCE PROCEDURES

Cigna-HealthSpring Life & Health Insurance Company Comments

Cigna did not concur with our third recommendation—that it continue to examine its existing compliance procedures for diagnoses that are at high risk for being miscoded and enhance those procedures as necessary. Specifically, Cigna stated that it “has a strong and effective compliance program that is designed to comply with all relevant legal and regulatory requirements,” and that it had made numerous changes to its compliance program since 2015 and 2016. In addition, Cigna said that it has “put forth significant effort to educate providers regarding the appropriate use of some of the specific codes targeted by OIG in this audit.” Further, Cigna noted that in 2021, it underwent a CMS program audit that had no findings related to Cigna’s compliance program. Cigna also cited a recent OIG contract-level RADV audit (of another contract) that described Cigna’s policies and procedures as generally effective.⁵²

Cigna also stated that we made “potentially misleading statements” with regard to the Federal regulations that MA organizations are required to follow regarding compliance programs. Cigna said that it believed that we have “expanded [CMS’s] MA compliance program requirements” because we did not take into consideration that CMS gives MA organizations “broad discretion to design their own compliance and risk adjustment data accuracy programs,” and that MA organizations “are not held to a standard of guaranteeing the accuracy of the risk adjustment data that [are] submitted.”

Finally, Cigna stated that “[t]he fact that OIG identified supposedly unsupported diagnoses . . . does not indicate that Cigna’s compliance program is ineffective, particularly when measured by MA program guidance.”

Office of Inspector General Response

Cigna’s response implied that we opined on the effectiveness of its entire compliance program. That was not our intention or our focus for this audit. Rather, we limited our audit to selected diagnoses that we determined to be at high risk for being miscoded. Our audit revealed a significant error rate for some of these high-risk groups. Although a prior CMS program audit did not result in any findings, and although the OIG contract-level RADV audit—which had a different objective than this audit—found Cigna’s policies and procedures to be

⁵² *Medicare Advantage Compliance Audit of Diagnosis Codes That Cigna HealthSpring of Florida, Inc. (Contract H5410) Submitted to CMS*. Available online at <https://oig.hhs.gov/oas/reports/region3/31800002.pdf>. Accessed on Nov. 18, 2022. See also Appendix B of this report.

generally effective, we continue to believe that Cigna should enhance its compliance procedures with respect to these high-risk groups of diagnoses.

Moreover, although we acknowledge that CMS gives discretion to MA organizations when designing a compliance plan, Federal regulations also require MA organizations to implement procedures for "promptly responding to compliance issues as they are raised" and to "[correct] such problems promptly and thoroughly to reduce the potential for recurrence" (42 CFR § 422.503(b)(4)(vi)(G)). The continued improvement of Cigna's existing procedures and internal data quality reviews (based on the results of this audit) will assist Cigna in attaining better assurance with regard to the "accuracy, completeness and truthfulness" of the risk adjustment data that it submits in the future. Accordingly, we maintain that our third recommendation is valid.

APPENDIX A: AUDIT SCOPE AND METHODOLOGY

SCOPE

CMS paid Cigna \$2,140,237,283 to provide coverage to its enrollees for 2016 and 2017. We identified a sampling frame of 8,667 unique enrollee-years on whose behalf providers documented high-risk diagnosis codes during the 2015 and 2016 service years. Cigna received \$134,347,953 in payments from CMS for these enrollee-years for 2016 and 2017. We selected for audit 300 enrollee-years with payments totaling \$4,939,748.

The 300 enrollee-years included 30 acute stroke diagnoses, 30 acute heart attack diagnoses, 60 major depressive disorder diagnoses, 30 embolism diagnoses, 30 vascular claudication diagnoses, 30 lung cancer diagnoses, 30 breast cancer diagnoses, 30 colon cancer diagnoses, and 30 prostate cancer diagnoses. We limited our review to the portions of the payments that were associated with these high-risk diagnosis codes, which totaled \$720,395 for our sample.

Our audit objective did not require an understanding or assessment of Cigna's complete internal control structure, and we limited our review of internal controls to those directly related to our objective.

We performed audit work from August 2019 through April 2022.

METHODOLOGY

To accomplish our objective, we performed the following steps:

- We reviewed applicable Federal laws, regulations, and guidance.
- We discussed with CMS program officials the Federal requirements that MA organizations should follow when submitting diagnosis codes to CMS.
- We identified, through data mining and discussions with medical professionals at a MAC, diagnosis codes and HCCs that were at high risk for noncompliance. We also identified the diagnosis codes that potentially should have been used for cases in which the high-risk diagnoses were miscoded.
- We consolidated the high-risk diagnosis codes into specific groups, which included:
 - 74 diagnosis codes for acute stroke,
 - 38 diagnosis codes for acute heart attack,
 - 29 diagnosis codes for major depressive disorder,
 - 85 diagnosis codes for embolism,
 - 4 diagnosis codes for vascular claudication,
 - 24 diagnosis codes for lung cancer,

- 65 diagnosis codes for breast cancer
 - 20 diagnosis codes for colon cancer, and
 - 2 diagnosis codes for prostate cancer.
- We used CMS's systems to identify the enrollee-years on whose behalf providers documented the high-risk diagnosis codes. Specifically, we used extracts from CMS's:
 - Risk Adjustment Processing System (RAPS)⁵³ to identify enrollees who received high-risk diagnosis codes from a physician during the service years,
 - Risk Adjustment System (RAS)⁵⁴ to identify enrollees who received an HCC for the high-risk diagnosis codes,
 - Medicare Advantage Prescription Drug System (MARx)⁵⁵ to identify enrollees for whom CMS made monthly Medicare payments to Cigna, before applying the budget sequestration reduction, for the relevant portions of the service and payment years (Appendix C),
 - Encounter Data System (EDS)⁵⁶ to identify enrollees who received specific procedures, and
 - Prescription Drug Event (PDE) file⁵⁷ to identify enrollees who had Medicare claims with certain medications dispensed on their behalf.
- We interviewed Cigna officials to gain an understanding of: (1) the policies and procedures that Cigna followed to submit diagnosis codes to CMS for use in the risk adjustment program and (2) Cigna's monitoring of those diagnosis codes to identify and detect noncompliance with Federal requirements.
- We selected for audit a stratified random sample of 300 enrollee-years (Appendix C).

⁵³ MA organizations use the RAPS to submit diagnosis codes to CMS.

⁵⁴ The RAS identifies the HCCs that CMS factors into each enrollee's risk score calculation.

⁵⁵ The MARx identifies the payments made to MA organizations.

⁵⁶ The EDS contains information on each item (including procedures) and service provided to enrollees.

⁵⁷ The PDE file contains claims with prescription drugs that have been dispensed to enrollees through the Medicare Part D (prescription drug coverage) program.

- We used an independent medical review contractor to perform a coding review for the 300 enrollee-years to determine whether the high-risk diagnosis codes submitted to CMS complied with Federal requirements.⁵⁸
- The independent medical review contractor's coding review followed a specific process to determine whether there was support for a diagnosis code and the associated HCC:
 - If the first senior coder found support for the diagnosis code on the medical record, the HCC was considered validated.
 - If the first senior coder did not find support on the medical record, a second senior coder performed a separate review of the same medical record:
 - If the second senior coder also did not find support, the HCC was considered to be not validated.
 - If the second senior coder found support, then a physician independently reviewed the medical record to make the final determination.
 - If either the first or second senior coder asked a physician for assistance, the physician's decision became the final determination.
- We used the results of the independent medical review contractor to calculate overpayments or underpayments (if any) for each enrollee-year. Specifically, we calculated:
 - a revised risk score in accordance with CMS's risk adjustment program and
 - the payment that CMS should have made for each enrollee-year.
- We estimated the total overpayment made to Cigna during the audit period.

⁵⁸ Our independent medical review contractor used senior coders all of whom possessed one or more of the following qualifications and certifications: Registered Health Information Technician (RHIT), Certified Coding Specialist (CCS), Certified Coding Specialist – Physician-Based (CCS-P), Certified Professional Coder (CPC), CPC – Instructor, and Certified Risk Adjustment Coder (CRC). RHITs have completed a 2-year degree program and have passed an AHIMA certification exam. AHIMA also credentials individuals with CCS and CCS-P certifications and the AAPC credentials both CPCs and CRCs.

- We limited the total overpayment that we recommended for recovery to the sampled enrollee-years.⁵⁹
- We discussed the results of our audit with Cigna officials on February 28, 2022.

We conducted this performance audit in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

⁵⁹ Federal regulations at 42 CFR § 422.311 state: “the Secretary annually conducts RADV audits to ensure risk-adjusted payment integrity and accuracy.” Recovery of improper payments from MA organizations will be conducted in accordance with the Secretary’s payment error extrapolation and recovery methodologies. CMS may apply extrapolation to audits for payment year 2018 and subsequent payment years. 88 Fed. Reg. 6643, 6655 (Feb. 1, 2023).

APPENDIX C: STATISTICAL SAMPLING METHODOLOGY

SAMPLING FRAME

We identified Cigna enrollees who: (1) were continuously enrolled in Cigna throughout all of the 2015 or 2016 service year and January of the following year, (2) were not classified as being enrolled in hospice or as having end-stage renal disease status at any time during 2015 or 2016 or in January of the following year, and (3) received a high-risk diagnosis during 2015 or 2016 that caused an increased payment to Cigna for 2016 or 2017, respectively.

We presented the data for these enrollees to Cigna for verification and performed an analysis of the data included on CMS's systems to ensure that the high-risk diagnosis codes increased CMS's payments to Cigna. After we performed these steps, our finalized sampling frame consisted of 8,667 enrollee-years.

SAMPLE UNIT

The sample unit was an enrollee-year, which covered either payment year 2016 or 2017.

SAMPLE DESIGN AND SAMPLE SIZE

The design for our statistical sample comprised nine strata of enrollee-years. For the enrollee-years in each respective stratum, each individual received:

- an acute stroke diagnosis (that mapped to the HCC for Ischemic or Unspecified Stroke) on only one physician claim during the service year but did not have that diagnosis on a corresponding inpatient or outpatient hospital claim (1,399 enrollee-years);
- a diagnosis (that mapped to an Acute Heart Attack HCC) on only one physician or outpatient claim during the service year but did not have that diagnosis on a corresponding inpatient hospital claim either 60 days before or 60 days after the physician or outpatient claim (609 enrollee-years);
- a major depressive disorder diagnosis (that mapped to the HCC for Major Depressive, Bipolar, and Paranoid Disorders) on only one claim during the service year but did not have an antidepressant medication dispensed on his or her behalf (4,869 enrollee-years);
- a diagnosis (that mapped to an Embolism HCC) on only one claim during the service year but did not have an anticoagulant medication dispensed on his or her behalf (256 enrollee-years);

- a diagnosis related to vascular claudication (that mapped to the HCC for Vascular Disease) on only one claim during the service year (a diagnosis that had not been documented during the 2 years that preceded the service year), but had medication for neurogenic claudication dispensed on his or her behalf (442 enrollee-years);
- a lung cancer diagnosis (that mapped to the HCC for Lung and Other Severe Cancers) on only one claim during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments related to the lung cancer diagnosis administered within a 6-month period before or after the diagnosis (119 enrollee-years);
- a breast cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors) on only one claim during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments related to the breast cancer diagnosis administered within a 6-month period before or after the diagnosis (448 enrollee-years);
- a colon cancer diagnosis (that mapped to the HCC for Colorectal, Bladder, and Other Cancers) on only one claim during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis (243 enrollee-years); or
- a prostate cancer diagnosis (that mapped to the HCC for Breast, Prostate, and Other Cancers and Tumors), for an individual 74 years old or younger, on only one claim during the service year but did not have surgical therapy, radiation treatments, or chemotherapy drug treatments administered within a 6-month period before or after the diagnosis (282 enrollee-years).

The specific strata are shown in Table 3 on the following page.

Table 3: Sample Design for Audited High-Risk Groups

Stratum (High-Risk Groups)	Frame Count of Enrollee-Years	CMS Payment for HCCs in Audited High-Risk Groups	Sample Size
1 – Acute stroke	1,399	\$2,853,179	30
2 – Acute heart attack	609	1,121,163	30
3 – Major depressive disorder	4,869	11,853,541	60
4 – Embolism	256	638,640	30
5 – Vascular claudication	442	903,526	30
6 – Lung cancer	119	759,024	30
7 – Breast cancer	448	515,140	30
8 – Colon cancer	243	563,755	30
9 – Prostate cancer	282	329,439	30
Total	8,667	\$19,537,407	300

SOURCE OF RANDOM NUMBERS

We generated the random numbers with the OIG, Office of Audit Services (OAS), statistical software.

METHOD FOR SELECTING SAMPLE ITEMS

We sorted the items in each stratum by beneficiary identification number and then consecutively numbered the items in each stratum in the stratified sampling frame. After generating 300 random numbers according to our sample design, we selected the corresponding frame items for review.

ESTIMATION METHODOLOGY

We used the OIG, OAS, statistical software to estimate the total amount of overpayments to Cigna at the lower limit of the two-sided 90-percent confidence interval (Appendix D). Lower limits calculated in this manner are designed to be less than the actual overpayment total 95 percent of the time.

APPENDIX D: SAMPLE RESULTS AND ESTIMATES**Table 4: Sample Details and Results**

Audited High-Risk Groups	Frame Size	CMS Payment for HCCs in Audited High-Risk Groups (for Enrollee-Years in Frame)	Sample Size	CMS Payment for HCCs in Audited High-Risk Groups (for Sampled Enrollee-Years)	Number of Sampled Enrollee-Years With Unvalidated HCCs	Overpayment for Unvalidated HCCs (for Sampled Enrollee-Years)
1 – Acute stroke	1,399	\$2,853,179	30	\$66,086	29	\$62,466
2 – Acute heart attack	609	1,121,163	30	51,144	29	41,309
3 – Major depressive disorder	4,869	11,853,541	60	143,843	3	7,247

Upper Limit	\$7,548,502

**APPENDIX E: FEDERAL REGULATIONS REGARDING COMPLIANCE PROGRAMS
THAT MEDICARE ADVANTAGE ORGANIZATIONS MUST FOLLOW**

Federal regulations (42 CFR § 422.503(b)) state:

Any entity seeking to contract as an MA organization must

(4) Have administrative and management arrangements satisfactory to CMS, as demonstrated by at least the following

(vi) Adopt and implement an effective compliance program, which must include measures that prevent, detect, and correct non-compliance with CMS' program requirements as well as measures that prevent, detect, and correct fraud, waste, and abuse. The compliance program must, at a minimum, include the following core requirements:

(A) Written policies, procedures, and standards of conduct that—

- (1) Articulate the organization's commitment to comply with all applicable Federal and State standards;
- (2) Describe compliance expectations as embodied in the standards of conduct;
- (3) Implement the operation of the compliance program;
- (4) Provide guidance to employees and others on dealing with potential compliance issues;
- (5) Identify how to communicate compliance issues to appropriate compliance personnel;
- (6) Describe how potential compliance issues are investigated and resolved by the organization; and
- (7) Include a policy of non-intimidation and non-retaliation for good faith participation in the compliance program, including but not limited to reporting potential issues, investigating issues, conducting self-evaluations, audits and remedial actions, and reporting to appropriate officials

(F) Establishment and implementation of an effective system for routine monitoring and identification of compliance risks. The

system should include internal monitoring and audits and, as appropriate, external audits, to evaluate the MA organization, including first tier entities', compliance with CMS requirements and the overall effectiveness of the compliance program.

- (G) Establishment and implementation of procedures and a system for promptly responding to compliance issues as they are raised, investigating potential compliance problems as identified in the course of self-evaluations and audits, correcting such problems promptly and thoroughly to reduce the potential for recurrence, and ensure ongoing compliance with CMS requirements.
- (1) If the MA organization discovers evidence of misconduct related to payment or delivery of items or services under the contract, it must conduct a timely, reasonable inquiry into that conduct.
 - (2) The MA organization must conduct appropriate corrective actions (for example, repayment of overpayments, disciplinary actions against responsible employees) in response to the potential violation referenced in paragraph (b)(4)(vi)(G)(1) of this section.
 - (3) The MA organization should have procedures to voluntarily self-report potential fraud or misconduct related to the MA program to CMS or its designee.

Re: Response to Draft Report Number: A-07-19-01192

Cigna HealthSpring Life & Health Insurance Company, Inc. ("Cigna") appreciates the opportunity to respond to the Draft Report provided by the U.S. Department of Health and Human Services Office of Inspector General ("OIG") in connection with the Medicare Advantage Compliance Audit of Specific Diagnosis Codes that Cigna (contract H4513) Submitted to CMS.^{1/} Through contract H4513, Cigna provides healthcare and prescription drug benefits to more than 115,000 Medicare Advantage ("MA") beneficiaries in Texas.

We are a committed partner to OIG, the Centers for Medicare & Medicaid Services ("CMS"), and the MA program. We believe the MA program serves Medicare beneficiaries so well because of the partnership between CMS and MA organizations ("MAOs") like Cigna. In the spirit of that partnership, we previously shared details regarding our risk adjustment policies, procedures, and practices with CMS a number of times over the course of many years. CMS has not instructed us that we are required to make any changes to our risk adjustment program.

We believe that the basic premise of OIG's audit is inconsistent with risk adjustment data validation regulations and CMS standards for data accuracy. OIG's sampling methodology targeted diagnoses that were already suspected to not be supported and did not include looking for unreported, unrelated diagnoses. OIG ignored the fact that there may be supported diagnoses not submitted to CMS.

^{1/} OIG, DRAFT – Medicare Advantage Compliance Audit of Specific Diagnosis Codes that Cigna -HealthSpring Life & Health Insurance Company, Inc. (Contract H4513) Submitted to CMS, A-07-19-01192 (April 2022) ("Draft Report").

As a result, OIG's audit was skewed toward identifying "overpayments" and was not an unbiased audit seeking to promote payment integrity and accuracy.

We believe these issues affected the audit results. In particular, we do not believe the audit results reflect the strength of Cigna's compliance activities. Cigna has a strong and effective compliance program that is designed to comply with all relevant legal and regulatory requirements. Cigna's current compliance program recently received positive feedback from both CMS and OIG. In Cigna's contract-level RADV audit of H5410 in 2021, OIG observed that Cigna "ha[s] a compliance program to ensure that [it] submitted accurate diagnosis codes for use in CMS' risk adjustment program" and that our "policies and procedures [are] generally effective." Also in 2021, Cigna underwent a CMS Program Audit and there were no findings related to the effectiveness of Cigna's compliance program.

As we describe in detail below, Cigna requests that OIG revise its Draft Report and withdraw its recommendations. We stand ready to work collaboratively with OIG, CMS, and other stakeholders to address the attached response together in an open, cooperative, and transparent way. We would appreciate the opportunity to meet prior to the finalization of the Draft Report to discuss our feedback and how it might be incorporated into the Final Report.

Thank you for your consideration.

Sincerely,

Thomas A. Young
Medicare Compliance Officer

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

EXECUTIVE SUMMARY

Cigna appreciates the opportunity to respond to the Draft Report provided by OIG. Through contract H4513, Cigna provides healthcare and prescription drug benefits to more than 115,000 MA beneficiaries in Texas.

We believe that the basic premise of OIG's audit is inconsistent with risk adjustment data validation ("RADV") regulations and CMS standards for data accuracy and that the audit methodology was flawed. These issues affected the audit results.

- OIG's audit was skewed toward identifying "overpayments" and was not an unbiased audit seeking to ensure payment integrity and accuracy.
- OIG's sampling methodology targeted diagnoses that were already suspected to not be supported and the review did not include looking for unreported, unrelated diagnoses. This type of biased review cannot produce a comprehensive picture of accuracy because it deliberately ignores the fact that there may be supported diagnoses not submitted to CMS.
- The audit methodology shared with us does not discuss how OIG and its contractor identified or evaluated potential underpayments. In general, the overall intent of MAO payment audits is to determine whether the MAO has been accurately paid. However, targeting nine specific diagnoses to the exclusion of anything that had previously not been submitted, artificially inflates the proposed "overpayment." OIG should have considered the previously unreported diagnosis codes when considering and calculating its proposed "overpayment."
- The flaws in OIG's audit methodology are evidenced by the fact that no MAO has performed well during any of the audits targeting high-risk diagnoses. Even MAOs like Cigna, that have had very high accuracy ratings in contract-level RADVs, have scored much lower because of many flaws in the methodology. In fact, OIG shared that Cigna's performance is in the "upper echelon" of MAOs under review in this audit series.
- We believe that 6 of the sampled enrollee-years that OIG and its contractor did not validate should have been validated under the applicable statutes, regulations, and CMS guidance. Our review also indicates that OIG and its contractor did not capture 19 previously unreported diagnoses that accurately reflect our enrollees' health status.
- OIG determined whether a diagnosis was at high-risk for noncompliance and was valid based on what a provider decided to recommend to a member, whether a member decided to seek recommended treatment within an OIG-defined period of time, and where or how a member sought treatment. This is inherently problematic and arbitrary. By applying these arbitrary standards of medical practice and "health status," OIG supplants its medical knowledge for that of members' treating providers and in turn applies arbitrary payment standards to Cigna.
- OIG's narrowly defined documentation timing standards conflicted with its sampling methodology. Specifically, OIG included members' diagnoses in its sample based on whether a provider recommended and a member followed up with treatment within an OIG-defined period of time. But, when OIG's defined period of time for treatment (for example, 6 months after a cancer diagnosis) fell outside of the audit time (2015 and 2016 dates of service), OIG refused to

i

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

consider documentation outside of the audit time, even if the records were from a patient visit two or three days removed from when the original diagnosis was reached. By rigidly adhering to an artificially limited time period, and refusing to consider records from subsequent visits based solely on how the calendar fell, OIG improperly limited Cigna's ability to offer substantiating proof.

- OIG's extrapolation of potential overpayments is not appropriate or authorized by Congress.

In addition to these flaws in the OIG's audit methodology, Cigna does not agree with OIG's recommendation to conduct additional audits related to the high-risk diagnoses and Cigna does not agree with OIG's recommendation that Cigna examine existing compliance procedures.

For these reasons, discussed in greater detail below, we respectfully request OIG recalculate its estimated overpayment amount to account for these errors and withdraw its recommendations for extrapolation, additional auditing, and compliance program review.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

I. Cigna Does Not Concur with OIG's Findings Because the Audit Design and Intent is Inconsistent with RADV Regulations and Standards for Data Accuracy.

We respectfully request that OIG withdraw its findings given that its overall audit design and intent are inconsistent with risk adjustment data validation regulations and CMS standards for data accuracy. Specifically, (a) OIG's audit does not ensure payment accuracy; (b) OIG's sampling and review methodology was improperly skewed toward identifying "overpayments"; (c) OIG ignores the long-standing principle that MAOs are not required to have perfect data; and (d) OIG fails to recognize that perfection in risk adjustment data is not possible.

a. OIG's Audit Does Not Ensure Payment Accuracy

MA regulations at 42 C.F.R. §§ 422.2 and 422.311(a) establish that a payment audit of an MAO conducted by the Secretary of HHS ensures the integrity and accuracy of risk adjustment payment data. Over the last fifteen years, CMS has developed and proposed multiple audit and sampling methodologies and has undergone multiple rounds of industry engagement, in an attempt to establish a sampling methodology that ensures payment integrity and accuracy. However, OIG's audit was not designed to ensure risk adjustment payment integrity and accuracy.

OIG's audit methodology was so targeted that it could not equally identify overpayments and underpayments. In particular, the sample frame targeted nine specific diagnosis categories that OIG hypothesized, prior to conducting the audit, are likely to be at high risk for noncompliance based on medical claims data and prescription drug claims data, and therefore likely to have resulted in an "overpayment." This biased targeting resulted in findings that do not ensure accuracy because the audit was not designed to look at payment accuracy, which would include both overpayments and underpayments. OIG neither (1) simultaneously conducted an audit of members for which Cigna was most likely underpaid (i.e., members with no or few submitted HCCs), nor (2) allowed Cigna to demonstrate support for and receive credit for diagnosis codes that had not previously been submitted to CMS for the audited members that were unrelated to the target diagnosis codes ("net new").

These issues affected the audit results. In our view, the issues indicate that OIG's audit methodology is not sufficiently designed to identify underpayments, and, as a consequence, does not appear to generate a statistically valid "net" overpayment figure for the audit sample. And, as discussed in more detail below, this reinforces our concern that the proposed overpayment figure used by OIG cannot be an adequate basis for a valid extrapolation.

The flaws in OIG's targeted audit methodology are evidenced by the fact that no MAO has performed well during any of the audits targeting high-risk diagnoses. Even MAOs like Cigna, which recently completed a contract-level RADV audit of H5410 that resulted in a 97% payment accuracy rate finding, are scoring much lower because of the flawed audit methodology. In fact, OIG shared that Cigna's performance is in the "upper echelon" of MAOs under review in this audit series. Further, it indicates that if OIG's targeted audit was designed for payment accuracy, as required by 42 C.F.R. § 422.311(a), then the findings would be different and would be a much more accurate reflection of the MAO's risk adjustment data validation.

Finally, the timing of the audit also makes payment accuracy unachievable as a practical matter. This audit covered dates of service in 2015 and 2016. The five and six year gap between the encounters at issue and the audit creates a significant data validation issue for Cigna. Providers may have moved, left our network, retired, or passed away. Paper records may have been lost. Electronic health record (EHR)

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

systems may have been upgraded or replaced, making older electronic records harder or impossible to access. Facilities and other practices may not cooperate with requests seeking records from that far in the past (and they face no realistic sanction for deciding they cannot or do not wish to cooperate). These and similar practical realities make it impossible for OIG to assess payment accuracy via a RADV-styled audit of targeted high-risk diagnoses.

b. *OIG's Sampling and Review Methodology was Improperly Skewed Towards Identifying "Overpayments"*

i. Sampling Methodology

OIG's sampling methodology targeted diagnoses that were already suspected to not be supported and as a result, OIG's audit was not an unbiased audit seeking to promote payment integrity and accuracy. OIG's audit was first biased towards overpayment by creating a universe of members who had only certain diagnoses, then OIG and a Medicare Administrative Contractor ("MAC") (as discussed below) limited that universe to instances where such diagnoses did not have evidence of Medicare-reimbursed follow-up care which the OIG determined to be an indication that the diagnosis was at high-risk of noncompliance, and then identified a sample from that limited universe. OIG only focused on samples that it viewed to be high-risk diagnoses so that it could only identify a potential overpayment. OIG did not simultaneously create a sample of members for whom it would seek to identify under-reported diagnoses or underpayments. As a result, OIG skewed any potential findings to only identify overpayments and exclude all other diagnoses.

Further, OIG's development of its sampling methodology was arbitrary and relied on a source that lacks sufficient MA experience. OIG relied on medical professionals from a MAC to identify HCCs that were at a high risk for noncompliance.^{2/} As CMS describes, "a MAC is private health care insurer that

/ MACs do not process MA claims or encounter data.

MACs are assigned to CMS-established jurisdictions, and there are currently 12 MACs that focus on Parts A and B FFS claims. No MAC is assigned to evaluate the MA risk adjustment system. OIG did not explain why it consulted a MAC, disclose the MAC it consulted, indicate whether the MAC it consulted had expertise to assist OIG in determining which diagnoses submitted by an MA plan may be "high risk for noncompliance," or disclose the type of or qualifications of medical professionals employed by the MAC that OIG relied upon. This lack of transparency results in Cigna being unable to evaluate how the standards it, and its contracted treating providers, are being held to, were developed or the qualifications of the entity developing such standards. Further, given that MACs have expertise in identifying potential errors in FFS data, OIG's reliance on a MAC and its recognition of a MAC's familiarity with FFS errors further

^{2/} See Draft Report, Appendix A: Audit Scope and Methodology, page 19.

^{3/} See CMS, "What's a MAC?" at [https://www.cms.gov/Medicare/Medicare-Contracting/Medicare-Administrative-Contractors/What-is-a-MAC#:~:text=A%20Medicare%20Administrative%20Contractor%20\(MAC,%20Service%20\(FFS\)%20beneficiaries](https://www.cms.gov/Medicare/Medicare-Contracting/Medicare-Administrative-Contractors/What-is-a-MAC#:~:text=A%20Medicare%20Administrative%20Contractor%20(MAC,%20Service%20(FFS)%20beneficiaries).

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

underscores the need for a FFS Adjuster. But as discussed below in *Section II.e*, OIG did not apply a FFS Adjuster to any of its findings.

In addition, OIG's sampling methodology arbitrarily used the lack of Medicare prescription drug data or a member's decision to not seek follow up care that was evidenced in Medicare data within an OIG-invented timeframe to flag diagnoses as being at high risk for noncompliance. By developing and applying this sampling methodology, OIG was replacing its clinical expertise for that of members' treating providers. Further, OIG's reliance on the lack of Medicare prescription drug data to flag and potentially invalidate a provider-reported diagnosis stands in stark contrast to MA risk adjustment rules, which do not recognize pharmacies and prescription drug data as acceptable sources for risk adjustment data.

ii. Review Methodology

OIG's review of medical records was also skewed to only identify overpayments. Once OIG identified the sample of members that it considered to have the targeted high-risk diagnoses, OIG's reviewers only reviewed the limited acceptable medical records for such members for evidence of the targeted high-risk diagnosis or a related diagnosis. OIG ignored the fact that for each identified member, there may be supported diagnoses not previously submitted to CMS (i.e., "underpayments"), creating additional bias toward identifying "overpayments." As OIG is aware, an MAO cannot reopen payment years to add diagnoses that it determines were not previously reported. The payment years subject to this audit were closed multiple years ago. By OIG limiting its review to only instances of potential "overpayments," OIG knew that Cigna would be unable, on its own, to demonstrate that it was not in fact "overpaid" because Cigna is not able to submit diagnoses identified in 2021 as support for dates of services in 2015 and 2016. The only way for Cigna to be credited for such previously unreported codes, and for this audit to ensure payment accuracy, is for OIG to take such diagnoses into account.

We also note that the medical record review was not limited to coding and documentation issues. Instead, it incorporated a review of the clinical validity of the provider's diagnosis. CMS requires that plans only be responsible for the accuracy of the coding of the diagnosis as provided by a practitioner.^{4/} The ICD Guidelines and American Hospital Association (AHA) Coding Clinic similarly state that coders do not have the ability or authority to question a provider's diagnostic statement, as documented.^{5/} For that reason, CMS has not permitted the certified coders conducting its medical record reviews to attempt to assess the clinical validity of diagnoses.^{6/} Unfortunately, we believe that OIG's contractor went beyond assessing coding and questioned the clinical validity of providers' diagnostic statements. For instance, the audit methodology indicates that a physician was required to serve as a tie-breaker when at least one coder already determined a code to be supported. The fact that a practitioner submitted the code to the MAO

^{4/} 65 Fed. Reg. 40170, 40251 (June 29, 2000) ("we have restricted the attestation requirement to confirmation of the completeness of the data and the accuracy of coding.") CMS also has refused on a number of occasions to specific clinical criteria for particular diagnoses. See *supra* n.30.

^{5/} ICD-10-CM Official Guidelines for Coding and Reporting, 13 (2019) ("[A]ssignment of a diagnosis code is based on the provider's diagnostic statement that the condition exists. The provider's statement that the patient has a particular condition is sufficient."); AHA Coding Clinic, *Ask the Editor* (2016) ("Coders should not be disregarding physician documentation and deciding on their own, based on clinical criteria, abnormal test results, etc., whether or not a condition should be coded.")

^{6/} CMS, *Statement of Work for the Recovery Audit Program*, 23 (2011) ("[C]ertified coders shall ensure they are not looking beyond what is documented by the physician. ... Clinical validation is beyond the scope of [a coding] validation, and the skills of certified coder.")

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

and at least one coder found it to be supported should not require a physician tie-breaker unless that physician was questioning the clinical validity of the provider's diagnostic statements.^{7/}

Further, in direct conflict with the Coding Guidelines and the Coding Clinic, as discussed in Section II.c.v, OIG's review methodology was specifically designed to question a provider's diagnostic statement, as documented, because OIG's methodology was clinically targeted to determine whether a given member was prescribed or received care that OIG determined should have been provided.

c. OIG Disregards that MAOs Are Not Required to Have Perfect Data

The perfection standard posited by the Draft Report reflects either a misunderstanding of CMS regulations or a rejection of the data standards set by CMS. For instance, the Draft Report cites 42 C.F.R. § 422.504(f) in taking the position that MA organizations "are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS." Importantly, however, the attestation referred to in the Draft Report and defined by subsection 422.504(f) is limited to the plan's "best knowledge, information and belief." CMS included this limitation to "allow for honest mistakes and unavoidable margins of error"^{8/} and "in recognition of the fact that [MA organizations] cannot reasonably be expected to know that every piece of data is correct."^{9/} CMS also recognized at the time that "it would be unfair and unrealistic to hold [MA organizations] to a '100 percent accuracy' certification standard."^{10/} CMS has since reiterated that there is no requirement "to verify every diagnosis submitted by every provider."^{11/} OIG, itself, also has recognized that an MA organization's attestation "does not constitute an absolute guarantee of accuracy."^{12/}

The Draft Report also cites 42 C.F.R. § 422.503(b)(vi), which requires organizations to adopt an "effective" compliance program, to suggest that because OIG concluded that some HCCs were not valid, Cigna should evaluate its compliance program to ensure compliance with 42 C.F.R. § 422.503(b)(vi). Perfection is not required in order for a compliance program to be "effective." OIG has "recognize[d] that the implementation of an effective compliance program may not entirely eliminate fraud, abuse and waste from an organization."^{13/}

^{7/} Because the information has not been provided to date, we do not know how many records were subject to physician review during this audit. However, a recent report regarding another MA organization indicated that the physician reviewed the medical records related to approximately 10% of the audit sample. See OIG, *Medicare Advantage Compliance Audit of Diagnosis Codes that Humana, Inc. (Contract H1036) Submitted to CMS, A-07-16-01165*, 15 n.14 (Apr. 2021).

^{8/} 65 Fed. Reg. 40170, 40250 (June 29, 2000).

^{9/} *Id.* at 40268.

^{10/} *Id.*

^{11/} 79 Fed. Reg. 29843, 29925 (May 23, 2014).

^{12/} 64 Fed. Reg. at 61900. The draft report also appears to suggest that perfection is required by 42 C.F.R. § 422.310(d)(1), which states that MA organizations "must submit data that conform to CMS' requirements for data equivalent to Medicare fee-for-service data, when appropriate, and to all relevant national standards." That regulation, however, does not relate to data validation. That rule refers to the "national standards" that define the format used by providers to submit claims in the FFS program. See 63 Fed. Reg. 34968, 35006 (June 26, 1998) ("The format of the data we will require will be identical to the data we require of original Medicare providers..."); see also *id.* at 35007 (directing the use of the HCFA 1500 paper form or the electronic UB-92).

^{13/} 64 Fed. Reg. 61893, 61895 (Nov. 15, 1999). See also United States Sentencing Manual § 8B2.1(a) ("The failure to prevent or detect the instant offense does not necessarily mean that the program is not generally effective in preventing and detecting criminal conduct."); Application Note 2(A)(i) ("effectiveness" must be assessed based on "a applicable industry practice or the standards called for by any applicable governmental regulation"). We are not aware of OIG ever having indicated that an "effective" compliance program in any context needs to or is required to achieve perfection. Cf. Fed. Reg. 23731, 23732 (May 5, 2003) ("The OIG recognizes that the implementation of a compliance program may not entirely eliminate improper conduct from

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

A perfection standard also would conflict with the "same methodology" requirement in 42 U.S.C. § 1395w-23(b)(4)(D). This provision mandates CMS calculate risk adjustment payments in the MA program using the "same methodology" as when calculating the average risk factor for the FFS program. CMS does not audit the FFS data it uses to establish the average FFS risk score using the RADV documentation standards; it, therefore, accepts that those data contain significant errors. Similarly, as discussed in greater detail below in connection with the extrapolation methodology used to prepare the Draft Report, a perfection standard also would violate the actuarial equivalence requirement in 42 U.S.C. § 1395w-23(a)(1)(C)(i).^{14/} Finally, we note that the federal courts uniformly decline to require perfection as a standard of measure in the Medicare program.^{15/}

d. Perfection in Risk Adjustment Is Not Possible.

The perfection standard reflected in the Draft Report also is inconsistent with the realities and limitations of attempting to perform a risk adjustment function. As CMS has recognized, risk adjustment data "come into [MAOs] in great volume and from a number of sources."^{16/} In particular, an overwhelming majority of the risk adjustment data for our Texas contract (more than 64%) were submitted by the healthcare providers that treated our enrolled beneficiaries. Although we do make coding and documentation training available to those providers, we ultimately cannot control their submissions.

In addition, coding and documentation disagreements are inevitable and often arise from factors outside the control of any MAO. Diagnosis coding is an inherently subjective process and there often are substantial differences in interpretation and opinion among health care practitioners and certified coders regarding a broad array of coding issues. CMS generally does not require providers to use any particular diagnostic or clinical criteria and allows providers to use their best professional judgment.^{17/} OIG is aware of these differences in interpretation as evidenced by its review methodology that included multiple reviewers for coding disagreements. "One study examining coding variation found that when 11 experienced, active medical coders reviewed 471 medical records and were told they would be reevaluated, all of the coders differed in one or more data fields for more than half of the records."^{18/} In addition, the coding standards (which have never gone through notice and comment) are often vague and ambiguous and the source of variable coding throughout the health care industry.^{19/}

the operations of a pharmaceutical manufacturer."); 70 Fed. Reg. 4858, 4859 (Jan. 31, 2005) ("The OIG recognizes that implementation of a compliance program may not entirely eliminate improper or unethical conduct from the operations of health care providers.").

^{15/} See, e.g., *U.S. ex rel. Janssen v. Lawrence Mem. Hosp.*, 949 F.3d 533, 543-44 (10th Cir. 2020) (citing *U.S. ex rel. Conner v. Salina Reg. H. Ctr.*, 543 F.3d 1211, 1220-21 (10th Cir. 2008)); *U.S. ex rel. Wilkins v. United Health Group, Inc.*, 559 F.3d 295, 310 (3d Cir. 2011).

^{16/} 65 Fed. Reg. at 40528.

^{17/} See, e.g., 75 Fed. Reg. at 73401 ("We believe that physicians can use their best clinical judgment in the detection and diagnosis of cognitive impairments...."); 76 Fed. Reg. at 73308 (similar quote).

^{18/} Kimberly O'Malley, *Measuring Diagnoses: ICD Code Accuracy*, 40 Health Serv. Res. 1620 (2005).

^{19/} For instance, in a series of prior audits, OIG identified Kwashiorkor as a condition that had been frequently miscoded. OIG, *CMS Did Not Adequately Address Discrepancies in the Coding Classification for Kwashiorkor*, A03-14-00010 (Nov. 2017) ("We reviewed the medical records for 2,145 inpatient claims at 25 providers and found that all but 1 claim incorrectly included the diagnosis code for Kwashiorkor...."). OIG determined that the root cause of this problem was an ambiguity in the ICD guidelines adopted by CMS. See *Id.* ("The ICD-CM coding classification contained a discrepancy between the tabular list and the alpha index on the use of diagnosis code 260. In the alpha index, four other malnutrition diagnoses corresponded to diagnosis code 260, but in the tabular list, diagnosis code 260 was only for Kwashiorkor.").

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

We do not think it is correct to automatically conclude that a diagnosis is unsupported if the relevant medical record is missing. When a provider submits a diagnosis code, that submission is evidence that the provider in fact made the relevant diagnosis. We agree that MAOs should be required to make a good faith effort to locate the relevant records. However, when the record cannot be obtained from the provider through reasonable diligence, particularly after a significant period of time has elapsed, the absence of the record is not, in our view, a sufficient basis to reject a diagnosis code submitted by a provider.^{20/}

Additionally, obtaining medical records from providers is often very challenging. For many of our provider partners who seek to provide such records, responding to medical record requests for visits that occurred five to six years prior can be administratively burdensome, and such burden has been further exacerbated by the COVID-19 public health emergency and staff shortages. For MAOs, the consolidation of hospital systems and large provider groups and the increasing number of providers who are publicly traded or private investor-backed has led to some large groups and health systems refusing to respond to records requests in a timely fashion, if at all, especially when they know that an MAO requires their participation in certain areas to satisfy network adequacy requirements. MAOs have very little leverage, and almost no recourse, when providers do not provide the medical records requested, even though the consequence of a provider's lack of cooperation is significant for the MAO, as is demonstrated by the Draft Report.

OIG designed and conducted an audit that was inconsistent with RADV regulations and CMS standards for data accuracy. By not focusing on payment accuracy and reviewing for both "overpayments" and "underpayments," OIG skewed any potential results towards identifying "overpayments." Further, OIG ignored long-standing principles that perfection in risk adjustment data is not possible and MAOs are not required to have perfect data. For these reasons, we respectfully request OIG withdraw its findings and reconsider its audit design and methodology.

II. Cigna Does Not Concur with OIG's Estimated and Extrapolated Repayment Amount and Respectfully Requests OIG Recalculate to Address Errors in OIG's Analysis of Certain Enrollee-Years, Remove The Impact of Underlying Biases, and Ensure Actuarial Equivalence

We respectfully request OIG withdraw its recommended repayment amount and recalculate it, when possible, to (a) address errors in OIG's analysis of certain enrollee-years; (b) include previously unreported diagnoses; (c) remove the impact of underlying biases; and (c) ensure actuarial equivalence.

a. OIG's Recommended Repayment Amount is Incorrect Because Certain Sample Enrollee-years that OIG Found to be Unsupported are Supported by Documentation in the Relevant Medical Records

^{20/} Because RADV audits are not defined by statute, the Administrative Procedure Act (APA) places the burden on OIG to advance an adequate basis to overturn CMS's risk adjustment payments. See 5 U.S.C. § 556(d) ("Except as otherwise provided by statute, the proponent of a rule or order has the burden of proof."); see also *DWCP v. Greenwich Collieries*, 512 U.S. 267, 276 (1994) ("the drafters of the APA used the term 'burden of proof' to mean the burden of persuasion"); *Steadman v. SEC*, 450 U.S. 91, 95 (1981) (APA defines "the degree of proof which must be adduced by the proponent of a rule or order to carry its burden of persuasion in an administrative proceeding").

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

We believe that 6 of the sampled enrollee-years that OIG and its contractor did not validate should have been validated under the applicable statutes, regulations, and CMS guidance. Discussions of these enrollee-years are attached at Exhibit A. Please note that these exhibits contain protected health information and are not eligible for public disclosure.

b. OIG's Recommended Repayment Amount is Incorrect Because It Does Not Consider Previously Unreported Diagnoses

Similarly, our review indicates that OIG and its contractor did not capture 19 other previously unreported diagnoses that accurately reflect our enrollees' health status. This includes diagnoses that are related to the targeted high-risk categories and some that are unrelated. A list of these enrollee-years are attached at Exhibit B. Though documented, OIG did not validate any of these diagnosis codes.

For a number of reasons, discussed above, we are concerned that the audit methodology was not structured to equally identify both overpayments and underpayments. In particular, the audit methodology shared with us does not discuss how OIG and its contractor identified or evaluated potential underpayments, including the additional diagnoses we identified in our review. In general, the overall intent of payment audits is to determine whether the MAO has been paid accurately. However, targeting nine specific diagnoses to the exclusion of anything that previously had not been submitted artificially inflates the proposed "overpayment." When calculating a proposed "overpayment" amount, OIG should have sought to determine accuracy, which must offset any proposed "overpayments" by underpayments.

c. OIG's Review Methodology was Needlessly Opaque and Did Not Adequately Identify the Independent Medical Review Contractor or the Coding and Documentation Standards Applied during the Medical Record Review. OIG Should Update its Draft Report to Include Additional Information Regarding its Medical Record Review.

i. OIG did not provide information regarding its independent medical review contractor or the credentials of reviewers.

We request that OIG provide additional information regarding its review. For example, OIG has not identified the "independent medical record review contractor." Given the importance of this audit, we believe we have the right to know who is performing the review so we can evaluate whether there is a conflict of interest, assess the contractor's credentials, coding policies, procedures, and training, and see if the positions taken are consistent with prior work undertaken by the contractor, or statements made by it.

Further, Cigna received only the "final" determination by the medical record review contractor. The Draft Report indicates, however, that there were two or three levels of review. We believe it is important for us to be able to evaluate the results at each level, as the subjective nature of coding determinations would be revealed by differing conclusions among contractor personnel. It also does not appear the individuals conducting each level of review were consistently subject to inter-rater reliability ("IRR") (which we believe to be a standard practice in CMS audits). If they were subject to IRR, we should have the ability to evaluate the results of such reviews. We believe these issues affect our appeal rights under 42 C.F.R. § 422.311 and should be disclosed pursuant to the Data Quality Act and generally accepted audit practices.

ii. OIG did not provide the coding and document standards applied during its review.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

MAOs, and their network providers, are expected to submit diagnosis codes in accordance with ICD-10 coding guidelines. But, because of the lack of specificity, CMS has directed providers and plans to rely on coding and documentation guidance from industry experts such as the American Health Information Management Association (AHIMA), the American Medical Association (AMA), the American Hospital Association (AHA), and the American Academy of Professional Coders (AAPC). The scope of these resources is quite broad, they are not always consistent with one another, and they change over time. For example, while ICD-10 greatly increased the codes and descriptive nature of such codes when compared to ICD-9, ICD-10 still does not have a code for every specific diagnosis that a provider may make. There are many times where providers must decide whether the medical diagnosis that they are making aligns with one ICD-10 versus another, and coding sources do not consistently align the same diagnosis with the same ICD-10. Further, the sources that CMS recommends providers rely on often do not respond to questions in a timely manner (e.g., the AHA Coding Clinic, a well-respected source, takes more than six months to respond). Because of these inconsistencies and variations, OIG should identify the specific coding and documentation standards that were used to evaluate the targeted high-risk diagnoses, as required by relevant auditing standards.

iii. Any coding and documentation standards applied during OIG's review were not validly established.

Even if OIG were to provide its coding and document standards, any standards applied during OIG's review were not validly established. The Medicare statute provides that any "policy" that "establishes or changes a substantive legal standard governing ... payment" must be established through notice and comment rulemaking.^{21/} The Supreme Court has explained that this obligation is broad and is likely to invalidate many policies found only in the Medicare manuals.^{22/} The HHS Office of General Counsel has further advised that, when a Medicare manual "set[s] forth payment rules that are not closely tied to statutory or regulatory standards, the government generally cannot use violations of that guidance in enforcement actions, because ... it was not validly issued."^{23/} In late 2020, HHS promulgated regulations stating that a component of HHS may not "use any guidance" to compel regulated entities "to take any action, or refrain from taking any action, beyond what is required by the terms of an applicable statute or regulation."^{24/}

As applied to this audit, the coding and documentation standards are offered as the difference between valid risk adjustment payments and alleged overpayments. The audit uses sub-regulatory standards to define the scope of Cigna's entitlement to retain risk adjustment payments from CMS. CMS indicated in a 2018 proposed rule that the RADV coding and documentation guidance defines "the

^{21/} 42 U.S.C. § 1395hh(a)(2). The APA requires that all substantive rules be established through notice and comment. 5 U.S.C. § 553. However, because the notice and comment obligation imposed by the Medicare statute is broader than the equivalent APA requirement, see generally *Azar v. Allina Health Services*, 139 S. Ct. 1804 (2019), we focus on the Medicare statute.

^{22/} See *Allina Health*, 139 S. Ct. at 1814.

^{23/} Memorandum from Kelly M. Cleary, *Impact of Allina on Medicare Payment Rules*, 2 (Oct. 31, 2019); see also, e.g., *Polansky v. Exec. Health Res., Inc.*, 422 F. Supp. 3d 916 (E.D. Pa. 2019).

^{24/} 45 C.F.R. § 1.3(a)(2). Although HHS has proposed to rescind this regulation, it has not finalized that proposal, and the regulation therefore remains binding on the agency.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

payment standard" for MA risk adjustment payments.^{25/} To be valid, that standard must be established through notice and comment.

The notice and comment issue is made more significant by the fact that many aspects of the payment standard are defined by private entities. The ICD-CM coding guidelines are a core RADV requirement. Those guidelines are established jointly by CMS and two private entities (the AHA and AHIMA) through a largely closed process that does not involve notice and comment. As noted above, the RADV process also relies on publications from the AMA, AHIMA, the AAPC, and others, which do not involve public input, are not always consistent with each other, and change without notice. The Medicare statute and the APA do not allow CMS to delegate its responsibility to establish risk adjustment standards to private, non-governmental entities.^{26/} OIG's potential reliance on these standards is improper for all of the reasons stated.

iv. OIG's narrowly defined documentation requirements conflicted with OIG's sampling methodology such that records that would substantiate a diagnosis were not acceptable if outside of the narrow time frame of the audit.

For many of the targeted high-risk diagnoses, OIG's determining factor for whether such diagnosis should be in the sample was whether a subsequent or previous claim or diagnosis was submitted to the MAO and then to CMS. For example:

- Diagnoses for lung, breast, colon, and prostate cancer were considered suspect by OIG and therefore included in the potential sample, if CMS had not received evidence of "surgical therapy, radiation treatments, or chemotherapy treatment drugs administered within a 6-month period before or after the diagnosis."
- Acute heart attack diagnoses from outpatient providers were included in the potential sample if the diagnosis was not also reported from an inpatient hospital encounter either 60 days prior or after the diagnosis in question.
- Acute stroke diagnoses from outpatient providers were included in the potential sample if the diagnosis was not also reported by either another outpatient encounter or an inpatient encounter.
- Both major depressive disorder and embolism diagnoses were included in the potential sample if the diagnosed member did not fill a prescription drug associated with the condition through their Medicare Part D plan, with no specific time frame set forth.

OIG developed the parameters for when a diagnosis would be considered a high risk of noncompliance; however, OIG's documentation requirements relating to timing prohibited Cigna from submitting documentation that would substantiate a diagnosis. For example, records for members diagnosed with cancer in late 2016 who later sought treatment in early 2017 would not be reviewed by OIG even though such treatment was obtained within OIG's arbitrarily defined 6-month window. Further,

^{25/} See 83 Fed. Reg. 54928, 55041 (Nov. 1, 2018) ("If a payment has been made to an MA organization based on a diagnosis code that is not supported by medical record documentation, that entire payment is in error and should be recovered in full, because the payment standard has not been met.").

^{26/} See, e.g., *U.S. Telecom Ass'n v. FCC*, 359 F.3d 554, 565-56 (D.C. Cir. 2004) ("subdelegations to outside parties are assumed to be improper absent an affirmative showing of congressional authorization").

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

for members who were diagnosed with major depressive disorder or embolism late in a plan year and filled a related prescription early in the following plan year, records for such a prescription fill would both be time barred as being outside of the audit time period and not considered to be a valid source of risk adjustment data. This disregard of documentation and support for a diagnosis code based on an arbitrary date range in such a targeted audit ignores the fact that for MA members and their plan providers, the end of a calendar year does not change how providers deliver care. Further, as discussed directly below, when, where or whether a member elects to obtain follow-up care is not a valid basis to determine that a documented diagnosis is not supported.

v. OIG Determining Whether a Diagnosis is Valid Based on What a Provider Decides to Recommend to a Member, Whether a Member Decides to Seek Recommended Treatment, or Where or How a Member Seeks Recommended Treatment is Inherently Problematic and Arbitrary.

We know of no CMS guidance suggesting that the health status of a member that is reported through a diagnosis submitted by their treating provider is disproved solely by whether a provider prescribes a certain course of treatment or whether a member elects to follow through with such treatment. We believe that, absent indicia of fraud, the treating provider's notation of a diagnosis should be given wide latitude and deference, especially when significant time has passed from when the patient was seen and when the OIG reviewer evaluates the medical record. And we do not believe "indicia of fraud" includes a provider deciding to not prescribe treatment identified by OIG as being appropriate or by a member electing to not follow up. By applying these arbitrary standards of medical practice and "health status," OIG seeks to supplant its medical knowledge years later for that of members' treating providers.

As we discussed, OIG identified diagnoses that were at high risk of noncompliance by consulting with medical professionals at an MAC. How are a non-clinical federal agency and a randomly selected federal contractor well-suited to determine clinical guidelines that will identify whether a member has a given diagnosis assigned by the member's treating provider? If a member's provider decides not to prescribe a drug because such drug would interact poorly with the member's other drugs, this audit would identify the diagnosis as at high risk of noncompliance based on the provider's clinical decision making. Identifying such diagnoses as unsupported would be clinically inaccurate and such a finding would result in OIG and its MAC consultant supplanting the provider's clinical decision making with their own. OIG does not have this authority.

Further, if a provider counseled a member on treatment options all of the following common situations would result in the OIG considering the provider's diagnosis as being at "high risk of noncompliance:" (1) the member elected to not follow up, (2) the member was not able to afford the cost share charged for their prescribed prescription so they did not fill the prescription, (3) the member elected to fill a prescription through their Veterans Affairs ("VA") pharmacy, (4) the member paid cash and used a discount card (e.g., GoodRx, SingleCare, etc.), and (5) the member elected to use widely available manufacturer coupons (which continue to be offered by manufacturers to Part D members, sometimes with OIG's approval²⁷⁷). All of these situations result in an MA plan not receiving a claim or PDE for the

²⁷⁷ See e.g., OIG Advisory Opinion No. 14-05 (Jul. 21, 2014) (approving manufacturer's direct-to-patient products sales program that offers a brand name drug (for which there is a generic equivalent) at a discount much lower than the manufacturer's wholesale acquisition cost, allowing the patient to pay for the drug out of pocket with no charge to the insurer); OIG Advisory Opinion No. 07-04 (Mar. 30, 2007) (approving pharmaceutical company patient assistance program that provides

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

member filling a prescribed drug, but do not suggest that a member does not have a diagnosis that their provider assigned to them. Identifying such diagnoses as unsupported would be clinically inaccurate and such a finding would result in OIG and its MAC consultant supplanting the member's personal choices with their own. OIG does not have this authority.

For example, Cigna member assigned as "audit sample #11-280" was diagnosed with prostate cancer in 2014. The member was informed of the diagnosis and discussed treatment options with his provider, and elected to undergo watchful waiting with monitoring of his PSA levels. In 2015, the provider continued to monitor the member's PSA levels in June and documented in September that the member will continue to be monitored. Current American Society of Clinical Oncology guidelines state that men with low-volume Gleason prostate cancer (which this member had) may be considered for active surveillance, and that is what the member and his provider elected. The OIG invalidated the diagnosis of prostate cancer. Identifying such a diagnosis as unsupported was clinically inaccurate, as summarized on **Exhibit A**, and this finding results in OIG and its MAC consultant supplanting the member's personal choices with their own.

Additionally, OIG ignored information regarding members seeking care outside of the Medicare program. The most blatant example of this is care provided through the VA. Cigna, like many MAOs, offers MA plans to many veterans who receive benefits from the Veterans Health Administration as well as an MA plan. Such members may elect to see providers under either benefit. Under OIG's audit, diagnoses that are documented by the member's provider are at "high risk of noncompliance" if such member seeks follow up care at the VA, because such care does not produce a Medicare claim. Invalidating on such basis is clinically inaccurate.

For example, Cigna member assigned as "audit sample #11-292" was diagnosed with and treated for prostate cancer in 2006, and continued to be prescribed Lupron for his prostate cancer in 2016. Further, in 2016, the member was prescribed an additional drug to treat prostate cancer (Casodex) and his treating provider noted that that member was obtaining oncology follow-up care through the VA. As OIG is well aware,^{28/} Lupron is a widely used drug to treat prostate cancer, covered under a member's medical benefit and not under Part D. Even though the member was actively being treated with Lupron and Casodex, and was obtaining oncology follow-up care through the VA, OIG invalidated the diagnosis. Identifying such a diagnosis as unsupported was clinically inaccurate, as summarized on **Exhibit A**.

vi. Cigna understands some of the coding and documentation standards applied during this audit are inconsistent with the statute and/or medical practice.

As the Draft Report recognizes, the Medicare statute requires that risk adjustment payments be made based on the "health status" of each enrolled member.^{29/} The risk adjustment system relies on the ICD-CM diagnosis codes only as a proxy for such statuses.^{30/} Often, however, the coding and documentation standards published by the AHA, AHIMA, the AAPC, etc. turn on formalities or criteria that do not address the beneficiary's health status. Such standards also have the effect of preventing Cigna and other plans from presenting important, credible evidence regarding their members' health statuses.

free outpatient prescription drugs to financially needy Part D enrollees entirely outside of the Part D benefit); OIG Advisory Opinion No. 06-04 (Apr. 18, 2006) (same).

^{28/} See OIG, *Medicare Reimbursement for Lupron*, OIG-03-03-00250, January 2004.

^{29/} See Draft Report at 1, 2, 3, and 5.

^{30/} See *Id.* at 1 ("To determine the health status of enrollees, CMS relies on ... diagnosis codes ...").

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

Cigna has submitted detailed comments to OIG and CMS previously relating to examples of how the coding and documentation standards applied during RADV audits, including this type of audit, are inconsistent with the statute that establishes payment based on health status. Some examples include the limited definition of a "medical record,"^{31/} limitations on physician^{32/} and provider and source types,^{33/} the signature requirement,^{34/} exclusion of attestations for all matters other than signatures, and inaccurate clinical guidelines.^{35/}

In this specific audit, the exclusion of prescription data as a validation source when OIG itself used the lack of prescription data to determine whether certain diagnoses were considered high-risk for noncompliance, is arbitrary and further demonstrates the inaccuracy of the audit results. Additionally, the fact that RADV guidance currently precludes MAOs from using prescription data to establish beneficiary health status, even though the relationship between some medications and health status is clear (e.g., insulin is prescribed for diabetes), is particularly problematic given that the RADV rules for the Affordable Care Act expressly allow for the use of prescription data in risk adjustment.^{36/}

We believe many of the above issues would have been addressed if the RADV rules and payment standards for MA had been established through notice and comment, and OIG had followed them. As the Supreme Court recently explained: "Notice and comment gives affected parties fair warning of potential changes in the law and an opportunity to be heard on those changes—and it affords the agency a chance to avoid errors and make a more informed decision."^{37/} The partnership between CMS and committed plans, like Cigna, works best when policy is the product of full and frank dialogue as occurs in notice and comment rulemaking. Because this dialogue has not taken place as it applies to documentation standards, it is inappropriate for OIG to rely on such standards in this audit.

d. Extrapolation of Potential Overpayments is Inappropriate and Not Authorized by Congress

We do not believe that extrapolation has been authorized by Congress in this situation. Part C of the Medicare statute does not authorize extrapolated recoveries and, in the absence of explicit Congressional authorization, we believe extrapolation is not available.^{38/}

Significantly, Congress addressed extrapolation in Part E of the Medicare statute. That provision states that an audit involving a contractor "may not use extrapolation... unless the Secretary determines that—(A) there is a sustained or high level of payment error; or (B) documented educational intervention

^{31/} CMS, *Risk Adjustment User Group 2007/2008 – February 2008 Questions & Answers* (Feb. 13, 2008).

^{37/} *Allina Health*, 139 S. Ct. at 1816.

^{38/} We note that CMS previously told Congress that it lacked such authority and unsuccessfully requested a legislative change to authorize extrapolation in RADV audits. See Departments of Labor, Health and Human Services, Education, and Related Agencies Appropriations for 2011: Hearings Before the H.R. Comm. on Appropriations, 111th Cong. pt. 7 at 14 (2010) (written statement of William Corr, Deputy Sec'y, Dep't of Health & Human Servs.); see also Ctrs. for Medicare & Medicaid Servs., Dep't of Health & Human Servs., *Fiscal Year 2011 Performance Budget 177* (2010) (describing proposal that would "[c]larify in statute that CMS can extrapolate the error rate found in the risk adjustment validation (RADV) audits to the entire MA plan payment for a given year when recouping overpayments"). We believe this reflects an acknowledgement that CMS does not have the authority. See *U.S. House of Representatives v. Burwell*, 185 F. Supp. 3d 165, 186 (D.D.C. 2016).

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

has failed to correct the payment error.”^{39/} Neither of these conditions have been met here. Because of the many faults in the sampling and review methodology of this audit, discussed in detail above, we believe it is not possible to accurately identify a sustained or high level of payment error with the targeted methodology used by OIG in this audit. Further, Cigna did not fail to correct a payment error after receiving documented educational intervention by OIG or CMS. Instead, five to six years after diagnoses were reported by treating providers, OIG elected to work with an undisclosed MAC to develop a list of diagnoses and criteria for such diagnoses that OIG and the MAC determined were high risk. Cigna only received notice of what conditions OIG and the MAC considered high risk when it received the audit notice in 2019.^{40/}

Even if extrapolation were permitted, the methodology used would have to adhere to the final methodology established by CMS. In 2010, CMS created regulations governing the conduct of RADV audits using the Secretary’s authority to establish MA program standards.^{41/} At the time, the regulations applied only to audits conducted by CMS.^{42/} Four years later, however, the regulations were amended to apply to all RADV audits conducted by any component of HHS, including OIG.^{43/} The preamble explained that the amendments were intended to clarify that the RADV regulations applied to RADV audits conducted by OIG pursuant to its authority under the Inspector General Act.^{44/} The preamble also addressed the statistical sampling and extrapolation methodologies to be used during such audits.^{45/} It stated that audits would be conducted using the methodology published by CMS in February 2012,^{46/} unless an updated methodology was published after opportunity for stakeholder comment.^{47/} To date, no update has been made to that methodology.^{48/} Even to the extent that extrapolation has been authorized by statute (which we believe is not the case), the 2014 rulemaking made the February 2012 methodology binding for all RADV audits.^{49/} And, as discussed further below, the February 2012 methodology adopted the use of a “FFS adjuster” to function as “an offset” to “account[] for the fact that the documentation standard used in RADV audits ... is different from the documentation standard used” in the FFS program.^{50/} OIG’s proposed extrapolation disregarded this necessary adjustment.

^{39/} 42 U.S.C. § 1395ddd(f)(3).

^{40/} As OIG is aware, while Cigna received notice of the audit in 2019, the audit was postponed because of the COVID-10 Public Health Emergency and the burden that record collection would place on health professionals during the PHE.

^{41/} See 74 Fed. Reg. 54634, 54674-75 (Oct. 22, 2009) (explaining that the RADV appeals process was created pursuant to section 1856(b)(1) of the Social Security Act); 75 Fed. Reg. 19678, 19742 (Apr. 15, 2010) (same).

^{42/} See 75 Fed. Reg. at 19804 (former 42 C.F.R. § 422.2: the term RADV audit meant “a CMS-administered payment audit”); *id.* at 19806 (former 42 C.F.R. § 422.311(a): “CMS annually conducts RADV audits ...”). We note, however, that OIG generally adhered to CMS’s RADV policies in place at that time.

^{43/} See 42 C.F.R. § 422.2 (RADV audit means “a payment audit of a MA organization administered by the Secretary”); 42 C.F.R. § 422.311(a) (“the Secretary annually conducts RADV audits ...”).

^{44/} See 79 Fed. Reg. 29843, 29934 (May 23, 2014).

^{45/} See *id.* at 29927-28 (discussing the Final RADV Methodology).

^{46/} CMS, *Notice of Final Payment Error Calculation Methodology for Part C Medicare Advantage Risk Adjustment Data Validation Contract-Level Audits* (Feb. 24, 2012) (“Final RADV Methodology”).

^{47/} See *supra* n.45.

^{48/} We are, of course, aware that CMS published a proposal to change the final methodology in November 2018. As discussed below, however, the February 2012 methodology remains binding on OIG until a new approach is finalized and takes effect.

^{49/} We note that the decision by HHS to standardize all RADV audits is sound policy. It would be inconsistent with the APA for different components of HHS to conduct the same type of audits using different methodologies. This would raise the possibility of identically situated MA plans receiving different audit outcomes based on which HHS component conducted the audit.

^{50/} Final RADV Methodology at 4-5.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

OIG's audit was designed to analyze targeted high-risk diagnoses that OIG expected to fail. As discussed earlier, this process is contrary to the data validation processes set forth in the February 2012 methodology. We are not aware of an analysis establishing that OIG's approach is superior to the final audit methodology that HHS adopted through the 2014 rulemaking, and warrants extrapolation. For these reasons, extrapolation is inappropriate and unauthorized by Congress.

e. *OIG's Estimated and Extrapolated Repayment Amount is Incorrect Because it is Not Adjusted to Ensure Actuarial Equivalence*

Statute and regulation require CMS to pay MAOs an amount that is "actuarially equivalent" to the expected cost that CMS would have otherwise incurred had it provided required Medicare benefits directly to the MAO's enrollees.^{53/} CMS does this by making risk-adjusted payments to MAOs that are based on actuarially sound calculations of the expected cost of providing traditional Medicare benefits to enrollees with differing health statuses.^{54/}

Actuarial Standard of Practice 45, section 3.2 requires that the "type of input data that is used in the application of risk adjustment should be reasonably consistent with the type of data used to develop the model."^{55/} In 2011, the American Academy of Actuaries wrote that the inconsistency between the unaudited data to create the HCC model and extrapolation in RADV audits "not only creates uncertainty, it also may create systematic underpayment, undermining the purpose of the risk-adjustment system and potentially in payment inequities."^{56/} More recently, most qualified statisticians and actuaries to consider the question concluded that a significant FFS adjuster was essential to meeting the statutory requirement of actuarial equivalence.^{55/}

CMS developed the MA risk adjustment model using FFS claims data from the traditional Medicare program. The FFS claims data is unaudited and contains numerous errors that CMS must account for when determining whether similar errors for MA enrollees resulted in an overpayment. In 2012, CMS published a notice stating that it would incorporate the FFS error rate into its methodology for calculating recovery amounts for unsupported HCCs identified during its RADV audits. CMS said that it would first identify a "payment recovery amount" based on the value of supported and unsupported HCCs identified during its review.^{56/} Then, "to determine the final payment recovery amount, CMS [would] apply a Fee-for-Service

^{53/} 42 U.S.C. § 1395w-24(a)(5)(A), (a)(6)(A)(i)-(iii).

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

Adjuster ("FFS Adjuster") amount as an offset to the preliminary recovery amount.^{57/} The FFS Adjuster would be based "on a RADV-like review of records submitted to support [traditional Medicare] claims data."^{57/}

CMS tried to shift away from this principle in 2014 when it implemented a rule stating that MAOs receive an "overpayment" when they submit any diagnosis code to CMS that is not sufficiently supported by underlying medical records, without adjusting for error rates in traditional Medicare data.^{58/} This rule was struck down when a federal district court found that it violated the actuarial equivalence mandate by defining "overpayment" as the payment of funds to MAOs based on unsupported diagnosis codes without applying a FFS Adjuster or other mechanism to maintain actuarial equivalence.^{59/} Although the district court's ruling was partially overturned by the D.C. Circuit's finding that actuarial equivalence does not apply to the overpayment rule,^{60/} the D.C. Circuit itself distinguished the overpayment rule from the actuarial equivalence standard that applies to CMS' calculation and disbursement of monthly payments to MAOs^{61/} and from RADV audits, which more broadly impact payments to MAOs because such audits are designed to require repayment for all unsupported diagnosis codes.^{62/}

Amidst this litigation, CMS issued a proposed rule in 2018 suggesting that diagnosis coding errors in unaudited traditional Medicare data do not systematically impact payments to MAOs.^{63/} Many MAOs and numerous other parties, including actuarial and statistical experts, submitted comments to CMS explaining that the 2018 proposal does not satisfy the actuarial equivalence requirement. CMS was required to take action on this rule in November 2021 but instead, CMS extended its deadline for an additional year to November 2022 as it continues to contemplate how to handle this significant issue and potential significant change in practice and policy.^{64/} As a result, the proposed rule remains subject to the administrative rulemaking process.

The actuarial equivalence requirement extends to OIG's estimation and extrapolation of a potential "overpayment" amount in this audit. OIG did not apply a FFS Adjuster to account for errors in the data used to create the risk adjustment payment model. The lack of FFS Adjuster violates important principles of administrative law, in particular the requirement for prospective notice and comment rulemaking. It also would mark a departure from OIG's past audit practices. In prior contract-level RADV audits, OIG

^{61/} See *id.* at 884.

^{62/} See *id.* at 892. Cigna does not agree with the D.C. Circuit's decision regarding the overpayment rule because actuarial equivalence in the MA risk adjustment system is statutorily required and cannot be achieved or maintained without it applying to all payment contexts within the risk adjustment system, but in any event, the D.C. Circuit's decision by its own terms was limited to the overpayment rule and "expresses no opinion" with respect to actuarial equivalence in RADV audits. *Id.* at 893 n.1.

^{63/} 83 Fed. Reg. 54982, 55041 (Nov. 1, 2018).

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

acknowledged that the actuarial equivalence requirement made it inappropriate to estimate an extrapolated audit liability in the absence of a FFS Adjuster:

Although an analysis to determine the potential impact of error rates inherent in FFS data on MA payments was beyond the scope of our audit, we acknowledge that CMS is studying this issue and its potential impact on audits of [MAOs]. Therefore, because of the potential impact of these error rates on the CMS model that we used to recalculate MA payments for the beneficiaries in our sample, we (1) modified one recommendation to have [the MAO] refund only the overpayments identified for the sampled beneficiaries rather than refund the estimated overpayments and (2) added a recommendation that [the MAO] work with CMS to determine the correct contract-level adjustments for the estimated overpayments.^{65/}

OIG made similar statements in two prior audits involving Cigna affiliates.^{66/} Because the relevant circumstances have not changed since those prior audits, the APA requires, in our view, that OIG follow the same approach in this audit.^{67/}

Considering this history, it is not possible for OIG to determine whether Cigna received an overpayment without establishing an actuarially sound methodology that takes into account diagnosis coding errors in the FFS data. As a result, OIG's estimated and extrapolated repayment amount is both legally and actuarially unsound.

f. *OIG's Extrapolated Repayment Amount Relies on a Confidence Interval that is Too Conservative and Inconsistent with CMS RADV Audit Practice*

OIG acknowledged it was taking a conservative position by using the lower limit of a two-sided 90-percent confidence interval to calculate the extrapolated repayment amount, rather than the statistically valid and more robust practice of using the lower limit of a 95-percent or 99-percent confidence interval.^{68/} OIG provides no explanation for its decision to do so, which is unusual because CMS uses the lower limit of a 99-percent confidence interval when calculating extrapolated repayment amounts for its Medicare Advantage RADV audits.

For the reasons discussed here, we believe that OIG's estimated and extrapolated repayment amounts are incorrect. We respectfully request OIG withdraw its recommended repayment amount and recalculate it to (a) address errors in OIG's analysis of certain enrollee-years; (b) include previously unreported diagnoses; (c) remove the impact of underlying biases; (d) disregard unwarranted extrapolation, and (d) ensure actuarial equivalence.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

III. Cigna Does Not Concur with OIG's Recommendation that Cigna Conduct Additional Auditing Related to the High-Risk Diagnoses Included in the Audit and Respectfully Requests that OIG Update its Draft Report to Withdraw this Recommendation

OIG recommends that Cigna "identify, for the high-risk diagnoses included in [the Draft Report], similar instances of noncompliance that occurred before or after [the] audit period and refund any resulting overpayments to the Federal Government[.]"^{69/} However, MA regulations do not require the sort of audits that OIG recommends and do not require data perfection. By making this recommendation, OIG is holding MAOs to standards that are unknown, vague, and nonexistent. Further, if Cigna undertook an audit similar to OIG's, it could not result in "risk adjustment payment integrity and accuracy"^{70/} because Cigna would not be permitted to submit diagnosis codes that it determined were supported but not previously submitted given that all plan years other than 2021, and 2022 are closed for resubmissions.

As discussed above in Section I, a payment audit designed to target errors without considering and recognizing diagnoses that are supported but not previously submitted, does not ensure payment accuracy and is improper. For OIG to recommend that Cigna repeat such an audit across multiple years on its own is excessively penal. We respectfully request that OIG withdraw its recommendation that Cigna conduct additional audits.

IV. Cigna Does Not Concur with OIG's Recommendation that Cigna Examine Existing Compliance Procedures and Respectfully Requests that OIG Update its Draft Report and Withdraw its Recommendation

OIG recommends that Cigna "continue its examination of its existing compliance procedures to identify areas where improvements can be made to ensure that diagnosis codes that are at high risk for being miscoded comply with Federal requirements...and take the necessary steps to enhance those procedures."^{71/}

However, Cigna has a strong and effective compliance program that is designed to comply with all relevant legal and regulatory requirements. In fact, in 2021, when conducting a contract-level RADV audit of H5410, OIG observed that Cigna "ha[s] a compliance program to ensure that [it] submitted accurate diagnosis codes for use in CMS' risk adjustment program" and that our "policies and procedures [are] generally effective." Also in 2021, Cigna underwent a CMS Program Audit and there were no findings related to Cigna's compliance program.

During its audit, OIG reviewed Cigna's diagnosis data from 2015 and 2016, and issued a finding regarding the overall effectiveness of policies and procedures that are in place today. But as part of its ongoing efforts to further strengthen its compliance program, Cigna has made numerous changes to that program over the last several years. This is standard practice for a company like Cigna. The current policies and procedures have no bearing on 2015 and 2016 dates of service and as such, there is no basis for findings related to Cigna's current compliance program. It is beyond the scope of OIG's audit to make recommendations related to Cigna's current compliance activities.

OIG's audit was not designed to determine whether Cigna's current practices would have addressed the issues potentially identified in 2015/2016 data. Cigna's current compliance program

^{69/} Draft Report at 18.

^{70/} See 42 C.F.R. §422.311(a).

^{71/} Draft Report at 18.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

recently received positive feedback from both CMS and OIG. Cigna's recent contract-level RADV in Florida found a 97% coding accuracy rate and included positive statements regarding Cigna's compliance program. Also in 2021, Cigna underwent a CMS Program Audit and there were no findings related to Cigna's compliance program.

The Draft Report cites 42 C.F.R. § 422.503(b)(vi), which requires organizations to adopt an "effective" compliance program. But, as stated above, OIG has "recognize[d that] the implementation of an effective compliance program may not entirely eliminate fraud, abuse and waste from an organization."^{72/} OIG's Draft Report makes two potentially misleading statements in this respect.^{73/}

First, the Draft Report states that "[f]ederal regulations state that [MAOs] must monitor the data that they receive from providers and submit to CMS."^{74/} However, this statement is incomplete. CMS gives MAOs broad discretion to design their own compliance and risk adjustment data accuracy programs and has declined to require MAOs to implement any specific oversight measures.

Second, the Draft Report also states that federal regulations "state that [MAOs] are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS for payment purposes."^{75/} This statement is again incomplete because it fails to account for the qualified attestation standard that CMS explicitly adopted. MAOs are not held to a standard of guaranteeing the accuracy of the risk adjustment data that is submitted. Instead, MAOs have to attest that the submissions are accurate to their best knowledge, information and belief.

Relying on these misleading broad characterizations of CMS regulations, OIG has inappropriately expanded the MA compliance program requirements. CMS is undoubtedly aware of industry-wide trends related to the high-risk diagnoses audited by OIG. Nevertheless, CMS has not opted to take any action to implement regulations or additional requirements, let alone the broad recommendations OIG makes in its Draft Report. We observe again that we have shared details regarding our risk adjustment policies and procedures with CMS many times over the years. CMS has not asked us to change our policies or procedures or identified any specific areas that require additional enhancements. For this reason, too, we think that the second recommendation should be withdrawn.

OIG's recommendations based on 2015 and 2016 dates of service also fail to consider changes in medical documentation practices that have occurred over the last 6 to 7 years. During that time, MAOs, including Cigna, have put forth significant effort to educate providers regarding the appropriate use of some of the specific codes targeted by OIG in this audit (e.g., when to use acute stroke versus history of stroke, heart attack versus history of a heart attack). OIG's recommendation ignores this effort and the likely effect of this effort on coding in 2022.

Additionally, at the end of 2015, which was after many of the service dates at issue in the audit, providers transitioned from ICD-9 to ICD-10 coding. The more specific diagnosis codes available under ICD-10 changed physician diagnosis coding practices so that they were more easily able to identify "history of" codes as being the appropriate code to report for their applicable patients. As a result, the related

^{72/} 64 Fed. Reg. 61894, 61895 (Nov. 15, 1999).

^{73/} 64 Fed. Reg. at 61900. The Draft Report also appears to suggest that perfection is required by 42 C.F.R. § 422.310(d)(1), which states that MA organizations "must submit data that conform to CMS' requirements for data equivalent to Medicare fee-for-service data, when appropriate, and to all relevant national standards." However, 310(d)(1) does not establish or reference any standards that require 100% accuracy in order for a compliance program to be effective.

^{74/} Draft Report at 9.

^{75/} Draft Report at 8.

RESPONSE TO DRAFT AUDIT REPORT A-07-19-01192

compliance functions required today are entirely different from those needed to ensure compliance under ICD-9.

It also seems that, simply by virtue of the fact that it discovered supposedly unsupported diagnosis codes through its targeted audit, OIG believes Cigna's compliance policies and procedures must not have been effective. But as we have discussed throughout our comments, perfection is not the standard that CMS imposes and OIG has long recognized that. The fact that OIG identified supposedly unsupported diagnoses, through its skewed audit sampling and review methodology, does not indicate that Cigna's compliance program is ineffective, particularly when measured by MA program guidance.

V. Conclusion

For the reasons described, we believe that the overall intent and design of OIG's audit is contrary to MA regulations and the goal of payment accuracy audits. Cigna respectfully requests OIG withdraw its recommendations and update its Draft Report to account for the inherent bias in such a targeted audit. Cigna further requests that OIG revise its Draft Report and withdraw its recommendations that Cigna (a) refund to the Federal Government \$6,281,045 of estimated overpayments, (b) identify similar instances of noncompliance outside of the audit period and refund any resulting overpayments, and (c) examine existing compliance procedures to identify where improvements can be made to ensure diagnosis codes that are at high risk for being miscoded comply with Federal requirements.

Office of Inspector General

<https://oig.hhs.gov>

The mission of the Office of Inspector General (OIG), as mandated by Public Law 95-452, as amended, is to protect the integrity of the Department of Health and Human Services (HHS) programs, as well as the health and welfare of beneficiaries served by those programs. This statutory mission is carried out through a nationwide network of audits, investigations, and inspections conducted by the following operating components:

Office of Audit Services

The Office of Audit Services (OAS) provides auditing services for HHS, either by conducting audits with its own audit resources or by overseeing audit work done by others. Audits examine the performance of HHS programs and/or its grantees and contractors in carrying out their respective responsibilities and are intended to provide independent assessments of HHS programs and operations. These audits help reduce waste, abuse, and mismanagement and promote economy and efficiency throughout HHS.

Office of Evaluation and Inspections

The Office of Evaluation and Inspections (OEI) conducts national evaluations to provide HHS, Congress, and the public with timely, useful, and reliable information on significant issues. These evaluations focus on preventing fraud, waste, or abuse and promoting economy, efficiency, and effectiveness of departmental programs. To promote impact, OEI reports also present practical recommendations for improving program operations.

Office of Investigations

The Office of Investigations (OI) conducts criminal, civil, and administrative investigations of fraud and misconduct related to HHS programs, operations, and beneficiaries. With investigators working in all 50 States and the District of Columbia, OI utilizes its resources by actively coordinating with the Department of Justice and other Federal, State, and local law enforcement authorities. The investigative efforts of OI often lead to criminal convictions, administrative sanctions, and/or civil monetary penalties.

Office of Counsel to the Inspector General

The Office of Counsel to the Inspector General (OCIG) provides general legal services to OIG, rendering advice and opinions on HHS programs and operations and providing all legal support for OIG's internal operations. OCIG represents OIG in all civil and administrative fraud and abuse cases involving HHS programs, including False Claims Act, program exclusion, and civil monetary penalty cases. In connection with these cases, OCIG also negotiates and monitors corporate integrity agreements. OCIG renders advisory opinions, issues compliance program guidance, publishes fraud alerts, and provides other guidance to the health care industry concerning the anti-kickback statute and other OIG enforcement authorities.

Notices

THIS REPORT IS AVAILABLE TO THE PUBLIC
at <https://oig.hhs.gov>

Section 8M of the Inspector General Act, 5 U.S.C. App., requires that OIG post its publicly available reports on the OIG website.

OFFICE OF AUDIT SERVICES FINDINGS AND OPINIONS

The designation of financial or management practices as questionable, a recommendation for the disallowance of costs incurred or claimed, and any other conclusions and recommendations in this report represent the findings and opinions of OAS. Authorized officials of the HHS operating divisions will make final determination on these matters.

Report in Brief

Date: January 2022
Report No. A-02-18-01029

U.S. DEPARTMENT OF HEALTH & HUMAN SERVICES OFFICE OF INSPECTOR GENERAL

Why OIG Did This Audit

Under the Medicare Advantage (MA) program, the Centers for Medicare & Medicaid Services (CMS) makes monthly payments to MA organizations according to a system of risk adjustment that depends on the health status of each enrollee. Accordingly, MA organizations are paid more for providing benefits to enrollees with diagnoses associated with more intensive use of health care resources than to healthier enrollees, who would be expected to require fewer health care resources.

To determine the health status of enrollees, CMS relies on MA organizations to collect diagnosis codes from their providers and submit these codes to CMS. Some diagnoses are at higher risk for being miscoded, which may result in overpayments from CMS.

For this audit, we reviewed one MA organization, Healthfirst Health Plan, Inc. (Healthfirst), and focused on seven groups of high-risk diagnosis codes. Our objective was to determine whether selected diagnosis codes that Healthfirst submitted to CMS for use in CMS's risk adjustment program complied with Federal requirements.

How OIG Did This Audit

We sampled 240 unique enrollee-years with the high-risk diagnosis codes for which Healthfirst received higher payments for 2015 through 2016. We limited our review to the portions of the payments that were associated with these high-risk diagnosis codes, which totaled \$787,928.

Medicare Advantage Compliance Audit of Specific Diagnosis Codes That Healthfirst Health Plan, Inc., (Contract H3359) Submitted to CMS

What OIG Found

With respect to the seven high-risk groups covered by our audit, most of the selected diagnosis codes that Healthfirst submitted to CMS for use in CMS's risk adjustment program did not comply with Federal requirements. For 155 of the 240 enrollee-years, the diagnosis codes that Healthfirst submitted to CMS were not supported in the medical records and resulted in net overpayments of \$516,509.

These errors occurred because the policies and procedures that Healthfirst had to detect and correct noncompliance with CMS's program requirements, as mandated by Federal regulations, were not always effective. On the basis of our sample results, we estimated that Healthfirst received at least \$5.2 million in net overpayments for these high-risk diagnosis codes in 2015 and 2016.

What OIG Recommends and Healthfirst Comments

We made a series of recommendations to Healthfirst, including that it: refund to the Federal Government the \$5.2 million of net overpayments; identify, for the diagnosis codes described in this report, similar instances of noncompliance that occurred before or after our audit period and refund any resulting overpayments to the Federal Government; and continue its examination of existing compliance procedures to identify areas where improvements can be made to ensure diagnosis codes that are at high risk for being miscoded comply with Federal requirements and take the necessary steps to enhance those procedures.

Healthfirst objected to all of our recommendations; however, it did not object to any of the errors we identified. Instead, Healthfirst requested we limit our recommended recovery to the overpayments identified in our sample—not the extrapolated value of those overpayments. Healthfirst stated that OIG lacked the authority to use extrapolation to recommend a repayment and disagreed with our extrapolation methodology. It also stated that our audit methodology did not account for a payment principle known as "actuarial equivalence" and disagreed that it should perform audits of high-risk diagnoses or enhance its compliance program. After reviewing Healthfirst's comments, we maintain that our findings and recommendations are valid. No statutory authority limits our use of extrapolation to estimate a recovery and we correctly applied Federal requirements underlying the MA program.

INTRODUCTION

WHY WE DID THIS AUDIT

Under the Medicare Advantage (MA) program, the Centers for Medicare & Medicaid Services (CMS) makes monthly payments to MA organizations based in part on the characteristics of the enrollees being covered. Using a system of risk adjustment, CMS pays MA organizations the anticipated cost of providing Medicare benefits to a given enrollee, depending on such risk factors as the age, sex, and health status of that individual. Accordingly, MA organizations are paid more for providing benefits to enrollees with diagnoses associated with more intensive use of health care resources relative to healthier enrollees, who would be expected to require fewer health care resources. To determine the health status of enrollees, CMS relies on MA organizations to collect diagnosis codes from their providers and submit these codes to CMS.¹ We are auditing MA organizations because some diagnoses are at higher risk for being miscoded, which may result in overpayments from CMS.

This audit is part of a series of audits in which we are reviewing the accuracy of diagnosis codes that MA organizations submitted to CMS.² Using data mining techniques and considering discussions with medical professionals, we identified diagnoses that were at higher risk for being miscoded and consolidated those diagnoses into specific groups. (For example, we consolidated 27 major depressive disorder diagnoses into 1 group.) This audit covered Healthfirst Health Plan, Inc. (Healthfirst),³ for contract number H3359⁴ and focused on seven groups of high-risk diagnosis codes for payment years 2015 and 2016.

OBJECTIVE

Our objective was to determine whether selected diagnosis codes that Healthfirst submitted to CMS for use in CMS's risk adjustment program complied with Federal requirements.

¹ The providers code diagnoses using the International Classification of Diseases (ICD), Clinical Modification (CM), *Official Guidelines for Coding and Reporting* (ICD Coding Guidelines). The ICD is a coding system that is used by physicians and other health care providers to classify and code all diagnoses, symptoms, and procedures. Effective October 1, 2015, CMS transitioned from the ninth revision of the ICD coding guidelines (ICD-9-CM) to the tenth revision (ICD-10-CM). Each revision includes different diagnosis code sets.

² See Appendix B for a list of related Office of Inspector General reports.

³ Healthfirst Health Plan, Inc. is a subsidiary of Healthfirst, Inc.

⁴ All subsequent references to "Healthfirst" in this report refer solely to contract number H3359.

BACKGROUND

Medicare Advantage Program

The MA program offers beneficiaries managed care options by allowing them to enroll in private health care plans rather than having their care covered through Medicare's traditional fee-for-service program.⁵ Beneficiaries who enroll in these plans are known as enrollees. To provide benefits to enrollees, CMS contracts with MA organizations, which in turn contract with providers (including hospitals) and physicians.

Under the MA program, CMS makes advance payments each month to MA organizations for the expected costs of providing health care coverage to enrollees. These payments are not adjusted to reflect the actual costs that the organizations incurred for providing benefits and services. Thus, MA organizations will either realize profits if their actual costs of providing coverage are less than the CMS payments or incur losses if their costs exceed the CMS payments.

For 2019, CMS paid MA organizations \$273.8 billion, which represented 34 percent of all Medicare payments for that year.

Risk Adjustment Program

Federal requirements mandate that payments to MA organizations be based on the anticipated cost of providing Medicare benefits to a given enrollee and, in doing so, also account for variations in the demographic characteristics and health status of each enrollee.⁶

CMS uses two principal components to calculate the risk-adjusted payment that it will make to an MA organization for an enrollee: a base rate that CMS sets using bid amounts received from the MA organization and the risk score for that enrollee. These are described as follows:

- **Base rate:** Before the start of each year, each MA organization submits bids to CMS that reflect the MA organization's estimate of the monthly revenue required to cover an enrollee with an average risk profile.⁷ CMS compares each bid to a specific benchmark amount for each geographic area to determine the base rate that an MA organization is paid for each of its enrollees.⁸

⁵ The Balanced Budget Act of 1997, P.L. No. 105-33, as modified by section 201 of the Medicare Prescription Drug, Improvement, and Modernization Act, P.L. No. 108-173, established the MA program.

⁶ The Social Security Act (the Act) §§ 1853(a)(1)(C) and (a)(3); 42 CFR § 422.308(c).

⁷ The Act § 1854(a)(6); 42 CFR § 422.254 *et seq.*

⁸ CMS's bid-benchmark comparison also determines whether the MA organization must offer supplemental benefits or must charge a basic beneficiary premium for the benefits.

- **Risk score:** A risk score is a relative measure that reflects the additional or reduced costs that each enrollee is expected to incur compared with the costs incurred by enrollees on average. CMS calculates risk scores based on an enrollee's health status (discussed below) and demographic characteristics (such as the enrollee's age and sex). This process results in an individualized risk score for each enrollee, which CMS calculates annually.

To determine an enrollee's health status for the purposes of calculating the risk score, CMS uses diagnoses that the enrollee receives from acceptable data sources, including certain physicians and hospitals. MA organizations collect the diagnosis codes that physicians document on the medical records and submit these codes to CMS. CMS then maps certain diagnosis codes, on the basis of similar clinical characteristics and severity and cost implications, into Hierarchical Condition Categories (HCCs).⁹ Each HCC has a factor (which is a numerical value) assigned to it for use in each enrollee's risk score.

As a part of the risk adjustment program, CMS consolidates certain HCCs into related-disease groups. Within each of these groups, CMS assigns an HCC for only the most severe manifestation of a disease in a related-disease group. Thus, if MA organizations submit diagnosis codes for an enrollee that map to more than one of the HCCs in a related-disease group, only the most severe HCC will be used in determining the enrollee's risk score.

For enrollees who have certain combinations of HCCs (in either the Version 12 model or the Version 22 model), CMS assigns a separate factor that further increases the risk score. CMS refers to these combinations as disease interactions. For example, if MA organizations submit diagnosis codes (in the Version 12 model) for an enrollee that map to the HCCs for acute stroke, acute myocardial infarction, and chronic obstructive pulmonary disease (COPD), CMS assigns a separate factor for this disease interaction. By doing so, CMS increases the enrollee's risk score for each of the three HCC factors and by an additional factor for the disease interaction.

The risk adjustment program is prospective. Specifically, CMS uses the diagnosis codes that the enrollee received for 1 calendar year (known as the service year) to determine HCCs and calculate risk scores for the following calendar year (known as the payment year). Thus, an enrollee's risk score does not change for the year in which a diagnosis is made. Instead, the risk score changes for the entirety of the year after the diagnosis has been made. Further, the risk score calculation is an additive process—as HCC factors (and, when applicable, disease interaction factors) accumulate, an enrollee's risk score increases, and the monthly risk-adjusted payment to the MA organization also increases. In this way, the risk adjustment

⁹ CMS transitioned from one HCC payment model to another during our audit period. As part of this transition, for 2015, CMS calculated risk scores based on both payment models. CMS refers to these models as the Version 12 model and the Version 22 model, each of which has unique HCCs. CMS blended the two separate risk scores into a single risk score that it used to calculate a risk-adjusted payment. Accordingly, for 2015, an enrollee's blended risk score is based on the HCCs from both payment models. For 2016, CMS calculated risk scores on the Version 22 model.

program compensates MA organizations for the additional risk of providing coverage to enrollees expected to require more health care resources.

CMS multiplies the risk scores by the base rates to calculate the total Medicare monthly payment that an MA organization receives for each enrollee before applying the budget sequestration reduction.¹⁰ Miscoded diagnoses submitted to CMS may result in HCCs that are not validated and incorrect enrollee risk scores, which may lead to improper payments (overpayments) from CMS to MA organizations. Conversely, correctly coded diagnoses that MA organizations do not submit to CMS may lead to improper payments (underpayments).

High-Risk Groups of Diagnoses

Using data mining techniques and discussions with medical professionals, we identified diagnoses that were at higher risk for being miscoded and consolidated those diagnoses into specific groups. For this audit, we focused on seven high-risk groups:¹¹

- *Acute stroke*: An enrollee received one acute stroke diagnosis (which maps to the HCC for Ischemic or Unspecified Stroke) on one physician claim during the service year but did not have that diagnosis on a corresponding inpatient hospital claim. A diagnosis of history of stroke (which does not map to an HCC) typically should have been used.
- *Acute heart attack*: An enrollee received one diagnosis that mapped to either the HCC for Acute Myocardial Infarction or to the HCC for Unstable Angina and Other Acute Ischemic Heart Disease (Acute Heart Attack HCCs) on only one physician claim but did not have that diagnosis on a corresponding inpatient hospital claim (either within 60 days before or 60 days after the physician's claim). A diagnosis for a less severe manifestation of a disease in the related-disease group typically should have been used.
- *Acute stroke and acute heart attack combination*: An enrollee met the conditions of both the acute stroke and acute heart attack high-risk groups in the same year.¹²
- *Embolism*: An enrollee received one diagnosis that mapped to either the HCC for Vascular Disease or to the HCC for Vascular Disease With Complications (Embolism

¹⁰ Budget sequestration refers to automatic spending cuts that occurred through the withdrawal of funding for certain Federal Government programs, including the MA program, as provided in the Budget Control Act of 2011 (BCA) (P.L. No. 112-25 (8-2-2011)). Under the BCA, the sequestration of mandatory spending began in April, 2013.

¹¹ Unless otherwise specified, the HCCs described in this report have the same name under both the Version 12 and Version 22 models.

¹² We combined these enrollees into one group because an individual's risk scores could have been further increased if that enrollee also had a COPD diagnosis (which was not part of our audit). If our audit identified an error that invalidated either the acute stroke or acute heart attack HCC, then the disease interaction factor would also be identified as an error. By combining these enrollees in one group, we eliminated the possibility of including the disease interaction factor twice in overpayment calculations (if any).

HCCs) but did not have an anticoagulant medication dispensed on his or her behalf. An anti-coagulant medication is typically used to treat an embolism. A diagnosis of history of embolism (an indication that the provider is evaluating a prior acute embolism diagnosis, which does not map to an HCC) typically should have been used.

- *Vascular claudication*: An enrollee did not receive a diagnosis related to vascular claudication (which maps to the HCC for Vascular Disease) for 2 years and then, in the subsequent year, received that diagnosis but had medication dispensed on his or her behalf that is frequently dispensed for a diagnosis of neurogenic claudication.¹³ In these instances, the vascular claudication diagnoses may not be supported in the medical records.
- *Major depressive disorder*: An enrollee received one major depressive disorder diagnosis (which maps to the HCC for Major Depressive, Bipolar, and Paranoid Disorders) during the service year but did not have an antidepressant medication dispensed on his or her behalf. In these instances, the major depressive disorder diagnoses may not be supported in the medical records.
- *Potentially mis-keyed diagnosis codes*: An enrollee received multiple diagnoses for a condition but received only one—potentially mis-keyed—diagnosis for an unrelated condition (which mapped to a possibly unvalidated HCC). For example, ICD-9 diagnosis code 250.00 (which maps to the HCC for Diabetes Without Complication) could be transposed as diagnosis code 205.00 (which maps to the HCC for Metastatic Cancer and Acute Leukemia and, in this example, would be unvalidated). Using an analytical tool that we developed, we identified 811 scenarios in which diagnosis codes could have been mis-keyed because numbers were transposed or other data entry errors occurred that could have resulted in the assignment of an unvalidated HCC.

In this report, we refer to the diagnosis codes associated with these groups as “high-risk diagnosis codes.”

Healthfirst Health Plan, Inc.

Healthfirst is an MA organization based in New York, New York. As of December 31, 2016, Healthfirst provided coverage under contract number H3359 to approximately 136,875

¹³ Vascular claudication and neurogenic claudication are different diagnoses. Vascular claudication is a condition that can result in leg pain while walking and is caused by insufficient blood flow. Neurogenic claudication is a condition that can also result in leg pain but is caused by damage to the neurological system, namely the spinal cord and nerves.

enrollees. For the 2015 and 2016 payment years (audit period),¹⁴ CMS paid Healthfirst approximately \$3.3 billion to provide coverage to its enrollees.¹⁵

HOW WE CONDUCTED THIS AUDIT

Our audit included enrollees on whose behalf providers documented diagnosis codes that mapped to one of the seven high-risk groups during the 2014 and 2015 service years, for which Healthfirst received increased risk-adjusted payments for payment years 2015 and 2016, respectively. Because enrollees could be classified in more than one high-risk group or have high-risk diagnosis codes documented in more than 1 year, we classified these individuals according to the condition and the payment year, which we refer to as "enrollee-years." We identified 5,721 unique enrollee-years and limited our review to the portions of the payments that were associated with these high-risk diagnosis codes (\$14,847,742). We selected for audit a sample of 240 enrollee-years, which comprised (1) a stratified random sample of 200 (out of 5,646) enrollee-years for the first 6 high-risk groups and (2) a non-statistical sample of 40 (out of 75) enrollee-years for the remaining high-risk group.

Table 1 details the number of sampled enrollee-years for each high-risk group.

Table 1: Sampled Enrollee-Years

High-Risk Group	Number of Sampled Enrollee-Years
1. Acute Stroke	49
2. Acute Heart Attack	30
3. Acute Stroke/Acute Heart Attack combination	11
4. Embolism	30
5. Vascular Claudication	35
6. Major Depressive Disorder	45
Total for Stratified Random Sample	200
7. Potentially Mis-keyed Diagnosis Codes	40
Total for All High-Risk Groups	240

Healthfirst provided medical records as support for the selected diagnosis codes associated with the 240 enrollee-years. We used an independent medical review contractor to review the medical records to determine whether the selected diagnosis codes that Healthfirst submitted to CMS were supported. If the contractor identified a diagnosis code that should have been submitted to CMS instead of the selected diagnosis code, we included the financial impact of the resulting HCC (if any) in our calculation of overpayments.

¹⁴ The 2015 and 2016 payment year data were the most recent data available at the start of the audit.

¹⁵ All of the payment amounts that CMS made to Healthfirst and the overpayment amounts that we identified in this report reflect the budget sequestration reduction.

We conducted this performance audit in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

Appendix A contains the details of our audit scope and methodology, Appendix C contains our statistical sampling methodology, and Appendix D contains our sample results and estimates.

FINDINGS

With respect to the seven high-risk groups covered by our audit, most of the selected diagnosis codes that Healthfirst submitted to CMS for use in CMS's risk adjustment program did not comply with Federal requirements. For 85 of the 240 sampled enrollee-years, the medical records supported the diagnosis codes that Healthfirst submitted to CMS. However, for the remaining 155 enrollee-years, the diagnosis codes were not supported in the medical records.

These errors occurred because the policies and procedures that Healthfirst had to detect and correct noncompliance with CMS's program requirements, as mandated by Federal regulations, were not always effective. As a result, the HCCs for these high-risk diagnosis codes were not validated. On the basis of our sample results, we estimated that Healthfirst received at least \$5.2 million in net overpayments for 2015 and 2016.¹⁶

FEDERAL REQUIREMENTS

Payments to MA organizations are adjusted for risk factors, including the health status of each enrollee (the Social Security Act (the Act) § 1853(a)). CMS applies a risk factor based on data obtained from the MA organizations (42 CFR § 422.308).

Federal regulations state that MA organizations must follow CMS's instructions and submit to CMS the data necessary to characterize the context and purposes of each service provided to a Medicare enrollee by a provider, supplier, physician, or other practitioner (42 CFR § 422.310(b)). MA organizations must obtain risk adjustment data required by CMS from the provider, supplier, physician, or other practitioner that furnished the item or service (42 CFR § 422.310(d)(3)).

Federal regulations also state that MA organizations are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS for payment purposes and that such data must conform to all relevant national standards (42 CFR § 422.504(l) and 42 CFR

¹⁶ Specifically, we estimated that Healthfirst received at least \$5,221,901 (\$5,023,530 for the statistically sampled groups plus \$198,371 for the group of potentially mis-keyed diagnosis codes) in net overpayments. To be conservative, we recommend recovery at the lower limit of a two-sided 90-percent confidence interval. Lower limits calculated in this manner are designed to be less than the actual overpayment total 95 percent of the time.

§ 422.310(d)(1)). In addition, MA organizations must contract with CMS and agree to follow CMS's instructions, including the *Medicare Managed Care Manual* (the Manual) (see 42 CFR § 422.504(a)).

CMS has provided instructions to MA organizations regarding the submission of data for risk scoring purposes (the Manual, chap. 7 (last rev. Sept. 19, 2014)). Specifically, CMS requires all submitted diagnosis codes to be documented in the medical record and to be documented as a result of a face-to-face encounter (the Manual, chap. 7, § 40). The diagnosis must be coded according to the ICD Coding Guidelines (42 CFR § 422.310(d)(1) and 45 CFR §§ 162.1002(b)(1) and (c)(2)-(3)). Further, the MA organizations must implement procedures to ensure that diagnoses come only from acceptable data sources, which include hospital inpatient facilities, hospital outpatient facilities, and physicians (the Manual, chap. 7, § 40).

Federal regulations state that MA organizations must monitor the data that they receive from providers and submit to CMS. Federal regulations also state that MA organizations must "adopt and implement an effective compliance program, which must include measures that prevent, detect, and correct non-compliance with CMS's program requirements" Further, MA organizations must establish and implement an effective system for routine monitoring and identification of compliance risks (42 CFR § 422.503(b)(4)(vi), See Appendix E).

MOST OF THE SELECTED HIGH-RISK DIAGNOSIS CODES THAT HEALTHFIRST SUBMITTED TO CMS DID NOT COMPLY WITH FEDERAL REQUIREMENTS

Most of the selected high-risk diagnosis codes that Healthfirst submitted to CMS for use in CMS's risk adjustment program did not comply with Federal requirements. As shown in the figure on the following page, the medical records for 155 of the 240 sampled enrollee-years did not support the diagnosis codes. In these instances, Healthfirst should not have submitted the diagnosis codes to CMS and received the resulting net overpayments.

Figure: Analysis of High-Risk Groups

Incorrectly Submitted Diagnosis Codes for Acute Stroke

Healthfirst incorrectly submitted diagnosis codes for acute stroke for all 49 sampled enrollee-years. Specifically:

- For 26 enrollee-years, the medical records indicated in each case that the individual had previously had a stroke, but the records did not justify an acute stroke diagnosis at the time of the physician's service.

For example, for 1 enrollee-year, the medical record (for a service that occurred in 2014) indicated that the individual had an acute stroke in 1998. The independent medical review contractor noted that "there is no evidence of an acute stroke or any related condition that would result in an assignment of the submitted HCC [Ischemic or Unspecified Stroke] or a related HCC. There is mention of a history of a stroke [diagnosis]" The history of stroke diagnosis code does not map to an HCC.

- For 21 enrollee-years, the medical records did not contain sufficient information to support an acute stroke diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor stated that "there is no documentation of any condition that will result in assignment of [the] HCC [for Ischemic or Unspecified Stroke]. The patient was admitted from [the] emergency room for suspected acute [Cerebrovascular Accident] which was ruled out at discharge."

- For the remaining 2 enrollee-years, Healthfirst did not provide any medical records to support the acute stroke diagnosis; therefore, the HCC for Ischemic or Unspecified Stroke was not validated.

As a result of these errors, the HCCs for Ischemic or Unspecified Stroke were not validated, and Healthfirst received \$129,370 in overpayments for these 49 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Acute Heart Attack

Healthfirst incorrectly submitted diagnosis codes for acute heart attack for all 30 sampled enrollee-years. Specifically:

- For 19 enrollee-years, the medical records did not support an acute myocardial infarction diagnosis. However, we identified support for another diagnosis of a less severe manifestation of the related-disease group as detailed below:
 - For 14 enrollee-years, we identified support for an old myocardial infarction diagnosis.
 - For 8 enrollee-years, which occurred in payment year 2015, the old myocardial infarction diagnosis mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Healthfirst should not have received an increased payment for the acute myocardial infarction diagnosis. Rather, it should have received a lesser increased payment for the old myocardial infarction diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor noted that "there is no documentation of any condition that will result in the assignment of [the Unstable Angina and Other Acute Ischemic Heart Disease] HCC. There is documentation of history of myocardial infarction [diagnosis] that results in [the] HCC [for Angina Pectoris/Old Myocardial Infarction] which should have been assigned instead of the submitted HCC."

- For 6 enrollee-years, which occurred in payment year 2016, the old myocardial infarction diagnosis did not map to an HCC.¹⁷ Accordingly, Healthfirst should not have received an increased payment for acute myocardial infarction.

¹⁷ In contrast to the enrollee-years that occurred in payment year 2015 (for which CMS used the Version 12 model), for payment year 2016, CMS used only the Version 22 model, which did not include an HCC for Old Myocardial Infarction, to calculate risk scores (footnote 9).

- For 2 enrollee-years, which occurred in payment year 2016, we identified support for an acute ischemic heart disease diagnosis, which mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Healthfirst should not have received an increased payment for the acute myocardial infarction diagnosis. Rather, it should have received a lesser increased payment for the acute ischemic heart disease diagnosis.
- For 2 enrollee-years, which occurred in payment year 2015, we identified support for both an old myocardial infarction diagnosis and an unspecified angina pectoris diagnosis,¹⁸ both of which mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Healthfirst should not have received an increased payment for the acute myocardial infarction diagnosis. Rather, it should have received a lesser increased payment for the old myocardial infarction and unspecified angina pectoris diagnoses.
- For the remaining 1 enrollee-year, which occurred in payment year 2016, we identified support for an unspecified angina pectoris diagnosis, which mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Healthfirst should not have received an increased payment for the acute myocardial infarction diagnosis. Rather, it should have received a lesser increased payment for the unspecified angina pectoris diagnosis.
- For 10 enrollee-years, the medical records did not support either an acute myocardial infarction diagnosis or a diagnosis of a less severe manifestation of the related-disease group.
- For the 1 remaining enrollee-year, Healthfirst did not provide any medical records to support the acute myocardial infarction diagnosis; therefore, the HCC for Acute Heart Attack was not validated.¹⁹

As a result of these errors, the Acute Heart Attack HCCs were not validated, and Healthfirst received \$49,653 in net overpayments for these 30 sampled enrollee-years.

¹⁸ Angina pectoris is defined as a disease marked by brief sudden attacks of chest pain or discomfort caused by deficient oxygenation of the heart muscles, usually due to impaired blood flow to the heart.

¹⁹ For this 1 enrollee-year, we found in CMS's Risk Adjustment Processing System (RAPS) and Encounter Data System (EDS) a diagnosis code submitted by Healthfirst that mapped to an HCC for a less severe manifestation of the related-disease group, which we included in our calculation of the overpayment.

Incorrectly Submitted Diagnosis Codes for Acute Stroke and Acute Heart Attack Combination

Healthfirst incorrectly submitted diagnosis codes for all 11 of the sampled enrollee-years for which physicians had documented conditions for both the acute stroke and acute heart attack high-risk groups in the same year (footnote 12).

For 10 enrollee-years, the medical records did not support either the acute stroke diagnosis, the acute myocardial infarction diagnosis, or both (table 2).

Table 2: Acute Stroke and Acute Heart Attack Combination Findings

Count of Enrollee-Years	Acute Stroke HCC		Acute Heart Attack HCC	
	Medical Record Validated HCC	Support for Different HCC Found	Medical Record Validated HCC	Support for Different HCC Found
4	No	No	No	Yes – Old Myocardial Infarction ²⁰
4	No	No	No	No
1	No	No	No	Yes – Angina Pectoris
1	No	No	Yes	N/A

For the one remaining enrollee-year, Healthfirst did not provide any medical records to support either diagnosis; therefore, the HCCs for Acute Heart Attack and Acute Stroke were not validated.²¹

As a result of these errors, the HCCs for either Ischemic or Unspecified Stroke, Acute Heart Attack, or both, were not validated, and Healthfirst received \$46,496 in net overpayments for these 11 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Embolism

Healthfirst incorrectly submitted diagnosis codes for embolism for 27 of 30 sampled enrollee-years. Specifically:

- For 16 enrollee-years, the medical records did not contain sufficient information to support an embolism diagnosis.

²⁰ For these 4 enrollee-years, which occurred in payment year 2015, the old myocardial infarction diagnosis mapped to an HCC for a less severe manifestation of the related-disease group.

²¹ For this enrollee-year, we found in CMS's RAPS a diagnosis code submitted by Healthfirst that mapped to an HCC for a less severe manifestation of the heart attack related-disease group, which we included in our calculation of the overpayment.

For example, for 1 enrollee-year, the independent medical review contractor noted that "there is no documentation of any condition that will result in the assignment of [an Embolism] HCC. There is documentation of deep vein thrombosis [diagnosis] as a working diagnosis that would not be coded based on outpatient guidelines of suspected/ruled out diagnoses."²²

- For 7 enrollee-years, the medical records indicated in each case that the individual had previously had an embolism, but the records did not justify an embolism diagnosis at the time of the physician's service.

For example, for 1 enrollee-year, the independent medical review contractor noted that "there is no documentation of any condition that will result in the assignment of [an Embolism] HCC. There is documentation of a history of deep vein thrombosis [diagnosis] that does not result in an HCC."

- For the remaining 4 enrollee-years, Healthfirst did not provide any medical records to support the embolism diagnoses; therefore, the Embolism HCCs were not validated.

As a result of these errors, the Embolism HCCs were not validated, and Healthfirst received \$72,442 in overpayments for these 27 sampled enrollee-years.

Incorrectly Submitted Diagnosis Codes for Vascular Claudication

Healthfirst incorrectly submitted diagnosis codes for vascular claudication for 4 of 35 sampled enrollee-years. Specifically:

- For 3 enrollee-years, the medical records did not support a vascular claudication diagnosis.

For example, for 1 enrollee-year, the independent medical review contractor noted that "there is no documentation of any condition that would result in the assignment of [the Vascular Disease] HCC."

- For the 1 remaining enrollee-year, Healthfirst did not provide any medical records to support the vascular claudication diagnosis; therefore, the HCC for Vascular Disease was not validated.

As a result of these errors, the HCCs for Vascular Disease were not validated, and Healthfirst received \$8,738 in overpayments for these 4 sampled enrollee-years.

²² ICD-9-CM Coding Guidelines, which were applicable for the reviewed diagnosis code, state that diagnoses documented as "suspected" or "rule out" should not be coded for outpatient services.

Incorrectly Submitted Diagnosis Codes for Major Depressive Disorder

Healthfirst incorrectly submitted diagnosis codes for major depressive disorder for 4 of 45 sampled enrollee-years. Specifically:

- For 2 enrollee-years, the medical records did not support a major depressive disorder diagnosis.²³

For example, for 1 enrollee-year, the independent medical review contractor noted that “there is no documentation of any condition that will result in the assignment of [the Major Depressive, Bipolar, and Paranoid Disorders] HCC. There is [an] assessment of anxiety [diagnosis] which does not result in an HCC.”

- For the remaining 2 enrollee-years, Healthfirst did not provide any medical records to support the major depressive disorder diagnoses; therefore, the HCCs for Major Depressive, Bipolar, and Paranoid Disorders were not validated.

As a result of these errors, the HCCs for Major Depressive, Bipolar, and Paranoid Disorders were not validated, and Healthfirst received \$11,438 in overpayments for these 4 sampled enrollee-years.

Potentially Mis-keyed Diagnosis Codes

Healthfirst submitted potentially mis-keyed diagnosis codes for 30 of 40 sampled enrollee-years. In each of these cases, the enrollee-years received multiple diagnoses for a condition but received only one—potentially mis-keyed—diagnosis for an unrelated condition.

- For 24 enrollee-years, the medical records did not support the diagnosis for the unrelated condition. Because of these errors, Healthfirst submitted unsupported diagnosis codes that mapped to unvalidated HCCs to CMS.

For example, for 1 enrollee-year, Healthfirst submitted 107 diagnosis codes for acute myeloid leukemia (205.00) and only one diagnosis code for diabetes mellitus (250.00) to CMS. The independent medical review contractor limited its review to the diabetes mellitus diagnosis, for which it did not find support.

- For 3 enrollee-years, the medical records did not support the diagnosis for the unrelated condition. However, we identified support for another diagnosis that mapped to an HCC for a less severe manifestation of the related-disease group. Accordingly, Healthfirst should not have received an increased payment for the submitted diagnosis.

²³ For these 2 enrollee-years, the independent medical review contractor identified support for a diagnosis code for a milder form of depression, which does not map to an HCC.

Rather, it should have received a lesser increased payment for the other diagnosis identified.

For example, for 1 enrollee-year, the medical records did not support a dissection of aorta diagnosis, which maps to the HCC for Vascular Disease With Complications. The independent medical review contractor noted that "there is no documentation of any condition that will result in the assignment of [the Vascular Disease with Complications] HCC. There is documentation of abdominal aortic aneurysm [diagnosis,] which results in [the Vascular Disease] HCC [that] should have been assigned instead of the submitted HCC." Accordingly, Healthfirst should not have received payment for the dissection of aorta diagnosis. Rather, it should have received a lesser increased payment for the abdominal aortic aneurysm diagnosis.

- For the remaining 3 enrollee-years, Healthfirst did not provide any medical records to support the potentially mis-keyed diagnosis code; therefore, the HCCs associated with the potentially mis-keyed diagnosis codes were not validated.²⁴

Appendix F contains the HCCs that were not validated for the 30 enrollee-years (Table 6) and the HCCs for the less severe manifestation of the related-disease group that were supported for the 4 enrollee-years (Table 7).

As a result of these errors, the HCCs associated with the potentially mis-keyed diagnosis codes were not validated, and Healthfirst received \$198,371 in net overpayments for these 30 sampled enrollee-years.

THE POLICIES AND PROCEDURES THAT HEALTHFIRST USED TO DETECT AND CORRECT NONCOMPLIANCE WITH FEDERAL REQUIREMENTS WERE NOT ALWAYS EFFECTIVE

The errors we identified occurred because the policies and procedures that Healthfirst had to detect and correct noncompliance with CMS's program requirements, as mandated by Federal regulations (42 CFR § 422.503(b)(4)(vi)), were not always effective.

Healthfirst had compliance procedures in place during our audit period to determine whether the diagnosis codes that it submitted to CMS to calculate risk-adjusted payments were correct. These procedures included a provider education program that was designed to promote accurate diagnosis codes, which provided instructions to its providers on the proper coding of several frequently miscoded diagnoses, one of which was acute stroke. In addition, Healthfirst's compliance procedures included routine internal medical reviews to compare diagnosis codes from a random sample of claims to the diagnoses that were documented on the associated medical records. However, these internal medical reviews did not focus on any

²⁴ For 1 enrollee-year, we found in CMS's RAPS and CMS's EDS a diagnosis code submitted by Healthfirst that mapped to an HCC for a less severe manifestation of the related-disease group, which we included in our calculation of the overpayment.

specific high-risk diagnosis codes, including those we identified as being at a higher risk for being miscoded. As a result, Healthfirst's compliance procedures to prevent and detect incorrect high-risk diagnoses during our audit period were not always effective. Additionally, Healthfirst was not always able to obtain medical records from its providers to support diagnosis codes submitted to CMS to calculate risk-adjusted payments.²⁵

Healthfirst explained that, after our audit period, it revised its procedures for conducting internal medical reviews to include reviews of targeted diagnosis codes that we identified as being at a higher risk for being miscoded. In addition, Healthfirst updated its provider education program to include steps to notify providers of errors identified during the internal medical reviews, and provide them with guidance on how to avoid coding errors.

HEALTHFIRST RECEIVED NET OVERPAYMENTS

As a result of the errors we identified, the HCCs for these high-risk diagnosis codes were not validated. On the basis of our sample results, we estimated that Healthfirst received at least \$5,221,901 in net overpayments (\$5,023,530 for the statistically sampled groups plus \$198,371 for the group of potentially mis-keyed diagnosis codes) in 2015 and 2016. (See Appendix D for sample results and estimates).

RECOMMENDATIONS

We recommend that Healthfirst Health Plan, Inc.:

- refund to the Federal Government the \$5,221,901 of estimated net overpayments;
- identify, for the high-risk diagnoses included in this report, similar instances of noncompliance that occurred before or after our audit period and refund any resulting overpayments to the Federal Government;
- identify, for the potentially mis-keyed diagnosis codes described in this report, similar instances of noncompliance that occurred during our audit period but were not included in our non-statistical sample and refund any resulting overpayments to the Federal Government; and
- continue its examination of existing compliance procedures to identify areas where improvements can be made to ensure that diagnosis codes that are at high risk for being miscoded comply with Federal requirements (when submitted to CMS for use in CMS's risk adjustment program) and take the necessary steps to enhance those procedures.

²⁵ For example, Healthfirst stated that the records associated with some patients were not in the providers' electronic record systems or were not available because the associated physician or medical practice was no longer active.

HEALTHFIRST COMMENTS AND OFFICE OF INSPECTOR GENERAL RESPONSE

In written comments on our draft report, Healthfirst objected to all of our recommendations. However, it did not object to any of the errors we identified. Instead, Healthfirst requested we limit our recommended recovery to the overpayments identified in our sample rather than the extrapolated value of those overpayments. Specifically, Healthfirst stated that OIG lacked the authority to use extrapolation to recommend a repayment and disagreed with our extrapolation methodology. Moreover, Healthfirst argued that our audit methodology did not account for a payment principle known as “actuarial equivalence.” Healthfirst also disagreed that it should perform additional audits of the high-risk diagnoses included in this report. Lastly, Healthfirst stated that, although it regularly evaluates its compliance programs, it believes its current compliance program is sufficient to meet its current obligations.

After reviewing Healthfirst’s comments and for the reasons detailed below, we maintain that our findings and recommendations are valid.

A summary of Healthfirst’s comments and our responses follows. Healthfirst’s comments are included in their entirety as Appendix G.

HEALTHFIRST DID NOT AGREE WITH THE EXTRAPOLATION METHODOLOGY THAT THE OFFICE OF INSPECTOR GENERAL USED TO ESTIMATE OVERPAYMENTS

Healthfirst Comments

Healthfirst stated that OIG lacks the authority to base a recommendation for recovery on an extrapolation of individual overpayment amounts across a “broader universe.” Specifically, Healthfirst referenced 42 U.S.C. § 1395ddd(f)(3), stating that it provides only “limited authority for CMS to extrapolate, and such authority is limited to *contractors* auditing *providers* under Medicare Parts A and B in limited circumstances not present here with respect to [MA organizations]” (emphasis in original). It further argued that there is “simply no statutory authority for the use of extrapolation of audit results of MAOs providing services under Part C.”

Additionally, Healthfirst stated that CMS drafted regulations on extrapolation for 2011 through 2013; however, according to Healthfirst, nothing was published and there is no approved extrapolation methodology for the audit period (payment years 2015 and 2016). Healthfirst noted that using an unpublished extrapolation methodology is inconsistent with the Act’s rulemaking requirements for notice and comment set forth in *Azar v. Allina Health Services*,²⁶ and therefore, “any purported authority for such extrapolation fails to comply with the required rule-making processes.”

Healthfirst further claimed that retroactivity is prohibited by Federal law. Specifically, it stated that the Act “prohibits retroactive rules absent a statutory requirement, significant public

²⁶ *Azar v. Allina Health Services*, 139 S. Ct. 1804 (2019).

safety concern or other critical need [42 U.S.C. § 139hh(e)(1)(A)], none of which are present here.” Additionally, Healthfirst noted that seeking records from providers to support HCCs for services provided in 2015 and 2016 is often difficult. Healthfirst stated that, for these reasons, it believes that “even if a valid rule authorizing extrapolation i[s] promulgated, it should not be applied retroactively, and that extrapolation by the OIG based on audit findings from 201[5]-2016 is similarly not permissible.”

Healthfirst also stated that our methodology for calculating the extrapolated repayment amount is faulty. Healthfirst specifically referenced our use of the 90-percent confidence interval instead of, according to Healthfirst, the “statistically valid and more robust practice” of using the lower limit of the 95- or 99-percent confidence interval. Additionally, Healthfirst noted that CMS uses the lower limit of the 99-percent confidence interval level for calculating extrapolated repayment amounts for its Risk Adjustment Data Validation (RADV) audits. Healthfirst stated that, if it were permissible to extrapolate, OIG would have to use the lower limit of the 99-percent confidence interval to be consistent with CMS’s practice for RADV audits.

Office of Inspector General Response

Healthfirst relies on 42 U.S.C. § 1395ddd(f)(3) to say that OIG has no authority to extrapolate. This conclusion is misguided. No statutory or other authority limits our ability to recommend a recovery to CMS based upon sampling and extrapolation. Extrapolation has long been recognized as a permissible method of calculating overpayments in Medicare. Further, current case law supports the use of extrapolation as a means to determine overpayments so long as the methodology used is statistically valid.^{27, 28}

Healthfirst alleged that OIG cannot use extrapolation without publishing our methodology through notice-and-comment rulemaking. OIG disagrees. We also note that because we are not recommending the application of any new statutory or regulatory requirements, the criteria cited by Healthfirst that prohibit retroactivity is not applicable to this audit.

Additionally, our estimation methodology does not need to mirror CMS’s estimation methodology. Our use of the lower limit of a two-sided 90-percent confidence interval provided a reasonably conservative estimate of the total amount overpaid to Healthfirst for the

²⁷ See *John Balko & Assoc. v. Sebelius*, 2012 U.S. Dist. LEXIS 183052 at *12 (W.D. Pa. 2012), *aff’d* 555 F. App’x 188 (3d Cir. 2014); *Maxmed Healthcare, Inc. v. Burwell*, 152 F. Supp. 3d 619, 634–37 (W.D. Tex. 2016), *aff’d*, 860 F.3d 335 (5th Cir. 2017); *Anghel v. Sebelius*, 912 F. Supp. 2d 4, 18 (E.D.N.Y. 2012); *Miniet v. Sebelius*, 2012 U.S. Dist. LEXIS 99517 at *17 (S.D. Fla. 2012); and *Transyd Enters., LLC v. Sebelius*, 2012 U.S. Dist. LEXIS 42491 at *13 (S.D. Tex. 2012).

²⁸ We properly executed our statistical sampling methodology in that we defined our sampling frame and sample unit, randomly selected our sample, applied relevant criteria in evaluating the sample, and used statistical sampling software (i.e., the OIG, Office of Audit Services, statistical software RAT-STATS) to apply the correct formulas for the extrapolation.

enrollee-years and time period covered in our sampling frame. Further, we note that this approach, which is routinely used by the Department of Health and Human Services (HHS) for recovery calculations,²⁹ results in a lower limit (the estimated overpayment amount to refund) that is less than the actual overpayment amount 95 percent of the time.

HEALTHFIRST DID NOT AGREE WITH THE OFFICE OF INSPECTOR GENERAL'S APPLICATION OF CMS REQUIREMENTS FOR CALCULATING OVERPAYMENTS

Healthfirst Comments

Healthfirst stated that OIG's extrapolated calculation of overpayments violated certain CMS requirements mandated under the MA program. Specifically, Healthfirst stated that OIG's methodology did not account for a payment principle known as "actuarial equivalence," which, according to Healthfirst, is mandated by the Act.

Healthfirst cited the provision of the Act that mandates that risk-adjusted payments be made in a manner that ensures "actuarial equivalence" between CMS payments for health care coverage under MA and CMS payments under Medicare's traditional Fee-for-Service (FFS) program. Healthfirst stated that "CMS developed the [MA] risk adjustment model using unaudited [FFS] claims data from the traditional Medicare program, which CMS has acknowledged contain high levels of erroneous diagnoses. Accordingly, in order to ensure actuarial equivalence between the FFS and MA programs, CMS should measure overall rates of erroneous diagnoses in the [MA] program against the rates of erroneous diagnoses found within the traditional Medicare FFS program." It further stated that, in 2012, "CMS said that it would first identify a 'payment recovery amount' based on the value of supported and unsupported HCCs identified during its review. Then, 'to determine the final payment recovery amount, CMS [would] apply a Fee-for-Service Adjuster [(FFSA)] amount as an offset to the preliminary recovery amount'"

Healthfirst stated that "CMS departed from the principle that an FFSA is necessary by issuing a proposed rule in 2018 suggesting that diagnosis coding errors in unaudited traditional Medicare data do not systematically impact payments to [MA organizations] and released a corresponding study purporting to support this premise." Healthfirst added that this rule is not final and is still subject to the administrative rule-making process.

Healthfirst also noted that a Federal district court vacated a different MA rule implemented by CMS because "the rule violated the [Act's] actuarial equivalence mandate by defining

²⁹ HHS has used the two-sided 90-percent confidence level when calculating recoveries in both the Administration for Child and Families and Medicaid programs. See, for example, *New York State Department of Social Services*, DAB No. 1358, 13 (1992); and *Arizona Health Care Cost Containment System*, DAB No. 2981, 4-5 (2019). In addition, HHS contractors rely on the one-sided 90-percent confidence interval, which is less conservative than the two-sided interval, for recoveries arising from Medicare FFS overpayments. See, for example, *Maxmed Healthcare, Inc. v. Burwell*, 152 F. Supp. 3d 619, 634-37 (W.D. Tex. 2016), *aff'd*, 860 F.3d 335 (5th Cir. 2017); and *Anghel v. Sebelius*, 912 F. Supp. 2d 4, 17-18 (E.D.N.Y. 2012).

'overpayment' as the payment of funds to [MA organizations] based on unsupported diagnosis codes, while not applying the same documentation standards to the traditional Medicare data used to calculate payments to [MA organizations]."³⁰ Healthfirst noted that the Federal district court decision concluded "that CMS systematically devalues [MA organization] payments when it uses unaudited traditional Medicare data to set [MA organization] payment rates while measuring [MA organization] 'overpayments' based on audited patient records." Healthfirst cited to the opinion by the U.S. Court of Appeals for the D.C. Circuit, which ruled on the U.S. District Court's decision; specifically, Healthfirst highlighted that the Appeals Court held that "the actuarial-equivalence requirement does not pertain to the statutory overpayment-refund obligation" ³¹ However, Healthfirst noted that the court did not invalidate actuarial equivalence for use in RADV audits, for which the court stated "[w]e express no opinion on whether the actuarial equivalence requirement . . . requires such an adjuster in the [contract-level RADV audit . . .] context."

Healthfirst asserted that "the [MA] program requirements apply to OIG's audits" and that, without applying the FFSA, OIG's extrapolated repayment calculations violate the "actuarial equivalence" mandate. Accordingly, Healthfirst requested that OIG withdraw our overpayment calculation and limit any recovery to the specific encounters reviewed during this audit and for which the unsupported codes were found.

Office of Inspector General Response

Our audit methodology correctly applied CMS requirements to properly identify the overpayment amount associated with unsubstantiated HCCs for each sample item.

We used the results of the independent medical review contractor's review to determine which HCCs were not substantiated and, in some instances, to identify HCCs that should have been used but were not used in the sampled enrollees' risk score calculations. We followed CMS's risk adjustment program requirements to determine the payment that CMS should have made for each enrollee. We used the overpayments and underpayments identified for each enrollee to estimate net overpayments.

Healthfirst stated that we did not consider "actuarial equivalence" in our overpayment calculations. To this point, we recognize that CMS, not OIG, is responsible for making operational and program payment determinations for the MA program, including the application of any FFSA. Moreover, CMS has not issued any requirements that compel us to reduce our net overpayment calculations.³² If CMS deems it appropriate to apply an FFSA, it will adjust our overpayment finding by whatever amount it determines necessary. Thus, we

³⁰ *UnitedHealthcare Ins. Co. v. Azar II*, 330 F. Supp. 3d 173 (D.D.C. 2018).

³¹ *United Healthcare Insurance Co. v. Becerra*, 9 F.4th 868 (D.C. Cir. 2021).

³² In 2018, CMS proposed not to include an FFSA in any final RADV payment error methodology (Proposed Rule at 83 Fed. Reg. 54982, 55041).

believe that the steps that we followed for this audit provide a reasonable basis for our findings and recommendations, including our estimation of net overpayments.³³

HEALTHFIRST DID NOT AGREE WITH THE OFFICE OF INSPECTOR GENERAL'S RECOMMENDATION TO PERFORM ADDITIONAL REVIEWS BEFORE AND AFTER THE AUDIT PERIOD

Healthfirst Comments

Healthfirst disagreed with our second recommendation—that Healthfirst perform additional reviews to determine whether similar instances of high-risk diagnoses occurred before or after the audit period and to refund any overpayments—because, according to Healthfirst, “[MA] regulations do not require the sort of audits that OIG recommends.” In addition, Healthfirst stated that it does not have the information necessary to identify additional potentially mis-keyed diagnosis codes similar to those that we identified and for which we recommended that Healthfirst refund any resulting overpayments to the Federal Government (third recommendation).

Healthfirst stated that MA regulations “do not require [MA organizations] to ensure data perfection as the [d]raft [r]eport implies.” In this respect, Healthfirst stated that “[t]he government has long acknowledged that [MA organizations] are not expected to submit perfect risk adjustment data” and that “OIG has issued non-binding guidance stating that [MA organizations] should establish an ‘information collection and reporting system reasonably designed to yield accurate information.’” Moreover, Healthfirst stated that CMS recognizes that MA organizations submit encounter data “in great volume from a number of sources” and that for the certification of these data, CMS holds MA organizations responsible for making good faith efforts to certify their accuracy, completeness, and truthfulness.

In this respect, Healthfirst stated that our citations of Federal regulations for MA organizations like Healthfirst to monitor the data that they receive from providers and submit to CMS were misleading. Specifically, Healthfirst stated that our citations did not address the “broad discretion” that CMS provided to MA organizations to design their own compliance programs and did not “account for the qualified ‘good faith’ attestation standard that CMS explicitly adopted.” Thus, according to Healthfirst, OIG’s second recommendation “would dramatically expand the [MA] compliance program requirements.”

³³ OIG audit findings and recommendations do not represent final determinations by CMS. Action officials at CMS will determine whether an overpayment exists and will recoup any overpayments consistent with its policies and procedures. In accordance with 42 CFR § 422.311, which addresses audits conducted by the Secretary (including those conducted by the OIG), if a disallowance is taken, MA organizations have the right to appeal the determination that an overpayment occurred through the Secretary’s RADV appeals process.

Office of Inspector General Response

We do not agree with Healthfirst's interpretation of Federal requirements. We recognize that MA organizations have the latitude to design their own federally mandated compliance programs. We also recognize that CMS applies a "good faith attestation" standard when MA organizations certify the great volume of data that they submit to CMS for use in the risk adjustment program. However, contrary to Healthfirst's assertions, we believe that our second recommendation conforms to the requirements specified in Federal regulations (42 CFR § 422.503(b)(4)(vi) (see Appendix D)).

These Federal regulations state that MA organizations must "implement an effective compliance program, which must include measures that prevent, detect, and correct noncompliance with CMS' program requirements." Further, these regulations specify that Healthfirst's compliance plan "must, at a minimum, include [certain] core requirements," which include "an effective system for routine monitoring and identification of compliance risks . . . [including] internal monitoring and audits and, as appropriate, external audits to evaluate . . . compliance with CMS requirements and the overall effectiveness of the compliance program." These regulations also require MA organizations to implement procedures and a system for investigating "potential compliance problems as identified in the course of self-evaluations and audits, correcting such problems promptly and thoroughly to reduce the potential for recurrence." Thus, CMS has, through the issuance of these Federal regulations, assigned the responsibility for dealing with potential compliance issues to the MA organizations.

We believe that the error rates identified in this report demonstrate that Healthfirst has compliance issues that need to be addressed. These issues may extend to periods of time beyond our scope. Accordingly, we maintain that our second recommendation is valid.

With regard to the potentially mis-keyed diagnosis codes, during the course of our audit work, we explained to Healthfirst officials how we selected each target area, including mis-keyed diagnosis codes. Additionally, after the issuance of our draft report we provided Healthfirst with a spreadsheet detailing the 811 scenarios that we identified in which diagnosis codes could have been mis-keyed. Therefore, Healthfirst has the information necessary to identify additional mis-keyed diagnosis codes similar to those that we identified. Accordingly, we maintain that our third recommendation is also valid.

HEALTHFIRST DID NOT AGREE WITH THE OFFICE OF INSPECTOR GENERAL'S RECOMMENDATION TO ENHANCE ITS EXISTING COMPLIANCE PROGRAM

Healthfirst Comments

Healthfirst noted that it made changes to its compliance program after the end of our audit period. Additionally, Healthfirst stated that it regularly evaluates its compliance programs to respond to regulatory changes and to identify opportunities for improvement. Healthfirst

stated that it believes its current compliance program is sufficient to meet its current obligations and requested that we withdraw our fourth recommendation.

Office of Inspector General Response

We limited our review to selected diagnoses and HCCs that we determined to be at high risk for noncompliance (i.e., miscoded). Our audit revealed a significant error rate for some of these areas. After our audit period, Healthfirst revised its procedures to include internal medical reviews of these high-risk diagnoses. The continued improvement of those procedures, based on the results of this audit, as well as the results of Healthfirst's internal medical reviews, will assist Healthfirst in attaining better assurance with regard to the "accuracy, completeness and truthfulness" of the risk adjustment data that it submits in the future. Accordingly, we maintain that our fourth recommendation is valid.

APPENDIX A: AUDIT SCOPE AND METHODOLOGY

SCOPE

CMS paid Healthfirst \$3,333,485,481 to provide coverage to its enrollees for 2015 and 2016. We identified a sampling frame of 5,721 unique enrollee-years on whose behalf providers documented high-risk diagnosis codes during the 2014 and 2015 service years. Healthfirst received \$107,579,597 in payments from CMS for these enrollee-years for 2015 and 2016. We selected for audit 240 enrollee-years with payments totaling \$5,432,013.

The 240 enrollee-years included 49 acute stroke diagnoses, 30 acute heart attack diagnoses, 11 acute stroke diagnosis and acute heart attack diagnosis combinations, 30 embolism diagnoses, 35 vascular claudication diagnoses, 45 major depressive disorder diagnoses, and 40 potentially mis-keyed diagnoses. We limited our review to the portions of the payments that were associated with these high-risk diagnosis codes, which totaled \$787,928 for our sample.

Our audit objective did not require an understanding or assessment of Healthfirst's complete internal control structure, and we limited our review of internal controls to those directly related to our objective.

We performed audit work from August 2019 through September 2021.

METHODOLOGY

To accomplish our objective, we performed the following steps:

- We reviewed applicable Federal laws, regulations, and guidance.
- We discussed with CMS program officials the Federal requirements that MA organizations should follow when submitting diagnosis codes to CMS.
- We identified, through data mining and discussions with medical professionals at a Medicare administrative contractor, diagnosis codes and HCCs that were at high risk for noncompliance. We also identified the diagnosis codes that potentially should have been used for cases in which the high-risk diagnoses were miscoded.
- We consolidated the high-risk diagnosis codes into specific groups, which included:
 - 6 diagnosis codes for acute stroke,
 - 35 diagnosis codes for acute heart attack,
 - 56 diagnosis codes for embolism,
 - 4 diagnosis codes for vascular claudication, and
 - 27 diagnosis codes for major depressive disorder.

- We developed an analytical tool that identified 811 scenarios in which either ICD-9 or ICD-10 diagnosis codes, when mis-keyed into an electronic claim because of a data transposition or other data entry error, could result in the assignment of an incorrect HCC to an enrollee's risk score. For each of the 811 occurrences, the tool identified a potentially mis-keyed diagnosis code and the likely correct diagnosis code. Accordingly, we considered the potentially mis-keyed diagnosis codes to be high risk.
- We used CMS's systems to identify the enrollee-years on whose behalf providers documented the high-risk diagnosis codes. Specifically, we used extracts from CMS's:
 - Risk Adjustment Processing System (RAPS)³⁴ to identify enrollees who received high-risk diagnosis codes from a physician during the service years,
 - Risk Adjustment System (RAS)³⁵ to identify enrollees who received an HCC for the high-risk diagnosis codes,
 - Medicare Advantage Prescription Drug System (MARx)³⁶ to identify the total Medicare payments that CMS calculated, before applying the budget sequestration reduction, for Healthfirst for the payment years, and
 - Prescription Drug Event (PDE) file³⁷ to identify enrollees who had Medicare claims with certain medications dispensed on their behalf.
- We interviewed Healthfirst officials to gain an understanding of (1) the policies and procedures that Healthfirst followed to submit diagnosis codes to CMS for use in the risk-adjustment program and (2) Healthfirst's monitoring of those diagnosis codes to identify and detect noncompliance with Federal requirements.
- We selected for audit a sample of 240 enrollee-years that included (1) a stratified random sample of 200 enrollee-years and (2) a non-statistical sample of 40 enrollee-years.

³⁴ MA organizations use the RAPS to submit diagnosis codes to CMS.

³⁵ The RAS identifies the HCCs that CMS factors into each enrollee's risk score calculation.

³⁶ The MARx identifies the payments made to MA organizations.

³⁷ The PDE file contains claims with prescription drugs that have been dispensed to enrollees through the Medicare Part D (prescription drug coverage) program.

- We used an independent medical review contractor to perform a coding review for the 240 enrollee-years to determine whether the high-risk diagnosis codes submitted to CMS complied with Federal requirements.³⁸
- The independent medical review contractor's coding review followed a specific process to determine whether there was support for a diagnosis code and the associated HCC:
 - If the first senior coder found support for the diagnosis code on the medical record, the HCC was considered validated.
 - If the first senior coder did not find support on the medical record, a second senior coder performed a separate review of the same medical record:
 - If the second senior coder also did not find support, the HCC was considered to be not validated.
 - If the second senior coder found support, then a physician independently reviewed the medical record to make the final determination.
 - If either the first or second senior coder asked a physician for assistance, the physician's decision became the final determination.
- We used the results of the independent medical review contractor to calculate overpayments or underpayments for each enrollee-year. Specifically, we calculated:
 - a revised risk score in accordance with CMS's risk adjustment program and
 - the payment that CMS should have made for each enrollee-year.
- We estimated the total net overpayment made to Healthfirst during the audit period.
- We discussed the results of our audit with Healthfirst officials.

We conducted this performance audit in accordance with generally accepted government auditing standards. Those standards require that we plan and perform the audit to obtain sufficient, appropriate evidence to provide a reasonable basis for our findings and conclusions based on our audit objectives. We believe that the evidence obtained provides a reasonable basis for our findings and conclusions based on our audit objectives.

³⁸ Our independent medical review contractor used senior coders all of whom possessed one or more of the following qualifications and certifications: Registered Health Information Technician (RHIT), Certified Coding Specialist (CCS), Certified Coding Specialist – Physician-Based (CCS-P), Certified Professional Coder (CPC), and Certified Risk Coder (CRC). RHITs have completed a 2-year degree program and have passed an American Health Information Management Association (AHIMA) certification exam. The AHIMA also credentials individuals with CCS and CCS-P certifications and the American Academy of Professional Coders credentials both CPCs and CRCs.

<i>Some Diagnosis Codes That Essence Healthcare, Inc., Submitted to CMS Did Not Comply With Federal Requirements</i>	<u>A-07-17-01170</u>	4/30/2019

APPENDIX C: STATISTICAL SAMPLING METHODOLOGY

SAMPLING FRAME

We identified Healthfirst enrollees who (1) were continuously enrolled in Healthfirst throughout all of the 2014 or 2015 service year and January of the following year, (2) were not classified as being enrolled in hospice or as having end-stage renal disease status at any time during 2014 or 2015 or in January of the following year, and (3) received a high-risk diagnosis during 2014 or 2015 that caused an increased payment to Healthfirst for 2015 or 2016, respectively.

We presented the data for these enrollees to Healthfirst for verification and performed an analysis of the data included on CMS's systems to ensure that the high-risk diagnosis codes increased CMS's payments to Healthfirst. After we performed these steps, our finalized sampling frame consisted of 5,721 enrollee-years.

SAMPLE UNIT

The sample unit was an enrollee-year, which covered either payment year 2015 or 2016.

SAMPLE DESIGN

The design for our statistical sample was comprised of six strata of enrollee-years with either:

- an acute stroke diagnosis (which maps to the HCC for Ischemic or Unspecified Stroke) on one physician claim during the service year but did not have that diagnosis on a corresponding inpatient hospital claim (1,071 enrollee-years);
- a diagnosis that mapped to an Acute Heart Attack HCC on only one physician claim but did not have that diagnosis on a corresponding inpatient hospital claim either 60 days before or 60 days after the physician claim (560 enrollee-years);
- an acute stroke diagnosis and a diagnosis that mapped to an Acute Heart Attack HCC in the same year and that met the criteria mentioned in the previous two bullets (11 enrollee-years);
- a diagnosis that mapped to an Embolism HCC but for which an anticoagulant medication was not dispensed (362 enrollee-years);
- a vascular claudication diagnosis (which maps to the HCC for Vascular Disease) on one claim during the service year (and did not occur during the 2 years that preceded the service year), but for which medication was dispensed for neurogenic claudication during the service year (1,547 enrollee-years); or

- a major depressive disorder diagnosis (which maps to the HCC for Major Depressive, Bipolar, and Paranoid Disorders) on one claim during the service year but for which antidepressant medication was not dispensed (2,095 enrollee-years).

The specific strata are shown in Table 3.

Table 3: Sample Design for Audited High-Risk Groups

Stratum (High-Risk Groups)	Frame Count of Enrollee- Years	CMS Payment for HCCs in Audited High-Risk Groups*	Sample Size
1 – Acute Stroke	1,071	\$2,712,635	49
2 – Acute Heart Attack	560	1,203,268	30
3 – Acute Stroke / Acute Heart Attack Combination	11	54,748	11
4 – Embolism	362	954,907	30
5 – Vascular Claudication	1,547	3,712,264	35
6 – Major Depressive Disorder	2,095	5,839,986	45
Total – First Six Strata	5,646	\$14,477,808	200

*Rounded to the nearest whole dollar amount.

After we selected the 200 enrollee-years, we identified an additional group of 75 enrollee-years, from which we non-statistically selected 40 enrollee-years that represented individuals who received 1 of the 811 potentially mis-keyed diagnosis codes (which mapped to a potentially unvalidated HCC) and multiple instances of diagnosis codes for unrelated conditions that were likely keyed correctly. Thus, we selected for audit a total of 240 enrollee-years.

SOURCE OF RANDOM NUMBERS

We generated the random numbers with the Office of Inspector General (OIG), Office of Audit Services (OAS), statistical software.

METHOD FOR SELECTING SAMPLE ITEMS

We consecutively numbered the items in each stratum in the stratified sampling frame. After generating 200 random numbers according to our sample design, we selected the corresponding frame items for review. We also systematically selected a non-statistical sample of 40 items from the potentially mis-keyed group. This resulted in at least 1 enrollee-year being selected from each HCC group.

ESTIMATION METHODOLOGY

We used the OIG, OAS, statistical software to estimate the total amount of net overpayments to Healthfirst at the lower limit of the two-sided 90-percent confidence interval (Appendix D). Lower limits calculated in this manner are designed to be less than the actual overpayment total 95 percent of the time. We also identified the net overpayments from the non-statistical sample of 40 potentially mis-keyed diagnosis codes and added that amount to the estimate for the statistical sample to obtain the total net overpayments.

APPENDIX D: SAMPLE RESULTS AND ESTIMATES

Table 4: Sample Details and Results

Audited High-Risk Groups	Frame Size	CMS Payment for HCCs in Audited High-Risk Groups (for Enrollee-Years in Frame)	Sample Size	CMS Payment for HCCs in Audited High-Risk Groups (for Sampled Enrollee-Years)	Number of Sampled Enrollee-Years With Incorrect Diagnosis Codes	Net Overpayment for Unvalidated HCCs (for Sampled Enrollee-Years)
1 – Acute Stroke	1,071	\$2,712,635	49	\$129,370	49	\$129,370
2 – Acute Heart Attack	560	1,203,268	30	63,009	30	49,653
3- Acute Stroke/ Acute Heart Attack Combination	11	54,748	11	54,748	11	46,496
4 – Embolism	362	954,907	30	79,669	27	72,442
5 – Vascular Claudication	1,547	3,712,264	35	82,178	4	8,738
6 – Major Depressive Disorder	2,095	5,839,986	45	126,317	4	11,438
Totals— First Six Strata	5,646	\$14,477,808	200	535,291	125	\$318,137
7 – Potentially Mis-keyed Diagnoses	75	\$369,934	40	\$252,638	30	\$198,371
Totals – All	5,721	\$14,847,742	240	\$787,928*	155	\$516,509*

* Difference in total is due to rounding.

Table 5: Estimated Net Overpayments in the Sampling Frame
(Limits Calculated at the 90-Percent Confidence Level)

	Estimated Net Overpayment for Statistical Sample	Overpayment for Potentially Mis-keyed Diagnosis Group	Total Estimated Net Overpayments
Point Estimate	\$5,593,899	\$198,371	\$5,792,270
Lower Limit	\$5,023,530	\$198,371	\$5,221,901
Upper Limit	\$6,164,268	\$198,371	\$6,362,639

**APPENDIX E: FEDERAL REGULATIONS REGARDING COMPLIANCE PROGRAMS
THAT MEDICARE ADVANTAGE ORGANIZATIONS MUST FOLLOW**

Federal regulations (42 CFR § 422.503(b)) state:

Any entity seeking to contract as an MA organization must

(4) Have administrative and management arrangements satisfactory to CMS, as demonstrated by at least the following

(vi) Adopt and implement an effective compliance program, which must include measures that prevent, detect, and correct non-compliance with CMS's program requirements as well as measures that prevent, detect, and correct fraud, waste, and abuse. The compliance program must, at a minimum, include the following core requirements:

(A) Written policies, procedures, and standards of conduct that—

- (1) Articulate the organization's commitment to comply with all applicable Federal and State standards;
- (2) Describe compliance expectations as embodied in the standards of conduct;
- (3) Implement the operation of the compliance program;
- (4) Provide guidance to employees and others on dealing with potential compliance issues;
- (5) Identify how to communicate compliance issues to appropriate compliance personnel;
- (6) Describe how potential compliance issues are investigated and resolved by the organization; and
- (7) Include a policy of non-intimidation and non-retaliation for good faith participation in the compliance program, including but not limited to reporting potential issues, investigating issues, conducting self-evaluations, audits and remedial actions, and reporting to appropriate officials. . . .

- (F) Establishment and implementation of an effective system for routine monitoring and identification of compliance risks. The system should include internal monitoring and audits and, as appropriate, external audits, to evaluate the MA organization, including first tier entities', compliance with CMS requirements and the overall effectiveness of the compliance program.
- (G) Establishment and implementation of procedures and a system for promptly responding to compliance issues as they are raised, investigating potential compliance problems as identified in the course of self-evaluations and audits, correcting such problems promptly and thoroughly to reduce the potential for recurrence, and ensure ongoing compliance with CMS requirements.
 - (1) If the MA organization discovers evidence of misconduct related to payment or delivery of items or services under the contract, it must conduct a timely, reasonable inquiry into that conduct.
 - (2) The MA organization must conduct appropriate corrective actions (for example, repayment of overpayments, disciplinary actions against responsible employees) in response to the potential violation referenced in paragraph (b)(4)(vi)(G)(1) of this section.
 - (3) The MA organization should have procedures to voluntarily self-report potential fraud or misconduct related to the MA program to CMS or its designee.

APPENDIX F: BREAKOUT OF POTENTIALLY MIS-KEYED DIAGNOSIS CODES**Table 6: Potentially Mis-keyed Diagnosis Codes and Associated Overpayments**

Number of Sampled Enrollee-years	One Diagnosis for a Condition (Determined To Be Incorrect)			Multiple Diagnoses for a Condition (Not Reviewed)		Net Overpayment

APPENDIX G: HEALTHFIRST COMMENTS

VIA Electronic Mail "KiteWorks" to brenda.bernier@oig.hhs.gov

October 18, 2021

Brenda M. Tierney
Regional Inspector General for Audit Services
Office Of Audit Services
Region II
Jacob K. Javits Federal Building
25 Federal Plaza
Room 3900
New York, NY 10278

RE: Report Number: A-02-18-01029

Dear Ms. Tierney:

Healthfirst Health Plan, Inc. ("Healthfirst") writes in response to the United States Department of Health and Human Services ("HHS") Office of Inspector General's ("OIG's") Draft Report for Audit No. A-02-18-01029 ("Draft Report"). For the reasons described below, Healthfirst respectfully requests that OIG withdraw its recommendations that Healthfirst (i) repay an extrapolated amount of \$5,221,901 (and instead limit repayment to the \$516,509 in erroneous payments that were actually identified) and (ii) conduct additional self-audits beyond OIG's sample for periods during, prior to and after OIG's audit period and calculate any repayments based on those audits. Healthfirst objects to OIG's recommendations because (A) extrapolation is not permitted, (B) even if permitted, the proposed extrapolation methodology is inconsistent with the legal and regulatory requirements underlying the Medicare Advantage ("MA") program, and (C) there are currently open CMS audits in process for periods preceding the OIG's audit period and thus any self-audit would be duplicative and premature.

A. The Recommended Repayment Amount is Based on Extrapolation, For Which OIG Has No Authority and Which is Calculated Incorrectly

OIG reviewed medical records from a sample of Healthfirst beneficiaries and found overpayments totaling \$516,509. The remaining over \$4.5 million dollars OIG seeks to recoup is based on OIG's proposed extrapolation of those specific individual overpayments across a broader universe. Thus, OIG proposes to essentially use a sample to calculate a contract-wide error rate for similar codes and recover "overpayments" on that larger amount. OIG lacks authority to base its recovery on such an extrapolation. The Social Security Act ("SSA") only provides limited authority for CMS to extrapolate, and such authority is limited to contractors auditing providers under Medicare Parts A and B in limited circumstances not present here with respect to Medicare Advantage Organizations ("MAOs").¹ The applicable statute, entitled "LIMITATION ON USE OF EXTRAPOLATION," states:

A [Medicare contractor] may not use extrapolation to determine overpayment amounts to be recovered by recoupment, offset, or otherwise unless [CMS] determines that—

(A) there is a sustained or high level of payment error; or

¹ 42 U.S.C. § 1395dd(f)(3).

Healthfirst | 100 Church Street, New York, NY 10007 | www.healthfirst.org

(B) documented educational intervention has failed to correct the payment error.

The language of that section does not provide CMS with authority to use extrapolation for anyone other than providers and suppliers under Medicare Parts A and B. There is simply no statutory authority for the use of extrapolation of audit results of MACs providing services under Part C.²

While CMS purported to enact draft regulations regarding extrapolation for 2011, 2012 and 2013, they were never published with a prior notice and comment period.³ More recently, CMS published for comment a methodology for audits of Part C contractors for 2020 and 2021, which have received substantial negative comments, in part based on the actuarial equivalence argument discussed in paragraph B below.

There is no published methodology whatsoever for the 2015 and 2016 audit period here, and therefore there was no opportunity for the public or the MACs to understand the details of the methodology or make comments. Utilizing unpublished extrapolation methodology is inconsistent with the SSA requirements for notice-and-comment rulemaking as indicated by the Supreme Court in *Azar v. Allina Health Services*.⁴ Thus any purported authority for such extrapolation fails to comply with the required rule-making processes.

In addition, the methodology OIG employs in its extrapolation is faulty. OIG used the lower bound of a 90% confidence interval to calculate the extrapolated repayment amount, rather than the statistically valid and more robust practice of using the lower bound of a 95% or 99% confidence interval.⁵ In CMS's most recent disclosure of its own methodology for calculating extrapolated repayment amounts for its RADV audits, CMS stated that it uses the lower bound of a 99% confidence interval.⁶ Accordingly, although we believe that extrapolation is impermissible here, Healthfirst respectfully requests that even if OIG were permitted to extrapolate, it would have to recalculate the extrapolated "overpayment" amount using the lower bound of the more statistically robust 99% confidence interval consistent with CMS practice for RADV audits.

² That this section is limited providers and suppliers under Medicare Parts A and B is clear from the context and from additional language in this section: "There shall be no administrative or judicial review under section 1869 [referring to appeal rights specific to Medicare Parts A and B], section 1878 [referring to additional appeal rights specific to certain providers of services under Part A], or otherwise, of determinations by [CMS] of sustained or high levels of payment errors under this paragraph." See *America's Health Insurance Plans, Comments to the Proposed Rule* (August 17, 2019), www.ahip.org/wp-content/uploads/AHIP_RADV_comments_FTS&L_8-27-19.pdf at 25.

³ CMS proposed its methodology for conducting RADV audits, including extrapolation, via the CMS website on December 20, 2010, instead of the Federal Register. See *Policy and Technical Changes to the Medicare Advantage, Medicare Prescription Drug Benefit, Program of All-Inclusive Care for the Elderly (PACE), Medicaid Fee-for-Service, and Medicaid Managed Care Programs for Years 2020 and 2021*, 83 Fed. Reg. 54982, 55038 (proposed Nov. 1, 2018).

⁴ 139 S. Ct. 1804 (2019).

⁵ Federal Judicial Center, National Academies Press, *Reference Manual on Scientific Evidence* 245 (3d ed. 2011) ("The 95% confidence level is the most popular, but some authors use 99%, and 90% is seen on occasion.")

⁶ Centers for Medicare and Medicaid Services, *Notice of Final Payment Error Calculation Methodology for Part C Medicare Advantage Risk Adjustment Data Validation for Contract-Level Audits*, at 4 (Feb. 24, 2012) (to be codified at 42 C.F.R. Parts 422, 423, 438, and 498) (hereinafter *Notice of Error Calculation*).

B. The Recommended Extrapolated Repayment Amount is Incorrect Because it is Not Adjusted to Ensure Actuarial Equivalence to the Fee-For-Service Medicare Program as Required by Law

The SSA requires CMS to pay MACs an amount that is "actuarially equivalent" to the expected cost that CMS would have otherwise incurred had it provided required Medicare benefits directly to the MACs' enrollees. Actuarial equivalence measures whether different benefit packages have "the same value, based on the estimated spending that would be incurred by the insurer."⁷ Because the SSA ties Medicare Advantage compensation to the expected cost of providing traditional Medicare benefits to an enrollee of average risk, the "actuarial equivalence" mandate requires CMS to base risk-adjusted payments on actuarially sound calculations of the expected cost of providing traditional Medicare benefits to enrollees with different health status.⁸ That conclusion is confirmed by the SSA's separate requirement that CMS report to Congress on the "actuarial soundness" of the agency's proposed risk adjustment methodology.⁹ CMS developed the Medicare Advantage risk adjustment model using unaudited Fee-for-Service ("FFS") claims data from the traditional Medicare program, which CMS has acknowledged contain high levels of erroneous diagnoses. Accordingly, in order to ensure actuarial equivalence between the FFS and MA programs, CMS should measure overall rates of erroneous diagnoses in the Medicare Advantage program against the rates of erroneous diagnoses found within the traditional Medicare FFS program.¹⁰ CMS previously formally signaled its agreement with the requirement of measuring error rates in Medicare Advantage diagnoses against those in the traditional Medicare program. In 2012, CMS published a notice stating that it was adopting this requirement as part of its methodology for calculating recovery amounts for unsupported Hierarchical Condition Categories ("HCCs") identified during its RADV audits. Specifically, CMS said that it would first identify a "payment recovery amount" based on the value of supported and unsupported HCCs identified during its review.¹¹ Then, "to determine the final payment recovery amount, CMS [would] apply a Fee-for-Service Adjuster ('FFS Adjuster') amount as an offset to the preliminary recovery amount," and base the FFS Adjuster "on a RADV-like review of records submitted to support [traditional Medicare] claims data."¹²

This announcement reflected CMS's view (stated in internal CMS documents) that without applying an FFS Adjuster to calculated repayment amounts, audited MACs are underpaid.¹³ In a CMS presentation titled "Model Calibration Factor," for example, CMS explained that:

¹³ See *Azar*, 1:16-cv-00157-RMC (D.D.C. Oct. 2, 2017) (ECF 44-3) (Document authored by CMS titled "Model Calibration Factor"); *Azar*, 1:16-cv-00157-RMC (D.D.C. Oct. 2, 2017) (ECF 44-4) (Document authored by CMS titled "Three RADV Policy Issues").

"[i]n RADV audits, we expect coding perfection from [MAOs],¹⁴ while "[i]n [traditional] Medicare, some portion of diagnoses on [traditional Medicare] claims are not documented in medical records."¹⁵

As a result, for RADV audits, MAOs "are being held to a different (higher) standard for diagnoses"¹⁶ absent an FFS adjuster.

CMS said that these different document standards matter because traditional Medicare data were used to calculate MA payments and the "[i]nclusion of undocumented diagnoses tends to reduce risk adjustment values."¹⁴ CMS then used numerical examples to demonstrate that MAOs would be underpaid (i.e., MAOs' costs would exceed CMS reimbursement) if MAOs were audited to a standard of data perfection without properly calibrating the overpayment amount to account for traditional Medicare data errors.¹⁷ CMS departed from the principle that a FFS adjuster is necessary by issuing a proposed rule in 2018¹⁸ suggesting that diagnosis coding errors in unaudited traditional Medicare data do not systematically impact payments to MAOs¹⁹ and released a corresponding study purporting to support this premise.²⁰ Healthfirst and numerous other parties, including actuarial and statistical experts, have submitted comments to CMS objecting to this approach and advocating for the use of a "fee-for-service adjuster" as originally proposed in connection with the proposed rule.²¹

In September 2018, a federal district court in *UnitedHealthcare Ins. Co. v. Azar II* ("Azar"), 330 F. Supp. 3d 173 (D.D.C. 2018), vacated CMS's Medicare Advantage Overpayment Rule because the rule violated the SSA's actuarial equivalence mandate by defining "overpayment" as the payment of funds to MAOs based on unsupported diagnosis codes, while not applying the same documentation standards to the traditional Medicare data used to calculate payments to MAOs.²² In doing so, the court concluded that CMS systematically devalues MAO payments when it uses unaudited traditional Medicare data to set MAO payment rates while measuring MAO "overpayments" based on audited patient records.²³ CMS presented a study that purported to deny the need for a fee-for-service adjuster, but the court in Azar

²² *Azar*, 330 F. Supp. 3d at 187-90; *Azar*, Case No. 16-cv-157 (RMC), 2020 WL 417867 (D.D.C. Jan. 27, 2020).

²³ *Id.* at 186-87 ("[T]he 'expected' value of payments from CMS for healthcare costs [to MAOs] will be lower than the 'expected' payments CMS itself will make under traditional Medicare, since CMS does not audit or engage in similar self-examination for accuracy of its own records. The consequence is inevitable: while CMS pays for all diagnostic codes, erroneous or not, submitted to traditional Medicare, it will pay less for Medicare Advantage coverage because essentially no errors would be reimbursed.")

found that CMS's study "does not persuade" and concluded that the government had failed to "adequately respond" to criticisms of the study raised during litigation.²⁴ On January 27, 2020, the same court reaffirmed this position in denying the government's request to reconsider the court's prior holding.²⁵ The D.C. Circuit in *United Healthcare Insurance Co. v. Becerra*, 9 F.4th 868 (D.C. Cir. 2021), while overturning *Azar* in part, recognized the requirement of actuarial equivalence in conducting RADV audits. The *Becerra* court recognized that "the system-level adjustment that CMS said it would apply in the context of contract-level RADV audits came in direct response to concerns about actuarial equivalence." *Becerra*, 9 F.4th at 872. The court expressly limited its holding, striking down actuarial equivalence in the overpayment context: "we hold that the actuarial-equivalence requirement does not pertain to the statutory overpayment-refund obligation, or the Overpayment Rule challenged here . . ." *Id.* The Court, however, noted that it was not invalidating actuarial equivalence as applied to RADV audits, saying "[w]e express no opinion on whether the actuarial equivalence requirement . . . requires such an adjuster in the [contract-level RADV audit] context." *Id.* at n. 1 (emphasis added). Notably, the Overpayment Rule itself applies only to known overpayments. *Id.* at 880. Any RADV audit can necessarily only identify individual overpayments, and it is therefore not proper to require repayment of extrapolated results across the contract without adjusting to account for the error rate in the FFS program in order to ensure actuarial equivalency (if such extrapolation is indeed ever proper, as discussed above).

These Medicare Advantage program requirements apply to OIG's audits and calculation of estimated repayment amounts for the same program. Thus, OIG's extrapolated repayment calculations, by failing to apply an FFS adjuster, violate the "actuarial equivalence" mandate that underpins the Medicare Advantage program.

Healthfirst accordingly requests that OIG withdraw its overpayment calculation and limit any recovery in this audit to the specific encounters that were reviewed during this audit and for which the unsupported codes were found.

C. Retroactivity is Prohibited By Federal Law and is Unnecessary and Unjustified

This audit relates to services provided in 2015 and 2016, necessarily requiring looking back to significantly prior periods. The SSA prohibits retroactive rules absent a statutory requirement, significant public safety concern or other critical need²⁶, none of which are present here. In addition, retroactivity poses major operational barriers for MAOs and providers. Seeking records from providers for services provided in 2015 and 2016 to support HCCs reported on claims related to those services is often difficult. Most provider records from that period and earlier were paper, and while many providers have now converted to electronic records, it is not likely that they converted their older paper records. Additionally, providers have often moved, closed their practices, or may be deceased, all of which makes obtaining supporting records difficult even they existed at the time the claims were submitted.

Both because retroactivity is prohibited and because, practically speaking, provider records are sparse if available for past periods, we believe that even if a valid rule authorizing extrapolation if promulgated, it should not be applied retroactively, and that extrapolation by the OIG based on audit findings from 2016-2016 is similarly not permissible.

²⁴ *Azar*, 2020 WL 417867, at *1, *5.

²⁵ *Id.*

²⁶ 42 U.S.C. § 1395h(e)(1)(A): "A substantive change in regulations, manual instructions, interpretive rules, statements of policy, or guidelines of general applicability under this subchapter shall not be applied (by extrapolation or otherwise) retroactively to items and services furnished before the effective date of the change, unless the Secretary determines that- (i) such retroactive application is necessary to comply with statutory requirements; or (ii) failure to apply the change retroactively would be contrary to the public interest."

D. Healthfirst Requests that OIG Withdraw Its Recommendation that Healthfirst Undertake Additional Auditing for the Condition Categories Subject to OIG's Audit

OIG recommends that Healthfirst "identify, for the high-risk diagnoses included in [the Draft Report], similar instances of noncompliance that occurred before or after [the] audit period and refund any resulting overpayments to the Federal Government[.]"²⁷ As further set forth below, MAOs are not required to audit to the standard that OIG suggests. Medicare Advantage regulations do not require the sort of audits that OIG recommends and certainly do not require MAOs to ensure data perfection as the Draft Report implies. In fact, the *Bacerra* court notes that "[n]othing in the Overpayment Rule obligates insurers to audit their reported data," a fact the court notes that CMS did not dispute. *Bacerra* at 884. Even if Healthfirst were to undertake additional audits, OIG has not provided Healthfirst with the information necessary to identify additional "potentially miskeyed diagnoses" similar to those audited by OIG here. Further, the implementation of ICD-10 in 2016 introduced a more precise alpha-numeric coding system which greatly reduced the likelihood of miskeying errors, which would likely moot this category of errors with respect to that year and going forward.

The government has long acknowledged that MAOs are not expected to submit perfect risk adjustment data. For example, it has stated that MAOs "cannot reasonably be expected to know that every piece of data is correct, nor is that the standard that [CMS], the OIG, and [the U.S. Department of Justice] believe is reasonable to enforce."²⁸ OIG has issued non-binding guidance stating that MAOs should establish an "information collection and reporting system reasonably designed to yield accurate information."²⁹ This guidance affords MAOs broad discretion in designing compliance mechanisms. As the federal district court acknowledged in *Azar*, there is a disconnect when the government "treats diagnosis codes as categorically valid for its own purposes under traditional Medicare," but then requires "Medicare Advantage insurers to certify 'based on best knowledge, information, and belief' that the information they provide to CMS, including all diagnosis codes, is 'accurate, complete, and truthful.'"³⁰

This understanding is reflected in MAOs' annual data accuracy attestation requirements. MAOs are required to certify that their risk adjustment data is accurate based on their "best knowledge, information, and belief."³¹ CMS has acknowledged that "[t]he requirement that the CEO or CFO certify as to the accuracy, completeness and truthfulness of data, based on best knowledge, information and belief, does not constitute an absolute guarantee of accuracy."³² CMS has stated that MAOs "will be held responsible for making good faith efforts to certify the accuracy, completeness, and truthfulness of encounter data submitted."³³ This "good faith" standard is not defined by CMS or OIG but it recognizes "that encounter data [can] come into [MAOs] in great volume from a number of sources, presenting significant verification challenges for the organizations."³⁴

²⁷ Draft report at "Report in Brief".

²⁸ 65 Fed. Reg. 40169, 40268 (June 29, 2000).

²⁹ 64 Fed. Reg. 61893, 61900 (Nov. 15, 1999) (noting also that MAOs "should exercise due diligence to ensure that these systems are working properly" but that "[t]he exact methods used . . . can be determined by the organization and that these methods 'should ordinarily [include] sample audits and spot checks of this system to verify whether it is yielding accurate information'").

³⁰ *Azar*, 330 F. Supp. 3d at 179–80.

³¹ 42 C.F.R. § 422.504(j)(2).

³² 64 Fed. Reg. at 61900.

³³ 65 Fed. Reg. at 40268.

³⁴ *Id.* Notably, OIG's Draft Report appears at times to conflate the source of diagnosis codes in a manner that suggests MAOs have more information than they actually do about the accuracy of the risk adjustment data submitted to CMS. See, e.g., Draft Report at 3 ("MA organizations collect the diagnosis codes that physicians document on the medical records and submit th[ose] codes to CMS."); *id.* at 12 ("Healthfirst had submitted diagnosis codes in which physicians had documented conditions. . . ."). Providers document patient encounters in their medical records and submit claims to MAOs with diagnosis codes based on those encounters. MAOs then

OIG's Draft Report makes two potentially misleading statements in this respect. First, the Draft Report states that "[f]ederal regulations state that [MAOs] must monitor the data that they receive from providers and submit to CMS."³⁹ As noted above, given the high volume of diagnosis codes that are submitted to MAOs through provider claims submissions, CMS gives MAOs broad discretion to design their own compliance and risk adjustment data accuracy programs. CMS has declined to require MAOs to implement any specific oversight measures, and certainly does not require verification of every code submitted by a provider. Second, the Draft Report also states that federal regulations "state that [MAOs] are responsible for the accuracy, completeness, and truthfulness of the data submitted to CMS for payment purposes."⁴⁰ This statement is misleading and not accurate because it suggests that the standard for accuracy, completeness and truthfulness is absolute and fails to account for the qualified "good faith" attestation standard that CMS explicitly adopted.

Accordingly, OIG's recommendation would dramatically expand the Medicare Advantage compliance program requirements.⁴¹ CMS is certainly aware of industry-wide trends pertaining to the seven categories audited by OIG through CMS's years of RADV audits, communications with MAOs, and review of the traditional Medicare data it uses to calculate MAO payments. But CMS has not opted to take any steps to implement regulations in response to these trends, let alone the expansive steps OIG proposes in its Draft Report. Healthfirst therefore respectfully requests that OIG withdraw this recommendation.

E. Healthfirst Will Continue to Identify Opportunities to Enhance its Existing RADV Compliance Program

As OIG acknowledges, Healthfirst has made significant changes to its RADV compliance program since the close of OIG's audit period. While Healthfirst regularly evaluates its compliance programs in order to both respond to regulatory changes and to identify opportunities for improvement, Healthfirst believes that its current RADV compliance program is sufficient to meet its current obligations. Accordingly, Healthfirst requests that OIG withdraw its recommendation that Healthfirst make changes to its existing RADV compliance program.

CONCLUSION

For the foregoing reasons, Healthfirst requests that OIG withdraw all recommendations, with the exception of the recommendation that Healthfirst repay actual overpayments in the amount of \$516,509.

extract diagnosis codes from provider claims data to submit to CMS. Contrary to OIG's description in the Draft Report, the majority of the diagnosis codes MAOs submit to CMS come from the claims data submitted to MAOs by providers and are not identified by MAOs following a review of patient medical records. Recognizing that MAOs are not the original source of most risk adjustment data, CMS applies a "good faith" standard to the sexual data accuracy attestation, having expressly acknowledged that MAOs are not guaranteeing through that attestation absolute accuracy. OIG's Draft Report, and in particular its audit recommendations, appear to be in direct conflict with this express guidance from CMS.

³⁹ Draft Report at 8.

⁴⁰ *Id.* at 7.

⁴¹ The fact that the CMS compliance requirements are not more comprehensive and prescriptive is consistent with (1) the fact that HCC coefficients are based on unaudited traditional Medicare data and (2) the implausibility of expecting MAOs to audit more than a small subset of the vast amount of data submitted to CMS that is generated by healthcare providers who are neither employed by an MAO nor under the direction and control of the MAO.

Measuring Coding Intensity in the Medicare Advantage Program

Richard Kronick¹ and W. Pete Welch²

¹Department of Health and Human Services—Agency for Healthcare Research and Quality

²Department of Health and Human Services—Office of the Assistant
Secretary for Planning and Evaluation

Background: In 2004, Medicare implemented a system of paying Medicare Advantage (MA) plans that gave them greater incentive than fee-for-service (FFS) providers to report diagnoses.

Data: Risk scores for all Medicare beneficiaries 2004–2013 and Medicare Current Beneficiary Survey (MCBS) data, 2006–2011.

Measures: Change in average risk score for all enrollees and for stayers (beneficiaries who were in either FFS or MA for two consecutive years). Prevalence rates by Hierarchical Condition Category (HCC).

Results: Each year the average MA risk score increased faster than the average FFS score. Using the risk adjustment model in place in 2004, the average MA score as a ratio of the average FFS score would have increased from 90% in 2004 to 109% in 2013. Using the model partially implemented in 2014, the ratio would have increased from 88% to 102%. The increase in relative MA scores appears to largely reflect changes in diagnostic coding, not

real increases in the morbidity of MA enrollees. In survey-based data for 2006–2011, the MA-FFS ratio of risk scores remained roughly constant at 96%. Intensity of coding varies widely by contract, with some contracts coding very similarly to FFS and others coding much more intensely than the MA average. Underpinning this relative growth in scores is particularly rapid relative growth in a subset of HCCs.

Discussion: Medicare has taken significant steps to mitigate the effects of coding intensity in MA, including implementing a 3.4% coding intensity adjustment in 2010 and revising the risk adjustment model in 2013 and 2014. Given the continuous relative increase in the average MA risk score, further policy changes will likely be necessary.

Medicare & Medicaid Research Review
2014: Volume 4, Number 2

Mission Statement

Medicare & Medicaid Research Review is a peer-reviewed, online journal reporting data and research that informs current and future directions of the Medicare, Medicaid, and Children's Health Insurance programs. The journal seeks to examine and evaluate health care coverage, quality and access to care for beneficiaries, and payment for health services.

Introduction

General

Enrollment in the Medicare Advantage Program has increased dramatically, growing from 9.3 million beneficiaries in March 2008 to 15.4 million in March 2014, an increase of 66% in just six years.

Concerns about overpayment as a result of favorable risk selection have confronted the Medicare program throughout the history of Medicare contracting with health maintenance organizations and other private plans. In the late 1980s, Medicare paid health plans using a system that adjusted for demographic factors such as age and gender, but plan enrollees were healthier than fee-for-service beneficiaries with the same demographic characteristics, and, as a result, health plans were estimated to be overpaid by approximately 11% (Brown, Bergeron, Clement, Hill, & Retchin, 1993).¹

In order to reward health plans for attracting sicker-than-average enrollees, and to discourage plans from constructing business models designed to avoid risk, Medicare and other payers have increasingly turned to diagnosis-based risk-adjusted payment systems in which health plans are paid more for enrollees expected to need more care. While mitigating the incentive to enroll only healthy people, diagnosis-based risk adjustment creates another set of incentives: to find and report as many diagnoses as possible. Risk-adjusted payment using plan-reported diagnostic information creates a dilemma—there are strong policy reasons to pay plans more if they enroll sicker people,

¹ Systems in which payment is based, at least in part, on patient diagnoses create an incentive for providers or plans to report all appropriate diagnoses. Most notably, after the advent of the inpatient prospective payment system, which used diagnosis related groups (DRGs), hospital case-mix increased.

but measuring morbidity using plan-reported diagnostic data provides strong incentives for plans to increase the reported morbidity of enrollees (Government Accountability Office, 2012).

Medicare Risk Adjustment

The first Medicare risk program was established under the Tax Equity and Fiscal Responsibility Act (TEFRA) of 1982. From 1982 to 1999, this program paid health plans (known as TEFRA health maintenance organizations [HMOs]) a monthly amount per enrollee based on 95 percent of the estimated costs of treating an average beneficiary in the traditional fee-for-service (FFS) program. This amount was adjusted for demographic factors such as age and gender (Hellinger & Wong, 2000; Lichtenstein, Thomas, Adams-Watson, Lepkowski, & Simone, 1991).

The Balanced Budget Act of 1997 made significant changes under the Medicare+Choice (M+C) program, including requiring the development of a new risk adjustment system that incorporated morbidity information. Medicare began using diagnoses from inpatient hospitalizations in 2000 to adjust payments to health plans. The Benefits Improvement Protection Act of 2000 required the use of ambulatory diagnoses in Medicare risk-adjustment, and Medicare implemented the CMS-HCC (Centers for Medicare & Medicaid Services-Hierarchical Condition Categories) risk adjustment model in 2004 and fully phased it in by 2007. The CMS-HCC incorporated both inpatient and ambulatory diagnoses that were categorized into 70 HCCs that were determined to be predictive of costs (Pope, *et al.*, 2004). In 2003 the Medicare Modernization Act (MMA) renamed the program "Medicare Advantage (MA)."

The MA payment system uses diagnostic information to assign a risk score to each beneficiary, where the average beneficiary in

fee-for-service has a risk score of 1.0. MA plans are paid the product of their bid multiplied by the enrollee's risk score—that is, if an MA plan bids \$1,000/month for an enrollee with a risk score of 1.0, and then enrolls a beneficiary with a risk score of 1.2, the plan gets paid \$1,200/month for that enrollee ($1.2 * \$1,000/\text{month}$).

This payment system creates incentives for MA plans to find and report as many diagnoses as can be supported by the medical record. For office-based services, physicians billing FFS are paid based on the procedures performed—for example, one amount for an intermediate office visit, a different amount for a skin biopsy—but are not paid based on the number of diagnoses that are reported (provided there is at least one that supports the need for the service provided). If, for example, a FFS patient with quadriplegia and a urinary tract infection (UTI) has an office visit for treatment of the UTI, the payment to the physician will be no more if both the UTI and quadriplegia are reported on the claim than if only the UTI is reported. Coding guidelines specify that the quadriplegia can legitimately be coded if it contributes to the complexity of care, but unlike the situation for MA plans, in FFS there is no incentive to report more than one diagnosis. In contrast, MA plans have a strong incentive to do so. In addition to the incentives to report more completely, the method of collecting diagnostic information also provides MA plans additional opportunities to increase risk scores. FFS diagnoses are drawn only from health care claims submitted for payment. MA plans may also review medical records and can report all diagnoses that are supported in the record, including those that were not reported by physicians on any health care claim or encounter record. MA plans can also employ nurses to visit enrollees in their homes to conduct health assessments and report diagnoses that are found.

As noted, payment to MA plans is calibrated based on coding patterns in FFS. If, for example, Jane Doe would have a risk score of 1.0 if she were in FFS, the implicit assumption in the design of the MA payment system is that she would have the same risk score of 1.0 if she were enrolled in MA. Alternatively, if the same Jane Doe had a risk score of 1.1 if enrolled in MA, then her plan would be overpaid. As we use the phrase, 'coding intensity' is the difference between the scores that a group of beneficiaries would have if enrolled in MA and their scores in FFS.

If we find that MA plans code with high intensity, that does not provide information about whether MA plans are 'overcoding' or whether FFS providers are 'undercoding.' Similarly, one cannot infer whether MA coding is any more or less accurate than FFS. However, for the purposes of creating an equitable MA payment system, the relevant question is whether MA risk scores are systematically different than those risk scores would be in FFS, and not which set of scores is more accurate. Suppose, for example, that average expenditure per FFS beneficiary is \$10,000/year, and that the average risk score for all FFS beneficiaries is 1.0. The goal of the payment system is to assure that—if all of those beneficiaries were to enroll in MA—the average payment to MA plans would be approximately \$10,000 per beneficiary. If, however, FFS systematically underreports diagnoses and MA reports them more completely, then the average risk score in MA would be greater than 1.0, and MA plans would be paid more than \$10,000 per beneficiary. The goal of the risk adjustment system is to assure that MA plans that enroll sicker-than-average beneficiaries are paid appropriately, but not to increase payment for an average beneficiary.

As a result of concern about the effects of incentives to increase coding intensity on MA plan payment levels, the Deficit Reduction Act

of 2005 directed CMS to measure and adjust for coding intensity (Department of Health and Human Services, 2007), and in the 2010 payment year CMS adjusted risk scores by 3.41% to reflect anticipated differences between MA and FFS coding (Department of Health and Human Services, 2009). The Government Accountability Office (2012) estimated that in 2010 MA beneficiary risk scores were at least 4.8% and perhaps as much as 7.1% higher than they likely would have been if the same beneficiaries had been continuously enrolled in FFS. The Affordable Care Act directs CMS to increase the coding intensity adjustment to at least 4.71% in 2014, and further increase it to at least 5.71% by 2018 (PPACA & HCERA, 2010). The American Taxpayer's Relief Act of 2012 further increases the minimum coding intensity adjustment to 4.91% in 2014 and 5.91% in 2018.

The risk adjustment model implemented in 2004 was recalibrated in 2007, 2009, and 2013.³ These changes slowed the growth in measured MA risk scores somewhat. Further, as described in more detail below, since 2014, CMS has adopted substantial changes to the model, particularly relating to several diagnoses that have been subject to coding intensity efforts by MA plans (Department of Health and Human Services, 2013). In 2014 the risk score is a blend, weighting the risk score calculated using the 2013 model by 25% and the risk score calculated using the 2014 model by 75%.

Concerns about coding intensity in MA plans would be minor if coding in FFS were relatively complete, because in that case there would be little opportunity for MA plans to legitimately increase risk scores through efforts at increasing diagnostic

³ HCCs are constrained for a variety of reasons, including methodological and policy reasons. Starting in 2013, the coefficients for the four most severe diabetes HCCs were constrained to the same amount, eliminating the opportunity to increase revenue by increasing the reported severity of diabetes within these four HCCs.

reporting. However, FFS coding is known to be both incomplete and variable. Incomplete coding is evidenced by lack of persistence in coding of chronic conditions. For instance, among Medicare beneficiaries diagnosed with quadriplegia in one year, only 61% had a diagnosis of quadriplegia reported in the subsequent year (Medicare Payment Advisory Commission, 1998). Coding intensity also varies geographically; in the Hospital Referral Regions (HRRs) with the most intense practice patterns, the probability that a beneficiary is diagnosed with three or more chronic conditions is double the probability in low-intensity HRRs, with no evidence of differences in underlying prevalence (Welch, Sharp, Gottlieb, Skinner, & Wennberg, 2011).

Incomplete and variable coding provide ample opportunities for MA plans to increase risk scores of beneficiaries through coding intensity efforts, and a number of vendors actively market services that help plans to do so (Gorman Health Group, 2013; Leprechaun, 2013), often advertising high returns on investment (ROIs) for their services.

This paper uses recent data as well as improved methods to estimate the effects of coding intensity on MA risk scores, with particular attention to variation over time in coding intensity, variation in coding intensity across plans, and variation in the diagnoses most subject to coding intensity efforts. Before describing our methods, we'll review what is known about risk selection in the MA program.

Evidence on Risk Selection

Concerns about overpayment as a result of favorable risk selection have confronted the Medicare program throughout its history of contracting with HMOs and other private plans. For example, Brown *et al.* (1993) found that health plans were overpaid by approximately 11% under the Medicare risk program during the late 1980s

because plans experienced favorable selection; on average, risk plan enrollees were healthier than fee-for-service beneficiaries with the same demographic characteristics, with lower prior reimbursements and fewer indicators of chronic health problems (Brown *et al.*, 1993). Several studies confirmed that the favorable risk selection for early HMOs continued during the early 1990s (Mello, Stearns, Norton, & Ricketts, 2003; Call, Dowd, Feldman, & Maciejewski, 1999; Physician Payment Review Commission, 1996; Riley, Chiang, Ingber, & Tudor, 1996). For example, Mello *et al.* (2003) found that Medicare beneficiaries with a history of cancer or stroke were significantly less likely to be enrolled in HMOs.

Recent analyses suggest that the various policy changes that have been implemented over the past decade—such as the implementation of the CMS-HCC model, the addition of an open enrollment period, and additional refinements of the risk adjustment system—have reduced the degree of selection bias between Medicare Advantage (MA) and the traditional FFS program. For example, Newhouse, Price, Huang, McWilliams, & Hsu (2012) recently found that differences in risk scores for beneficiaries switching from the traditional FFS program to MA and beneficiaries remaining in the traditional program narrowed by a factor of 3 between 2004 and 2008 (with the difference between risk scores for beneficiaries switching into MA and those staying in the traditional FFS program changing from -0.113 to -0.037); and differences in adjusted mortality rates narrowed by a factor of 2 between 1988 and 2008 (with mortality among beneficiaries in MA as a percentage of mortality among beneficiaries in the traditional FFS program increasing from 85 percent to 93 percent) and were almost equal between persons enrolled in MA for five or more years and traditional FFS enrollees (Newhouse *et al.*, 2012). Similarly, McWilliams,

Hsu, and Newhouse (2012) found reductions in differences between MA and FFS for self-reported health and health care use between 2001 and 2003 and between 2006 and 2007. However, there continues to be evidence of selection bias in disenrollment from MA plans (Riley, 2012; Medicare Payment Advisory Commission, 2012; Morrissey, Kilgore, Becker, Smith, & Delzell, 2012).

Methods

Ideally, we would measure coding intensity by running an experiment with a large group of beneficiaries, in which one-half of the group was randomly assigned to MA, the other half to FFS, and we observed the risk scores of each group. The difference between the average score in MA and FFS would be a good estimate of coding intensity. In the absence of performing this experiment, we use a variety of inferential approaches. As shown below, average MA risk scores increased much more rapidly than average FFS scores from 2004 to 2013. There are three potential explanations for the relative increase in MA scores. First, the composition of MA enrollment might have changed; for example, MA enrollees in 2013 might be older, relative to FFS, than MA enrollees in 2004, and, as a result have higher risk scores. Second, even if there were no change in the composition of MA enrollees, MA enrollees might have gotten sicker more quickly than FFS beneficiaries. Third, it is possible that coding intensity increased in MA. Below, we assess the plausibility of each of these three potential explanations concluding that greater coding intensity is by far the most likely explanation.

We evaluate whether changes in MA scores relative to FFS scores are due to coding intensity efforts or to changes in the composition of enrollees by analyzing the contribution of changes in risk scores for four types of beneficiaries: stayers,

leavers, joiners, and switchers—where stayers are beneficiaries in either MA or FFS for two consecutive years; leavers are beneficiaries, primarily decedents, who were in one sector in the first year, but not Medicare eligible in the second year; joiners are beneficiaries, primarily those turning 65, who were not Medicare eligible in the first year; and switchers are beneficiaries who move from FFS to MA (or vice-versa) between two consecutive years. To the extent that the contribution of leavers, joiners, or switchers differed between MA and FFS, then we will have evidence that part of the differential growth in risk scores between MA and FFS is a result of differences arising from enrollment decisions or mortality of beneficiaries, or “caseload dynamics” for shorthand. However, if risk scores increase more rapidly for MA stayers than for similar FFS stayers, then we will have evidence that coding intensity accounts for part of the more rapid growth in MA scores.

Our analysis assumes that in the absence of coding intensity efforts, the risk score for a given MA beneficiary would increase, on average, at the same rate as the risk score for an otherwise similar FFS beneficiary from one year to the next. This appears to be a reasonable assumption, and would only be incorrect if MA beneficiaries were actually getting sicker more quickly than FFS beneficiaries. We analyze changes in the relative mortality rate of MA and FFS enrollees as an independent method of assessing the relative morbidity of beneficiaries in the two sectors. If MA enrollees are, in fact, getting sicker more quickly than FFS beneficiaries, we would expect to see MA mortality rates increase relative to FFS mortality.

Data

For each year from 2004 to 2013, we used three Medicare administrative files with beneficiary level data: the Enrollment Database (EDB); the

Common Medicare Environment, which contains the MA contract number; and the Risk Adjustment Processing System, which contains the risk score. For each year from 2004 to 2013, we computed the risk score using each HCC's coefficient (i.e., weight) that was used to pay plans in 2004–2006. Analyses of coding intensity based on risk scores have not appeared in the peer-reviewed literature.

We excluded beneficiaries not enrolled in both Parts A and B, because diagnostic information would be incomplete. Beneficiaries enrolled in cost contracts, hospice, or the ESRD program were also excluded, because of differences in payment methodology. Risk scores were computed prior to any normalization and MA-wide adjustment for differences in coding.

Decomposition of Risk Score Growth

To decompose the changes in risk scores, we analyze beneficiaries based on their enrollment as of July 1 of each of two consequent years (called a “cohort”). We analyze nine cohorts, from the first cohort under the new adjustment system in 2004–2005 through the most recent one in 2012–2013, estimating the contribution of each type of beneficiary—stayers, joiners, leavers, and switchers—to the overall change in risk score. The decomposition method is described in the Supplemental Appendix.

Contract-Level Analyses

To assess the extent to which coding intensity differs across contracts, we calculate the rate of increase in risk scores for stayers for contracts that continuously participated in Medicare from 2004 through 2011, had at least 10,000 enrollees in both 2004 and 2011, and whose ratio of 2011 enrollment to 2004 enrollment was between 25% and 300%. The subset of contracts account for approximately 85% of enrollment in 2004 and 42% in 2011.

For each contract and cohort, we define the excess increase in risk score for stayers as the difference between the increase in risk scores for stayers in the contract and the increase in risk scores for FFS beneficiaries, controlling for age and decedent status (details are in the Supplemental Appendix).³ The cumulative excess increase in risk score is the sum of this amount over the seven cohorts from 2004 to 2005 through 2010 to 2011. Contracts are divided into deciles (weighted by 2011 enrollment) based on the cumulative excess increase in scores for stayers.

The growth in relative prevalence of each HCC was calculated separately for the MA and FFS sector as well as by decile of coding intensity among the continuously participating contracts.

Analysis of Medicare Current Beneficiary Survey (MCBS) Data

We analyze the MCBS to provide an assessment of the relative risk of MA and FFS beneficiaries that is independent of the data reported by MA plans or FFS providers. As described more fully in the Supplemental Appendix, in the first stage of the analysis, we use MCBS data from 2004 to 2011 to estimate a regression model to predict the sum of Part A plus Part B expenditures. The regression is estimated on FFS enrollees. Independent variables are demographic characteristics (age, gender, Medicaid status, and institutional status), self-reported health status (excellent, very good, good, fair, or poor), and self-report of whether the respondent has ever been diagnosed with hypertension, heart attack, heart failure, stroke, cancer, or diabetes, and dummy variables for each year. In the second stage, we use the regression coefficients to predict expenditures for each FFS

³ The contract-level analysis implicitly assumes that the increase in FFS risk scores for a beneficiary of a given age and decedent status is uniform geographically.

and MA respondent in the sample, and compare the average predictions for MA and FFS.

Results

Mean risk scores in MA increased faster than in FFS from 2004 to 2013—by 0.305 in MA, compared to 0.106 in FFS (Exhibit 1). As measured using the risk model in effect in 2004, MA scores grew from 90.2% of FFS scores in 2004 to 109.1% in 2013, an increase of 18.9 percentage points.⁴

Decomposition of Risk Score Growth

Risk scores among MA stayers increased more quickly than risk scores among FFS stayers in every

cohort (Exhibit 2). Across the two-year cohorts, the growth in risk scores for FFS stayers averaged 0.088. In contrast, in MA the growth in mean risk scores for stayers was 0.106 in 2004–2006, 0.119 in 2006–2010, and 0.132 in 2010–2013. The difference between the rate of growth in risk scores for MA and FFS stayers is substantial, with average MA scores increasing one-third more rapidly than FFS scores.

As was shown in Exhibit 1, the average MA risk score increased 0.025 more rapidly than the average FFS score from 2004 to 2005. Differential changes between MA and FFS in caseload dynamics account for approximately one-half of this 0.025 difference (Exhibit 3). As was shown in Exhibit 2, risk scores for FFS stayers increase by approximately 0.088 per year. However, as was shown in Exhibit 1, the

⁴ As noted, the payment rules, however, did change in a variety of ways.

Exhibit 1. Mean Risk Scores, MA vs. FFS, 2004–2013 (2004 Model)

NOTE: 2004 HCC model, which here has been normalized to 1.00 for FFS in 2004. For payment purposes, this model was modified and recalibrated in 2007, 2009, 2013, and 2014. Risk scores were adjusted by -3.41%, starting in 2010. Diagnoses from FFS diagnostic radiology claims were excluded starting in 2008.

Exhibit 3. Sources of Differential Growth in MA and FFS Risk Scores, 2004–2005

NOTE: 2004 model. Caseload dynamics is the sum of leavers (e.g., decedents), joiners (e.g., newly eligibles), and switchers. Total is the sum of caseload dynamics and stayers.
SOURCE: Authors' analysis of Medicare administrative data.

average FFS risk score increases by approximately 0.012 per year. Caseload dynamics account for the difference between the 0.088 growth for stayers and the 0.012 for all FFS beneficiaries—relatively high risk score decedents exit the caseload and are replaced by relatively low risk score 65 year olds.

From 2004 to 2005, caseload dynamics caused greater restraint in the growth of FFS risk scores than in MA (Exhibit 3). Decedents are a greater proportion of FFS beneficiaries than of MA enrollees and, similarly, 65 year olds are a greater proportion of FFS than of MA. Primarily as a result of the greater proportion of decedents in FFS, the average MA risk score in 2005 increased by 0.009 more than the average FFS score. Similarly, as a result of the greater proportion of 65 year olds in FFS, the average MA score increased by 0.008 more than the average FFS score. These

effects were partially balanced by the effects of switchers—relatively low risk beneficiaries switching from FFS to MA, and relatively high risk beneficiaries switching from MA to FFS. Despite the partially counterbalancing effect of switchers, the net effect of caseload dynamics was to cause the average MA score to increase 0.012 more rapidly than the average FFS score from 2004 to 2005. The remaining 0.013 of the difference in growth rate between MA and FFS scores is accounted for by the fact that risk scores for stayers increased more rapidly in MA than in FFS.

Although caseload dynamics accounted for part of the more rapid growth in MA risk scores in 2004–2005, in 2012–2013 the effects of caseload dynamics reversed, causing the average MA risk score to grow more slowly than FFS (Exhibit 4). Decedents have a similar effect in 2012–2013 as in

Exhibit 4. Sources of Differential Growth in MA and FFS Risk Scores, 2012–2013

SOURCE: Authors' analysis of Medicare administrative data.

2004–2005, but the effects of joiners and switchers are different in the latter period than in the former. In contrast to the 2004–2005 results, in 2012–2013 the proportion of 65 year olds was similar in MA and FFS, and joiners do not have much effect on the difference between MA and FFS in risk score growth rates. Switchers had a small negative effect in 2004–2005, but a much larger negative effect in 2012–2013.⁵ As was shown in Exhibit 2, the difference between MA and FFS in the rate of increase in risk scores for stayers widened in 2013, accounting for the larger effect of stayers in Exhibit 4 than in Exhibit 3.

On average over the 2004–2013 period, caseload dynamics had virtually no net effect on

the difference between MA and FFS in the rate of growth of risk scores, and the greater increase in risk scores for MA stayers compared to FFS appears to account for most of the reason for the differential growth (Exhibit 5). Caseload dynamics led to more rapid increases in risk scores in MA in the early part of the period, but to slower increases in the latter part and, on balance, made very little contribution to the differential growth in scores.

We have shown that more rapid increase in risk scores for MA stayers than for FFS stayers largely accounts for the more rapid growth in MA risk scores seen in Exhibit 1.

Relative Morbidity of MA Enrollees: Analyses of Mortality and MCBS Data

We analyze mortality rates in MA and FFS during the 2004–2012 period to test the hypothesis that

⁵ The difference between 2004–05 and 2012–13 is primarily a result of the fact that disenrollees from MA to FFS had higher risk scores in the latter cohort than in the earlier one.

Exhibit 5. Sources of Differential Growth in MA and FFS Risk Scores, Average 2004–2013

NOTE: 2004 model. Caseload dynamics is the sum of leavers (e.g., decedents), joiners (e.g., newly eligibles), and switchers. Total is the sum of caseload dynamics and stayers.

SOURCE: Authors' analysis of Medicare administrative data.

MA beneficiaries declined in health relative to FFS beneficiaries. Mortality rates declined somewhat more rapidly in MA than in FFS from 2004 to 2012, providing no support for the hypothesis that the underlying morbidity of MA beneficiaries increased relative to FFS (See Supplemental Appendix Exhibit A3 & A4). As noted earlier, mortality rates were lower in MA than in FFS.

We use MCBS data to provide an assessment of relative risk of MA and FFS beneficiaries that is independent of data reported by MA plans or FFS providers. As described in the Supplemental Appendix, we predict spending for each MA and FFS beneficiary using demographic information, self-reported health status, and the respondent's report of whether she has ever been diagnosed with hypertension, heart attack, heart failure, stroke, cancer, or diabetes. Predicted expenditures for MA

enrollees average approximately 96% of predicted expenditures for FFS beneficiaries, and the ratio does not appear to have changed systematically over the 2006 to 2011 period. Results from this analysis are shown in the Supplemental Appendix Exhibit A8.

Contract-Level Analyses

There is a striking amount of heterogeneity across MA contracts in the extent to which risk scores for stayers increased from 2004 to 2011 (Exhibit 6). The fourteen contracts accounting for 10% of MA enrollment that coded least aggressively had cumulative increases in risk scores for stayers at or below the level in FFS (i.e., cumulative excess increase at or below zero). Conversely, the four contracts in the top decile, including one with over 200,000 members, had a cumulative excess increase

Exhibit 6. Cumulative Excess Increase in Risk Scores, All Enrollees vs. Stayers Only, by Contract, 2004–2011

NOTE: 2004 model. Continuously participating contracts (N=86).

SOURCE: Authors' analysis of Medicare administrative data.

of 0.59 or more (at least 0.08 per year). Contracts in which risk scores for stayers increased more rapidly than in FFS also had overall risk scores that increased more rapidly than FFS ($r=.92$).

Increases in diagnostic coding are especially large in a relatively small number of largely discretionary HCCs (Exhibit 7).⁶ For example, in 2012, 1.2% of FFS beneficiaries were coded with drug or alcohol dependence, compared to 8.1% of beneficiaries in the 10% of MA contracts with the highest level of coding intensity (as measured by the cumulative excess increase in risk scores for stayers shown in Exhibit 6). Similarly, polyneuropathy is recorded three times as often in the top decile of MA plans as in FFS. In addition, MA plans, particularly those in the top decile of coding intensity, both increased the rate at which diabetes was reported, and shifted the distribution towards the highest paying diabetes HCC (HCC 15). Among the top decile of plans, the prevalence of this HCC increased from 2.5% in 2004 to 20.1% in 2012. In contrast, for diagnoses such as heart attack and hip fracture, where there is little discretion in diagnosis, prevalence in the top decile of plans is similar to, or below, FFS levels (see Supplemental Appendix Exhibit A5).

In 2014 Medicare started using a revised model, which we term the “2014 model.” In part as a result of the analysis shown in Exhibit 7, the polyneuropathy HCC was restructured to remove diabetic neuropathy, and the renal failure HCC was restructured to exclude chronic kidney disease stages 1–3 and was split into acute and

chronic kidney conditions, among other changes. These changes build on the changes made in 2013 that constrained the payment weights for each of the four most severe diabetes HCCs to be equal, removing the ability of MA plans to generate extra revenue by increasing the reported severity of diabetes within these four HCCs.

As a result of the changes to the model in 2013 and 2014, the impact of coding effort on risk scores is smaller using the new 2014 model than with the older 2004 model. As shown in Exhibit 8, if the 2014 model had been in place in 2013, the average MA risk score in 2013 would have been slightly higher than the average FFS score. Even using the new model, the average MA score increased substantially relative to the average FFS score from 2004 to 2013, but the rate of increase was somewhat slower than when measured with the 2004 model—an increase of 2.2% per year in relative MA score using the 2004 model (Exhibit 1)—compared to approximately 1.6% per year using the 2014 model. This result suggests that some coding intensity efforts—such as increasing the reported severity of diabetes or coding chronic kidney disease more aggressively—have been neutralized by the 2014 model, but others have not.

Discussion

In the 2004–2013 period, the mean MA risk score increased 2.2 percentage points per year more quickly than the mean FFS score using the 2004 model and 1.6 percentage points more quickly using the 2014 model. Comprehensive risk adjustment was first implemented in Medicare Advantage in 2004 and was not fully phased in until 2007 when 100% of Part C payments were risk adjusted. It is possible that during this phase-in period when plans were first reporting diagnosis codes from ambulatory settings, the level of coding by MA plans was not as comprehensive

⁶ An HCC is considered “discretionary” if it is based on diagnoses that providers may or may not record for patients having the diagnosis. For example, there is relatively little discretion in whether a diagnosis of “hip fracture” should be recorded for a patient presenting with an apparent hip fracture. In contrast, there is substantial discretion about whether a patient being assessed in an annual wellness visit should be recorded as exhibiting “alcohol or drug abuse.” Discretion might also result from either a choice of ICD-9 codes (e.g., pneumonia vs. sepsis in an inpatient setting) or underlying ambiguity of the condition (e.g., depression vs. anxiety).

2014: Volume 4 (2)

Exhibit 8. Mean Risk Scores, MA vs. FFS, 2004–2013 (2004 & 2014 Models)

NOTE: CMS will use the "2014 model" for payment purposes for the first time in 2014, when it will receive a weight of 75%. This exhibit simulates past payment assuming full implementation. Here, both models have been normalized to 1.00 of the FFS mean in 2004.

SOURCE: Authors' analysis of Medicare administrative data.

as FFS. If that were the case, the relatively faster growth in risk scores during this period could be attributable to plans "catching up" to FFS, rather than coding more intensely than FFS. The true difference in average MA and FFS risk, which is beyond the scope of this paper, is a worthy topic for future research.

It appears that most of the reason that MA risk scores increased more quickly than FFS scores is due to increases in relative coding intensity—measured as increases in risk scores for stayers—with little of it accounted for by changes in enrollment mix. There is little sign of coding intensity slowing; in fact, Exhibit 2 shows that it may be increasing (using the 2004 model).

Our conclusion is supported by several findings. Our analysis of joiners, leavers, switchers, and stayers shows clearly that changes in the

composition of the MA caseload do not account for the increase in relative MA risk scores. Risk scores for stayers increased more quickly for MA enrollees than for FFS beneficiaries—by an average of 0.088 for FFS stayers, compared to 0.120 for MA stayers (Exhibit 2), and it is this difference that accounts for the relative increase in MA risk scores (Exhibit 5).

In principle, risk scores for stayers could have increased more quickly in MA because of differences in characteristics at baseline; for example, risk scores typically increase more quickly for older beneficiaries than for younger beneficiaries. If MA enrollees were older than FFS beneficiaries, then MA scores (unadjusted for age) would have increased more quickly than FFS, even if there were no change in coding intensity. However, the age distribution of MA enrollees is

relatively similar to the age distribution of FFS beneficiaries, and slight differences between the sectors in the age distribution do not account for differences in the rate of growth of risk scores. As a second example, risk scores may increase more quickly for beneficiaries with lower initial risk scores than for those with higher initial scores, because of regression toward the mean. However, baseline risk scores are higher in MA than in FFS in the later part of the analysis period, precluding a regression-toward-the-mean explanation for MA's more rapid growth in scores.

In addition, if MA enrollees were actually sicker, relative to FFS beneficiaries, in 2013 than in 2004, then we would have expected to see some reflection of this in our analysis of mortality rates and of self-reported health status information. In contrast, mortality rates in MA declined more quickly than mortality rates in FFS, and there was no evidence of a trend in self-reported illness, suggesting that MA enrollees did not actually become relatively sicker over the time period.

In an observational study such as this one, it is never possible to conclusively rule out all alternative hypotheses. MA risk scores increased more rapidly than FFS scores. We have shown that this did not result from a change in the composition of MA enrollees. And we have shown that using two independent measures of health status—self-reported health from the MCBS and information on mortality—that there is no indication that MA enrollees actually were getting any sicker than FFS beneficiaries. While it is theoretically possible that some explanation other than greater coding intensity accounts for the relative increase in MA risk scores, we are unable to suggest any plausible alternative hypotheses.

We have also shown that there is substantial heterogeneity across plans in coding intensity, with some plans coding at approximately the same level

as FFS, while several others created a cumulative increase in coding intensity from 2004 to 2011 of 60% or more.

Coding more carefully may have real health benefits. Better identification of problems and better documentation of problems that have been identified could improve the quality of treatment provided and may even lower costs—or they may lead to unnecessary treatment and higher costs. In either case, however, the purpose and design of the risk-adjusted payment system is not to improve the quality of coding. It is to ensure that plans are paid according to the health of the patients they enroll. It is unlikely that the increased payments achieved by plans through increased coding intensity are related to substantial health benefits that better coding might produce.

CMS and the Congress have responded to the increase in risk scores over time in several ways. First, starting in 2010, CMS lowered payment by 3.41% by applying an across-the-board coding adjustment. The coding intensity adjustment will increase to 4.91% in 2014 and to at least 5.91% in 2018. Second, starting in 2013, CMS set the four most severe diabetes HCCs (HCC15-HCC18) to have the same payment coefficient (Department of Health and Human Services, 2012). As a result, recording diagnoses that move enrollees from HCC18 (diabetes with ophthalmologic or unspecified manifestation) into HCC15 (diabetes with renal or peripheral circulatory manifestation) will no longer increase revenue for MA plans. Third, CMS made further changes to the model in 2014, removing some of the HCCs that were the subject of MA efforts at increasing coding intensity.⁷

⁷ CMS is also recovering overpayments identified by risk adjustment data validation (RADV) audits of selected MA contracts.

Relative MA risk scores have been increasing at least 1% per year (Exhibit 8) and are likely to continue to do so, even though MCBS-based risk scores have been roughly constant.^a The legislated increase in coding intensity adjustment is 0.25% per year from 2014 through 2018. The President's Budget for 2015 proposes increasing the minimum adjustment to 0.67% per year through 2020, plateauing at 8.51% in 2020 and thereafter, much closer to the expected increase in relative risk scores. The across-the-board adjustments do not address the substantial heterogeneity in plan-level results shown in Exhibit 6.

It is challenging to accurately measure the effects of coding intensity on MA risk scores and even more challenging to devise optimal policy responses. Uncertainty about the extent to which coding intensity would persist beyond the early years of using diagnostic information, uncertainty about whether some of the changes observed in MA risk scores might have been due to changes in underlying morbidity of MA enrollees, and heterogeneity across plans in coding intensity each create challenges in evaluating appropriate policy responses. In addition, it is unclear to what extent MA plans coded less completely than FFS in 2004, and how much of the increase in coding intensity reflects MA simply catching up to FFS levels, and how much represents going above and beyond. The Department of Health and Human Services is continuing its analysis of the relative risk of MA and FFS enrollees to improve the ability of the Medicare program to accurately pay for MA beneficiaries.

EXPERT REPORT OF JEAN ACEVEDO

SEPTEMBER 29, 2023

Amended April 5, 2024

I. QUALIFICATIONS

1. I am a Certified Professional Coder (“CPC”) and Certified ENT Coder (“CENTC,” i.e., coding focused on ear, nose, and throat conditions), and have been so designated since 1999 and 2008, respectively, through the American Academy of Professional Coders (“AAPC”).¹ I achieved AAPC Fellow status in January 2017, which indicates that I have been recognized for my professional achievements in coding and continuous adherence to the ethical and professional standards of the AAPC.² I have also held the Certified in Healthcare Compliance (“CHC”) certification from the Health Care Compliance Association (“HCCA”) since 2002.³ Additionally, I have been a health care risk manager since 1989 (currently inactive).

2. I have experience in all areas of medical coding and reimbursement, particularly with Current Procedural Terminology (“CPT”), Healthcare Common Procedure Coding System (“HCPCS”), the International Classification of Diseases, Ninth and Tenth Revisions, Clinical Modification (ICD-9-CM and ICD-10-CM)⁴ diagnosis coding,⁵ and third-party payer billing and payment rules, including the Centers for Medicare and Medicaid Services (“CMS”) Medicare Advantage risk adjustment program.

3. From 2007 through 2022, I developed and taught the regulatory and compliance modules of the Certificate in Medical Business Management program at Florida Atlantic University’s School of Business.

4. For the past twenty-three years, I have maintained an active healthcare consulting practice as the founder and senior consultant of Acevedo Consulting Incorporated (“ACI”). ACI assists clients in the healthcare industry in all areas concerning reimbursement, including coding

¹ *Coding Certifications*, AAPC, <https://www.aapc.com/certifications?tag=coding> (last visited Sept. 29, 2023).

² *AAPC Fellow Application Process*, AAPC, <https://www.aapc.com/recognition/aapc-fellow.aspx> (last visited Sept. 29, 2023) (“Fellows are highly experienced in their position within the business of healthcare. This status indicates your professional achievement and continuous adherence to the ethical and professional standards of AAPC. Fellowship is earned through hard work, written demonstration of your professional expertise, and regular commitment to dedicated leadership in the healthcare community.”).

³ *Certified in Healthcare Compliance (CHC)*, HCCA, <https://www.hcca-info.org/certification/become-certified/chc> (last visited Sept. 29, 2023).

⁴ For purposes of this report, I use the term “ICD-9” to refer to “ICD-9-CM” and “ICD-10” to refer to “ICD-10-CM,” respectively. Furthermore, I use the term “ICD” to refer both to ICD-9 and ICD-10.

⁵ See *ICD-10, ICD-10-CM, & ICD-10-PCS*, University of Kansas Medical Center, <https://guides.library.kumc.edu/icd10> (last visited Sept. 29, 2023).

and medical records review. The firm's clients span the gamut of the United States' healthcare system, from large Medicare Advantage Organizations ("MAOs") to small private health insurers, small physician practices to large healthcare systems, and the federal government.

5. I have provided education on ICD coding rules to large and small physician organizations, Accountable Care Organizations ("ACOs"), and a national MAO. I have also advised physician practice groups on accuracy and compliance with the coding and Medicare Advantage risk adjustment rules on a proactive basis as well as assisting them through risk adjustment audits by any one of the Medicare contractors. I have had a longstanding contract with a large Program of All-Inclusive Care for the Elderly ("PACE") to provide documentation and education on ICD-10 coding, and to provide monthly quality reviews and feedback on the accuracy and completeness of the providers' documentation.

6. A copy of my Curriculum Vitae, including a list of all publications I have authored, is attached as **Appendix A**. A list of my prior testimony is attached as **Appendix B**.

II. COMPENSATION

7. My contract with the United States Department of Justice is on an hourly basis. For my work on this case, I am being compensated at my standard billing rate of \$325.00 per hour for guidance and development of my report. My rate for testifying at a deposition or appearing at any proceeding is \$468.75 per hour. My compensation is not contingent on the content of my opinions or the outcome of this matter.

III. SCOPE OF ASSIGNMENT

8. I have been engaged by the Plaintiffs to provide expert testimony in this matter. Specifically, I have been asked to provide background on medical record coding, including ICD-9 and ICD-10 diagnosis coding, and its relationship to the Hierarchical Condition Categories ("HCCs") used in the Medicare Advantage risk adjustment program. I have also been asked to provide expert testimony on the following topics: (1) the documentation standards required in risk adjustment coding; (2) the standards and guidelines governing medical record coding; and (3) industry best practices for achieving accurate and complete coding in the Medicare Advantage context. The relevant time period for my report covers dates of service in 2008 through 2016.

9. I reserve the right to supplement or revise my opinions should additional information become available.

IV. BASIS FOR OPINIONS

10. I have reviewed publicly-available materials for the relevant time period, including the ICD-9 official Coding Guidelines applicable during the 2008–2014 dates-of-service years and the ICD-10 official Coding Guidelines applicable during the 2015–2016 dates-of-service years; the CMS 2008 Risk Adjustment Data Technical Assistance for Medicare Advantage Organizations Participant Guide (“2008 Participant Guide”); the CMS Medicare Managed Care Manual, Chapter 7 – Risk Adjustment; and various publications regarding coding. I have also reviewed deposition transcripts from this case. A complete list of the materials that I have relied upon as a basis for my opinions rendered in this report is attached as **Appendix C**.

V. BACKGROUND

A. Introduction to Medical Record Coding

11. When an individual goes to a doctor’s office, an urgent care center, hospital, or other health care facility, the physician or other provider documents one or more of the following in the patient’s medical record: the patient’s complaint and related history, a physical examination, and the assessment/impression and plan. In determining whether to pay for a healthcare service, the patient’s insurance company or other payer generally requires information on what was done to the patient (i.e., the medical service provided), and why. There are industry-standard medical “codes” used to report “what was done” and “why” on claims made to insurance companies. These codes ensure that all healthcare providers are speaking the same language when submitting a claim for payment.

12. While the American Medical Association has created Current Procedural Terminology (“CPT”) codes to describe “what was done” (e.g., an office visit, an ultrasound, a blood draw, etc.), ICD diagnosis codes tell the insurer “why”—i.e., what health condition the medical service addresses. ICD diagnosis codes designate diseases, symptoms, abnormal findings, and other elements of the patient’s diagnosis. For example, when a physician sees a patient for a new patient office visit, the CPT code may be 99204, which represents the service provided. If the medical record appropriately documents that the patient exhibits symptoms of

diabetes and that blood tests confirm that the patient has diabetes mellitus, the proper ICD-10-CM code is E11.9, which represents the diagnosis.

13. When insurance payment is on a “fee-for-service” basis, the physician is paid based on the specific CPT code submitted for the office visit, and the payment amount is the same regardless of how sick the patient is. Continuing the example from paragraph 12, the physician would be paid based on CPT code 99204 (new patient office visit), regardless of the patient’s confirmed diabetes mellitus diagnosis (E11.9). The ICD code does not impact the payment.

14. By contrast, in the Medicare Advantage program discussed further below, the reported ICD codes are relevant because payment is on a “risk adjusted” basis. This means that CMS pays MAOs a monthly amount per beneficiary based on the risk profile of that beneficiary. Generally, the sicker a beneficiary is, the higher the payment. The risk adjustment system sets the monthly payment amount by estimating the healthcare expenditures a patient is likely to require in a given year, based in part on the health status of the patient, which in turn is based on the Hierarchical Condition Categories (“HCCs”) reported for that patient. As explained below, ICD codes underlie HCCs, and therefore, may impact payment in this system.

B. ICD-9 and ICD-10 Coding

15. The International Classification of Diseases is a medical classification system maintained by the World Health Organization (“WHO”) and used worldwide for health management and clinical purposes. WHO issues new revisions of the ICD periodically.

16. At the beginning of the relevant time period, ICD-9 was the operative classification system. There were approximately 14,000 ICD-9 diagnosis codes. When the United States Department of Health and Human Services switched to ICD-10 in 2015, that number rose to almost 70,000, because ICD-10 allows for greater specificity and more granularity in describing a patient’s condition, variants of that condition, or complications present with certain conditions.⁶

⁶ *International Classification of Diseases, (ICD-10-CM/PCS) Transition - Background*, Centers for Disease Control and Prevention, https://www.cdc.gov/nchs/icd/icd10cm_pcs_background.htm (last visited Sept. 29, 2023).

17. Depending on the date-of-service year in the relevant time period, the authoritative source for diagnosis coding is the ICD-9 or ICD-10 Coding Guidelines published by the Centers for Disease Control and Prevention (CDC).⁷ There are a number of additional sources that explain coding rules and guidelines that must be followed for proper reporting of diagnoses. These additional sources include coding guidelines, manuals, and training published by CMS.⁸ Organizations such as hospitals and MAOs also subscribe to the American Hospital Association's "Coding Clinic," another recognized source for ICD-9 and ICD-10 guidance.

18. There are two recognized organizations that certify professional coders, the AAPC and American Health Information Management Association ("AHIMA"). The main credential provided by the AAPC is the CPC (Certified Professional Coder) and the main credential provided by AHIMA is the CCS (Clinical Coding Specialist).⁹

19. Coding certification from either the AAPC or AHIMA requires following the AAPC and AHIMA's guidelines for ethical coding.¹⁰

C. ICD Coding and Reporting Process

20. In the Medicare Advantage context, both ICD and CMS have set out rules on the provider documentation (and content of that documentation) needed to assign and report particular ICD codes on insurance claims. Historically, before this process became electronic, physicians handwrote notes in patient charts, the billing staff looked up the applicable diagnosis code(s) supported by notes in patient charts in an ICD code book, and then the staff would report the assigned ICD codes on a claim submitted for payment.

21. With the adoption of electronic medical records (EMRs) beginning in 2011, it has become increasingly common for physicians to select the ICD-9 or ICD-10 code(s) as they

⁷ *International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM)*, Centers for Disease Control and Prevention, <https://www.cdc.gov/nchs/icd/icd-10-cm.htm> (last visited Sept. 29, 2023); *ICD-9-CM Addenda, Conversion Table, and Guidelines*, Centers for Disease Control and Prevention, https://www.cdc.gov/nchs/icd/icd9cm_addenda_guidelines.htm (last visited Sept. 29, 2023).

⁸ See, e.g., *ICD-10 Resources*, Centers for Medicare & Medicaid Services, <https://www.cms.gov/medicare/coding-billing/icd-10-codes/icd-10-resources> (last visited Sept. 29, 2023).

⁹ See *Certified Professional Coder (CPC) Certification*, AAPC, <https://www.aapc.com/certifications/cpc> (last visited Sept. 29, 2023); *Certified Coding Specialist (CCS)*, AHIMA, <https://www.ahima.org/certification-careers/certification-exams/ccs/> (last visited Sept. 29, 2023).

¹⁰ See *Code of Ethics*, AAPC, <https://www.aapc.com/about-us/code-of-ethics> (last visited Sept. 29, 2023); *Ethics*, AHIMA, <https://www.ahima.org/who-we-are/governance/ethics/> (last visited Sept. 29, 2023).

complete their notes in the EMR system. This is especially true in an outpatient office or clinic setting. As a physician starts to type “diabetes” in the section of the note where diagnoses are listed, the EMR presents a list of possible ICD codes. For example, if the patient has Type 2 diabetes mellitus without complications, the physician should select E11.9 as the corresponding ICD-10 code. Billing staff may verify that the physician selected the correct code(s) and then include them on an insurance claim. In hospital settings, which tend to have more resources than the typical outpatient provider’s office, dedicated coders may look at the appropriate sections of medical charts and, following the applicable payer rules for the type of medical facility, report diagnosis codes on the insurance claim.

D. Medicare Advantage Program

22. The federal government’s Medicare program provides health insurance for people ages 65 or older as well as younger individuals with certain disabilities.¹¹ Medicare beneficiaries have the option to enroll in “Traditional Medicare” or “Medicare Advantage.” Medicare Advantage beneficiaries enroll in plans administered by private insurance companies known as “Medicare Advantage Organizations,” or “MAOs.”¹²

23. CMS enters into annual contracts with MAOs that participate in the Medicare Advantage program and imposes numerous requirements on the MAOs pursuant to statutes, regulations, guidance materials, and through the contracts.¹³

Risk Scores Under the CMS-HCC Risk Adjustment Model

24. In the Medicare Advantage program, CMS pays MAOs a monthly premium for each beneficiary enrolled in the MAOs’ plans.¹⁴ The amount of payment depends in part on the beneficiary’s “risk score,” which is calculated using the CMS Hierarchical Condition Category (“HCC”) Risk Adjustment Model.¹⁵

25. Each beneficiary’s risk score is newly calculated each payment year based on health conditions documented in the beneficiary’s medical records during the prior year (referred

¹¹ 42 U.S.C. § 426 *et seq.*; 42 C.F.R. § 406.5; 42 C.F.R. §§ 406.10–406.13.

¹² 42 U.S.C. § 1395w *et seq.*; 42 C.F.R. § 422 *et seq.*

¹³ 42 U.S.C. § 1395w *et seq.*; 42 C.F.R. § 422 *et seq.*

¹⁴ 42 U.S.C. § 1395w-23(a)(1)(A); 42 C.F.R. § 422 *et seq.*

¹⁵ 42 U.S.C. § 1395w-23(a)(1)(C); 42 C.F.R. §§ 422.300–422.308.

to as the “service year” or “date-of-service” (“DOS”) year). For example, a beneficiary’s risk score for payment year 2016 is based on conditions documented in that beneficiary’s medical records during encounters that took place in 2015, but that risk score would not reflect conditions documented in that beneficiary’s medical records during encounters in 2014 or in 2016.

26. The purpose of these individualized risk scores is to capture anticipated differences in the costs of coverage for beneficiaries given differences in their health status and demographic background.¹⁶ Thus, the risk score is calculated based on both the health status of the beneficiary and demographic factors (e.g., a patient’s gender and age, disability status, institutional status).¹⁷

Hierarchical Condition Categories (HCCs)

27. The health status component of the risk score is based on the HCCs or Hierarchical Condition Categories reported for the beneficiary. CMS groups ICD-9/ICD-10 diagnosis codes with other clinically similar diagnosis codes.¹⁸ These diagnosis code groupings are in turn grouped into “condition categories.”¹⁹ Similar “condition categories” are organized hierarchically based on severity of the condition and cost implications, such that the most severe and costly condition category is at the “top” of the hierarchy.²⁰ Once hierarchically organized, these condition categories become HCCs.

28. This hierarchical organization ensures a beneficiary’s risk score will incorporate only the HCC that represents the most severe and costly manifestation of a disease documented in a given year. For example, if claims data shows a patient has both diabetes without complications (ICD-10 code E11.9, HCC 19), and diabetes with acute complications (ICD-10 code E11.8, HCC 18), only HCC 18 is used in computing the patient’s risk score, as it is the more severe form of diabetes.

¹⁶ See Medicare Managed Care Manual, Ch. 7, § 20 (June 7, 2013) (“Risk adjustment allows CMS to pay plans for the risk of the beneficiaries they enroll, instead of an average amount for Medicare beneficiaries. By risk adjusting plan payments, CMS is able to make appropriate and accurate payments for enrollees with differences in expected costs Risk scores measure individual beneficiaries’ relative risk and risk scores are used to adjust payments for each beneficiary’s expected expenditures.”).

¹⁷ See *id.* § 70 (“Risk scores are used to adjust payments and bids based on the health status (diagnostic data) and demographic characteristics (such as age and gender) of an enrollee.”).

¹⁸ *Id.* § 70.1.

¹⁹ *Id.*

²⁰ *Id.*

29. Each year, CMS determines the groupings of diagnosis codes that “map” to a given HCC.²¹ If a beneficiary has a condition corresponding to a diagnosis code that maps to an HCC, that HCC will be incorporated into the calculation of the beneficiary’s risk score. For example, under the current CMS-HCC Risk Adjustment Model, of the approximately 70,000 total ICD-10 codes, over 9,700 of those codes map to one or more of the 86 HCCs in the model.²²

30. Multiple ICD codes can map to the same HCC. ICD-10 codes each contain up to 7 characters. Although slight variations in the last characters in the code string leads to distinct ICD-10 codes, these distinct ICD-10 codes may still map to the same HCC. For example:

- a. E11.10 (Type 2 diabetes mellitus with ketoacidosis without coma) and E11.11 (Type 2 diabetes mellitus with ketoacidosis with coma) both map to HCC 17 (diabetes with acute complications).
- b. M35.00 (Sjögren syndrome, unspecified) and M35.3 (Polymyalgia rheumatica) both map to HCC 40 (Rheumatoid arthritis and inflammatory connective tissue disease).

31. However, certain diagnosis codes indicating historical conditions or potential risk for future conditions may be documented in the patient’s medical record and assigned an ICD code, but they would not map to an HCC. For example:

- a. If an individual is diagnosed with thyroid cancer, it is appropriate to assign the ICD-10 code C73 (malignant neoplasm of the thyroid gland). After the thyroid is removed, if the patient is asymptomatic and no further treatment is being provided, then Z85.850 (personal history of malignant neoplasm of thyroid) is the proper ICD-10 code to report.
- b. If a patient’s blood sugar has been elevated on lab tests, but there is not enough information to diagnose the patient with diabetes mellitus, the proper code to report in this situation is a code for abnormal glucose (R73.09), rather than E11.9 (diabetes mellitus without complications).

²¹ Not all ICD-9/ICD-10 diagnosis codes map to an HCC included in the CMS-HCC Risk Adjustment Model, and therefore not all ICD-9/ICD-10 diagnosis codes affect risk adjustment payments.

²² Amerigroup, *CMS-HCC Risk Adjustment Model (V24), ICD-10-CM to CMS-HCC Crosswalk*, https://provider.amerigroup.com/dam/publicdocuments/ALL_CARE_CMSHCCRAModel_mrdcoding_tip_s.pdf (last visited Sept. 29, 2023).

32. Where a patient has several diseases corresponding to several HCCs, the risk adjustment model allows those multiple HCCs to be assigned and accounted for in the risk score. The number of HCCs reported and the severity of the HCCs tend to increase the risk score. Thus, a 72-year-old male with COPD, diabetes mellitus, and coronary artery disease would have a higher risk score than a 72-year-old male with diabetes mellitus only.

Medical Record Documentation to Support HCCs Under CMS Rules

33. During the relevant time period, CMS had specific rules governing the submission of diagnosis codes for inclusion in the HCC risk adjustment model. HCC coding requires clinical support in medical record documentation.

34. As explained in the 2008 Participant Guide, CMS requires that diagnosis codes submitted for risk adjustment result from a face-to-face encounter between a beneficiary and a provider of a qualifying physician specialty.²³ In addition, the medical record for a particular encounter used as the basis for submission of a diagnosis code must be signed and include the provider's credentials.²⁴

35. In addition, both the ICD guidelines and CMS specify that all conditions reported should be based on documentation showing that conditions exist at the time of the encounter/visit and "require or affect patient care, treatment or management."²⁵

36. Importantly, regulations and official CMS publications require all diagnosis codes submitted by MAOs to be documented in the medical record, and ICD Coding Guidelines must be followed for coding and reporting.²⁶ For example, the Medicare Managed Care Manual, Chapter 7 states that MAOs must:

²³ 2008 Participant Guide, § 7.2.4.2; *see also id.* Table 3H (setting forth acceptable physician specialties, which include physicians and other qualified healthcare providers, such as nurse practitioners and physician assistants).

²⁴ *Id.* § 7.2.4.2 ("For purposes of risk adjustment data submission and validation, the MA organizations must ensure that the provider of service for face-to-face encounters is appropriately identified on medical records via their signature and physician specialty credentials.").

²⁵ ICD-9, § IV.K (effective Oct. 1, 2011), https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf; ICD-10, § IV.J (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>; *see also* 2008 Participant Guide, § 6.4.1.

²⁶ *See, e.g.*, 45 C.F.R. § 162.1002(a)(1)(i), (b)(1), (c)(2)(i) (establishing the ICD, including the ICD Guidelines, as the national standard for diagnosis coding); 42 C.F.R. § 422.310(d)(1) ("MA organizations

Ensure the accuracy and integrity of risk adjustment data submitted to CMS. ***All diagnosis codes submitted must be documented in the medical record*** and must be documented as a result of a face-to-face visit. The diagnosis must be coded according to International Classification of Diseases, (ICD) Clinical Modification Guidelines for Coding and Reporting.²⁷

In addition, the 2008 Participant Guide states:

Standard ICD-9-CM coding practices support the CMS-HCC model. ***In all cases, the documentation must support the code selected and substantiate that the proper coding guidelines were followed.***²⁸

OPINIONS

a. Diagnosis Codes Submitted for Risk Adjustment Must Be Supported By Documentation in the Medical Record Meeting CMS Requirements.

37. The principal requirement for assigning and reporting diagnosis codes in the Medicare Advantage risk adjustment model is that the codes are supported by appropriate medical record documentation.²⁹

38. As referenced above, the medical record cannot merely contain a list of the patient's conditions without supporting documentation showing that the conditions "require or affect patient care, treatment or management."³⁰ In the absence of such documentation, the coder cannot assign codes for listed conditions. In my experience, such documentation may include physician notes on disease progression or stabilization, patient response to the treatment, and whether test results were reviewed by the physician.

39. In sum, the diagnosis codes that MAOs submit to CMS for risk adjustment purposes must be (1) based on a face-to-face encounter; (2) by a qualified provider (either a physician or other qualified healthcare provider); (3) documented in the medical record; and (4) coded in compliance with the ICD Guidelines.³¹

must submit data that conform to CMS' requirements for data equivalent to Medicare fee-for-service data, when appropriate, and to all relevant national standards.").

³¹ 2008 Participant Guide, § 7.2.4.2.

b. Coding is Governed by Objective Standards and Guidelines.

40. It is my opinion that, if a coder is knowledgeable of the official ICD and CMS coding rules discussed above, he or she should be able to identify an objectively correct ICD code or set of ICD codes that can be reported based on a particular medical record and thus there should be little variance in code assignment among coders.

41. The coding rules are by design clear, consistent, and specific. They offer detailed instructions on what codes should be assigned based on features of a patient's condition and what is documented in the medical record. If qualified coders properly follow these rules, they are able to identify appropriate ICD codes and rule out inappropriate codes.

Coding is a Methodical Step-By-Step Process.

42. To begin, coders must follow a methodical step-by-step process in arriving at a code assignment under the ICD guidelines. The "Alphabetical Index" and "Tabular List" in both the ICD-9 and ICD-10 set out these directions.

43. The Alphabetical Index lists conditions and subvariants of conditions in alphabetical order. At the first step of coding, a coder looks up in the Alphabetical Index a condition he or she identifies that meets the medical record documentation requirements.

44. This Index supplies the initial ICD code string for that condition. For example, for Parkinson's disease with dementia a coder would look up "Parkinsonism," under which there are sub-listings of around twenty variations of "Parkinsonism," including with "dementia."³²

³²ICD-10-CM Index to Diseases and Injuries, *available at* https://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/ICD10CM/2022/ (Table and Index zip.zip) (last visited April 5, 2024).

Parkinsonism (idiopathic) (primary) G20
 - with neurogenic orthostatic hypotension (symptomatic) G90.3
 - arteriosclerotic G21.4
 - dementia G31.83 [F02.80]
 - - with behavioral disturbance G31.83 [F02.81]
 - due to
 - - drugs NEC G21.19
 - - - neuroleptic G21.11
 - medication-induced NEC G21.19
 - neuroleptic induced G21.11
 - postencephalitic G21.3
 - secondary G21.9
 - - due to
 - - - arteriosclerosis G21.4
 - - - drugs NEC G21.19
 - - - - neuroleptic G21.11
 - - - encephalitis G21.3
 - - - external agents NEC G21.2
 - - - syphilis A52.19
 - - specified NEC G21.8
 - syphilitic A52.19
 - treatment-induced NEC G21.19
 - vascular G21.4

The index directs the coder that “Parkinson’s with Dementia without behavioral disturbance” may be coded with the ICD code strings “G20” (Parkinsonism) and “F02.80.”

Next, the coder must consult the “Tabular List” for further step-by-step instructions on the requirements to assign a code.³³ In this case, the Tabular List entry for “G20” (Parkinson’s disease) instructs the coder to: Use additional code to identify: dementia with behavioral disturbance (F02.81) dementia without behavioral disturbance (F02.80). Therefore, the proper codes for Parkinson’s with dementia without behavioral disturbance are G20 and F02.80.

³³ ICD-10-CM Tabular List of Diseases and Injuries, *available at* https://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/ICD10CM/2022/ (Table and Index zip.zip) (last visited April 5, 2024).

G20 Parkinson's disease

Hemiparkinsonism
Idiopathic Parkinsonism or Parkinson's disease
Paralysis agitans
Parkinsonism or Parkinson's disease NOS
Primary Parkinsonism or Parkinson's disease

Use additional code to identify:

dementia with behavioral disturbance (F02.81)
dementia without behavioral disturbance (F02.80)

Excludes1: dementia with Parkinsonism (G31.83)

45. As shown above, the coding rules provide clear instructions on (1) the specific items the medical record documentation must contain to support a condition, *supra* ¶¶ 37–39, (2) how to look up a particular condition or variants of a condition in the Alphabetical Index to identify the ICD code and further requirements for assigning the code, and (3) the step-by-step process of applying those requirements to arrive at code assignment.

46. In addition, there are rules about how a coder should use these resources. For example, it is well established a coder must use the Alphabetical Index and Tabular List sequentially and follow the instructional notations in both.³⁴ Coders may never select a final code based just on what the Alphabetical Index provides. As long as the coder follows this order of operations, the instructions in the Alphabetical Index and Tabular List are consistent and will lead the coder to the proper code assignment.

Coding Rules Are Highly Specific and Particularized to Features of Patients' Conditions.

47. The ICD guidelines provide specific rules for assigning ICD codes regarding how particular features of a patient's condition should be coded. This specificity makes clear to coders under what circumstances a particular ICD code should be assigned.

48. For example, ICD-10 specifies the codes to assign when a condition occurs on the left or right side of the body, and in some cases provides a code indicating that a condition occurs on both sides of the body (bilaterally). If the medical record does not specify which side the condition occurs, the rules generally require the coder to assign the code denoting the side is

³⁴ ICD-9, § I.B.1–2 (effective Oct. 1, 2015), https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf; ICD-10, § I.A.1, § I.B.1 (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>.

unspecified.³⁵ If, however, the condition occurs bilaterally, but there is no specific ICD code designating that the condition occurs bilaterally, the guidelines require the coder to report the ICD codes for both the right and left sides of the body separately.³⁶

49. For example, ICD-10 provides codes based on where the condition staphylococcal arthritis manifests: M00.011 (Staphylococcal arthritis, right shoulder), M00.012 (Staphylococcal arthritis, left shoulder), and M00.019 (Staphylococcal arthritis, unspecified shoulder). There is no code designating this condition as bilateral. If the medical record indicates that the patient has staphylococcal arthritis in both shoulders, the coder should report *both* M00.011 (right shoulder) and M00.012 (left shoulder) as there is no specific ICD code designating this condition as bilateral.

Difficult Coding Scenarios Do Not Indicate that Coding is a Subjective or Ambiguous Process.

50. The existence of difficult coding scenarios does not mean coding itself is a subjective process with no right answers as to whether a code is properly assigned or not. Nor do these difficult scenarios show that the coding guidelines themselves are ambiguous or fail to provide objective rules for a coder to follow.

51. Rather, difficult scenarios generally are caused by and reflect (1) the varying degrees of skill level and experience among coders; (2) errors in how those coders apply the guidelines and rules; and (3) problems extrinsic to the guidelines and the required coding process, such as problems with the medical record documentation itself. All of these issues, however, are far less likely to be present in sophisticated coding programs that use certified, well-trained coders and implement sufficient quality assurance processes to check coders' work.

52. Below, I address some potentially difficult coding scenarios, and explain why they do not demonstrate the coding process and guidelines are fundamentally subjective or ambiguous:

- a. **Updated coding guidelines:** One potential source of error during the relevant time period was coders' relative levels of experience with and training on operative coding

³⁵ ICD-10, § I.B.13 (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>.

³⁶ *Id.*

guidelines. The CDC transitioned from ICD-9 to ICD-10 in 2015. While some less-experienced coders may have erred in applying the new ICD-10 guidelines, this does not indicate that the guidelines themselves were unclear or ambiguous.

For example, as the table below shows, under ICD-10, coders are required to assign a single combination code (E11.331) where a patient has both diabetes mellitus with diabetic retinopathy. ICD-9, however, provided a different rule where these conditions were required to be coded separately (250.52, 362.05). Under the new rule, the objectively correct code is the single combination code. In my experience, coders who were unfamiliar with the operative ICD-10 rules might attempt to search for two separate codes or simply miss the combination code and apply a different diabetes code. This example does not illustrate that ICD-10 is itself ambiguous or allows for varying or inconsistent results (i.e., different diabetes code assignments) among coders. Rather, it indicates that lack of experience with the operative rules may lead to error.

ICD-9 Coding	ICD-10 Coding
250.52 – Diabetes with ophthalmic manifestations, type II or unspecified type, controlled	E11.331 – Type II diabetes mellitus with moderate non-proliferative diabetic retinopathy with macular edema
362.05 – Moderate non-proliferative diabetic retinopathy	

Notably, the coding industry attempts to provide training and other resources to address varying levels of experience on the part of coders. For example, during the transition to ICD-10, there were numerous continuing education classes that focused on educating coders on the new rules. The AAPC also required its certified members to pass a proficiency assessment on ICD-10 “format and structure, groupings and

categories of codes, ICD-10-CM official guidelines, and coding concepts.”³⁷ A major focus on my work during this time was providing trainings on ICD-10 rules, including trainings customized for specific practice groups.

- b. **Problems extrinsic to coding rules, guidelines, and resources:** Some difficult coding scenarios are due to problems extrinsic to the coding rules, for example, issues in the medical record documentation itself or its legibility. These issues do not indicate that the coding rules or process themselves are subjective, and experienced coders are trained to handle these circumstances properly.

For example, a provider might use the abbreviation “PE” in a medical record, which typically stands for “pulmonary embolism,” but may also mean “pulmonary edema” or “physical exam.” Under this circumstance, unless the coder is able to verify the meaning of the ambiguous or illegible term (e.g., via a physician query), the coder should not assume the meaning of the term and base a coding assignment on it.³⁸ Rather, a code assignment is only appropriate if based on clear and consistent medical record documentation.³⁹

53. I also reviewed the deposition transcripts of some United witnesses that discuss difficult coding scenarios. For example, United coding supervisor, Tammy Dickey, testified: “if

³⁷ See *ICD-10 Proficiency Assessment*, AAPC (Mar. 26, 2013), <https://www.aapc.com/blog/24145-icd-10-proficiency-assessment/#:~:text=The%20assessment%20will%20measure%20your,for%20other%20exams%20or%20assessments>.

³⁸ ICD-10 at 1 (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf> (stating that “The importance of consistent, complete documentation in the medical record cannot be overemphasized. Without such documentation accurate coding cannot be achieved.”). The AHIMA Standards of Ethical Coding also provide that coders should “[a]ssign and report . . . only the codes and data that are clearly and consistently supported by health record documentation in accordance with applicable code set and abstraction conventions” and should “[q]uery and/or consult as needed with the provider for clarification and additional documentation prior to final code assignment in accordance with acceptable healthcare industry practices.” *American Health Information Management Association Standards of Ethical Coding (2016 Version)*, AHIMA (revised and approved Dec. 12, 2016), https://bok.ahima.org/doc?oid=302237#.X0-0BRNKg_U.

³⁹ *Id.*

you gave the same record to ten coders, you would probably be get [sic] five sets of answers.”⁴⁰ To the extent this example illustrates that coding is subjective and the rules lack clarity, I disagree. In my opinion, what Ms. Dickey describes does not reflect a phenomenon in ICD coding. ICD coding is highly specific and governed by a set of particularized rules. In my opinion and experience, there is not substantial variance in ICD coding among qualified coders, nor have I experienced this level of variance in my own practice.

c. There Are Well-Established Industry Best Practices For Achieving Complete and Accurate Coding.

54. In the Medicare Advantage context, there are industry best practices for achieving accurate and complete coding. In my opinion, these best practices include: (1) requiring coders to be certified; (2) providing extensive and ongoing training to the coders, including training in Medicare Advantage risk adjustment; (3) requiring coders to meet high quality standards in order to graduate from training; (4) requiring coders to maintain high quality standards after training; (5) providing coders with resources to address coding questions; (6) providing remedial training to coders who fall below the organization’s standards; (7) terminating coders who fail to perform up to the organization’s standards despite remedial training; and finally, (8) maintaining robust quality assurance processes to check the coders’ work on an ongoing basis. Issues with coding accuracy and completeness are more likely to be avoided when an organization’s policies and procedures encompass these elements.

55. Although coders approach their work with varying types of experience, the impact of these variances is limited when they are certified and provided with training that augments their prior work experience. For example, coders who have only worked on electronic medical records should be trained on coding from handwritten records and vice versa. In addition, coders should be exposed to different medical specialties during training if they had previously only worked in one specialty.

56. As discussed throughout this report, using certified coders is key in ensuring accurate and complete coding. Coders certified by the AAPC or AHIMA have had their knowledge tested by an independent body and must obtain a number of Continuing Education Credits (“CEUs”) to retain their certification. In addition, organizations participating in the

EXPERT REBUTTAL REPORT OF JEAN ACEVEDO TO
SEPTEMBER 29, 2023 EXPERT REPORT OF BARBARA BLAIR
January 29, 2024

I. INTRODUCTION

1. I have reviewed the September 29, 2023 expert report of Barbara Blair (“Blair Report”). I respond below to Blair’s opinions section-by-section. This report incorporates my September 29, 2023 expert report (“Opening Report”) and assumes familiarity with the case background and abbreviations used there.

2. I have three overarching concerns with Blair’s opinions that I discuss more fully in the body of this rebuttal:

3. **First**, Blair’s two overarching opinions, which she refers to as Opinion One and Opinion Two, are at odds with each other, and she unjustifiably switches between them depending on the conclusion she is trying to support. In her first opinion, she seems to claim that MA program coding tends to be more reliable than provider coding (to justify programs like chart reviews, which supplement provider-reported codes with additional codes identified by a chart review coder to address “undercoding”). Yet, in her second opinion, she opines that provider coding tends to be more reliable than MA program coding (apparently to justify why the codes reported only by the provider coder, but not identified by the MA chart review coder, tend to be correct and should not be deleted from claims, therefore rejecting that provider “overcoding” is an issue). In my experience, the deficiencies in provider coding that Blair describes in her first opinion lead *both* to provider undercoding and overcoding. Throughout her report, Blair improperly and implausibly focuses only on how provider coders’ lack of experience, expertise, and training in ICD coding leads to error in one direction (i.e., missed codes) but not the other (i.e., unsupported or misassigned codes).

4. **Second**, the explanation that Blair provides for why provider coding should be deferred to over MA program coding violates fundamental principles of coding. Blair claims that provider

coders deserve deference because they may have access to unique information about a patient's condition to support assigned codes that is unavailable to the MA program coder. But Blair's examples are all instances where the provider coders' information is *not* clearly documented in the medical record, as ICD and MA program rules require. For instance, Blair gives the example of a provider coder who is on-site at the provider's office, infers when undated additions to a chart were made, and then assigns a code based on that unwritten date-of-service (DOS) information. Blair Report ¶ 59. Another example Blair gives is a provider coder who can uniquely interpret the provider's handwriting, idiosyncratic note-taking, or abbreviations while the MA program coder (or any coder outside the provider's office) cannot. *Id.* ¶¶ 29, 58. Blair's opinion that these are circumstances in which the provider-only codes are "properly supported" in the medical record is oxymoronic and violates the fundamental rule of coding: all diagnosis codes submitted by MAOs for payment under the MA program must be clearly and unambiguously documented in the medical record per ICD Coding Guidelines and MA program rules.¹ A coder's idiosyncratic assumptions or reliance on unwritten information to support code assignment are not proper. Unless clear written documentation for a code is obtained, such as through a physician query or retrieval of additional medical records, the codes in Blair's examples are not properly supported under ICD.

5. ***Third***, Blair relies throughout her report on hypotheticals to support her conclusions. Based on my experience, each of her hypotheticals is highly theoretical. They do not reflect actual, common, or likely scenarios in ICD coding. Rather, the hypotheticals appear designed to support predetermined conclusions, rather than describe realistic extrinsic support for those conclusions.

¹ ICD-9, § IV.K (effective Oct. 1, 2011), https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf; ICD-10, § IV.J (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>; see also 2008 Participant Guide, § 6.4.1.

II. REBUTTAL TO BACKGROUND SECTION

A. Medical Record Documentation and Diagnosis Coding

6. Blair begins the background section with an overview of the MA diagnosis coding process. In describing common coding errors, Blair's overview is skewed. She identifies only "undercoding" (or instances where provider coders miss reporting codes documented in the medical record) and entirely ignores "overcoding" (or instances where provider coders report codes not properly documented in the medical record). In my significant experience working with providers of varying sizes and with varying resources, both types of errors are common.

7. In ¶ 18 of her report, Blair recognizes providers have "historically" received less training in MA diagnosis coding than in fee-for-service (FFS) procedure and services coding. But Blair opines that this deficiency in training and experience somehow leads only to undercoding: "providers did not always submit all of a patient's applicable diagnosis codes on a claim." Blair Report ¶ 18. In my experience, the relative lack of training and experience in MA diagnosis coding causes provider coders to report codes not properly supported in the medical record and not compliant with ICD and MA program rules.

8. Blair also takes inconsistent positions on the reliability of MA program coding versus provider coding. On the one hand, she emphasizes in ¶ 18 that MA coders provide a useful corrective to provider coding: "MA Plan chart reviews may identify these additional diagnosis codes that are supported by documentation in a patient's medical record but that were not submitted on the claim" by the provider coder. On the other hand, Blair takes the position that provider coders are more reliable than MA coders. She opines at ¶ 58: "A coder in the provider's office may be better situated [than an MA coder] to identify many properly supported diagnosis codes."

9. Blair provides no credible explanation for how MA program coders are both (i) more effective than provider coders at identifying the complete set of properly supported codes in a medical record, and yet (ii) tend to miss properly supported codes only the provider coder can identify.

10. Blair's attempt to explain the inconsistency is not valid, because she relies on an improper approach to coding (dubbed "assumption coding"), *see infra* ¶ 74. She opines that provider coders are able to identify "properly supported" codes that MA program coders miss, because the former possess unique (often unwritten) information about a patient's condition. Blair Report ¶¶ 29, 57-62. This justification violates a fundamental rule of MA program coding. A code cannot be assigned unless it is clearly and unambiguously supported by written documentation in the medical record. "Assumption coding" defeats the purpose of the ICD rules to enforce uniform coding, by leading to non-uniform interpretation of medical records and assignment of codes.

11. Ultimately, as discussed in my Opening Report at ¶¶ 54-55, accuracy and completeness in coding is contingent on how experienced and well-trained coders are, whether they are held to quality control standards, and whether they are subject to oversight. Coders subject to these processes and standards code more accurately and completely than coders lacking such qualifications, standards, and resources. In my experience, working in both provider and MA program settings, these measures tend to be more institutionalized in the latter context. Consequently, MA program coding tends to be more reliable, accurate, and complete than provider coding on average.

B. Sources of Coding

12. Blair discusses at ¶¶ 20-22 in her report "Sources of Coding." She claims that there is a "multitude" of sources governing MA diagnosis coding and that they provide only a "framework"

for coders. She opines that the various “Sources of Coding” sometimes offer conflicting guidance and that coders are forced to apply their own “judgment and experience.”

13. I disagree. Coding rules do not provide merely a “framework” for coding. Nor are the rules in conflict. Blair describes coding rules and guidance as an assortment of miscellaneous references from which coders may pick and choose on what to rely, but this is inaccurate.

14. For example, in ¶¶ 20-21, Blair states that coding guidance includes, but is not limited to, the ICD-9 and ICD-10 and their Tabular List and Alphabetic Index, the Coding Clinic, CMS materials, and providers’ own references about how to interpret the coding guidelines.

15. As I explained in my Opening Report, there is a clear and definitive hierarchy among “Sources of Coding.” The ICD-9/10 (and their Tabular List and Alphabetic Index) are the authoritative rules on diagnosis coding and trump other references that Blair identifies.

16. As Blair recognizes at ¶¶ 19-20, the ICD-9/10 provides a highly specific code set and particularized rules for assigning each code. United’s own coders agreed in their depositions that ICD-9/10 are the definitive set of coding guidelines.² Coders are trained to apply the ICD-9/10 and these other sources in accordance with this hierarchy.

17. In ¶ 21 of her report, Blair opines that the “Sources of Coding” conflict with one another. However, she does not provide any actual examples of such conflicts. *See infra* ¶ 39. As discussed in my Opening Report at ¶ 17, no such conflicts exist in my experience. Rather, the ICD-9/10 guidelines provide the authoritative rules that trump other coding guidance and complement MA program requirements. *See infra* ¶¶ 18-19, 50.

18. Blair further claims in ¶ 21 that, due to the purported conflicts in the “Sources of Coding,” “[c]oders therefore use the available guidance as a framework but ultimately must also

² Dickey Dep. 34:18–35:10, May 24, 2022; Bradberry Dep. 34:2–10, 104:19–105:3, July 1, 2021.

rely on their judgment and experience.” Again, ICD-9/10 is an authoritative set of highly specific rules and not a “framework.” See ICD-9 (“These guidelines are a set of rules that have been developed to accompany and complement the official conventions and instructions provided within the ICD-9-CM itself.”).³ Further, use of ICD-10 for reporting diagnosis codes is mandated by the Department of Health and Human Services in the Health Insurance and Portability Act’s Transactions and Code Sets rule.⁴

19. The “Sources of Coding” that Blair lists beyond the ICD-9/10 (discussed below, ¶¶ 19(a)-(d)) do not provide coding rules that trump or conflict with the ICD-9/10:

- a. **The Coding Clinic** – This is a secondary source that provides answers to coder-submitted questions regarding highly specific scenarios under ICD-9/10. Blair has not identified any credible support or example of an instance where the Coding Clinic contradicts ICD-9/10. This is because the Coding Clinic applies, but does not supplant, ICD-9/10. For example, a question that was posed to the Coding Clinic was: “What is the correct code for a 20-year-old patient with gestational diabetes who presents due to diabetes with ketoacidosis?” The answer provided by the Coding Clinic was “Assign codes O24.419, Gestational diabetes mellitus in pregnancy, unspecified control, and E87.2, Acidosis, for gestational diabetes with ketoacidosis. Codes from categories E10 and E11 would not be appropriate if the patient does not have pre-existing diabetes mellitus.”⁵ This answer provided by the Coding Clinic mirrors the ICD-9/10 guidelines. ICD codes for diabetes mellitus, such as E10 and E11 noted, both have instructions to never assign either code (“Excludes 1”);

⁴ *International Classification of Diseases, (ICD-10-CM/PCS) Transition – Background*, Centers for Disease Control and Prevention (last reviewed Nov. 6, 2015), https://www.cdc.gov/nchs/icd/icd10cm_pcs_background.htm.

⁵ *Gestational Diabetes and Diabetic Ketoacidosis*, 7 AHA Coding Clinic for ICD 30 (Third Quarter 2020).

pointing the coder to “gestational diabetes (O24.4-).” Both the Coding Clinic and ICD instruct coders to assign the gestational diabetes code (O24.419) for a pregnant woman who developed diabetes mellitus during pregnancy and presents with ketoacidosis. The Coding Clinic’s instructions complement the ICD for reporting ICD codes.

- b. **CMS guidance on the MA program** – CMS sources, like the CMS 2008 Risk Adjustment Data Technical Assistance for Medicare Advantage Organizations Participant Guide (“2008 Participant Guide”), do not provide rules at the level of the ICD-9/10 code set or instruct how to assign those codes. Rather, they discuss MA program requirements. For example, the Participant Guide limits the types of providers and medical record documentation acceptable in the MA program. *See e.g.*, 2008 Participant Guide, §§ 3.2.3, 7.2.4.1. By contrast, the ICD-9/10 guidelines do not provide rules for assigning codes based on types of provider or unacceptable types of medical record documentation.

This is not a contradiction between CMS guidance and the ICD-9/10 guidelines. Rather, the CMS guidance and ICD-9/10 guidelines are complementary. CMS guidance expressly incorporates, and requires all submitted codes in the MA program to comply with, ICD-9/10. *See* 2008 Participant Guide, § 7.2.4. While ICD-9/10 provides requirements for code selection, CMS provides further requirements for when and under what circumstances those codes should be reported in the MA program (i.e., only if the code resulted from a diagnosis made by particular types of providers and supported by particular types of documentation from those providers).

- c. **CMS RADV guidance** – RADV guidance applies only in the RADV audit context. Based on my years of experience, coders do not rely on this guidance as a source for rules on code

assignment and would not defer to RADV guidance over ICD-9/10, and certainly not outside the RADV audit context.

CMS itself is clear – including in the RADV source that Blair cites – that this “Contract-Level Risk Adjustment Data Validation (RADV) Medical Record Reviewer Guidance has been created to provide information on the RADV medical record process” and that the “guidance does not give advice for specific diagnosis coding.”⁶ CMS further emphasizes that this guidance “does not contradict the *ICD-9-CM Official Guidelines for Coding and Reporting*.” *Id.* Blair ignores these clear statements by suggesting, in her misleading quoting of this source, that RADV guidance conflicts with (and thus, must carry the same authority as) ICD-9/10 in dictating how diagnosis codes are assigned. *See, e.g.,* Blair Report ¶¶ 37-41.

This is wrong. Blair’s suggestion that coders may use RADV guidance as a source for assigning and reporting codes in the MA program is practically impossible. She ignores that CMS publishes RADV guidance for auditing a particular DOS year many years *after* the submission window for diagnosis codes in that DOS year has closed. For example, in ¶ 53, Blair implies that RADV guidance issued in 2019, which may apply to DOS 2013 codes that are undergoing RADV audits in 2019 and onward, should somehow govern the coding of DOS 2013 codes at the time of their submission. But a coder assigning and

⁶ See Centers for Medicare & Medicaid Services, *Contract-Level Risk Adjustment Data Validation – Medical Record Reviewer Guidance* (effective Mar. 20, 2019) (“2019 RADV Guidance”), <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>, at 6-7.

submitting codes for DOS 2013 would have been doing so in 2015 at the latest,⁷ years before the 2019 guidance ever existed.

Furthermore, Blair's reliance on *future* RADV guidance not in existence at the time of the DOS violates the basic rule of coding that coders must apply the coding rules in effect during the DOS year and not the rules in effect after the fact. Blair herself emphasizes this rule. In ¶ 35, she writes: "MA Plan coders reviewing a medical record in 2013 that was created on the date of the patient visit in 2012 should apply the guidance that was effective on the date of service (2012), not the guidance effective on the date of review (2013)." The effective date for ICD codes is October 1 of the current year through September 30 of the subsequent year (e.g. 10/1/2023 through 9/30/2024).⁸ CMS is clear that one must only use the then-current Guidelines when assigning ICD-10 codes.⁹ By way of example, CMS's current guidance states, "The 2024 ICD-10-CM files below contain information on the ICD-10-CM updates for FY 2024. These 2024 ICD-10-CM codes are to be used for discharges occurring from October 1, 2023 through September 30, 2024 and for patient encounters occurring from October 1, 2023 through September 30, 2024."¹⁰ Blair's suggestion that RADV guidance issued in 2019 should nevertheless govern codes in the DOS period of this dispute (DOS 2009-2016) is wrong.¹¹

⁷ See Centers for Medicare & Medicaid Services, *Corrected Deadline for Submitting RAPS Data for Use in Risk Score Calculation Runs for Payment Years 2014, 2015, 2016* (Sept. 11, 2014), https://www.hhs.gov/guidance/sites/default/files/hhs-guidance-documents/correction%20-%20hpms%202014_2015_2016%20payment%20run%20notice_172.pdf (indicating the final submission deadline for DOS January 1, 2013 to December 31, 2023 was January 31, 2015).

¹¹ Blair's cited RADV guidance (*see, e.g.*, Footnotes 22 and 34 in the Blair Report) does not apply to DOS 2009-2016. Blair relies on RADV guidance that came into effect only on March 20, 2019, applying at the earliest to audits beginning on September 27, 2017. Blair Report ¶¶ 37-41. Although Blair claims those audits

Blair’s opinion also ignores the specific process and methodology of the RADV program in contrast to coding for MA program submission. I regularly provide consulting services for providers and plans that will undergo or are undergoing a RADV audit, and am experienced in this process. Blair’s suggestion that coding assignment rules and RADV guidance should be treated apples-to-apples is misleading.

Unlike in the former context, a RADV audit is a back-and-forth process between CMS and plans regarding particular HCCs under audit and the medical record support the plans must furnish to justify their assigned HCCs. Even if plans had failed to identify adequate medical record support for their submitted HCCs, they may attempt to correct or supplement this during the RADV audit with support that the plans did not (and could not have properly) relied on at the time that they submitted the HCCs for payment. *See, e.g.*, 2019 RADV Guidance at 8 (“CMS understands the constraint when provider medical records are incomplete or documented inadequately. Therefore, the RADV process . . . allows for multiple medical record submissions from multiple approved providers from any encounter date in the data collection period, even if a diagnosis from that encounter was not previously submitted to Medicare.”) (emphasis added).¹² In other words, although the plan had reported an “inadequately” “documented” HCC, the RADV process uniquely allows plans to re-submit the HCC based on a different medical record for a different DOS, even if the plan had never reported any diagnoses from that medical record previously.

may review codes from DOS 2013 onward, plainly this RADV guidance did not exist during the DOS years of this dispute.

¹² *See also* Centers for Medicare & Medicaid Services, *Contract-Level Industry-Wide Training Event* (Jan. 29, 2019), <https://www.cms.gov/research-statistics-data-and-systems/monitoring-programs/medicare-risk-adjustment-data-validation-program/other-content-types/radv-docs/radv-industry-slide-deck.pdf>, at 13 (allowing plans subject to RADV audit 20 weeks to provide supporting documentation, and allowing the plan to research and obtain documentation that may not have been available at the time of claim submission).

Given the unique context of RADV, Blair’s attempt at ¶ 31 to show a purported “conflict” between the official coding rules and RADV guidance is misleading. She writes:

“In a RADV audit, when a coder encounters abbreviations with multiple meanings, CMS instructs: ‘If more than one meaning applies or documentation is too limited to differentiate, and this is the only diagnosis listed within the record, evaluate on a case-by-case basis. Otherwise, use discretion to report or not based on other circumstances in the record.’”

Blair implies that the above-quoted language from RADV guidance is authorization by CMS to “a coder” to make a “discretion[ary]” inference about the meaning of an abbreviation during code assignment, even if the medical record is “too limited” to provide definitive clarity on the meaning.

This misquotes the source. In reality, Blair is quoting from a chart in the RADV guidance regarding the “Action” that a “RADV Auditor” may take when a medical record submitted to support an HCC under audit shows red flags. 2019 RADV Guidance at 59.

What the Reviewer May Encounter	Explanation/Examples	Reviewer Guidance	RADV Auditor Action
Non-English Documentation	Coder Guidance: The record submitted includes diagnoses, but the words are not English.	Identify the documentation that validates the CMS- HCC. If it is legible and can be translated, then it is acceptable to submit.	Refer to Medical Record Review Contractor (MRRC) Project Manager regarding resources for medical translation of pertinent sections of the medical record.
Abbreviation with Multiple Meanings	Coder Guidance: Several common abbreviations have more than one meaning. <i>Examples:</i> MD – major depression, muscular dystrophy, macular degeneration CRF – chronic renal failure, chronic respiratory failure	Evaluate the abbreviation within the context of the full medical record before submitting to support the condition.	If more than one meaning applies or documentation is too limited to differentiate, and this is the only diagnosis listed within the record, evaluate on a case- by-case basis. Otherwise, use discretion to report or not based on other circumstances in the record.

Per the chart above, during the RADV process, CMS's diagnosis coder (referred as the RADV Medical Record "Reviewer"¹³) must first review the medical record and determine whether the meaning of an "abbreviation" used by the provider is established "within the context of the full medical record before submitting [that record] to support the condition." Consistent with my opinion, only if the "medical record" clearly documents the abbreviation's meaning may that coder or "reviewer" then credit that record as proper "support [for] the condition."

Blair's key quote, which she claims shows the purported "discretion" of a diagnosis coder generally, is from the last column in the chart regarding the options that a RADV Auditor has and *not* the RADV coder: "If more than one meaning applies or documentation is too limited," then the auditor, not the coder, may investigate further on a "case-by-case basis" or consider "other circumstances in the record." This guidance confers "discretion" on the RADV auditor, consistent with the RADV process discussed above in which a plan may work to redress inadequate documentation with guidance from the auditor.

The above RADV guidance does not show a conflict in coding rules, because as explained, this is not guidance on code assignment for coders. Rather, this is guidance about how a RADV auditor performs the audit. Throughout the rest of this RADV guidance, *see generally* 2019 RADV Guidance, CMS makes clear that the coding rules to which plans are subject are the ICD-9/10 and the basic principles I have discussed

¹³ In the RADV audit context, the medical record coder (or "Reviewer") and the RADV Auditor play different roles. As the 2019 RADV Guidance at 14 explains: "CMS RADV reviewers are certified coders, experienced in risk adjustment data validation that are familiar with a variety of medical record layouts, electronic medical record entries, and handwritten medical record documentation. The following table presents . . . guidance on the action auditors may use to evaluate and resolve the issue[s]" regarding the "MA Organization's decision to submit [particular] medical record" support for HCCs under audit.

throughout my two reports.¹⁴ Regardless of CMS’s approach during a RADV audit, the fundamental coding rule is that there must be clear and unambiguous medical record documentation to support codes submitted for payment.

- d. **Provider-created reference documents** – Documents made by providers to summarize or interpret coding guidelines have no authority. Coders should not (and are trained not to) defer to such documents. Nor is it best practice for coders to rely on these informal references developed by and for the provider offices. Based on my experience training coders at provider offices, I have observed these internal reference documents, and they are frequently outdated, incomplete, or inaccurate under the coding rules. For example, some provider offices will list only common diagnosis codes applicable to their patients. Other times, provider references fail to keep up with updates to rules, such as during the transition to ICD-10. The best practice for coders in any setting is to refer back to the primary source itself (ICD-9/10), which provides comprehensive, specific, and uniform rules.

III. OPINION ONE – REBUTTAL

20. Blair summarizes her Opinion One as: “The identification of diagnosis codes supported by documentation in a medical record is a complex process, informed by a variety of coding guidance and dependent on a coder’s training, experience, and judgment.” Blair Report at 11.

¹⁴ A stark example is that, at the bottom of every page of the 2019 RADV guidance, the following reminder about the authoritative coding rules is stamped: “The general guidance in this document is not exclusive. . . . [The] rules, requirements, and instructions relating to medical record documentation substantiation of diagnoses and the coding of diagnoses [that] apply, includ[e], but [are] not limited to, that the supporting medical records be clear and unambiguous, the requirements set forth in Chapter 7 of the Medicare Managed Care Manual, the requirements of the International Classification of Diseases (ICD) Clinical Modification Guidelines for Coding and Reporting (ICD-9-CM)”

21. I disagree. None of Blair's positions affect my core opinions in the Opening Report. The coding rules are designed to limit coder discretion. The rules dictate the specific content that a medical record must clearly contain to support a code. They provide important defaults in coding, for instance, unless the medical record unquestionably documents the required information to support a code, the code cannot be assigned.

A. Blair's Description of Coding As "Complex" Is Not Meaningful.

22. The main opinion Blair offers is that medical record coding is "complex." This description is vague. Whatever "complex" means to Blair, coding is more precisely described as a professional technical skill, not a lay skill. Like any professional technical skill, coders must receive specialized training, and improve their coding abilities through repeated practice and experience. Coding accuracy is impacted by oversight of experienced coders and requirements that coders meet quality-control standards (like United's 95% accuracy standard for its chart review coders, Opening Report ¶¶ 51, 54-56).

23. Industry-wide, as Blair acknowledges at ¶ 44, there is a well-established norm that coders meet a 95% accuracy standard. Her acknowledgment of this standard shows codes can be objectively evaluated, determined to be correct or incorrect, and thus support the calculation of a coder's accuracy rate. In my experience, coders are capable of performing at this standard, because it is a professional expectation.

B. Variation in Coder Ability Does Not Undermine Objectivity of Coding Process.

24. Contrary to Blair's suggestion at ¶¶ 23-25, the reality that coders' abilities may vary and in turn impact coding accuracy does not mean that coding itself lacks objectively correct or incorrect answers under the coding rules. Opening Report ¶¶ 50-56. As discussed above, United

itself recognized this, as it measured coders' error rates, and required coders to stay under certain error rates to remain "in production" as an active coder.¹⁵

C. Coding is Not "Subjective."

25. I disagree with Blair's opinion that coding "involves judgment and can be a subjective exercise where coders may not always agree." Blair Report ¶ 22. Blair fails to define what she means by "subjective" and "involves judgment." The Opening Report sets out my opinions. Opening Report ¶¶ 40-56.

26. Throughout her report, Blair frequently claims that assignment of diagnosis codes may be based on what a coder subjectively "believes" about the medical record or coding guidelines. *See* Blair Report ¶ 34. This is misleading. Code assignment based on anything other than objectively clear, legible documentation – what a coder may "believe" or infer about a medical record does not qualify – is not an acceptable practice. *See, e.g.,* AHIMA's Standards of Ethical Coding ("AHIMA Standards") ("3. Assign and report, in any format, only the codes and data that are clearly and consistently supported by health record documentation in accordance with applicable code set and abstraction conventions, and requirements.").¹⁶

27. For any content in the medical record that is unclear, ambiguous, or subject to interpretation and disagreement, the coder must ignore that portion of the medical record, unless the coder obtains definitive clarity (for instance, through a physician query). *See id.* ("4.3. Query with established practice brief guidance when there is conflicting, incomplete, illegible, imprecise, or ambiguous information.").

¹⁵ Dickey Dep. 198:14–199:3, May 24, 2022.

¹⁶ *American Health Information Management Association Standards of Ethical Coding (2016 version)*, AHIMA (revised and approved Dec. 12, 2016), <https://bok.ahima.org/topics/coding-compliance-and-revenue-cycle/american-health-information-management-association-standards-of-ethical-coding-2016-version/>.

28. That coders may disagree on the proper code assignment also does not mean coding itself lacks objectively correct or incorrect answers. Blair assumes that the differing codes proposed by various coders based on a hypothetical medical record are somehow all defensible, but this is wrong. Neither Blair's report nor any of United's witnesses have to date identified an actual example where the same medical record documentation properly supports multiple coding assignments for the same condition.

D. Blair's "Six Factors"

29. The bulk of Blair's analysis in Opinion One discusses six factors that she claims make coding "complex" or "subjective" and causes coders to reach "different conclusions" when reviewing the same medical record:

Factor 1: Coder Certification, Experience, and Training

30. In my Opening Report, I discuss how varying levels of coder experience and training impact the accuracy and quality of coders' work. I refer back to and incorporate those opinions here. *See* Opening Report ¶¶ 51, 52(a), 52(b), 55.

31. Blair opines that "a coder with more specialized diagnosis code training, such as a coder with a CRC certification, may make different coding determinations than a coder with a more generalized training background." Blair Report ¶ 25. Blair also opines that "coders who work in an office with a medical specialist who focuses in one area, such as cardiology," may have more limited coding knowledge than coders with less of a specialized focus. *Id.* ¶ 23.

32. I agree with Blair that coders who have experience only in a specialized area and who lack training in risk adjustment coding generally code less accurately and completely in the MA context. I have observed that providers' coders will assign and report diagnosis codes improperly, because they do not understand or apply the ICD-9/10 rules properly.

33. By contrast, in organizations that require coder certification, ongoing training, and oversight and quality control of coders' work, the resulting coding tends to be more accurate and complete than at organizations that lack these requirements. These requirements also help minimize differences in coding ability across coders who came from different coding experiences or specialty areas.

Factor 2: Availability, Legibility, and Variability of Provider Documentation

34. Blair next opines that issues with provider documentation, such as the availability, legibility, and format of records, may cause variability in coding results across coders.

35. Proper application of coding rules constrains such variability. The basic rule of coding is that unless every factor necessary for assignment of a particular code is clearly documented in the medical record the coder is reviewing, the code cannot be assigned.

36. Blair raises issues of incomplete provider documentation, where providers may not turn over all their records, records may be missing pages, or records may not have been obtained from all providers. Blair Report ¶ 26. As discussed below at ¶ 75 and in my Opening Report at ¶ 35, the simple response is that coding rules require that a coder rely on the medical record before it. The coder cannot assume that a "theoretical" medical record or portion of a medical record not yet retrieved or accessible exists to support the code.

37. Blair further observes that legibility of provider records impacts coding: "[A] coder who cannot read a provider's handwriting may not identify a diagnosis code during a chart review that is, in fact, properly supported by documentation in the medical record." Blair Report ¶ 29. But Blair's claim is oxymoronic. A code is not "in fact, properly supported by documentation in the medical record" when that record is not legible except to those uniquely familiar with a provider's handwriting. That coder or any other coder may misinterpret the illegible documentation.

38. The rules forbid a coder to base code assignment on illegible or ambiguous records precisely to reduce variability in coding. *See* 2008 Participant Guide Table 6C (requiring that acceptable documentation supporting code assignment is documentation that is: “legible.”); ICD-10 (“consistent, complete documentation” is required and “[w]ithout such documentation accurate coding cannot be achieved.”).¹⁷ Until a coder obtains proper and clear documentation (redressing the illegibility), the code cannot be assigned.

Factor 3: Sources of Coding Guidance

39. Throughout her report, Blair makes general claims about how various sources of coding provide insufficient, confusing, or conflicting guidance. But Blair does not give any actual or realistic examples of these issues. Instead, working backwards from the conclusion she seeks to support, Blair constructs several hypotheticals to make her point. But these do not reflect likely real-world scenarios and are not extrinsic evidence that support her conclusion.

40. *First*, in ¶ 34, Blair opines that the coding rules are deficient because they fail to inform coders how to interpret ambiguous abbreviations like “CRF” in a medical record. According to Blair, “CRF” can mean either “chronic renal failure or chronic respiratory failure,” yet the ICD 9/10 provides no guidance on which to pick and how to assign the proper code. Along the same line of thinking, Blair complains that the ICD-9/10 Alphabetic Index and Tabular List do not list “CRF.”

41. This is a complete red herring. The problem in this scenario is *not* the ICD-9/10, but the medical record. The ICD-9/10 is clear that, under such a circumstance where the meaning of an abbreviation (i.e., CRF) is not clear, the coder cannot rely on this note in the medical record to

¹⁷ ICD-10 (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>, at 1.

assign a code. The coder must first obtain clarification from the provider about this note before proceeding to assign a code.

42. Blair's complaint about the absence of "CRF" in the ICD-9/10 index reveals how unrealistic this hypothetical is. Any coder with minimal training knows that the Alphabetic Index and Tabular List are not organized by abbreviation, but by the full names of conditions and diagnosis codes (to avoid the ambiguity of abbreviations such as this).

43. **Second**, Blair presents a hypothetical in ¶ 35 that coders have trouble keeping straight the coding rules that apply when the coder is performing coding in the present, but for conditions examined in another DOS year. This again is an unrealistic hypothetical. It is an elementary rule that a coder must apply the coding rules in effect during the applicable DOS year and not the coding rules in effect at the time coding is taking place. *See infra* ¶ 53. This is not an example of confusion in the rules at all, because there is an applicable well-known rule.

44. **Third**, in ¶ 36, Blair poses that the coding rules have been unclear on how a coder should interpret the phrase "evidence of" a given condition in a medical record. Blair claims that, until the Coding Clinic "clarified" how coders should interpret the term "evidence of" in 2009, there was widespread confusion among coders.

45. Blair cites no evidence of this industry-wide confusion. Nor does she cite any support or evidence for her claim that the Coding Clinic's 2009 Q&A response about "evidence of" represented a sea change in how the industry approached interpreting "evidence of" language in a medical record.

46. In my experience, and to the best of my recollection, this was not a widespread issue prior to 2009. Nor does the Coding Clinic's 2009 Q&A response suggest it was. Rather, the

response is a typical Coding Clinic entry where it provides an expert coding view on how to handle a specific scenario posed by a single questioner:

Third Quarter
Coding Uncertain Diagnoses, p 7

VOLUME 26 THIRD QUARTER
NUMBER 3 2009, Page 7

Coding Uncertain Diagnoses

Question: Is it appropriate to report codes for diagnoses recorded as “evidence of cerebral atrophy” and “appears to be a nasal fracture,” when documented on outpatient radiology reports?

Answer: The phrase “appears to be,” listed in the diagnostic statement fit the definition of a probable or suspected condition and would not be coded in the **outpatient** setting. The *Official Guidelines for Coding and Reporting*, Section IV.I. state, ‘Do not code diagnoses documented as “probable,” “suspected,” “questionable,” “rule out,” or “working diagnosis” or other similar terms indicating uncertainty. Rather, code the condition(s) to the highest degree of certainty for that encounter/visit, such as symptoms, signs, abnormal test results, or other reason for the visit.’ In terms of coding and reporting for hospital inpatients, according to the *Official Guidelines for Coding and Reporting*, Section III.B., it would not be appropriate to code abnormal findings from radiology reports.

However, when the provider documents “evidence of” a particular condition, it is not considered an uncertain diagnosis and should be appropriately coded and reported in the **outpatient** setting.

47. Before and after the 2009 Coding Clinic response, a coder in the MA context could never base a code assignment on the term “evidence of” alone. It is well-established that a condition may only be assigned a code if the medical record shows the condition was being treated, monitored, or managed on the given DOS. Blair puts too much emphasis on the single phrase “evidence of” to justify coding in a MA context.

48. I further disagree with Blair’s characterization that the Coding Clinic provides “guidance” on par with official coding guidelines. Blair Report ¶¶ 55, 61. The Coding Clinic does not set generally applicable guidelines or authoritative requirements. Rather, it is a secondary source for coders to ask questions about applying ICD-9/10 guidelines in the specific context the coders identify. Per AHIMA, *AHA Coding Clinic for ICD-10-CM/PCS and AHA Coding Clinic for HCPCS*, published quarterly by the AHA Central Office, provides expert guidance supporting coders,

auditors, and insurers with coding advice.¹⁸ In referring to previously published Coding Clinic Q&As, a coder must proceed with caution in determining whether a particular, specific Q&A response regarding a specific scenario is applicable to the scenario before the coder.

49. **Fourth**, Blair once again opines that conflict between RADV guidance and coding rules has led to coder confusion. Blair Report ¶¶ 37-41. But as addressed above in ¶ 19(c), RADV guidance is not guidance that coders are permitted to apply, nor have I observed coders applying it outside the RADV context. I have also explained above why Blair's opinion at ¶ 31 in her report – about how 2019 RADV guidance authorizes coder discretion or guesswork based on the coder's unique subjective judgment – is misleading. *Supra* ¶ 19(d). I have also discussed why it is improper for a coder to rely on RADV guidance issued many years after the relevant DOS year and effective only for years after that DOS. *Supra* ¶ 19(c).

50. In my experience, I have not encountered coders applying RADV guidance of the type cited by Blair in lieu of ICD-9/10 coding rules or as an interpretive source about those rules. As discussed above, RADV guidance focuses on describing how the audit process works and specifies the different roles and responsibilities of parties involved (e.g., the auditor). *Supra* ¶ 19(d). But the authoritative source of coding rules remains ICD-9/10. RADV guidance makes this explicit and repeatedly warns that ICD-9/10 must be deferred to and that RADV guidance is not intended to conflict with those rules (even if a reader misinterprets the guidance to create a conflict, as Blair does).

51. My opinion is based on extensive experience in training, educating, and reviewing the coding of both providers and MA plans, as well as working with providers with plans undergoing RADV and understanding the different process and RADV-specific guidance applicable there.

¹⁸ *AHA Coding Clinic*, AHIMA, <https://www.ahima.org/landing-pages/ghealth/ahima-ghealth-associates-directory/associates/aha-coding-clinic/> (last visited Jan. 22, 2024).

The record is not clear on what experience or background Blair bases her contrary opinions treating RADV guidance such as the 2019 guidance as “source of interpretation and application of coding guidelines.”

52. *Fifth*, in ¶ 40, Blair claims there is a lack of consensus around whether coders should apply the MEAT guidelines. But, as Blair recognizes, the MA guidelines are clear that MEAT is not required. As discussed in my Opening Report at ¶ 35, what is required is documentation showing that a condition existed at the time of the encounter/visit and “require[d] or affect[ed] patient care, treatment or management.”¹⁹

Factor 4: Human Error

53. Blair opines that another reason coding results vary across coders is human error – for instance, coders sometimes get tired or make mistakes and typos in what they code. In ¶ 42, Blair opines “this can lead coders to experience fatigue while reviewing medical records, which can result in mistakes, including missed diagnosis codes.”

54. Human error is inevitable, but Blair provides no evidence or explanation why human error is more likely to cause undercoding rather than overcoding. A “mistyping” error may just as well result in reporting a nonexistent and unsupported condition. For instance, mistyping the first letter of E08 (Diabetes mellitus due to underlying condition without complications) versus C08 (Malignant neoplasm of major salivary gland, unspecified), both from the ICD-10 code set, results in vastly different diagnoses. Nor does Blair explain why variability in coding due to inevitable human error is relevant. Mistakes in coding do not show that coding lacks objectively correct and incorrect results.

¹⁹ ICD-9, § IV.K (effective Oct. 1, 2011), https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf; ICD-10, § IV.J (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>; see also 2008 Participant Guide, § 6.4.1.

55. The fact that “human error” is responsible for reporting of nonexistent and unsupported codes was identified in a recent HHS Office of the Inspector General (OIG) report.²⁰ While not all related to human error, for some diagnosis codes that were not supported, the error rate was as high as 90%. The Toolkit used data from various audits OIG conducted from 2013 through 2019 payment years and identified possible “mis-keyed diagnosis codes” within the high-risk code groups addressed. OIG provides the following example: “For example, ICD-10 diagnosis code I720 (which maps to the HCC for Vascular Disease) could be transposed as diagnosis code I270 (which maps to the HCC for Congestive Heart Failure and in this example would be unvalidated). Using an analytical tool that we developed, we identified 3,780 scenarios in which diagnosis codes could have been mis-keyed because numbers were transposed or because other data-entry errors occurred that could have resulted in the assignment of an unvalidated HCC.” Again, a mistyped or mis-keyed error may just as well result in reporting a nonexistent or unsupported diagnosis.

Factor 5: Transition from ICD-9 to ICD-10

56. Blair opines that the transition from ICD-9 to ICD-10 led to confusion among coders in how to properly apply the new ICD-10. As discussed in my Opening Report at ¶ 16, ICD-10 made coding even more granular and particularized and provides more specific rules for code assignment than in ICD-9. The effect is that ICD-10 directs coders even more precisely to the correct code(s) and thus limits discretion.

57. That some coders were less familiar or experienced with ICD-10 coding rules causing them to err was a short-term issue. As discussed in my Opening Report at ¶ 52, during the transition period from ICD-9 to ICD-10, there were industry-wide efforts to ensure coder

²⁰ Amy Frontz, OIG, *Toolkit To Help Decrease Improper Payments in Medicare Advantage Through the Identification of High-Risk Diagnosis Codes* (Dec. 2023), <https://oig.hhs.gov/oas/reports/region7/72301213.pdf>, at 43.

competence and training in ICD-10. To maintain certifications, the AAPC required certified coders to take and pass an ICD-10-CM proficiency test. These efforts helped improve coder accuracy under ICD-10. In any case, errors based on lack of training or experience with ICD-10 do not indicate that ICD-10 itself is unclear or ambiguous.

Factor 6: Gray Areas of Coding

58. Blair opines in ¶ 48: “There are several additional areas in which coding involves a degree of subjectivity (often called “gray areas”), because they are open for interpretation and debated among medical coders and even the organizations that offer diagnosis coding guidance.”

59. Blair does not provide a clear definition of what she means by “gray areas” in coding. She claims only that any “area[] in which coding involves a degree of subjectivity” may “often [be] called ‘gray areas.’” Blair Report ¶ 48. I do not know in what context or to whom Blair is referring when she states this term is “often” used.

60. The only four examples Blair gives of “gray areas” do not meet her vague definition. *First*, Blair gives the example of problem lists. Blair Report ¶¶ 51-53. She claims that there has been confusion regarding problem lists, because CMS’s guidance on problem lists in the 2008 Participant Guide conflicts with CMS RADV guidance issued in 2019 on problem lists. This is another example in which Blair invents a change in guidance to create a purported conflict that does not in fact exist, just as she did in the context of coding abbreviations with multiple meanings, *see supra* ¶¶ 17-19. Blair correctly writes at ¶ 52:

“In 2008, CMS stated, ‘an acceptable problem list must be comprehensive and show evaluation and treatment for each condition that relates to an ICD-9 code on the date of service, and it must be signed and dated by the physician or physician extender.’”

But she goes on at ¶ 53 to mischaracterize 2019 RADV guidance to create the supposed conflict:

“The [2019] guidance stated, ‘[p]roblem lists are evaluated on a case-by-case basis when the problem list is not clearly dated as part of the face-to-face encounter indicated on the

coversheet, or there are multiple dates of conditions both before and after the DOS.’ In other words, CMS acknowledged the fact that problem lists may or may not relate to a given date of service, so the guidance left it to the discretion of individual coders to determine whether a problem list included sufficient details regarding what diagnoses were current.”

Once again, Blair is quoting from a chart in the RADV guidance that applies to “Actions” that a “RADV Auditor” may take. 2019 RADV Guidance at 42.

What the Reviewer May Encounter	Explanation/Examples	Reviewer Guidance	RADV Auditor Action
Problem Lists (within a medical record)	See related topic of Chronic and Other Additional Diagnoses . Lists of diagnoses (conditions, problems) may be numbered, bulleted, or separated by commas. A list may be documented in the patient history, assessment, discharge summary, or other areas of a medical record. When conditions commonly associated are listed under the same number or bullet, the conditions can assume to be linked. These diabetes examples are effective for ICD-9-CM and will be updated for ICD-10-CM. Example 1: 1. Hypertension 2. DM, neuropathy (link diabetes and neuropathy) Example 2: 1. Hypertension 2. DM 3. Neuropathy (do not link diabetes and neuropathy)	Evaluate the problem list for evidence of whether the conditions are chronic or past and if they are consistent with the current encounter documentation (i.e., have they been changed or replaced by a related condition with different specificity). Evaluate conditions listed for chronicity and support in the full medical record, such as history, medications, and final assessment. Do not submit conditions from lists labeled as PERTINENT NEGATIVES.	Problem lists are evaluated on a case-by-case basis when the problem list is not clearly dated as part of the face to face encounter indicated on the coversheet or there are multiple dates of conditions both before and after the DOS. Lists of conditions written by the patient are not acceptable. Lists of code numbers without narratives are not acceptable.

The chart above directs the coder (referred to as the “Reviewer”) to “evaluate the problem list” to determine “whether conditions are chronic or past” and, consistent with my opinion and with CMS’s longstanding guidance on coding from problem lists, the coder must decide “if th[ose conditions] are consistent with the current encounter documentation.”

Blair’s quote, which she claims shows the “discretion” of “individual coders” in fact comes from the far-right column that applies to a RADV Auditor and not to a coder. The chart allows the auditor, *not* the coder, the option to “evaluate[] on a case-by-case basis” under specific circumstances such as “when the problem list is not clearly dated.” In these instances, the RADV auditor, *not* the coder, is given certain “discretion.”

61. There is no conflict in the applicable guidance for coders. Furthermore, as discussed above, RADV guidance does not supplant the ICD-9/10 coding rules that govern code assignment and submission. *Supra* ¶¶ 17-19, 50.

62. **Second**, Blair gives the example in ¶ 54 of chronic conditions as another “gray area” in coding, due to variability in how providers may document, treat, or discuss chronic conditions with patients. But the examples Blair gives do not show a “gray area” in coding rules or invite coder discretion. Rather, they all address problems in medical record documentation, and the coding rule to apply in this context is clear: unless and until there is further clarification from the provider or additional unambiguous documentation is obtained, the coder cannot code the chronic condition in each of Blair’s examples. I quote these examples and give my contrary opinions below:

- “Providers may take varying amounts of time to document each chronic condition assessed as part of a visit” – documentation of chronic condition does not yet exist.
- “Patient might not have discussed her chronic condition at each visit” – chronic condition not addressed at visit and thus not documented for that DOS.
- “The provider might in fact have taken the chronic condition into account when considering treatment for other conditions addressed at a patient visit and might have included documentation supporting chronic condition” – no confirmation that adequate documentation exists if providers fail to note they assessed and treated the condition on a given DOS.

63. All of the above are hypotheticals by Blair regarding the possibility a patient has a chronic condition, but where either the provider did not properly or clearly document such a condition or where such documentation “might” exist but has yet to be located. These scenarios raise problems with documentation, not a “gray area” permitting a coder to code the chronic condition anyway based on his own judgment.

64. **Third**, Blair claims in ¶ 55 that coders may be confused when coding chronic conditions because different rules for coding chronic conditions apply to inpatient versus outpatient medical

records. This example is baffling because it is a basic rule of coding that any coder has to apply the coding rules that govern in a particular clinical setting where the patient encounter occurred.

65. Blair's specific example is even more baffling. She claims at ¶ 55 that there is an inconsistency between Coding Clinic guidance on coding chronic conditions *in the inpatient setting* versus ICD rules on coding chronic conditions in the *outpatient setting*. However, these are not conflicting coding references. A coder would not attempt to apply both at the same time since one addresses inpatient records and the other outpatient records.

66. Furthermore, if a coder mistakenly believed these rules somehow are both relevant simultaneously, a coder is trained to defer to the ICD rules and not a secondary source, like the Coding Clinic. *Supra* ¶¶ 17-19. This is not a "gray area" but shows the opposite: the clarity and specificity of the ICD rules and the hierarchy of rules a coder is trained to follow.

67. **Fourth**, Blair claims in ¶ 48 that "MA Plan coders performing a blind chart review may approach coding gray areas differently based on their knowledge and experience which may differ from that of the provider or coder in the provider's office that submitted diagnosis codes on the claim, which can cause discrepancies between the diagnosis codes identified by both."

68. To the extent there are "discrepancies" between the MA plan coder's and the provider coder's coding results, Blair's statement appears to make the basic point that different levels of coder experience and training impact coding accuracy. Blair also gives no support for her point that MA plan coders in fact "approach coding gray areas differently." As discussed above, MA plan coders are not permitted to assign codes in the examples Blair gives of "gray areas" (e.g., where the medical record is unclear as to a chronic condition or a coder mistakenly attempts to apply in-patient coding rules to an out-patient chart), let alone use different "approach[es]" to assign codes.

69. Blair continues to make conclusory and vague statements about “gray areas” in ¶ 50: “While regulators and the healthcare industry . . . attempt to clarify gray areas, disagreements remained unresolved for long periods of time in many cases and some remain unresolved today, rendering it difficult for coders to consistently approach these areas.” Blair does not explain what “gray areas” she is describing, what “disagreements” are unresolved, and based on what sources she is making these broad-stroke points. Presumably, because Blair is claiming to describe how the coding industry and government regulators have already “attempt[ed]” to address these issues, there should be some sources supporting these events, but she does not offer any.

IV. OPINION TWO – REBUTTAL

70. In Blair’s second opinion, she switches to opining on why provider coding may be more reliable than MA Plan coding: “During blind chart reviews, if a coder does not identify a diagnosis code that a healthcare provider submitted on a claim to the MA Plan, that code may still be supported by documentation in the patient’s medical record.” Blair Report at 27.

71. Blair justifies her position by suggesting (1) provider-submitted codes tend to be more reliable than MA plan coding and (2) provider coders are “better situated to identify many properly supported diagnosis codes” based on information that Blair admits cannot be found in the medical record. I disagree with both of these points.

72. **First**, the opposite of what Blair newly claims in Opinion Two (but that she endorsed in Opinion One) is true: in my extensive experience, working with both providers and MA plans, MA plan coding has typically been more reliable and accurate than provider coding. In all but the largest physician practices and academic medical centers, provider coders may not hold coding certifications. And, in the settings in which they do, there are rarely any checks or safeguards – such as the quality assurance programs at MA organizations – to ensure accuracy of coding.

73. As discussed, MA organizations tend to institutionalize industry best practices to support coding accuracy, while provider organizations do much less, if at all. For instance, articles by AHIMA and Rise Health cite to the importance of a 95% coding accuracy as an industry best practice.²¹ MA organizations tend to require such best practices, including that coders must be certified, continually trained, held to performance and quality control standards (e.g., 95% coding accuracy and completeness), and be subject to oversight and supervision by experienced coders.

74. **Second**, Blair’s rationale for why provider coding is more reliable than MA coding is that the former knows better than the latter whether a patient in fact has a condition irrespective of how it is documented in the medical record. Blair seems to equate a patient having a condition with a code being “properly supported” or sufficiently “document[ed] in the patient’s medical record.” Blair Report ¶¶ 57-62. So long as documentation *could* be obtained, because the patient in fact has the condition, then Blair’s position is it is appropriate to describe that condition and the corresponding code as “properly documented.” *Id.* at ¶¶ 57-59.

75. This opinion is at odds with the fundamental principle of coding that the medical record is the source of “truth” for code assignment. If a condition is clearly and unambiguously documented in the medical record, the code can be assigned; if not, the code cannot be assigned. That a medical record could be obtained or that a condition could be assumed to exist is not sufficient. United’s own coding leadership recognized this fundamental principle as the “golden rule of coding.” *See* Dickey Dep. 145:10–12, May 24, 2022 (The “golden rule of coding [is] that if it’s not documented, then you don’t code it.”). Blair attempts to support her opinion based on several hypotheticals. I disagree with each:

²¹ *See Body of Knowledge*, AHIMA, <https://bok.ahima.org/> (last visited Jan. 22, 2024); Erik Simonsen, *Is 95% coding accuracy good enough?*, RISE (Dec. 23, 2021), <https://www.risehealth.org/insights-articles/is-95-coding-accuracy-good-enough/>.

Hypothetical: Provider coder is uniquely familiar with provider idiosyncrasies

76. Blair argues that the provider coder uniquely comprehends the provider's handwriting, abbreviations, or documentation practices, can ask the provider questions about the patient's condition, or can find additional medical records to support a code. Blair Report ¶ 58. Each of these points shows why the medical record documentation as it exists or is known fails to support a code, because the documentation is ambiguous, illegible, or incomplete.

77. As I have explained, where there is no clear support for a particular condition in the medical record, a coder has only three options: (1) Ask the physician for any additional documentation that exists; (2) Query the provider to obtain clarification on the medical record; or (3) Not code the suspected but undocumented condition.²²

78. For instance, ICD-10 repeatedly instructs coders that the proper way of handling ambiguous documentation (such as unclear handwriting and language or an incomplete record) is to query the provider: "Query the provider for clarification, if the complication is not clearly documented." (Complications of Care); "Whenever the documentation is unclear regarding a borderline condition, coders are encouraged to query for clarification." (Borderline Diagnosis); "If the documentation is not clear as to whether acute respiratory failure and another condition are equally responsible for occasioning the admission, query the provider for clarification." (Sequencing of acute respiratory failure and another acute condition). ICD-10, § I.B.16-17, § I.C.10.b.3.²³

²² See, e.g., AHIMA Standards (revised and approved Dec. 12, 2016), <https://bok.ahima.org/topics/coding-compliance-and-revenue-cycle/american-health-information-management-association-standards-of-ethical-coding-2016-version/> ("3. Assign and report, in any format, only the codes and data that are clearly and consistently supported by health record documentation in accordance with applicable code set and abstraction conventions, and requirements," "4. Query and/or consult as needed with the provider for clarification and additional documentation prior to final code assignment in accordance with acceptable healthcare industry practices.").

²³ ICD-10 (updated Apr. 1, 2022), <https://www.cms.gov/files/document/fy-2022-icd-10-cm-coding-guidelines-updated-02012022.pdf>.

Hypothetical: Condition listed only in undated problem list

79. In Figure 4 of her report at ¶ 59, Blair presents a hypothetical in which a provider coder reported respiratory failure and a MA Plan coder did not, where the problem list made a note suggesting the patient had the condition but “no date [was] specifically assigned” to the note.

80. Despite the improper lack of a date, Blair imagines in the hypothetical that the provider coder “might have included . . . respiratory failure on the claim” anyway because that coder knew, from being at the provider’s office, the relevant note was added “on the date of service, which means that respiratory failure was, in fact, a current condition for this patient.” Blair Report ¶ 59. Blair then claims that the “MA Plan coder might have determined that because there is no date on the problem list and the information within it, they are unable to support the coding of respiratory failure during their review.” *Id.*

81. This hypothetical is nonsensical and again violates a basic rule of coding: Blair characterizes the provider coder as having properly coded respiratory failure when that coder relied on information about the date of service *not in the medical record*. As discussed above at ¶ 78, any person attempting to assign the respiratory failure code must first take steps – such as a physician query – to obtain the necessary medical record support.

Hypothetical: Diagnosis code not linked to medication

82. In Blair’s next hypothetical, in ¶ 60 of her report at Figure 5, a MA Plan coder fails to identify a COPD diagnosis in a medical record even though COPD was included on the problem list and the record “documented that the provider renewed the medication Albuterol, a medication used to treat COPD, but did not explicitly mention COPD otherwise in the note.” “While the Albuterol was not specifically linked to a COPD diagnosis in the chart, COPD was the only past condition that would require this medication, and the orders noted that Albuterol was being

renewed, indicating the COPD was still current.” Blair Report ¶ 60. Blair’s hypothetical suggests “a coder at the provider’s office may have drawn this linkage” while “an MA Plan coder may fail to identify [the] diagnosis that is supported by the medical record.” *Id.*

83. This is another unrealistic hypothetical. It assumes, without explanation, that the MA Plan’s certified, highly trained coder, who is subject to quality control review, would miss the obvious link between a well-established COPD medication (Albuterol) and the management of COPD, even though the condition appears in the problem list before the MA Plan coder. In my experience, this is unlikely to occur, particularly at a MA organization enforcing strict performance standards. Blair does not explain how this hypothetical justifies that a provider coder is more likely than a MA coder to approach this situation correctly.

Hypothetical: Failure to identify specific diabetes subtype

84. In Blair’s final hypothetical, “[a]n MA Plan coder may see diabetes supported by the medical record but assume the diabetes does not have complications because the record does not include an additional diagnosis for the complication. The [provider’s] coder, on the other hand, may have more *intimate* knowledge of the patient’s current diagnoses and can identify a diabetes diagnosis with complications. For instance, if the provider or coding personnel at the provider’s office reviewed the record and noted an order for an arterial scan of the lower legs, which subsequently showed a diagnosis of peripheral artery disease, then they might have coded diabetes with complications.” *Id.* at ¶ 61 (emphasis added).

85. Blair provides a medical chart at Figure 6 that accompanies the hypothetical, but the chart only shows why the hypothetical and Blair’s points fail. Based on the chart, the MA Plan coder who did not code a diabetes complication for DOS 1/1/2015 is correct. The hypothetical chart has no indication that an arterial scan of the lower legs was actually performed, but only that

it was ordered. Nor does the record reflect a face-to-face encounter where a provider addressed the peripheral artery disease. As a result, the medical record does not provide adequate documented support for a coder to link peripheral artery disease to diabetes at the 1/1/2015 visit. As in Blair's other hypotheticals, it is irrelevant the provider's coder might theoretically and "intimately" know additional information about the patient, which Blair assumes is not documented in the record.

86. The opinions above are based on information currently available to me. I reserve the right to supplement or modify these opinions as necessary if new information later becomes available.

I. Qualifications

1. I, Barbara Blair, am a Senior Director at FTI Consulting (“FTI”). I received my Associate Degree from Rockland Community College in 1986, followed by my Bachelor of Science in Nursing from the University of Rochester in 1991 and, ultimately, my Master of Science in Nursing from the University of Rochester in 1992. Upon receiving my Associate Degree, I passed the exam to become a licensed Registered Nurse. I practiced as a Registered Nurse from 1986 to 1995 in different specialties, including medical/surgical, emergency medicine, short-stay patients, oncology, and cardiac critical care, and I have maintained my Registered Nurse license to date. Upon receipt of my master’s degree, I passed the exam to become a certified Adult Nurse Practitioner. I practiced as an Adult Nurse Practitioner from 1992 to 1995. As a Registered Nurse and an Adult Nurse Practitioner, I worked in a variety of medical settings, including a large metropolitan hospital, a private hospital, and a teaching hospital.
2. I transitioned from being a provider to being a consultant in 1995. I provide consulting services to healthcare organizations, working with providers and various members of their healthcare teams, including but not limited to nurses, therapists, and nutritionists. My work focuses on provider documentation and medical diagnosis coding. I lead trainings at hospitals, physician offices, and outpatient clinics. I became a Certified Coding Specialist (“CCS”) in 2000 and subsequently obtained several coding and compliance certifications, set forth more fully on my curriculum vitae, including Certified Professional Coder (“CPC”), Certified Risk Adjustment Coder (“CRC”), Certified Professional Compliance Officer (“CPCO”), a certificate of completion for Certified Documentation Expert Inpatient (“CDEI”), and am an American Health Information Management Association (“AHIMA”) ICD-10-Clinical Modification/Procedure Coding System trainer.
3. For the past twenty years, I have served as a lead coder for FTI, where I work with clients, including health insurance plans and providers. I provide clinical and coding expertise for various reviews related to diagnosis code identification and assignment. As part of these reviews, one of my focus areas is the proper identification of support for diagnosis codes in medical records for providers and Medicare Advantage Plans (“MA Plans”) with risk adjustment reimbursement models. My work in this area includes reviewing company policies and procedures around diagnosis coding; reviewing internal training related to

proper diagnosis coding; creating coder education related to proper diagnosis code identification; reviewing diagnosis coding in connection with internal and external investigations; supporting reviews related to due diligence for potential acquisitions; and providing support for mock Risk Adjustment Data Validation (“RADV”) reviews.

4. For a detailed summary of my experience, please refer to Exhibit A for my CV. I have been retained by counsel for UnitedHealth Group, Inc. in the matter of *United States ex rel. Poehling v. UnitedHealth Group, Inc. et al.* to opine on the topics as set forth in this report. FTI is being paid \$560 per hour for my work in this case. In addition, other employees of FTI have worked under my direction in this matter. The billing rates for these individuals range from \$350-\$625 per hour. Compensation for FTI’s services is not based on the outcome of this matter or the content of my opinions.

II. Introduction and Summary of Opinions

5. Health insurance programs in the United States are administered by the government, private companies, or a combination of both. At age 65 (or as a result of certain disabilities or other conditions), individuals become eligible to receive their healthcare coverage through Medicare, which includes the option to receive healthcare coverage either through the federal government or through private health plans. Medicare Parts A and B, also known as Traditional Medicare, are administered by the Centers for Medicare & Medicaid Services (“CMS”).¹ Medicare Part C, also known as Medicare Advantage (“MA”), is administered by private health insurance companies called MA Plans.²
6. In contrast to a fee-for-service model where a healthcare provider’s payment is based on the services provided, CMS pays MA Plans based on its risk adjustment model, which takes into account a patient’s health status and certain demographic details, rather than the healthcare services a provider rendered to a patient. MA Plans obtain information regarding a patient’s health status from providers who submit healthcare claims, which contain

¹ See CMS, *Fact Sheet: Introduction to Medicare*, available at <https://www.cms.gov/outreach-and-education/find-your-provider-type/employers-and-unions/fs1-intro-to-medicare.pdf>.

² See Medicare.gov, *Your health plan options*, available at <https://www.medicare.gov/health-drug-plans/health-plans/your-health-plan-options>.

- diagnosis codes, to the MA Plan.³ Diagnosis codes are a lengthy set of standardized codes used by providers and health insurance plans to identify and track a patient's health conditions. CMS uses diagnosis codes as a basis for reimbursement in the MA program.
7. After a patient visit, a provider submits the claim to the patient's MA Plan, which contains information about the patient visit, such as the services provided and relevant diagnosis codes. A provider may identify the diagnosis code(s) to submit on the claim or the provider may rely on coders to review the information documented in a patient's medical record and translate this information into diagnosis codes. The MA Plan then, in turn, submits the diagnosis codes for all of its beneficiaries to CMS, and CMS uses this information (along with other characteristics of the beneficiary, including demographic information) to determine payment to the MA Plan for providing health coverage to this beneficiary.
 8. After the submission of a claim, MA Plans often use certified coders to perform a separate review of patient medical records, sometimes called "chart review," during which a coder reviews the medical records to determine which diagnosis codes she believes are supported by the documentation in the medical record. MA Plan chart reviews typically occur retrospectively, meaning after the provider submitted diagnosis codes to the MA Plan.
 9. One form of chart review employed by MA Plans is referred to as a "blind review," meaning the coder reviews a patient's medical record without knowledge of any diagnosis codes assigned by other coders who may have reviewed the documentation, or any diagnosis codes submitted by a provider to the MA Plan on a claim. In a blind chart review, the coder identifies diagnosis codes the coder believes have supporting documentation in the patient's medical record. This determination of diagnosis codes entails judgment and can be subjective, often relying on a coder's training, experience, and interpretation and application of coding guidance, which is not always definitive. Although coding medical records is standard practice in the healthcare industry, for the variety of reasons noted and discussed in more detail below, coders may not agree as to which diagnosis codes have documentation in a medical record sufficient to support coding the diagnosis code.

³ The "diagnosis codes" (otherwise known as ICD-9-CM and ICD-10-CM codes) that are used by providers in the United States are derived from the International Classification of Diseases ("ICD") developed by the World Health Organization. ICD codes were developed to classify the cause of death for mortality statistics. *See* CDC, *International Classification of Diseases, Tenth Revision, Clinical Modification (ICD-10-CM)*, available at <https://www.cdc.gov/nchs/icd/icd-10-cm.htm>.

Therefore, coders may identify different diagnosis codes than the diagnosis codes identified by a provider, a coder in a provider's office, or another coder performing a chart review.

10. Based on the materials I have relied upon (listed in Exhibit B) and my experience as a clinician and certified coder, I have the following opinions:

Opinion One: The identification of diagnosis codes supported by documentation in a medical record is a complex process, informed by a variety of coding guidance and dependent on a coder's training, experience, and judgment.

Opinion Two: During blind chart reviews, if a coder does not identify a diagnosis code that a healthcare provider submitted on a claim to the MA Plan, that code may still be supported by documentation in the patient's medical record.

11. My opinions are based on my experience as a nurse and certified coder, my consulting experience, and my 25+ years working in the healthcare industry. I also considered various industry writings from accredited organizations such as AHIMA and the American Academy of Professional Coders ("AAPC"). A list of the documents I relied upon in reaching my opinions is included in Exhibit B.

III. Background

Medical Record Documentation and Diagnosis Coding

12. Healthcare providers evaluate patients to determine and provide appropriate care. When meeting with a patient, the provider assesses the patient's chief complaint, presentation, medical history, signs and symptoms and then documents these pertinent details in the patient's medical record (also referred to as "provider documentation"). The provider is also supposed to determine any relevant diagnoses for the patient (e.g., rheumatoid arthritis), which should be noted in the patient's medical record. Figure 1 below is a condensed example of a hypothetical medical record on a specific visit date (1/1/2014):

Figure 1: Example Patient Medical Record

- **Jane Smith, MD – 1/1/2014**
- **John Doe (1/1/1947)**
- **Chief Complaint:** Swelling and joint pain in hand
- **History of Present Illness:** Onset of joint pain in the past two weeks with recent swelling
- **Medication** Aspirin
- **Medical History/Problem List:** Chronic Back Pain, Hip Replacement, Diabetes
- **Lab/Imaging:** x-ray of right hand
- **Exam:** Well-nourished, well-developed male, tenderness in right hand
- **Assessment/Plan:** right hand pain due to rheumatoid arthritis, start prednisone, continue diabetic diet

13. In this example, the medical record states that a hypothetical patient complained of pain and swelling in his hand. The doctor examined the patient's hand, reviewed the patient's relevant medical history, documented the patient's diagnosis of rheumatoid arthritis, and developed a personal care plan to address the patient's hand pain. While meeting with the patient to discuss his hand pain, the doctor also discussed how the patient was managing his diet for diabetes.
14. At some point following the patient visit, the provider submitted a claim to the MA Plan specifying the services the provider rendered to the patient (e.g., x-ray of hand) as well as the diagnosis codes that described the patient's underlying health status (e.g., rheumatoid arthritis in the example described in Figure 1). The provider's office included diagnosis codes on the claim form using the standardized set of diagnosis codes.
15. An important step in the patient visit and claim creation process is the assignment of diagnosis codes on a claim. Although the provider typically submits diagnosis codes on the health insurance claim, the resulting claim may not include all diagnosis codes supported by documentation in the medical record. In the example in Figure 1, the record supported the diagnosis codes for both rheumatoid arthritis and diabetes. Given that the patient's hand pain, which the provider determined to be rheumatoid arthritis, was the primary focus of the visit, the provider's office might have inadvertently failed to include a diagnosis code for diabetes on the claim, even though the provider discussed the diet plan for diabetes with the patient during the same visit and documented diabetes in the medical record.
16. Separate and apart from the submission of diagnosis codes on the claim, an MA Plan may conduct its own reviews of medical records through a chart review process. Although these reviews can be performed in a variety of ways, one option is a "blind chart review." In a

blind chart review, a certified coder reviews the patient's medical record without knowledge of any diagnosis code(s) previously submitted by the provider on the claim, or diagnosis code(s) identified for that patient by another coder. The MA Plan coder will identify the diagnosis codes she determines—based on the coder's judgment, training, education, experience, interpretation of the medical record, and applicable coding guidance—are supported by documentation in the medical record. The documentation the MA Plan coder reviews may contain information captured from a single date of service, such as the example in Figure 1 above, or information captured on many dates of service. In the single date of service example in Figure 1, the provider submitted only the diagnosis code for rheumatoid arthritis on the claim, but the MA Plan coder later reviewing the medical record may have added a diagnosis code for diabetes through chart review because diabetes was supported by documentation in the medical record.

17. MA Plans often conduct chart reviews to determine whether additional diagnosis codes not included in the provider's claim are documented in the underlying medical records. These reviews help MA Plans obtain a more complete picture of a patient's health status, which is an important part of a patient's overall care management and helps ensure the coordination of comprehensive patient care.
18. Providers had historically received more training for the documentation of procedures and services under the fee-for-service model, as provider reimbursement was more commonly derived from the procedures providers performed or services providers rendered, rather than derived from a patient's diagnoses and the documentation of diagnoses. In the past, providers did not always submit all of a patient's applicable diagnosis codes on a claim and in fact may have submitted only one diagnosis code on a claim as the basis and support for the services rendered or procedures performed even though other diagnosis codes may have applied for the visit. During their blind reviews, coders conducting MA Plan chart reviews may identify these additional diagnosis codes that are supported by documentation in a patient's medical record but that were not submitted on the claim.

Establishment and Evolution of Diagnosis Coding

19. Diagnosis codes changed in a variety of ways between 2008 and 2016. Most significantly, a new version of diagnosis codes (ICD-10-CM or "ICD-10") was established in October

2015 after the previous version (ICD-9-CM or “ICD-9”) had been in use in the United States since 1979.⁴ There are over 68,000 unique codes in the current ICD-10-CM code set, which uses up to seven alphanumeric characters per diagnosis. There were roughly 13,000 unique codes in the ICD-9-CM code set, which was limited to a five numeric character format.⁵ The transition between ICD-9-CM and ICD-10-CM represented a significant improvement in terms of tracking and analyzing patient care. The larger set of unique diagnosis codes in ICD-10-CM allows for a higher degree of specificity when categorizing a particular diagnosis and can account for additional factors like laterality (right or left side of the body), recurrence, and severity.⁶

Sources of Coding

20. In order to assign diagnosis codes, coders rely on guidance from many sources to review provider documentation and translate the information contained in the medical record into diagnosis codes. Several key resources from professional organizations provide guidance to coders on numerous aspects of coding. These include, but are not limited to, the below examples:

- An official list of diagnosis codes contained within the Tabular List and Alphabetic Index is included in the vast majority of coding reference books with instructions and is annually updated by the National Center for Health Statistics (“NCHS”).⁷
- The Official Guidelines for Coding and Reporting are jointly published on an annual basis by AHA,⁸ AHIMA,⁹ CMS, and NCHS as a “companion document” to the NCHS diagnosis code list.¹⁰

⁴ See CDC, *International Classification of Diseases, (ICD-10-CM/PCS) Transition - Background*, available at https://www.cdc.gov/nchs/icd/icd10cm_pcs_background.htm.

⁵ See AHIMA, *ICD-10-CM Primer*, available at <https://library.ahima.org/doc?oid=106177>.

⁶ *Id.*

⁷ See, e.g., CDC, *FY 2016 release of ICD-10-CM - ICD-10-CM List of codes and Descriptions*, available at https://www.cdc.gov/nchs/data/icd/icd10cm/2016/ICD10CM_FY2016_code_descriptions.zip.

⁸ American Hospital Association is the national organization that represents and serves all types of hospitals, health care networks, and their patients and communities. See <https://www.aha.org/about>.

⁹ American Health Information Management Association is a global nonprofit association of health information professionals focused on health information management. See <https://www.ahima.org/who-we-are/about-us/>.

¹⁰ See, e.g., CMS, *ICD-10-CM Official Guidelines for Coding and Reporting: FY 2016*, available at <https://www.cms.gov/medicare/coding/icd10/downloads/2016-icd-10-cm-guidelines.pdf>.

- AHA, AHIMA, CMS, and NCHS coordinate to provide a quarterly newsletter referred to as the Coding Clinic, which has provided additional guidance since 1984 on topics that lack clarity in the code instructions or official guidelines.¹¹
- Coders also rely on materials published by CMS for MA Plans, which contain additional coding guidance. This includes feedback provided in connection with CMS's RADV audits of medical records for patients enrolled in MA Plans, the coding sections (Module 6 – Diagnosis Codes & Risk Adjustment, Module 7 – Risk Adjustment Data Validation) of the Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide (“coding sections of the CMS Participant Guide”),¹² and Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance (“RADV Reviewer Guidance”).¹³
- Coders may also rely on a provider's own coding references. It is not uncommon for providers to summarize their own interpretation of the above sources to assist coders with code assignment.

21. These resources, among others, provide coders with guidance on how to interpret documentation in a medical record and how to properly assign diagnosis codes. Even with the multitude of guidance described above, coders often use their own judgment to assign diagnosis codes because the coding guidance may be silent or ambiguous on a specific issue and the guidance alone does not address all areas of ambiguity present in diagnosis coding. And in certain cases, one set of coding guidance may actually conflict with another set of coding guidance. Coders therefore use the available guidance as a framework but ultimately must also rely on their judgment and experience.

IV. Opinions

Opinion One: The identification of diagnosis codes supported by documentation in a medical record is a complex process, informed by a variety of coding guidance and dependent on a coder's training, experience, and judgment.

22. In chart review, MA Plan coders review the available medical record documentation and translate the information within it into the applicable diagnosis codes supported by the documentation in the medical record. Provider documentation varies in terms of format, legibility, source of information, length, and complexity, which can impact and potentially complicate a coder's review. Determining which diagnosis codes are supported by documentation in the medical record involves judgment and can be a subjective exercise where coders may not always agree. Different coders may reach different conclusions as to which diagnosis codes are supported by documentation in a given medical record for a variety of reasons, including but not limited to (1) the coder's professional experience and training; (2) availability, legibility, and variability of provider documentation; (3) the interpretation and application of various sources of coding guidance; (4) human error; (5) the transition from ICD-9 to ICD-10 diagnosis code sets; and (6) coding "gray areas."

Coder Certification, Experience, and Training

23. Certified coders have varying levels of experience and training, as well as different coding certifications. For instance, one coder may have years of experience coding certain specific diagnoses, while another coder may have limited experience with those same diagnoses. This is seen often with coders who work in an office with a medical specialist who focuses in one area, such as cardiology. As a result of the provider's specialization, the coder focuses on a relatively small number of conditions. The coder in that specialized practice will have extensive coding experience with the conditions the cardiologist treats but less coding experience with conditions outside of the provider's specialty. The cardiology coder's experience differs from a coder supporting a family medicine practice, who experiences a different and likely broader range of conditions based on the patients the family practitioner treats.

24. Similarly, while some coders focus on coding the services (using procedure codes, for example) performed during the patient visit, and may only give cursory consideration to coding diagnoses, other coders may focus more closely on the documentation of diagnosis

codes. Still, other coders may have roles that require a detailed focus on the coding of both procedures and diagnoses for the same medical chart. The coder's work experience may influence her ability to identify diagnosis codes supported by documentation in a patient's medical record. For example, a coder who is more experienced with procedure codes and less experienced with diagnosis codes may be less effective at identifying all the diagnosis codes supported by the documentation in the medical record than a coder whose career focuses heavily on diagnosis coding.

25. Training, including various certifications coders may receive, also varies from coder to coder. Certain coding certifications are general, such as the Certified Professional Coder (CPC) certification, and include training for multiple types of medical codes like procedure codes and diagnosis codes.¹⁴ Other certifications, such as the Certified Risk Adjustment Coder (CRC) certification, are more specialized and focus only on diagnosis coding, including coding for complicated medical diagnoses like diabetes or depression. The AAPC explains that "Healthcare professionals earning their CRC credential possess demonstrated expertise in the complexity of diseases associated with chronic conditions and comorbidities, as well as mastery of ICD-10-CM guidelines and risk adjustment guidelines."¹⁵ While a coder with a more generalized training background and certification may understand the basics of what is required to generally identify diagnosis codes from within a medical record, that coder may not have the same depth of understanding and experience as a coder who received specific training for identifying diagnosis codes supported by documentation in a medical record. As a result, a coder with more specialized diagnosis code training, such as a coder with a CRC certification, may make different coding determinations than a coder with a more generalized training background.

Availability, Legibility, and Variability of Provider Documentation

26. In addition to varied coder backgrounds, the provider documentation available to coders during chart review varies greatly. MA Plans typically retrieve some of the patient's medical records from providers for review by the MA Plan's coders. This process can involve outreach to multiple providers for specific patients and, in some cases, working

¹⁴ See AAPC, *Certified Professional Coder (CPC)® certification*, available at <https://www.aapc.com/certifications/cpc>.

¹⁵ AAPC, *Certified Risk Adjustment Coder (CRC)® certification*, available at <https://www.aapc.com/certifications/crc>.

with those providers to supply the particular medical records. The medical record documentation retrieved for a given patient may be incomplete, as MA Plan chart reviews are limited to the documentation providers supply. As a result, the medical documentation provided may only contain a portion of the visits the patient had with the provider for a given year or may be missing key pages of the medical record related to the days those visits occurred. For example, scanned medical record documentation may only show the odd-numbered pages (pages 1, 3, 5, etc.) because the original medical record documentation was double-sided, and the provider's office only scanned in one side of the record. As another example, providers may have document retention limitations and store only the last year of records in their office and may store older records at an offsite location. A provider could have difficulty retrieving the offsite records for an MA Plan because they do not have time to go to the offsite location to retrieve the records, lack organization of those records, or find it difficult to identify records for a specific patient. Therefore, a provider's office may provide only what is stored on-site, which may not include information regarding every visit a patient had with the provider in a given year.

27. Additionally, due to the advanced age of patients enrolled in MA Plans, these patients often see multiple providers in a given year. These providers may be at the same location, or they could be spread out across various locations. Each provider may also have a different medical record for the patient. All of these factors make it challenging to collect complete medical records for patients. Even if an MA Plan retrieves multiple medical records for a patient for a given year, the MA Plan still may not have access to all of the patient's medical records, or all pages of a medical record, that may exist for every visit the patient had with a provider in a given year. Due to the large volume of records retrieved and also records reviewed, the MA Plan's coder may not know that documentation is missing or incomplete.
28. The completeness of medical records can influence whether a coder identifies a particular diagnosis code as being appropriately supported by documentation in the medical record. For example, consider a hypothetical case in which a patient visited a primary care physician the morning of May 5, 2016, and was diagnosed with an abnormal pap smear. Upon checkout, the office staff noted the group's oncologist had availability that afternoon to perform a biopsy. The biopsy ultimately confirmed that the patient had cervical cancer. The claim submission for May 5, 2016, would likely contain the diagnosis code for cervical

cancer. But when the MA Plan contacted the group to obtain the patient's medical records, the MA Plan got routed to the receptionist in the primary care physician's office to ask for the medical records for the patient's May 5, 2016, visit. The receptionist went into the primary care physician's electronic health record system, printed out the notes from the visit with the primary care physician on the morning of May 5, 2016, and sent those records to the MA Plan. In this example, if an MA Plan coder only had access to the primary care physician's notes in the patient's medical record for the morning of May 5, 2016, the coder likely would not have assigned the cancer diagnosis code because the conclusive pathology report from that afternoon indicating the patient had cancer was not included in what was provided to the MA Plan. Even though another provider diagnosed the patient with cervical cancer, which was documented in her medical records, the MA Plan coder may not have identified that diagnosis code in the course of chart review because the MA Plan coder did not have the full medical record.

29. In addition, the legibility and clarity of the available documentation affect a coder's ability to identify diagnosis codes. For example, a coder who cannot read a provider's handwriting may not identify a diagnosis code during a chart review that is, in fact, properly supported by documentation in the medical record.¹⁶ Some coders may be able to interpret the same provider's handwriting and identify the diagnosis code as supported by documentation in the medical record. A coder working closely with a provider, for example, may develop a familiarity with that provider's handwriting style, shorthand, and abbreviations and can better decipher the provider's handwriting than an MA Plan's coder less familiar with the provider. A coder in the provider's office could have also asked the provider to clarify what was documented in a medical record whereas an MA Plan coder would not have had the same opportunity.
30. The format of a medical record further impacts a coder's ability to assign diagnosis codes. For example, medical records stored only in hard-copy format are more likely to be unavailable or incomplete due to loss, damage, misfiling, or other issues. Electronic medical records ("EMR") may also be unavailable or incomplete. For instance, a patient's

¹⁶ See AAPC, *Medical Record Entries: What Is Timely and Reasonable?* (last updated, Sept. 1, 2013), available at <https://www.aapc.com/blog/25667-medical-record-entries-what-is-timely-and-reasonable>.

providers may use different EMR systems that store her medical records in varied formats. Additionally, providers may fail to update a shared EMR. Obtaining complete medical records for any given patient can be challenging if different portions of the patient's chart exist in hard-copy and electronic format or if a provider uses both hard-copy charts and EMR in a given year. Handwritten records remained common and were used by more than 50% of providers until 2013. As shown in Figure 2 below, less than 20% of physician offices and hospitals utilized EMRs in 2008 but by 2014 the vast majority of physician offices and hospitals utilized EMRs.¹⁷

Figure 2: Electronic Medical Record Transition¹⁸

31. Even after the majority of providers transitioned to EMR by 2014, some continued to use handwritten medical records or a combination of EMR and handwritten records.¹⁹ Even within an EMR, providers sometimes use shorthand or abbreviations without clear or consistent meaning. In a RADV audit, when a coder encounters abbreviations with multiple meanings, CMS instructs: “If more than one meaning applies or documentation is too limited to differentiate, and this is the only diagnosis listed within the record, evaluate on a case-by-case basis. Otherwise, use discretion to report or not based on other circumstances in the record.”²⁰ MA Plan coders do the same case-by-case evaluation and

¹⁷ See HealthIT.gov, *National Trends in Hospital and Physician Adoption of Electronic Health Records*, available at <https://www.healthit.gov/data/quickstats/national-trends-hospital-and-physician-adoption-electronic-health-records>.

¹⁸ *Id.*

¹⁹ *Id.*

²⁰ CMS, *Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance In effect as of 03/20/2019* at 59, (last updated, Nov. 14, 2018), available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>.

- employ their own discretion to conduct a chart review of medical records that contain abbreviations or shorthand. One coder may choose to interpret the shorthand or abbreviation as support for a particular diagnosis code while another may not. In either scenario, RADV guidance supports the coder's choice to consider the shorthand or abbreviation on a case-by-case basis.
32. Varied provider practices for documenting a patient's condition(s) may also impact a coder's ability to determine whether a diagnosis code is supported by documentation in the medical record. Patients enrolled in MA Plans generally see a variety of healthcare providers, including providers from different specialties (e.g., oncologists, cardiologists, and primary care physicians). These providers have different practices and processes for documenting patient health information in the medical record. For example, providers do not consistently document information about a patient's visit in the same location in a medical record. This may be confusing for coders that do not work with a specific provider on a regular basis or with specialists in a particular area. MA Plan coders often lack familiarity with how and where the provider documents conditions. Given all of the different ways providers may document their visits with patients, it can be difficult for an MA Plan coder reviewing documentation from a variety of providers to understand and identify all diagnosis codes potentially supported by documentation in the medical records reviewed.

The Interpretation and Application of Various Sources of Coding Guidance

33. Coders rely on a variety of sources of coding guidance. I have listed various sources of coding guidance above in the background section within. *See supra* at Paragraph 20. This coding guidance comes from nationally recognized organizations, including NCHS, AHA, AHIMA and CMS. The guidance includes annual guidance, such as the Official Guidelines for Coding and Reporting, and quarterly guidance, such as the Coding Clinic. MA Plan coders also need to understand and consider coding guidance published on an ad-hoc basis, including the coding sections of the CMS Participant Guide and RADV Reviewer Guidance, which is specific to diagnosis coding for the CMS Risk Adjustment program.
34. Coders interpret and apply various sources of coding guidance when conducting a chart review. This task is made more complicated by the number of sources of coding guidance,

the complexity and technical nature of the coding guidance, ambiguity or lack of clarity in coding guidance, changes to coding guidance over time, and conflicts in coding guidance. Despite the volume of available coding guidance, not every nuance or subject area of medical record documentation is addressed. Coders will therefore sometimes not identify diagnosis codes that are, in fact, supported by documentation in the medical record. Two coders that review the same medical record could reach different conclusions about whether a diagnosis code is supported by documentation in the medical record because they interpret or apply the coding guidance—or a lack thereof—differently. For example, in the medical record the physician may have written the standard abbreviation of “CRF.” A coder may look up “CRF” in the ICD coding index and find no guidance as to the appropriate code for “CRF.” CRF is a common abbreviation for either chronic renal failure or chronic respiratory failure. One coder may not feel comfortable assigning either of the chronic renal failure or chronic respiratory failure diagnoses based on the abbreviation due to there being more than one possible meaning whereas another coder may assign one of the diagnoses because the coder—based on her experience, training, and judgement—believes it is supported by the documentation in the record.

35. Coding guidance, such as the Coding Clinic referenced above, is effective as of a specified date. For example, updates to the Official Coding Guidelines specify the time period they relate to (e.g., FY 2016 or October 1, 2015-September 30, 2016). When coding charts, including those for MA patients, coders consider the dates of service in the review and identify and utilize the applicable coding guidance relevant to the dates of service in the review. Ultimately, the date of the patient visit will dictate the coding guidance applicable for reviewing a specific record. For example, MA Plan coders reviewing a medical record in 2013 that was created on the date of the patient visit in 2012 should apply the guidance that was effective on the date of service (2012), not the guidance effective on the date of review (2013). Coders may even be tasked with reviewing dates of service spanning multiple years in a single review such as a coder performing a review in 2013 on dates of service from 2010-2012, which means the coder would have to consider and apply different sources for different years while performing the same review.

36. As noted above, coders must consider which sources and versions of guidance should be applied at the relevant time. For example, in the third quarter of 2009, the Coding Clinic

issued guidance to address the use of the common phrase “evidence of” in provider documentation for diagnosis coding. Before this new guidance was issued, coders used their independent judgment to interpret whether the phrase “evidence of” and other context was enough for the coder to determine if a diagnosis was supported by documentation in the medical record. Before the new guidance was issued, if a medical record contained the phrase “evidence of COPD” some coders may have interpreted this as a conclusive statement supporting a diagnosis code for COPD. Other coders may have interpreted that statement to suggest the doctor saw signs of COPD but did not ultimately conclude the patient had COPD and accordingly not coded COPD. However, the third quarter 2009 Coding Clinic’s guidance states that “when the provider documents ‘evidence of’ a particular condition, it is not considered an uncertain diagnosis and should be appropriately coded and reported in the outpatient setting.”²¹ Therefore, after this guidance was issued, if a medical record contained “evidence of COPD,” this was enough for a coder to code COPD even though the medical record did not specifically state that the patient had COPD. If a coder identified the phrase “evidence of” in the medical record, she would consider if the date of the patient’s visit was before the conclusive guidance was issued. This is just one of the many clarifications and changes that have occurred over the past 15 years in the applicable coding guidance references that coders have to take into consideration.

37. In addition, CMS publishes RADV Reviewer Guidance periodically, and sometimes for each calendar year, in connection with its RADV audit process. CMS uses RADV audits to determine if an MA Plan can provide documentation to support the diagnosis codes submitted to CMS in a given year for a sample of beneficiaries. RADV Reviewer Guidance includes a summary of the diagnosis coding guidelines for the MA program. The RADV Reviewer Guidance also provides topics, examples, and guidance based on CMS’s review of RADV audit samples and notes “medical records can be unique in format, legibility, content, organization, etc.” and “the guidance and examples are not exhaustive in content,” and therefore “documentation issues will be considered on a case-by-case basis.”²²

²¹ AHA, Coding Clinic for ICD-9-CM, Volume 26, Number 3, Third Quarter, 2009 at 7.

²² CMS, *Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance In effect as of 03/20/2019* at 7, (last updated, Nov. 14, 2018), available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>.

- Similarly, the RADV Reviewer Guidance itself notes that it is merely a resource and other sources must be considered.²³
38. Once CMS completes the RADV audit process for a given year, CMS provides audit results to MA Plans that were subject to the audit. These RADV audit results help demonstrate the RADV coding auditors' interpretations of industry guidance, such as Coding Clinic guidance or the application of RADV Reviewer Guidance. While the RADV Reviewer Guidance only formally applies to the coders CMS engages to perform RADV audits on behalf of CMS, industry participants (including providers, plans, and their coders) look to RADV Reviewer Guidance—and the results of RADV audits—as a source of interpretation and application of coding guidelines. The results showing diagnoses the RADV coding auditors determine are supported in specific scenarios provide further coding guidance for MA Plan coders in similar situations in their own reviews.
39. For example, the RADV Reviewer Guidance states that reviewers may encounter a Consultation Report, which is a report prepared by a consulting physician to assist with a patient's care. The coding guidance specifies that if the consultation report contains an unconfirmed diagnosis and the diagnosis is not ruled out elsewhere, but also is not mentioned in the final discharge diagnosis, a decision to support the diagnosis should be made on a case-by-case basis.²⁴ Similarly, when discussing a RADV coding auditor's evaluation of diagnostic testing documentation, the guidance states that "the reviewer must use judgment based on the type of procedure/test or other documentation available when determining if a chief complaint or reason for a test is a current diagnosis or was a condition to be ruled out."²⁵
40. In addition to official coding guidance and CMS RADV guidance (such as the RADV Reviewer Guidance and the RADV audit results), the coding industry has also developed a variety of criteria for coders to use to identify diagnosis codes supported by documentation in a medical record. One common set of coding criteria is referred to as "MEAT" where the provider documentation must sufficiently show that a diagnosis is

²³ *Id.* (providing on each of the 72 pages that the RADV Reviewer Guidance contains general guidance that is not exclusive).

²⁴ *Id.* at 22.

²⁵ *Id.* at 34.

monitored/managed, evaluated, assessed and/or treated in order for a diagnosis code to be assigned.²⁶ For example, a provider can demonstrate evaluation (an element of MEAT) of Type 2 Diabetes by documenting “A1c results reviewed and discussed with patient” in the medical record. The adoption of the MEAT criteria, in the early 2010s, coincides with guidance from CMS available at the time to describe supporting documentation, but CMS has never officially defined, required, or codified the MEAT coding standard. As a result, one medical coder may follow the MEAT standard while others may follow a different coding standard. Providers may also determine how many elements of MEAT are necessary to support the diagnosis code and this varies across practices. Similarly, MA Plans may differ on how to implement the MEAT criteria when performing the chart reviews because CMS does not require MEAT. Some coders look for multiple elements of MEAT before assigning a diagnosis code, while other coders look for only one element. For example, one coder may have found a notation of “Type 2 Diabetes on Metformin,” which demonstrated one element of MEAT, and coded the condition. Another coder may have found that notation insufficient to support the diagnosis code because it related to only one element of MEAT rather than multiple. The lack of consensus on the use of MEAT among coders may result in coders reaching different conclusions about whether a condition is properly supported by documentation in a medical record.

41. General diagnosis coding guidance, results of CMS RADV audits, and ever-evolving industry guidance are all important sources of information for coders to consider. The available guidance changed (and continues to change) as diagnosis codes are published. Additionally, in certain instances, the available coding guidance lacks clarity, which makes it challenging for chart review coders to interpret and apply the available coding guidance in a similar manner. Even when guidance is available, coders may still have questions about what diagnosis codes are supported based on what information is documented in the medical record. In response to a series of questions posed by MA Plans, CMS recognized this complexity and the individualized nature of diagnosis code assignment and noted it is “unable to respond specifically to individual questions regarding risk adjustment requests for interpretation of RADV coding and reporting questions as a full review of the

²⁶ See AHIMA, *Cut Through the ICD-10 Noise with Documentation Guidelines*, (last updated Jan. 2015), available at <https://bok.ahima.org/doc?oid=300844>.

documentation is required before reporting or coding any diagnosis. For the purposes of risk adjustment data validation, all review is considered on a case by case basis due to multiple coding rules that may apply.”²⁷ The necessary interpretation of the changing guidance from various sources can lead coders to apply the guidance differently and ultimately find different diagnosis codes supported in medical records.

Human Errors

42. Coders also reach different conclusions as to which diagnosis codes are supported in a medical record because of human error. Coders review large volumes of technical medical documentation from a variety of sources and apply their judgment to determine which conditions are supported by documentation in a medical record. This may include reviewing information in varied formats with challenging handwriting and unique, unfamiliar abbreviations. This may also include long days reviewing medical records, some of which can be very complicated and hundreds of pages long. For example, records for multi-day stays in a hospital or emergency department, where the providers must detail every checkpoint, result, and decision, can be 75-100 pages long for each encounter. Medicare beneficiaries tend to have particularly voluminous records, as it is not uncommon for them to have multiple acute and chronic conditions. Based on a 2010 study, 36.4% of Medicare beneficiaries had four or more chronic conditions.²⁸ All of this can lead coders to experience fatigue while reviewing medical records, which can result in mistakes, including missed diagnosis codes.

43. Coders also sometimes mistype the diagnosis code at issue. For instance, coders might accidentally type in a similar, yet different, code than the one intended. For example, ICD-9-CM 402.01 (hypertensive heart disease, malignant, with heart failure) is a high-severity code, and ICD-9-CM 402.10 (hypertensive heart disease, benign, without heart failure) is

²⁷ CMS, *Question and Answer Session – CY 2011 RADV Industry Training* at 2 (last updated, March 20, 2014), available at <https://www.cms.gov/Medicare/Medicare-Advantage/Plan-Payment/Downloads/radvtrainingquestions.pdf>.

²⁸ *See* Kimberly Lochner & Christine Cox, *Prevalence of Multiple Chronic Conditions Among Medicare Beneficiaries, United States, 2010* (last updated Apr., 25, 2013), available at https://www.cdc.gov/pcd/issues/2013/12_0137.htm.

a less severe code,²⁹ but the codes are almost the same. This typographical error, while simple, is not uncommon.

44. Organizations that administer coder guidelines and training acknowledge that coders cannot be expected to be correct 100% of the time. AHIMA notes that a minimum of 95% (not 100%) is best practice for coding quality standards.³⁰ CMS historically has also targeted an 85-95% consistency standard for its Inter-Rater Reliability (IRR) quality control measures used in audit activities of non-MA Plan data.³¹ Furthermore, actual error rates may be higher than these numbers suggest, as these targets and thresholds do not guarantee that those levels are actually achieved.

Transition from ICD-9-CM to ICD-10-CM Code Sets

45. While providers had used the ICD-9 diagnosis code set since 1979, CMS mandated that providers exclusively use the ICD-10 diagnosis code set beginning in October 2015. This increased the total number of diagnosis codes fivefold and created a substantial number of new diagnosis codes that providers and coders needed to consider when reviewing medical records. Requiring this change midyear added more confusion for coders reviewing a medical record with patient visits in 2015.
46. Due to the transition from ICD-9 to ICD-10, coders performing a chart review for patient visits in 2015 had to consider whether the date of service was before or after October 1, 2015. If the date of service was before October 1, 2015, the coder had to use ICD-9 diagnosis codes. If the date of service was on or after October 1, 2015, the coder had to use ICD-10 diagnosis codes. This added layer of complexity could lead to coders missing diagnosis codes that were supported by documentation in the medical record.
47. As noted previously, the diagnosis code sets vary greatly in form and structure. Given that ICD-10 added tens of thousands of additional unique diagnosis codes, the code sets cannot be compared in a one-to-one manner. For example, a provider may have diagnosed a patient experiencing severe neck pain after a fall with a broken neck (first cervical vertebra). The

²⁹ See CDC, *ICD-9-CM Index to Diseases (FY12)*, at Dindex12.zip, available at https://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/ICD9-CM/2011/.

³⁰ See AHIMA, *Benchmarking Coding Quality – Audio Seminar/Webinar* (2008).

³¹ See 45 CFR § 153.630(b)(8).

relevant diagnosis would be a fracture of the first cervical vertebra. While there is one code for this diagnosis in ICD-9, there are ten possible diagnosis codes under ICD-10. If this diagnosis occurred on or after October 1, 2015, a coder was tasked with determining which specific ICD-10 diagnosis code, from the choice of ten, applied based on the type and severity of the broken neck. Figure 3 below shows the one ICD-9 code related to a fracture of the first cervical vertebra, along with the corresponding ten possible ICD-10 codes. Providers would also have to learn how to document with the level of detail and specificity that aligned with and would support the new ICD-10 codes.

Figure 3: ICD-9-CM to ICD-10-CM Translation ³²

Fracture of First Cervical Vertebra (Broken Neck)			
ICD-9-CM		ICD-10-CM	
Code	Code	Code	Code Description
805.01	Closed fracture of first cervical vertebra	S12.000A	Unspecified displaced fracture of first cervical vertebra, initial encounter for closed fracture
		S12.001A	Unspecified nondisplaced fracture of first cervical vertebra, initial encounter for closed fracture
		S12.01XA	Stable burst fracture of first cervical vertebra, initial encounter for closed fracture
		S12.02XA	Unstable burst fracture of first cervical vertebra, initial encounter for closed fracture
		S12.030A	Displaced posterior arch fracture of first cervical vertebra, initial encounter for closed fracture
		S12.031A	Nondisplaced posterior arch fracture of first cervical vertebra, initial encounter for closed fracture
		S12.040A	Displaced lateral mass fracture of first cervical vertebra, initial encounter for closed fracture
		S12.041A	Nondisplaced lateral mass fracture of first cervical vertebra, initial encounter for closed fracture
		S12.090A	Other displaced fracture of first cervical vertebra, initial encounter for closed fracture
		S12.091A	Other nondisplaced fracture of first cervical vertebra, initial encounter for closed fracture

Gray Areas of Diagnosis Coding

48. There are several additional areas in which coding involves a degree of subjectivity (often called “gray areas”), because they are open for interpretation and debated among medical coders and even the organizations that offer diagnosis coding guidance. There is

³² See CDC, *ICD-9-CM Index to Diseases (FY12)*, at Dindex12.zip, available at https://ftp.cdc.gov/pub/Health_Statistics/NCHS/Publications/ICD9-CM/2011/ and CDC, *FY 2016 release of ICD-10-CM - ICD-10-CM List of codes and Descriptions*, available at https://www.cdc.gov/nchs/data/icd/icd10cm/2016/ICD10CM_FY2016_code_descriptions.zip.

voluminous discussion and debate about these gray areas within the healthcare industry, and coders and applicable organizations like AHIMA or CMS frequently cannot agree on how to handle these topics. Since coders and the industry may have differing views on how to approach these gray areas, and because the guidance may be unclear or confusing, there is no uniform way for coders to resolve gray areas. Importantly, MA Plan coders performing a blind chart review may approach coding gray areas differently based on their knowledge and experience which may differ from that of the provider or coder in the provider's office that submitted diagnosis codes on the claim, which can cause discrepancies between the diagnosis codes identified by both.

49. When coders encounter gray areas, they may devote significant time and attention to try to resolve these gray areas and determine if a diagnosis code is properly supported by documentation in the medical record. This may result in a coder missing other diagnosis codes that may in fact be supported by documentation in the medical record. For example, a coder may spend a significant amount of time reviewing the medical record for a particular condition to try to identify whether there are enough details in the medical record to support that the condition is current and can be coded. The MA Plan coder may miss other properly supported diagnoses in the medical record because they are focused on assessing these gray areas that lack clarity or consistency in coding guidance.
50. Some of the most common gray areas that can cause coding discrepancies are the appropriate handling of "problem lists" and "chronic conditions," which are discussed in more detail below. The overarching concern is that most diagnosis coding guidelines require, among other things, that a condition be present or current on the date the patient visits their provider for a diagnosis code to be supported by documentation in the medical record. However, uniform and consistent handling of these gray areas adds complexity to the review of documentation to assess if a diagnosis code is supported. While regulators and the healthcare industry recognize this and attempt to clarify gray areas, disagreements remained unresolved for long periods of time in many cases and some remain unresolved today, rendering it difficult for coders to consistently approach these areas.

Gray Areas of Diagnosis Coding - Problem Lists

51. Providers use many different parts of a patient's medical record to keep track of a patient's history and current visit. Problem lists are a running list or database of the patient's diagnoses and are one part of a medical record that a provider may use to maintain information about a patient. This list may be on a sheet of paper within the patient's physical record or in a specific area in the EMR.
52. Problem lists have historically caused confusion because CMS guidance regarding problem lists varied over time. In 2008, CMS stated, "an acceptable problem list must be comprehensive and show evaluation and treatment for each condition that relates to an ICD-9 code on the date of service, and it must be signed and dated by the physician or physician extender."³³ This guidance defines the problem list as a portion of the medical record capturing only those conditions that are treated on a specific date of service. Under this definition, a coder can often rely on a signed and dated problem list to identify supported diagnosis codes because it includes a list of a patient's diagnoses current at the time of the visit diagnoses.
53. EMRs introduced further ambiguity and a lack of clarity regarding when the conditions listed in a problem list should be coded or not. In 2019, CMS issued guidance that applied retroactively to audits commencing after September 27, 2017 and covered dates of service going back as far as 2013. The guidance stated, "[p]roblem lists are evaluated on a case-by-case basis when the problem list is not clearly dated as part of the face-to-face encounter indicated on the coversheet, or there are multiple dates of conditions both before and after the DOS."³⁴ In other words, CMS acknowledged the fact that problem lists may or may not relate to a given date of service, so the guidance left it to the discretion of individual coders to determine whether a problem list included sufficient details regarding what diagnoses were current. The change in guidance, as well as the lack of additional guidance

³³ CMS, *2008 Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide* at Section 7.2.4.3., available at https://www.hhs.gov/guidance/sites/default/files/hhs-guidance-documents/2012183293-yv-participant-guide-publish_052909.pdf.

³⁴ CMS, *Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance In effect as of 03/20/2019* at 42, (last updated, Nov. 14, 2018), available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>.

clarifying how individual coders should exercise their discretion on a case-by-case basis, makes it difficult for coders to use problem lists uniformly.

Gray Areas of Diagnosis Coding – Chronic Conditions

54. Chronic conditions have historically been another coding gray area and a source of debate and discrepancies. “Chronic conditions” are generally defined as conditions that are ongoing, last an extended period of time (sometimes defined as a year or more), and either require continuous medical maintenance or routinely limit daily activities. Examples of chronic conditions include heart disease, cancer, and diabetes.³⁵ A patient might not have discussed her chronic condition at each visit she had with a provider. This did not mean the patient no longer had that medical condition. The provider might in fact have taken the chronic condition into account when considering treatment for other conditions addressed at a patient visit and might have included documentation supporting chronic condition diagnoses. Coders may disagree, however, as to whether a provider has adequately documented a particular chronic condition in the medical record. Providers may take varying amounts of time to document each chronic condition assessed as part of a visit, which can lead to varying judgment calls for coders reviewing medical records.

55. Furthermore, the coding guidance varies depending on the care setting. In the inpatient setting, guidance published by the Coding Clinic notes that chronic systemic diseases should generally be coded even in the absence of documented intervention or further evaluation at the time of care.³⁶ In other words, MEAT, or a similar coding standard, is not required to support diagnosis codes in the inpatient setting for these diseases. The official ICD guidance for outpatient services, on the other hand, instructs coders to code chronic diseases “as many times as the patient receives treatment and care for the condition(s)” but also specifies that coders should “code all documented conditions that coexist at the time of the encounter/visit and require or affect patient care treatment or management.”³⁷

³⁵ See CDC, *About Chronic Diseases*, available at <https://www.cdc.gov/chronicdisease/about/index.htm#:~:text=Chronic%20diseases%20are%20defined%20broadly,disability%20in%20the%20United%20States>.

³⁶ See AHA, Coding Clinic for ICD-9-CM, Volume 24, Number 3, Third Quarter, 2007 at 13-14.

³⁷ CMS, *ICD-9-CM Official Guidelines for Coding and Reporting: FY 2011*, available at https://www.cdc.gov/nchs/data/icd/icd9cm_guidelines_2011.pdf.

Setting aside the fact that coders may be unsure how to interpret the two pieces of outpatient guidance in tandem, the Coding Clinic and official ICD guidance on chronic conditions differ. Certain coders may find that a record that simply lists the diagnoses is sufficient to support a code, based on the Coding Clinic Guidance, while an MA Plan coder may find that record insufficient by mistakenly applying the additional requirements included in the outpatient guidelines to an inpatient record.

Opinion Two: During blind chart reviews, if a coder does not identify a diagnosis code that a healthcare provider submitted on a claim to the MA Plan, that code may still be supported by documentation in the patient's medical record.

56. Due to the many complexities detailed above, an MA Plan coder conducting a blind chart review may not identify diagnosis codes that a provider submitted on the claim that are in fact supported by documentation in the medical record.
57. As an initial matter, for all of the reasons discussed above, an MA Plan coder may fail to identify a properly supported diagnosis code due to differences in coder experience, the limited availability or quality of provider documentation, the wide variety of available guidance subject to individual interpretation and judgment, the potential for human error, and changes in diagnosis code sets. It is therefore possible that a provider or a coder in the provider's office will identify a properly supported diagnosis code that an MA Plan chart review coder will not identify during their blind chart review. Simply because the MA Plan coder does not identify the same diagnosis code during a blind chart review does not mean the code is not supported by documentation in the medical record.
58. A coder in the provider's office may be better situated to identify many properly supported diagnosis codes. For instance, coders in a provider's office may have access to a more complete set of the patient's medical records than an MA Plan coder. They are also more familiar with the provider and the provider's specialty and more likely to be able to interpret a provider's handwriting, abbreviations, or other documentation practices or be able to ask the provider to clarify what is documented in the record. All of these factors can lead to additional diagnosis codes submitted on a claim than those an MA Plan coder identifies in a blind chart review.

59. To give an example, the hypothetical condensed medical record shown in Figure 4 had no date specifically assigned to the problem list. The coder responsible for reviewing the medical record in the provider's office might have reviewed the record and found support in documentation outside the problem list for all conditions on the problem list except for respiratory failure. That coder might have included a diagnosis code for respiratory failure on the claim because the updated language about "fitting for nasal cannula scheduled" associated with respiratory failure was added to the record on the date of service, which means that respiratory failure was, in fact, a current condition for this patient, even if respiratory failure was only included in the problem list section of the medical record. At a later date, an MA Plan coder was asked to do a blind review on the same medical record. The MA Plan coder might have determined that because there is no date on the problem list and the information within it, they are unable to support the coding of respiratory failure during their review. In this case, a MA Plan coder did not code for respiratory failure during a chart review, while the original coder properly included it as a diagnosis code on the claim.

Figure 4: Supported Diagnoses – Only Noted in Problem List

- **Jane Smith, MD – 1/1/2016**
- **John Doe (1/1/1948)**
- **Chief Complaint:** Annual Wellness Visit
- **History of Present Illness:** Patient last seen during semi-annual visit
- **Medication:** Aspirin, Coumadin (1/1/2016)
- **Medical History/Problem List:** Depression, DVT right leg, High blood pressure, Respiratory Failure – has fitting for nasal cannula scheduled
- **Exam:** Well-nourished, well-developed male, right leg swelling decreased
- **Assessment/Plan:** Renew medications, HTN - stable, Depression - stable, DVT resolving

60. Another example where an MA Plan coder may fail to identify a diagnosis that is supported by the medical record is when a diagnosis is not explicitly linked to the management of that diagnosis in the provider documentation. For instance, the hypothetical medical record in Figure 5 included COPD on the patient's problem list. The chart also documented that the provider renewed the medication Albuterol, a medication used to treat COPD, but did not explicitly mention COPD otherwise in the note. The claim may have contained the diagnosis code for COPD given the renewal of the medication, whereas an MA Plan chart review coder may not have coded the diagnosis since the provider did not explicitly document the language "COPD" outside of the problem list or in relation to the Albuterol

renewal. While the Albuterol was not specifically linked to a COPD diagnosis in the chart, COPD was the only past condition that would require this medication, and the orders noted that Albuterol was being renewed, indicating the COPD was still current. A coder at the provider's office may have drawn this linkage and been comfortable including this diagnosis code on the claim given the "case-by-case" guidance around problem lists.

Figure 5: Supported Diagnoses – Diagnosis Not Linked to Medication

- Jane Smith, MD – 1/1/2018
- John Doe (1/1/1948)
- **Chief Complaint:** High blood pressure
- **History of Present Illness:** Persistent headache, coinciding with elevated blood pressure
- **Medication:** Lisinopril, Albuterol
- **Medical History/Problem List:** COPD, High Blood Pressure
- **Exam:** Well-nourished, well-developed male
- **Assessment/Plan:** Increase dosage of Lisinopril
- **Orders:** Change dose of Lisinopril to 10mg and renew Albuterol

61. Further, an MA Plan coder may fail to identify a specific diagnosis code related to a diabetic complication. There are a wide range of diagnosis codes associated with diabetes, which can cause discrepancies. Depending on the diabetes diagnosis code selected, the diagnosis code may correspond to different risk adjustment categories that range in severity (e.g., Diabetes with Acute Complications, Diabetes with Chronic Complications, and Diabetes without Complications). An MA Plan coder may see diabetes supported by the medical record but assume the diabetes does not have complications because the record does not include an additional diagnosis for the complication. The coder, on the other hand, may have more intimate knowledge of the patient's current diagnoses and can identify a diabetes diagnosis with complications. For instance, if the provider or coding personnel at the provider's office reviewed the record and noted an order for an arterial scan of the lower legs, which subsequently showed a diagnosis of peripheral artery disease, then they might have coded diabetes with complications. Guidance from the Coding Clinic, the coding index for ICD-10, and RADV Reviewer Guidance has differed over time on whether the linkage between diabetes and the complication can be assumed.³⁸ As demonstrated in

³⁸ Coding Clinic advice prior to Q2 2009 instructed coders to not assume a causal relationship between diabetes and certain manifestations as the physician should establish the relationship with terms such as "due to diabetes". After that, Coding Clinic noted that the language "with" was sufficient to demonstrate the diabetes was due to or associated with the other condition. Finally, in RADV Reviewer Guidance, it notes diabetes should be listed on the same line as the condition to consider it linked. See AHA, Coding Clinic for ICD-9-CM, Second

Figure 6 below, the provider or coder assigning the diagnosis code on the claim may have assumed the linkage and included the diagnosis code for the complication, whereas an MA Plan coder might not have assigned a secondary code because they lacked the scan. An MA Plan coder might also not have assigned the secondary code because they might have used guidance that suggested there must be explicit linkage in order to code the secondary code.

Figure 6: Supported Diagnoses – Diabetes Specification

62. These examples illustrate where an MA Plan coder may not identify a diagnosis code during the chart review that is in fact supported by documentation in the chart. The inclusion of this diagnosis code on the claim submitted to the MA Plan may in fact be appropriate because the provider or coder in the provider's office believed it was supported, whether because of experience with documentation related to a specific condition, access to additional medical records or information, a reliance on specific guidance, or any of the other reasons discussed above.

Quarter, 2009 and CMS, *Contract-Level Risk Adjustment Data Validation Medical Record Reviewer Guidance In effect as of 03/20/2019* at 42, (last updated, Nov. 14, 2018), available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Other-Content-Types/RADV-Docs/Medical-Record-Reviewer-Guidance.pdf>.

V. Conclusion

63. This report presents a summary of my work and opinions to date.

BARBARA BLAIR

ACADEMIC BACKGROUND:

University of Rochester	M.S.N.	1992
University of Rochester	B.S.N.	1991
Rockland Community College	A.S.	1986

CERTIFICATIONS AND LICENSES:

Certified Coding Specialist (CCS) - 2000

Certified Professional Coder (CPC) - 2004

Certified Professional Compliance Officer (CPCO) - 2013

Certified Risk Adjustment Coder (CRC) - 2016

Certificate of Completion for Certified Documentation Expert Inpatient (CDEI) - 2022

AHIMA Certified ICD-10-CM/PCS Trainer - 2013

Licensed Registered Nurse

Licensed Nurse Practitioner (Adult) - Retired

PROFESSIONAL AFFILIATIONS:

American Academy of Professional Coders (AAPC)

American Health Information Management Association (AHIMA)

American Association of Adult Nurse Practitioners (AANP)

EMPLOYMENT:

2003 – Present:	FTI Consulting, Inc., Senior Director (current position),
2000 – 2003:	KPMG LLP, Manager
1998 – 2000:	Orion Consulting Inc., Manager

1997 – 1998: Successful Solutions Inc., Manager

1995 – 1997: Hyatt, Imler, Ott & Blount LLP, Associate

SELECT PROFESSIONAL EXPERIENCE:

- Independent Review Organization (IRO): Lead reviewer on over a dozen reviews multi-year reviews for providers such as health systems, hospitals and medical centers, operating under Corporate Integrity Agreements with the U.S. Department of Health and Human Services Office of Inspector General (HHS OIG) for over 20 years.
- Risk Adjustment Data Validation (RADV) Audits: Lead reviewer on responses to RADV audits conducted by the Department of Health and Human Services (HHS) for over a decade. Assisted Medicare Advantage and commercial health plans and health systems with responses to Centers for Medicare & Medicaid Services (CMS) RADV audits, HHS audits and other RADV-like audit requests. The dates of service reviewed and analyzed spanned from 2007 through current. Frequently served in the capacity of a second level and quality control reviewer on large coding teams.
- Coding Reviews: Over the past 20 years, I have performed coding and clinical reviews to provide expertise and guidance for many different types of work. I have advised on corrective action and coding best practices based on the findings of reviews. These reviews included, but are not limited to the following:
 - o Department of Justice (DOJ) investigations
 - o Governmental response to contractor audits conducted by entities such as Recovery Audit Contractors, Medicare Administrative Contractors, Zone Program Integrity Contractors, Medicaid Integrity Contractors, etc.
 - o Disputes between payers and providers
 - o Due diligence for potential acquisitions
 - o Support of general compliance initiatives such as work plans, internal audits and focused reviews

VIII.	Requiring MA Plans to Delete Unsupported Diagnosis Codes without FFS Medicare Doing the Same Would Result in Improper Compensation to MA Plans	55
A.	Requiring MA Plans to Identify and Delete Unsupported Diagnosis Codes Would Result in CMS Undercompensating MA Plans Relative to FFS Medicare when MA Plans and FFS Medicare Have an Identical Pool of Enrollees and Identical Unsupported Diagnosis Codes.....	56
B.	When an MA Plan and FFS Medicare Have Different Pools of Enrollees or Different Probabilities of Unsupported Codes, Requiring MA Plans to Remove Unsupported Codes without FFS Medicare Doing the Same Would Result in Improper Compensation to MA Plans	60

IX.	CMS’s FFS Adjuster Study Is Flawed.....	63
A.	Overview of CMS Methodology to Estimate the Impact of Unsupported Codes in FFS Data on Payments to MA Plans.....	66
B.	CMS Uses a Flawed Methodology to Determine Whether an FFS Adjuster Is Necessary	67
C.	CMS Uses Data Wholly Inadequate for the Task of Estimating the Impact of Unsupported Codes in FFS Data on the CMS-HCC Model	78
D.	Contrary to the Conclusion of CMS’s Flawed FFS Adjuster Study, an FFS Adjuster Is Necessary and Unsupported Diagnosis Codes that Exist in FFS Data Likely Impact Payments to MA Plans	82
X.	Economic Theory and Historical Evidence Indicate that Requiring MA Plans to Remove Unsupported Diagnosis Codes Would Result in Higher Prices or Less Generous Plans .	85
A.	If Payments to MA Plans Decline, Some MA Plans Would Increase Their Bids, Thereby Increasing Government and Enrollee Expenses, or Increase Enrollee Cost Sharing	86
B.	If Payments to MA Plans Decline, Some MA Plans Would Reduce the Quality of Benefits Provided.....	90
C.	If Payments to MA Plans Decrease, Some MA Plans Would Exit the Market, Reducing the Number of Options Available to Consumers.....	91
D.	Correctly Estimating the Change in Government Payments to UnitedHealth, If UnitedHealth Were Required to Identify and Delete Unsupported Codes, Requires Accounting for Behavioral Responses from MA Plans	93

I. Qualifications

1. I am the Wayne and Jodi Cooperman Professor of Economics at Stanford University and the Trione Director of the Stanford Institute for Economic Policy Research. I received my B.S. and M.S. degrees in Electrical Engineering from the Massachusetts Institute of Technology in 1992 and 1994, respectively, and my Ph.D. in Economics from Harvard University in 1999. From 2009 to 2010, I served as the Senior Economist for Health Care Policy on the Council of Economic Advisers to the Executive Office of the President. I have previously served as a visiting or regular faculty member at the Wharton School of the University of Pennsylvania, the University of Maryland, the University of Chicago, and the Massachusetts Institute of Technology.

2. I am an expert in health economics. My research focuses on the effects of government programs such as Medicare, Medicaid, and Social Security on individuals and firms. I have studied diverse topics such as pharmaceutical pricing and utilization under the Medicare Part D and Medicaid programs,¹ the effectiveness of Medicare prescription drug coverage for seniors,² reimbursement issues in Medicare Advantage,³ and health insurance industry dynamics.⁴ My research has been published in leading economics journals, including the *American Economic Review*, the *Journal of Political Economy*, and the *Quarterly Journal of Economics*. I serve on

The Impact of Competitive Bidding in the Medicare Program,” forthcoming at *Review of Economics and Statistics*.

the editorial board of the Journal of Policy Analysis and Management and previously served as a Co-Editor for the American Economic Journal: Economic Policy and for the Journal of Public Economics. I have also taught courses on health economics, public economics, and econometrics at the undergraduate and graduate levels and received the Stanford University Economics Department Distinguished Faculty Teaching Award in 2022. I received the 2010 ASHEcon Medal from the American Society of Health Economists, awarded once every two years to the leading health economist in the United States under the age of forty.

3. I have received several research grants from the Social Security Administration, National Science Foundation, other federal agencies, and private foundations to support my research. I am frequently invited to present my work at professional conferences and invited seminars. I have testified to Congress about my research on three occasions. My curriculum vitae, including a list of my prior testimony from the past four years and my published works, is attached as **Appendix A**.

4. For my work on this matter, I am being compensated at my standard billing rate of \$1,000 per hour. I have been assisted in this matter by staff of Cornerstone Research, who worked under my direction. I receive compensation from Cornerstone Research based on its collected staff billings for its support of me in this matter. Neither my compensation in this matter nor my compensation from Cornerstone Research is in any way contingent or based on the content of my opinions or the outcome of this or any other matter.

II. Case Background and Summary of Allegations

5. UnitedHealth Group Incorporated (“UnitedHealth”) is a health care company with diversified businesses that fall under two platforms: health benefits and health services. The health benefits platform, UnitedHealthcare, provides health insurance. The health services platform, Optum, offers pharmacy, health care financial, and other services.⁵

6. UnitedHealth serves different customers and markets, such as employers and individual consumers through UnitedHealth Employer & Individual, and retirees and Medicare beneficiaries through UnitedHealth Medicare & Retirement. UnitedHealth Medicare &

⁵ UnitedHealth Group Incorporated, SEC Form 10-K for period ended December 31, 2021, filed on February 15, 2022 (“UnitedHealth 2021 Form 10-K”), pp. 1–2.

Retirement offers different products, including Medicare Advantage (“MA”) plans and Medicare Part D plans for seniors and other eligible Medicare beneficiaries.⁶

7. As described in more detail in Section V, Medicare beneficiaries can choose to receive their health benefits through MA plans managed by private insurers such as UnitedHealth rather than through the traditional Medicare fee-for-service program (“FFS Medicare”) that is managed by the federal government through the Centers for Medicare & Medicaid Services (“CMS”). The program is referred to as FFS Medicare because providers are paid based on the care that they deliver. FFS Medicare is sometimes called “Traditional Medicare,” or “TM.” For Medicare beneficiaries who elect to enroll in an MA plan, CMS pays the private insurers to coordinate and finance health benefits.⁷

8. In order to determine the amount that CMS will pay for each Medicare beneficiary who selects an MA plan, private insurers that provide MA plans are required to submit information using CMS’s Risk Adjustment Processing System (“RAPS”) on enrollees’ diagnoses stemming from one or more health care encounters.⁸ Each submission needs to cover the following items: the Medicare enrollee’s identification number, the date(s) of the health care encounter, the type of provider (e.g., physician or hospital), and the diagnosis code(s) reported by the provider for the encounter.⁹

9. In this matter, Plaintiffs allege that since 2005, UnitedHealth has conducted programs and engaged in activities to increase the number of diagnoses submitted to CMS.¹⁰ Plaintiffs

⁶ UnitedHealth 2021 Form 10-K, pp. 1, 4–5.

⁷ “What is Medicare Part C?,” U.S. Department of Health & Human Services, August 3, 2021 (“HHS, What is Medicare Part C”), available at <https://www.hhs.gov/answers/medicare-and-medicare/what-is-medicare-part-c>; “Medicare Managed Care Manual Chapter 8 – Payments to Medicare Advantage Organizations,” *Centers for Medicare & Medicaid Services*, revised September, 19, 2014 (“CMS, Medicare Managed Care Manual Chapter 8”), §§ 10, 140.2, available at <https://www.cms.gov/Regulations-and-Guidance/Guidance/Manuals/downloads/mc86c08.pdf>.

⁸ Beginning in 2016, CMS also began incorporating data submitted by MA plans to its “encounter data system,” in addition to RAPS, to generate risk scores. MA plans submit detailed information about each encounter between MA enrollees and health care providers to the encounter data system. Over the period 2016–2021, CMS calculated risk scores using a combination of RAPS data and encounter data, with an increasing emphasis on encounter data over time. As of 2022, CMS has based risk scores for MA plans entirely on encounter data. See “Report to the Congress: Medicare Payment Policy,” *MedPAC*, March 2022 (“MedPAC, Report to the Congress”), p. 433, available at https://www.medpac.gov/wp-content/uploads/2022/03/Mar22_MedPAC_ReportToCongress_v3_SEC.pdf.

⁹ “Medicare Managed Care Manual Chapter 7 – Risk Adjustment,” *Centers for Medicare & Medicaid Services*, revised September 19, 2014, (“CMS, Medicare Managed Care Manual Chapter 7”), § 120, Table 12, available at <https://www.cms.gov/Regulations-and-Guidance/Guidance/Manuals/downloads/mc86c07.pdf>.

¹⁰ United States’ Amended Complaint-In-Partial-Intervention and Demand for Jury Trial, *United States of America ex rel. Benjamin Poehling v. UnitedHealth Group, Inc. et al.*, November 17, 2017 (“Complaint”), ¶ 122 (“Defendants conducted millions of medical record reviews as part of their revenue-generating national Chart Review program.”).

further allege that UnitedHealth knew that many of the subsequent diagnoses reported by its providers “were not supported and validated by the beneficiaries’ medical records.”¹¹ Plaintiffs also assert that MA plans “are obligated to delete invalid diagnoses previously submitted by them to RAPS or to use other available means to return [...] payments based on invalid diagnoses,” and that these deletions represent the main mechanism by which CMS can ensure that its compensation to MA plans is proper or that it recovers improper compensation that it made.¹² Plaintiffs allege that UnitedHealth knew that it was “obliged to undertake good faith efforts to identify and delete those unsupported and invalid diagnoses,” but that it failed to either delete these unsupported diagnoses in the RAPS program or to return the overcompensation generated by these unsupported diagnoses.¹³ Plaintiffs allege that, as a result, UnitedHealth received MA risk-adjustment payments to which it was “not entitled,” and that UnitedHealth failed to return the overcompensation to UnitedHealth.¹⁴

10. Moreover, there has been discussion as to whether CMS needs to account for unsupported codes in the FFS data when assessing whether compensation to MA plans is proper. In October 2018, CMS put forth a study (the “FFS Adjuster Study”) in which it claimed that unsupported codes in FFS data do not “systematically” impact CMS’s payments to MA plans, and therefore that there is no need for CMS to account for such unsupported codes when assessing whether MA plans were overpaid.¹⁵ In 2023, CMS adopted a “Final Rule” which finalized CMS’s decision to not apply an “FFS adjuster” that would account for unsupported codes in FFS data when assessing payments to MA plans.¹⁶

¹¹ Complaint, ¶ 122.

¹² Complaint, ¶ 103.

¹³ Complaint, ¶¶ 122, 342.

¹⁴ Complaint, ¶ 342 (“Specifically, Defendants knowingly concealed or knowingly and improperly avoided or decreased an obligation to repay risk adjustment payments to which they were not entitled from the Medicare Program. In particular, Defendants knowingly and improperly failed to delete in the RAPS system the invalid diagnoses that had been submitted to the Medicare Program for risk adjustment payments which were made by the Medicare Program to them or knowingly and improperly failed to otherwise return to the Medicare Program the overpayments based on the invalid diagnoses.”).

11. I understand from counsel for UnitedHealth that the damages period ends in 2017.

III. Assignment

12. I have been retained by counsel for UnitedHealth to evaluate several topics:

- First, I have been asked to provide historical information about FFS Medicare and MA, including explaining how MA compares to FFS Medicare;
- Second, I have been asked to evaluate whether the MA program has provided benefits to Medicare enrollees;
- Third, I have been asked to explain how CMS compensates MA plans for insuring Medicare enrollees;
- Fourth, I have been asked to evaluate whether MA plans would be properly compensated if they were required to identify and delete unsupported diagnosis codes;
- Fifth, I have been asked to evaluate the methodology and conclusions of CMS's FFS Adjuster Study; and
- Finally, I have been asked to evaluate, as a matter of economic theory, whether and how private insurers such as UnitedHealth would respond if they had been required to identify and delete unsupported diagnosis codes without the government making any changes in how MA plans are paid.

13. In the process of preparing this report, I have reviewed a variety of documents, including academic articles, reports from organizations such as the Medicare Payment Advisory Commission, documents and depositions produced in this matter, and CMS's FFS Adjuster Study. A complete list of the documents that I have relied upon in forming my opinions is attached as **Appendix B**.

14. My work in this matter is ongoing. I reserve the right to update my opinions as additional information becomes available.

IV. Summary of Opinions

15. First, I conclude that the MA program has provided value to plan enrollees (Section VI). MA plans provide Medicare beneficiaries with a greater number of health insurance plans to choose from, making it possible for individuals to choose a plan that better fits their preferences and needs. Consistent with this, data on Medicare enrollment indicates that many Medicare beneficiaries have preferred MA plans to FFS Medicare: the share of Medicare beneficiaries choosing MA has increased from 13 percent in 2003 to 51 percent in 2023. There are several reasons why Medicare beneficiaries may prefer MA plans over FFS Medicare, including that most MA enrollees enjoy benefits not available to enrollees in FFS Medicare (e.g., coverage for eye exams and glasses, dental and fitness benefits, and hearing aids) and that MA enrollees frequently pay less in premiums than FFS Medicare enrollees for plans with comparable or more extensive coverage. Evidence also indicates that MA plans have often provided more efficient care than FFS Medicare. This means that MA patients can achieve the same health outcomes as patients in FFS Medicare while using fewer resources (e.g., going to a hospital less), which is beneficial for patients. This also has positive spillover effects for all Medicare enrollees.

16. Second, I explain that CMS compensates MA plans for enrollees in a way that exposes insurers to financial risk (Section VII). CMS pays a fixed, pre-arranged monthly payment to MA plans for each enrollee. The payment amount is based on an estimate of predicted health care expenditures for the enrollee that accounts for the diagnosis codes, which are grouped into Hierarchical Condition Categories (“HCCs”), and demographic characteristics of the enrollee. These predicted health care expenditures are estimated from the FFS Medicare population using a regression model that predicts the incremental health care expenditures of a specific HCC or demographic trait relative to the average per capita predicted health care expenditures of FFS Medicare enrollees. Thus, MA plans have an incentive to identify and record all relevant diagnoses that an enrollee has so they can receive proper compensation. Accordingly, CMS adjusts the fixed payments to MA plans to account for different coding patterns between MA plans and FFS Medicare.

17. Third, I conclude that CMS would underpay MA plans if MA plans were required to identify and delete unsupported diagnosis codes without requiring CMS to do the same in FFS

Medicare when MA plans and FFS Medicare have identical populations with identical distributions of unsupported diagnosis codes (Section VIII.A). An MA plan is undercompensated relative to FFS Medicare if the total payment it receives is less than the total expected cost of treating FFS Medicare enrollees with identical risk scores as beneficiaries enrolled in the MA plan, while also accounting for the plan's bid. Requiring MA plans to identify and delete unsupported diagnosis codes in this situation, while maintaining the coefficients from the CMS-HCC model estimated on FFS data with unsupported diagnosis codes, mechanically reduces payments to MA plans even though the expected cost of treating the patients in the MA plan remains unchanged. This results in MA plans being undercompensated relative to what CMS would spend in FFS Medicare.

18. Fourth, I conclude that requiring MA plans to remove unsupported diagnosis codes without requiring CMS to do the same in FFS Medicare would also result in improper compensation to MA plans when MA plans and FFS Medicare have different pools of enrollees or different rates of unsupported diagnosis codes (Section VIII.B). Proper compensation requires that the CMS-HCC model provides the true incremental cost of the HCC under FFS, which is not the case when the model is estimated on FFS data with unsupported diagnosis codes. Evidence indicates that FFS data do contain unsupported diagnosis codes and that these data are typically unaudited before the estimation of the CMS-HCC model. The resulting impact of estimating the CMS-HCC model using FFS data with unsupported diagnosis codes versus audited FFS data on payments to an MA plan depends on the pool of enrollees and distribution of unsupported codes in the MA plan data relative to the FFS data. Thus, neither the MA plan nor CMS can determine whether the MA plan was properly compensated without information on the extent to which the plan's pool of enrollees and probabilities of unsupported codes differ compared to the FFS Medicare population.

19. Fifth, I conclude that the existence of unsupported codes in FFS data likely impacts payment to MA plans under the CMS-HCC model, contrary to what CMS concludes in its FFS Adjuster Study (Section IX). This study aimed to evaluate how removing unsupported codes from the FFS data would impact the dollar coefficients and relative factors estimated by the CMS-HCC model, and, as a consequence, the risk scores used to determine payments to MA plans. An impact would imply that an adjustment, referred to as the "FFS adjuster," was needed

when assessing whether MA plans were properly compensated. CMS concluded that an FFS adjuster is unnecessary. However, this conclusion is flawed. CMS reached this erroneous conclusion by relying on an incorrect and flawed methodology and by using data that does not allow it to reliably determine how unsupported diagnosis codes in FFS data affect risk scores and therefore payments to MA plans. Some of the methodological errors in CMS's methodology include: (1) flaws in estimating the probability that an HCC is unsupported in the FFS data; and (2) CMS inappropriately deflating the dollar coefficients estimated from the audited FFS data to purportedly adjust for the effects of the auditing process on expenditures, despite actual expenditures being unaffected by auditing. Other studies have also concluded that the FFS Adjuster Study is flawed, that unsupported diagnosis codes in the FFS data likely impact payments to MA plans, and that an FFS adjuster is necessary.

20. Sixth, I conclude that requiring MA plans to remove unsupported diagnosis codes while making no other changes to the way MA plans are paid would result in higher prices for Medicare beneficiaries or less generous plans (Section X). Economic theory predicts that a firm faced with declining reimbursement along with similar costs would adjust their behavior. I conclude that MA plans required to remove codes would respond in one or more of the following ways: (1) by increasing their bids, thereby increasing government and patient expenses; (2) by reducing the quality of benefits provided; and/or (3) by exiting the market, reducing the number of available MA plans to choose from and thereby reducing consumer welfare. I draw this conclusion based on predictions consistent with economic theory, as well as historical evidence of how MA plans responded to changes in the amount of compensation they received from CMS. Correctly estimating the change in government payments to UnitedHealth if UnitedHealth were required to identify and delete unsupported codes would therefore need to account for such changes in UnitedHealth's behavior.

V. Background on FFS Medicare and Medicare Advantage

21. In this section, I first describe some of the characteristics of health insurance generally, and then I provide information about the two specific health insurance options that are available to Medicare beneficiaries: FFS Medicare and Medicare Advantage.

A. Key Characteristics of Health Insurance

22. Health insurance is a type of insurance that typically provides payment or reimbursement to health care providers for some or all of the cost of covered health care expenditures incurred by an insured individual. In the United States, private insurers provide some health insurance products, while federal and/or state governments provide other health insurance products. Medicare and Medicaid are two examples of public health insurance programs offered by the U.S. government and collectively insured about 40 percent of Americans in 2021.¹⁷ About 12 million individuals were dually eligible for Medicare and Medicaid in 2022.¹⁸ Medicare primarily covers people aged 65 and older, with eligibility conferred regardless of income, medical history, or preexisting conditions.¹⁹ Medicaid is a public health insurance program primarily serving low-income individuals that is jointly funded by the federal and state governments.²⁰

23. Health insurance often does not pay for or reimburse all of the health care expenditures incurred by covered individuals. Instead, enrollees may face “out-of-pocket” costs for health care expenditures that are not covered by health insurance.²¹ In addition to the premium that

¹⁷ Medicaid is a means-tested public health insurance program jointly funded by the federal and state governments that covers low-income individuals who meet certain eligibility requirements. States have some flexibility in designing their programs and there are significant differences across state Medicaid programs. See “Who is Eligible for Medicaid?,” *U.S. Department of Health & Human Services*, December 8, 2022, available at <https://www.hhs.gov/answers/medicare-and-medicaid/who-is-eligible-for-medicaid>; Robin Rudowitz, et al., “10 Things to Know about Medicaid,” *Kaiser Family Foundation*, June 30, 2023 (“Rudowitz et al., 10 Things to Know about Medicaid”), available at <https://www.kff.org/medicaid/issue-brief/10-things-to-know-about-medicaid>; “CMS Releases Latest Enrollment Figures for Medicare, Medicaid, and Children’s Health Insurance Program (CHIP),” *Centers for Medicare & Medicaid Services*, December 21, 2021, available at <https://www.cms.gov/newsroom/news-alert/cms-releases-latest-enrollment-figures-medicare-medicaid-and-childrens-health-insurance-program-chip>; “U.S. and World Population Clock,” *United States Census Bureau*, December 31, 2021, available at <https://www.census.gov/popclock>.

¹⁹ Juliette Cubanski, et al., “A Primer on Medicare: Key Facts About the Medicare Program and the People it Covers,” *Kaiser Family Foundation*, March 20, 2015 (“Cubanski et al., A Primer on Medicare”), pp. 2–3, available at <https://files.kff.org/attachment/report-a-primer-on-medicare-key-facts-about-the-medicare-program-and-the-people-it-covers> (“Medicare was established in 1965 under Title XVIII of the Social Security Act to provide health insurance to people age 65 and older, regardless of income or medical history. [...] People age 65 and older qualify for Medicare if they are U.S. citizens or permanent legal residents with at least five years of continuous residence. Individuals qualify without regard to their medical history or preexisting conditions, and do not need to meet an income or asset test.”).

²⁰ “Medicaid,” *Medicare.gov*, available at <https://www.medicare.gov/basics/costs/help/medicaid>, (“Medicaid is a joint federal and state program that helps cover medical costs for some people with limited income and resources.”); Rudowitz et al., 10 Things to Know about Medicaid (“Medicaid is jointly financed by the federal government and states and administered by states within broad federal guidelines.”).

²¹ “Out-of-Pocket Costs,” *HealthCare.gov Glossary*, available at <https://www.healthcare.gov/glossary/out-of-pocket-costs>.

enrollees (and/or their employer) may pay for health insurance, enrollees may face out-of-pocket costs in the form of a deductible, copayment, and coinsurance, along with the costs for any uncovered health care services. These costs are defined below.

- Premiums are the amount that enrollees and/or their employers pay, usually on a monthly basis, to a health insurer in order for the enrollee to receive some insurance coverage for their future health care expenditures.²²
- A deductible represents the amount of money that an enrollee must pay out of pocket for health care expenditures before the health insurance plan begins to pay for benefits (e.g., \$500 or \$1,000 annually).²³
- Copayments are an amount of money that an enrollee pays for certain medical services or supplies such as physician visits or prescription drugs. They are typically a set amount rather than a percentage (e.g., a copayment could be \$10, \$20, or a different set amount).²⁴ For some services, plans can charge coinsurance instead of a copayment, which is a percentage of the total cost paid to the health care provider (e.g., 10 percent or 20 percent) instead of a set dollar amount.²⁵

24. The amount of out-of-pocket expenses an enrollee faces can vary substantially in health insurance plans. For example, plans can set out-of-pocket limits, which are an amount of total out-of-pocket expenses incurred by an enrollee over a plan year, above which enrollee out-of-pocket costs are eliminated. These out-of-pocket limits have varied substantially across plans. In 2023, the average annual out-of-pocket limit for MA plans ranges from \$4,033–\$9,643, depending on the plan type.²⁶ FFS Medicare has no limit on out-of-pocket expenses for services

²² “Premium,” *HealthCare.gov Glossary*, available at <https://www.healthcare.gov/glossary/premium>.

²³ “Understanding Medicare Advantage Plans,” *Centers for Medicare & Medicaid Services*, July 2022 (“CMS, Understanding Medicare Advantage Plans”), p. 11, available at <https://www.medicare.gov/Pubs/pdf/12026-Understanding-Medicare-Advantage-Plans.pdf>.

²⁴ CMS, *Understanding Medicare Advantage Plans*, p. 11.

²⁵ CMS, *Understanding Medicare Advantage Plans*, p. 11.

²⁶ The average annual out-of-pocket limit for MA plans refers to the enrollee-weighted average out-of-pocket limit by plan type for Part A and Part B services. HMOs have an average out-of-pocket limit of \$4,033, while Regional PPOs have an average out-of-pocket limit of \$6,842 for in-network services and \$9,643 for in-network and out-of-networks services combined. Nancy Ochieng, et al., “Medicare Advantage in 2023: Premiums: Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings,” *Kaiser Family Foundation*, August 9, 2023 (“Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings”), available at <https://www.kff.org/medicare/issue-brief/medicare-advantage-in-2023-premiums-out-of-pocket-limits-cost-sharing-supplemental-benefits-prior-authorization-and-star-ratings>.

covered under Parts A and B.²⁷ In addition, as detailed further below, premiums under both FFS Medicare and MA vary widely by plan.

B. FFS Medicare

25. The federal government created Medicare in 1965 and then expanded it in 1972 to cover not only individuals aged 65 and over, but also certain people under 65 years old who have long-term disabilities. This program helps pay for a broad set of health care services, including hospitalizations, hospital outpatient visits, and physician visits.²⁸

26. From its inception in 1965 and until the introduction of the MA program, Medicare consisted of what is known today as Traditional Medicare, or FFS Medicare.²⁹ Under FFS Medicare, CMS typically pays health care providers on an FFS basis, meaning that CMS pays providers a specific amount for the health care services the provider rendered to the enrollee.³⁰

27. FFS Medicare provides two types of insurance that cover different health services:

²⁷ See “An Overview of Medicare,” *Kaiser Family Foundation*, February 13, 2019 (“KFF, An Overview of Medicare”), available at <https://www.kff.org/medicare/issue-brief/an-overview-of-medicare>. Currently, Medicare Part D limits cost-sharing after an enrollee’s out-of-pocket spending reaches \$7,400, qualifying them for “catastrophic coverage.” Beginning in 2024, Medicare Part D recipients will no longer pay copayments or coinsurance for covered drugs after their out-of-pocket spending reaches \$8,000. See “Catastrophic coverage,” *Medicare.gov*, available at <https://www.medicare.gov/drug-coverage-part-d/costs-for-medicare-drug-coverage/catastrophic-coverage>.

²⁸ People under 65 years old who receive benefits from the Social Security Disability Insurance (“SSDI”) program generally become eligible for Medicare after a two-year waiting period and people under 65 years old with end-stage renal disease and amyotrophic lateral sclerosis are eligible with no waiting period. See KFF, An Overview of Medicare.

²⁹ Medicare began contracting with private insurance plans through Medicare Part C in the mid-1980s with the name of this updated to Medicare + Choice in 1999 and to Medicare Advantage six years later. “Health Plans – General Information,” *Centers for Medicare & Medicaid Services*, modified September 6, 2023 (“CMS, Health Plans”), available at <https://www.cms.gov/medicare/enrollment-renewal/health-plans>; “History,” *Centers for Medicare & Medicaid Services*, modified September 6, 2023, available at <https://www.cms.gov/about-cms/who-we-are/history>. See also Thomas McGuire, et al., “An Economic History of Medicare Part C,” *The Milbank Quarterly*, 89(2), 2011 (“McGuire et al., Economic History of Medicare Part C”), pp. 289–332.

³⁰ See, e.g., “Fee Schedules – General Information,” *Centers for Medicare & Medicaid Services*, modified September 6, 2023, available at <https://www.cms.gov/medicare/medicare-fee-for-service-payment/feeschedulegeninfo>. Note that in some cases, diagnosis information may inform the reimbursement amount that providers receive under FFS Medicare. For example, for inpatient services, hospitals are paid a fixed payment for each patient discharged based on the Diagnoses Related Group (“DRG”), which combines information on the patient’s diagnosis and the services provided. See “Acute Inpatient PPS,” *Centers for Medicare & Medicaid Services*, modified September 6, 2023, available at <https://www.cms.gov/medicare/payment/prospective-payment-systems/acute-inpatient-pps>; “Glossary,” *Centers for Medicare & Medicaid Services*, available at <https://www.cms.gov/apps/glossary/> (“Diagnosis-Related Groups[:] A classification system that groups patients according to diagnosis, type of treatment, age, and other relevant criteria. Under the prospective payment system, hospitals are paid a set fee for treating patients in a single DRG category, regardless of the actual cost of care for the individual.”).

- Medicare Part A is the hospital insurance provided by FFS Medicare. This insurance covers inpatient care in hospitals and skilled nursing facilities, hospice care, and some home health care.³¹ Most enrollees do not have to pay a premium for Part A,³² but benefits are subject to a deductible and may require cost sharing.³³ In 2023, the deductible for each inpatient hospital benefit period is \$1,600.³⁴ Cost-sharing amounts for Part A are based on days of consecutive inpatient care. They can be as low as \$0 when an enrollee has less than sixty consecutive days of inpatient care, and up to the full cost of care when an enrollee has longer periods of care.³⁵
- Medicare Part B is medical insurance provided by FFS Medicare. This insurance helps cover the costs of physician visits, outpatient services, preventive services, and some home health visits.³⁶ Part B benefits are subject to an annual deductible (e.g., \$226 in 2023)³⁷ and, typically, a coinsurance payment of 20 percent.³⁸ Most Medicare enrollees pay a Part B premium, and these premiums are set at 25 percent of the projected average per capita Part B costs.³⁹ In 2023, the monthly Part B premium is \$164.90.⁴⁰

³¹ “What Part A Covers,” *Medicare.gov*, available at <https://www.medicare.gov/what-medicare-covers/what-part-a-covers>; “How Original Medicare works,” *Medicare.gov* (“CMS, How Original Medicare Works”), available at <https://www.medicare.gov/what-medicare-covers/your-medicare-coverage-choices/how-original-medicare-works>.

³² “Costs,” *Medicare.gov* (“CMS, Medicare Costs”), available at <https://www.medicare.gov/basics/costs/medicare-costs>.

³³ For example, a beneficiary may be responsible for the full cost of care for extended inpatient hospital and skilled nursing facilities stays. See CMS, Medicare Costs.

³⁴ Inpatient hospital benefit periods begin when a beneficiary is admitted as an inpatient and end after a beneficiary has not received any inpatient hospital or skilled nursing facility (“SNF”) care for 60 days. There is no limit to the number of benefit periods beneficiaries can have in a year. See CMS, Medicare Costs.

³⁵ In 2023, there is no copayment for the first 60 days of a benefit period. There is a \$400 daily copayment for days 61–90. After 90 days, beneficiaries can pay a \$800 daily copayment by using a “lifetime reserve day,” of which all beneficiaries receive 60 over the course of their lifetimes. After using all 60 lifetime reserve days, beneficiaries pay all costs for the remainder of a given stay. The copayment and deductible schedule resets whenever a beneficiary goes 60 consecutive days without care from a hospital or SNF. See CMS, Medicare Costs.

³⁶ KFF, An Overview of Medicare; CMS, How Original Medicare Works.

³⁷ “2023 Medicare Parts A & B Premiums and Deductibles 2023 Medicare Part D Income-Related Monthly Adjustment Amounts,” *Centers for Medicare & Medicaid Services*, September 27, 2022 (“CMS, 2023 Medicare Parts A & B Premiums and Deductibles”), available at <https://www.cms.gov/newsroom/fact-sheets/2023-medicare-parts-a-b-premiums-and-deductibles-2023-medicare-part-d-income-related-monthly>.

³⁸ CMS, Medicare Costs. No coinsurance or deductible is charged for some preventive services. See “What Part B Covers,” *Medicare.gov*, available at <https://www.medicare.gov/what-medicare-covers/what-part-b-covers>.

³⁹ Patricia A. Davis, “Medicare Part B: Enrollment and Premiums,” *Congressional Research Service*, May 19, 2022, available at <https://sgp.fas.org/crs/misc/R40082.pdf>.

⁴⁰ About seven percent of Part B recipients face higher premiums due to their relatively high incomes. See CMS, 2023 Medicare Parts A & B Premiums and Deductibles.

28. In 2021, FFS Medicare provided its enrollees with average benefits of \$5,207 and \$6,757 for Part A and Part B, respectively, with average cost sharing (excluding monthly premiums and uncovered services) of \$396 and \$1,621 for Part A and Part B, respectively.⁴¹

29. Since 2006, Medicare beneficiaries can also obtain coverage for outpatient prescription drugs.⁴² This type of insurance, offered through private insurers that contract with Medicare, is called Medicare Part D. Part D enrollees typically pay a monthly premium and are subject to other cost-sharing payments, with premiums, drug formularies, and other cost sharing varying substantially across plans.⁴³ For example, monthly premiums for Part D plans in 2023 range from \$1.60 to \$201.10.⁴⁴ In 2019, approximately 25 million FFS Medicare enrollees (about 66 percent of all FFS Medicare enrollees) were enrolled in a stand-alone prescription drug plan through Medicare Part D.⁴⁵

30. FFS Medicare has certain limitations. For example, it does not cover services such as long-term care, hearing aids, or dental care, and many services require significant cost sharing, such as the 20 percent copayment for Medicare Part B described above.⁴⁶ Moreover, among noninstitutionalized Medicare beneficiaries enrolled in FFS Medicare in 2020, Medicare covered 69 percent of total health care expenditures.⁴⁷ Because of the gaps in Medicare coverage, many FFS Medicare enrollees also enroll in Medicare supplemental insurance

⁴¹ “Health care spending and the Medicare program,” *MedPAC*, July 2023 (“MedPAC, Health care spending and the Medicare Program”), p. 12, available at https://www.medpac.gov/wp-content/uploads/2023/07/July2023_MedPAC_DataBook_SEC.pdf.

⁴² “Prior to 2006, Medicare paid for some drugs administered during a hospital admission (under Medicare Part A), or a doctor’s office (under Medicare Part B). Medicare did not cover *outpatient* prescription drugs until January 1, 2006, when it implemented the Medicare Part D prescription drug benefit, authorized by Congress under the ‘Medicare Prescription Drug, Improvement, and Modernization Act of 2003.’” See “Part D/Prescription Drug Benefits,” *Center for Medicare Advocacy*, available at <https://www.medicareadvocacy.org/medicare-info/medicare-part-d>.

⁴⁴ KFF, An Overview of the Medicare Part D Prescription Drug Benefit.

⁴⁵ A further 19.7 million individuals received Part D coverage through Medicare Advantage plans. These figures include both employer-only group plans and non-employer plans. See Juliette Cubanski, et al., “10 Things to Know About Medicare Part D Coverage and Costs in 2019,” *Kaiser Family Foundation*, June 4, 2019, available at <https://www.kff.org/medicare/issue-brief/10-things-to-know-about-medicare-part-d-coverage-and-costs-in-2019>; “Total Number of Medicare Beneficiaries by Type of Coverage,” *Kaiser Family Foundation*, 2019, available at <https://www.kff.org/medicare/state-indicator/total-medicare-beneficiaries>.

⁴⁶ CMS, Medicare Costs; “Medicare Advantage: A Policy Primer,” *Commonwealth Fund*, May 3, 2022, available at <https://www.commonwealthfund.org/publications/explainer/2022/may/medicare-advantage-policy-primer> (“Commonwealth Fund, Medicare Advantage: A Policy Primer”).

⁴⁷ This figure includes all public, private, and direct beneficiary spending on “all health care goods and services.” MedPAC, Health care spending and the Medicare program, p. 29.

policies, known as Medigap policies. Medigap plans are provided through private insurers and pay for costs not covered by FFS Medicare, including copayments.⁴⁸ These plans require enrollees to pay monthly premiums in addition to the premiums they may pay for Part B and Part D.⁴⁹

31. As an alternative to enrolling in FFS Medicare and supplementing it with Medigap, beneficiaries can choose to enroll in Medicare Advantage. This is described below.

C. Medicare Advantage

32. The federal government introduced the Medicare Advantage program within Medicare to (1) provide Medicare beneficiaries with health insurance plans that are an alternative to FFS Medicare, and (2) transfer to Medicare some of the efficiencies and cost savings that had been observed for health care plans in the private sector.⁵⁰ In particular, the Medicare Advantage program relies on private insurers to provide health insurance to Medicare enrollees through the use of managed care, whereby health care is provided through provider networks. Managed care plans use their capitation payments to manage the health care expenditures of enrollees.⁵¹ In this section, I first describe some features of current MA plans, and then briefly review the history of the MA program.

33. MA plans must provide enrollees with both Part A and Part B coverage, and may offer enrollees Part D prescription drug coverage as well.⁵² In 2023, 89 percent of MA plans offer prescription drug coverage and 97 percent of MA enrollees in “individual plans,” which are plans open for general enrollment to individual consumers, selected plans with this benefit.⁵³ MA plans can differ in the amount of premiums that they charge, the limits on out-of-pocket

⁵² CMS, Health Plans.

⁵³ Meredith Freed, et al., “Medicare Advantage 2023 Spotlight: First Look,” *Kaiser Family Foundation*, November 10, 2022 (“Freed et al., Medicare Advantage 2023 Spotlight: First Look”), available at <https://www.kff.org/medicare/issue-brief/medicare-advantage-2023-spotlight-first-look/>; Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings. Individual plans exclude employer group health plans and Special Needs Plans.

costs,⁵⁴ and the structure of out-of-pocket costs.⁵⁵ For example, in 2023, about 73 percent of enrollees in individual MA plans that offer prescription drug coverage pay no “incremental premium” (i.e., a premium in addition to the standard Part B premium), while only about three percent have incremental premiums of \$100 or more per month.⁵⁶ Overall, the average enrollment-weighted incremental premium among individual MA plans offering prescription drug coverage, including those that do not pay a premium, is \$15 per month in 2023.⁵⁷ The average enrollment-weighted premium for just the Part D portion of covered benefits is \$10 per month among these MA plans.⁵⁸ In contrast, the stand-alone prescription drug plans available to FFS Medicare enrollees require an additional Part D premium, which averages \$40 per month in 2023.⁵⁹

34. If MA enrollees are interested in switching to another plan, such as a different MA plan with drug coverage through Part D, they can do so during the Medicare Advantage Open Enrollment period. The Open Enrollment period occurs annually from January through March, and during this time, MA enrollees may switch to another MA plan or return to FFS Medicare.⁶⁰

⁵⁸ Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings.

⁵⁹ Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings.

⁶⁰ “What’s the Difference Between Medicare’s Open Enrollment Period and Medicare Advantage Open Enrollment?” *National Council on Aging*, November 12, 2022, available at <https://ncoa.org/article/whats-the-difference-between-medicare-open-enrollment-period-and-medicare-advantage-open-enrollment>.

35. MA plans vary according to their hospital and physician networks,⁶¹ their rules regarding how enrollees can access services,⁶² and the services they cover, which can include services not covered by FFS Medicare such as vision, hearing, or dental.⁶³ MA plan health care provider networks can be more limited than the set of providers that accept FFS Medicare.⁶⁴ In this regard, MA has more in common with an employer-sponsored plan than with FFS Medicare.⁶⁵

36. Medicare Advantage plans are offered by many of the same insurers that offer employer-sponsored health plans. Three private insurers account for approximately 61 percent of the 30.8 million enrollees in MA plans in 2023: 29 percent of MA enrollees have plans with UnitedHealth, 18 percent with Humana, and 14 percent with BlueCross BlueShield affiliates.⁶⁶ Other insurers offering MA plans include CVS Health, Kaiser Permanente, Centene, and Cigna, with shares ranging from 2 to 11 percent.⁶⁷

37. The MA program has undergone substantial changes over the course of its existence with regards to how the government compensates private insurers. The original version of the MA program began with the Social Security Amendments of 1972, which authorized the government to contract with private health insurers to offer private health plans as additional options for Medicare beneficiaries. However, a substantial increase in plan participation and enrollment only occurred when the Tax Equity and Fiscal Responsibility Act (“TEFRA”) of 1982 introduced some changes in the program’s risk sharing arrangements including, for

⁶¹ For example, a 2017 Kaiser Family Foundation study that examines 391 MA plans in 20 counties in 2015 finds heterogeneity in the size of plan’s physician networks: 22 percent of enrollees were in plans that included over 70 percent of physicians in the county in their network, while 35 percent of enrollees were in plans that included less than 30 percent of physicians in the county in their network. See Gretchen Jacobson, et al., “Medicare Advantage: How Robust Are Plans’ Physician Networks?,” *Kaiser Family Foundation*, October 5, 2017, Figure ES.1, available at <https://www.kff.org/medicare/report/medicare-advantage-how-robust-are-plans-physician-networks>. A similar 2016 Kaiser Family Foundation study also found heterogeneity in the size of plans’ hospital networks. See Gretchen Jacobson, et al., “Medicare Advantage Hospital Networks: How Much Do They Vary?,” *Kaiser Family Foundation*, June 20, 2016, Figure ES.1, available at <http://files.kff.org/attachment/Report-Medicare-Advantage-Hospital-Networks-How-Much-Do-They-Vary>.

⁶² HHS, What is Medicare Part C.

⁶³ CMS, Understanding Medicare Advantage Plans, p. 5.

⁶⁴ CMS, Understanding Medicare Advantage Plans, p. 5.

⁶⁵ As another example, MA plans and employer plans often have cost sharing that varies by service, whereas Medicare Part B enrollees pay a flat 20 percent. See CMS, Understanding Medicare Advantage Plans, p. 6. See also “Employer Health Benefits: 2021 Annual Survey,” *Kaiser Family Foundation*, November 2021, p. 92, available at <https://files.kff.org/attachment/Report-Employer-Health-Benefits-2021-Annual-Survey.pdf>.

⁶⁶ Nancy Ochieng, et al., “Medicare Advantage in 2023: Enrollment Update and Key Trends,” *Kaiser Family Foundation*, August 9, 2023 (“Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends”), available at <https://www.kff.org/medicare/issue-brief/medicare-advantage-in-2023-enrollment-update-and-key-trends>.

⁶⁷ Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends.

example, allowing plans to reduce cost sharing for beneficiaries. By 1997, enrollment in these private health plans had grown to about six million beneficiaries, located primarily in urban counties.⁶⁸

38. CMS pays MA plans a fixed payment per enrollee in exchange for providing health care coverage to beneficiaries who enroll.⁶⁹ To estimate these payments in the 1980s and 1990s, CMS used a model based primarily on demographics, such as gender, age, Medicaid status, and disability status, along with the enrollee's county of residence. The demographic factors served as a proxy for health risks, which are associated with enrollees' health care expenditures. The model assessed the relationship between these demographic factors and total spending in Parts A and B of FFS Medicare.⁷⁰ This quantification of the relationship between these demographic factors and spending was then used to adjust payments to MA plans up or down based on whether the demographic profile of an enrollee represented a higher or lower health and medical expenditure risk. This process of adjusting payments to MA plans up or down to account for the risk of future health expenditures is known as "risk adjustment."⁷¹ This type of risk adjustment based on demographic factors was limited in that it did not include any disease or health variables in trying to predict an enrollee's total health and medical expenditures.⁷² Although the payment model was limited with regard to the direct use of such health variables, it did consider the geographic variation in Medicare costs.⁷³ Studies such as the Dartmouth Atlas have shown that geographic differences in per-recipient Medicare spending can be substantial, even after controlling for demographic factors.⁷⁴

39. The Balanced Budget Act of 1997 ("BBA") took Medicare's system of providing fixed payments to private health plans to cover enrollees, renamed these plans Medicare+Choice

⁶⁸ Office of Health Policy, "Payment for Medicare Advantage Plans: Policy Issues and Options," *Office of the Assistant Secretary for Planning and Evaluation*, June 2009, p. 2, available at <https://aspe.hhs.gov/system/files/pdf/75816/report.pdf>.

⁶⁹ I refer to these payments as "payments to MA plans" throughout the remainder of this report.

⁷⁰ Brown et al., *How Does Risk Selection Respond to Risk Adjustment*, pp. 3335–3364 at p. 3339.

⁷¹ MedPAC, *Report to the Congress*, p. 413.

⁷² Gregory Pope, et al., "Risk Adjustment of Medicare Capitation Payments Using the CMS-HCC Model," *Health Care Financing Review*, 25(4), 2004 ("Pope et al., Risk Adjustment of Medicare Capitation Payments"), pp. 119–141 at p. 119.

⁷³ Pope et al., *Risk Adjustment of Medicare Capitation Payments*, pp. 119–141 at p. 119.

⁷⁴ For example, after adjusting for age, sex and race, FFS Medicare reimbursements per enrollee (Part A and Part B) for 2019 in the Des Moines hospital referral region ("HRR," a region with similar medical usage patterns used by the Dartmouth Atlas) was \$9,169.86. The same measure was \$14,675.29 in the Miami HRR. See "Medicare Reimbursements," *Dartmouth Atlas Project*, 2022, available at <https://www.dartmouthatlas.org/interactive-apps/medicare-reimbursements>; "FAQ," *Dartmouth Atlas Project*, available at <https://www.dartmouthatlas.org/faq>.

(“M+C”), and formally defined this system as Part C of Medicare.⁷⁵ The BBA required CMS to improve its risk-adjustment model by using health information (i.e., data on diagnoses of health care conditions for inpatients—but not for outpatients) in addition to demographic variables. CMS began to use this new model in 2000, but only 10 percent of the payments made to MA plans were based on the updated methodology of incorporating health information along with enrollee demographic variables.⁷⁶

40. In addition, the BBA authorized CMS to contract with private organizations to offer a variety of new health plan options (such as Health Maintenance Organization or Preferred Provider Organization plans, two types of plans that are commonly used in employer-sponsored health insurance) for enrollees in the M+C program.⁷⁷ The BBA also altered reimbursement to Part C plans, limiting plans’ reimbursements in many counties to be at most two percent higher than the prior year’s reimbursement.⁷⁸

41. The Benefits Improvement and Protection Act of 2000 (“BIPA”) addressed the limitation of a risk-adjustment model that only included data on diagnoses for inpatients by requiring the use of such data for outpatients as well.⁷⁹ Moreover, BIPA provided a phase-in schedule regarding the risk-adjusted portion of the payments to MA plans. This portion increased to 30 percent in 2004, to 50 percent in 2005, to 75 percent in 2006, and to 100 percent in 2007.⁸⁰

42. The Medicare Prescription Drug, Improvement, and Modernization Act of 2003 (“MMA”) renamed the M+C program as the Medicare Advantage program.⁸¹ The MMA included the most significant changes to the Medicare program since its creation by establishing

⁸¹ CMS, Health Plans.

a larger role for private health plans and enacting increases to payments to MA plans, effective in March 2004.⁸² The participation of plans in the MA program and enrollment both increased steadily after the MMA.⁸³

43. In more recent years, CMS has limited MA plans' profits through the implementation of a minimum Medical Loss Ratio ("MLR") to which MA plans must adhere. The MLR represents "the percentage of revenue used for patient care, rather than for such other items as administrative expenses or profit."⁸⁴ Starting in 2014, MA insurers needed to have an MLR of at least 85 percent for each contract—meaning that at least 85 percent of revenue must be used for patient care—or they could be subject to sanctions.⁸⁵ The MLR limits MA plans' ability to charge high premiums without offering patients correspondingly generous benefits, or to offer plans with few benefits without offering correspondingly low premiums.

VI. The Medicare Advantage Program Has Provided Value to Plan Enrollees

44. In this section, I explain why the Medicare Advantage program has provided value to Medicare enrollees. I first explain that Medicare enrollees are better off when they have more health insurance plans to choose from. This is because with more choices it is possible for individuals to choose a plan better tailored to their health care preferences and needs. Second, I discuss evidence indicating that Medicare beneficiaries have often preferred Medicare Advantage plans to FFS Medicare. Finally, I explain that Medicare Advantage plans have often provided better or more efficient care than FFS Medicare.

⁸⁵ CMS, Medical Loss Ratio. See also Deposition of Kirk Limmer (CMS), June 21, 2023 ("Limmer Deposition"), pp. 14:9–16, 116:5–117:20 ("A The medical loss ratio was enacted—enacted by Congress—to my understanding is to place—to basically ensure that a certain percentage of benefits within the total revenue—or a minimum—say, a minimum level of benefits is being passed on to the beneficiaries. And that the—I guess, conversely, that the non—non-benefit—well, I don't want to use the word non-benefit because that might be confusing. The portion that is not medical is—is limited by a certain percentage, also. So for Medicare, it is set at 85 percent. [...] it could be greater than 85 percent. But as long as they are, as long as the results that—and using the medical loss ratio formula—as long as those results are over 85 percent or—then—then there's no payment. If there—if it's below that, there are—there are specified actions that would be taken, including possible payments to CMS.").

A. Medicare Advantage Plans Provide Medicare Beneficiaries with More Choices

45. MA plans provide Medicare beneficiaries with alternatives to FFS Medicare that may better fit their health care preferences and needs. Beneficiaries choose between FFS Medicare and MA plans, or among different MA plans, based upon their preferences and upon plan features such as premiums, cost sharing, limits on out-of-pocket expenses, provider networks, conditions to access care, and the availability of benefits not offered by FFS Medicare (e.g., vision care coverage). All else equal, Medicare beneficiaries are made better off if they have more plans to choose from because a broader menu of plans allows each beneficiary to choose a plan more tailored to their specific preferences and health care needs.

46. The concept that increased choice makes consumers better off is well understood in economics. Economists use the term “utility,” where an individual is better off if they have higher utility and worse off if they have lower utility.⁸⁶ Typical economic models demonstrate that expanding an individual’s choices will leave them at least equally well off, and in many cases better off.⁸⁷ In the context of discussing Medicare, and Medicare Advantage in particular, Newhouse et al. (2014) state that “[i]n conventional economic theory, more choices always benefit a consumer because more choices offer the possibility of a better match between what is bought and the consumer’s preferences.”⁸⁸ This principle is consistent with CMS statements as to why it supports the growth of MA. For example, a CMS-contracted study states that the 2003 MMA was intended “to increase the choice of plans available to beneficiaries.”⁸⁹ In 2018, CMS Administrator Seema Verma stated that “[o]ur priority is to ensure that our seniors have more choices [...] We are focused on addressing the specific needs of beneficiaries and providing new flexibilities for Medicare Advantage plans to offer new health-related benefits. This is a big win for patients.”⁹⁰ In other words, the utility of Medicare beneficiaries will be, on average,

⁹⁰ “CMS proposes Medicare Advantage and Part D payment and policy updates to provide new benefits for enrollees, new protections to combat opioid crisis,” *Centers for Medicare & Medicaid Services*, February 1, 2018, available at <https://www.cms.gov/newsroom/press-releases/cms-proposes-medicare-advantage-and-part-d-payment-and-policy-updates-provide-new-benefits-enrollees>.

higher because of the increased choice that Medicare Advantage plans provide. This is because, for some individuals, the additional MA plan options will be a better fit than FFS Medicare or will be a better fit than already-existing MA plan options. This is an important reason why the Medicare Advantage program benefits Medicare beneficiaries.

B. Market Data and Academic Literature Indicate that Many Medicare Beneficiaries Have Preferred Medicare Advantage Plans to FFS Medicare

47. MA enrollment has grown tremendously over time since the passage of the MMA and the creation of the current MA program in 2003. As shown in Exhibit 1, MA plans enrolled approximately 5 million Medicare beneficiaries in 2003, and enrollment increased to approximately 31 million Medicare beneficiaries in 2023.

48. Enrollment has not only grown in absolute terms—the share of Medicare beneficiaries choosing Medicare Advantage has also increased over time. As shown in Exhibit 1, the share of Medicare beneficiaries selecting Medicare Advantage plans grew from 13 percent in 2003 to 51 percent in 2023. The Congressional Budget Office projects that under current law MA enrollment will continue to grow and could reach 62 percent of Medicare beneficiaries by 2033.⁹¹

⁹¹ Ochieng et al., Medicare Advantage in 2023: Enrollment and Key Trends.

Exhibit 1

Medicare Advantage Enrollment and Share of All Medicare Enrollment, 2003–2023

Source: Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends; Meredith Freed, et al., “A Dozen Facts About Medicare Advantage in 2020,” *Kaiser Family Foundation*, April 22, 2020 (“Freed et al., A Dozen Facts About Medicare Advantage in 2020”), available at <https://web.archive.org/web/20201210075019/https://www.kff.org/medicare/issue-brief/a-dozen-facts-about-medicare-advantage-in-2020>.

Note: Enrollment data is from March of each year, with the exception of 2006, which is from April. KFF updated its methodology so that starting in 2010, the data do not include cost plans. Cost plans are a Medicare managed care plan that can also be reimbursed by FFS Medicare for out of network services. Data from before 2010 include cost plans. Data for the period 2007 – 2023 are from KFF’s 2023 report, while data for before 2007 are from KFF’s 2020 report. About 60.0 million people are enrolled in Medicare Parts A and B in 2023.

49. The fact that a substantial share of Medicare beneficiaries selects MA over FFS Medicare reveals that many individuals prefer MA. According to economic theory, if an individual has two items they can choose from, option A and option B, and both are within their budget, then one can infer from their selection of option A that they prefer option A to option B.⁹² Applied to the choice of Medicare products, the fact that 51 percent of Medicare beneficiaries selected an MA plan rather than FFS Medicare in 2023 reveals that many Medicare beneficiaries prefer MA plans over FFS Medicare. The steady growth in the share of individuals selecting MA plans

⁹² It is possible that an individual who selected option A is indifferent between option A and option B, but nonetheless selected option A. Economists would say the individual “weakly” prefers option A to option B in this instance. See David Besanko and Ronald Braeutigam, *Microeconomics, Fifth Edition*, (Jefferson City: John Wiley & Sons, Inc., 2014), p. 134.

over time also reveals that the fraction of Medicare beneficiaries who prefer MA plans to FFS Medicare is growing.

50. There is similar evidence indicating that UnitedHealth MA plans are attractive to Medicare beneficiaries. In 2023, UnitedHealth had more MA enrollees than any other insurer (29 percent for UnitedHealth as compared to 18 percent for Humana, 14 percent for BlueCross BlueShield, 11 percent for CVS Health, 6 percent for Kaiser Permanente, and 22 percent for all other plans). Additionally, UnitedHealth's share of enrollees among MA insurers has grown substantially over the past decade (from 22 percent in 2013 to 29 percent in 2023), while the share for many other leading MA insurers (such as Humana, BlueCross BlueShield, and Kaiser Permanente) has been relatively flat.⁹³ Taken together, these facts reveal that many Medicare beneficiaries prefer UnitedHealth MA plans to other MA plans and to FFS Medicare, and that the number of individuals with this preference has been increasing over time.

51. In addition to market data indicating that many Medicare beneficiaries prefer MA plans, survey data shows that MA plan enrollees are satisfied with their health insurance plans. For example, Duggan et al. (2016) analyze data from the 2007–2011 Consumer Assessment of Healthcare Providers and Systems (“CAHPS”) survey that contains enrollees’ ratings of plans for every MA plan that is at least one year old.⁹⁴ Surveyors questioned 600 individuals from each MA contract and collected responses from over 160,000 MA enrollees in each year between 2007 and 2011. Duggan et al. (2016) find that “MA enrollees are on average quite satisfied with their plans.”⁹⁵

52. There are several reasons why Medicare beneficiaries may prefer MA plans over FFS Medicare.

53. First, most MA enrollees enjoy benefits not available to their counterparts who are enrolled in FFS Medicare. For example, in 2023, more than 90 percent of MA plans offer coverage for eye exams and glasses, dental care, fitness benefits, and/or hearing aids, while FFS

⁹³ Humana saw slight growth in its share of enrollees from 17 percent to 18 percent, while both BlueCross BlueShield and Kaiser Permanente saw a decline in market share over the past decade. CVS Health's share of enrollees among MA insurers grew from 7 percent in 2013 to 11 percent in 2023, representing the only substantial growth in market share aside from UnitedHealth among insurers with at least 6 percent of MA enrollees. See Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends.

⁹⁴ Duggan et al., Who Benefits when the Government Pays More, pp. 50–67 at pp. 55, 62.

⁹⁵ Duggan et al., Who Benefits when the Government Pays More, pp. 50–67 at footnote 12.

Medicare does not cover these benefits.⁹⁶ Additionally some MA enrollees have access to other benefits not covered under FFS Medicare such as meal, transportation, and in-home support benefits.⁹⁷ As acknowledged by Sean Creighton, former Director for Payment Policy and Risk Adjustment at CMS, beneficiaries of MA plans enjoy “an array of additional benefits that are not available to them in fee-for-service,” including prescription drug coverage at a reduced cost and an out-of-pocket maximum that limits enrollees’ out-of-pocket spending.⁹⁸

54. Second, many MA enrollees pay less in premiums than FFS Medicare enrollees for plans with comparable coverage (health care expenditures covered under Parts A, B, and D) or even for plans with more extensive coverage (e.g., vision or dental coverage in addition to services covered under Parts A, B, and D).⁹⁹ In 2023, most MA plans (about 89 percent) offer prescription drug coverage, and most MA enrollees (about 92 percent) are enrolled in these plans.¹⁰⁰ Among MA plans with Part D coverage, 73 percent of MA enrollees with prescription drug coverage pay no incremental premium (i.e., no premium other than their Medicare Part B premium), and the average enrollment-weighted incremental premium for MA enrollees (across

⁹⁶ 97 percent of individual MA plans include telehealth benefits beyond what was allowed under FFS Medicare prior to the COVID-19 public health emergency. Freed et al., Medicare Advantage 2023 Spotlight: First Look. FFS Medicare currently covers a range of telehealth services, but most of this coverage is temporarily available due to a broad, but time-limited, expansion triggered by the COVID-19 pandemic. MA plans have been able to offer telehealth benefits since 2020 due to a pre-pandemic CMS policy adjustment. See Wyatt Koma, et al., “FAQs on Medicare Coverage of Telehealth,” *Kaiser Family Foundation*, May 23, 2022, available at <https://www.kff.org/medicare/issue-brief/faqs-on-medicare-coverage-of-telehealth/>; “CMS finalizes policies to bring innovative telehealth benefit to Medicare Advantage,” *Centers for Medicare & Medicaid Services*, April 5, 2019, available at <https://www.cms.gov/newsroom/press-releases/cms-finalizes-policies-bring-innovative-telehealth-benefit-medicare-advantage>.

⁹⁸ Deposition of Sean Creighton (CMS), March 23, 2022 (“Creighton Deposition, day 1”), pp. 33:7–34:6, 41:21–45:23.

⁹⁹ Statement of Jonathan Morse Acting Director of the Center for Program Integrity, Centers for Medicare and Medicaid Services on “Efforts to Combat Waste, Fraud and Abuse in the Medicare Program” before the U.S. House Ways and Means Committee, Subcommittee on Oversight, July 19, 2017, p. 1, available at <https://waysandmeans.house.gov/wp-content/uploads/2017/07/20170719OS-Testimony-Morse.pdf> (“Additionally, while average premiums have remained stable, access to most Medicare Advantage supplemental benefits has increased, and enrollment is growing faster than in original Medicare. Medicare Advantage plans may offer additional benefits and cost-sharing arrangements that are at least as generous as the standard Parts A and B benefits under original Medicare.”).

¹⁰⁰ Freed et al., Medicare Advantage 2023 Spotlight: First Look. I calculate the share of MA enrollees that are enrolled in an MA plan with Part D coverage using the number of MA-PD enrollees in 2023 (28.3 M), divided by the total number of MA enrollees in 2023 (30.8M). $28.3\text{M} / 30.8\text{M} = 92$ percent. See Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends; Juliette Cubanski and Anthony Damico, “Key Facts About Medicare Part D Enrollment and Costs in 2023,” KFF, July 7, 2023, available at <https://www.kff.org/medicare/issue-brief/key-facts-about-medicare-part-d-enrollment-and-costs-in-2023>.

all plans that offer prescription drug coverage) is just \$15 per month in 2023.¹⁰¹ The average enrollment-weighted premium for just the Part D portion of covered benefits is \$10 per month among these MA plans.¹⁰²

55. In contrast, enrollees in FFS Medicare only receive prescription drug coverage if they enroll in Medicare Part D, which costs, on average, \$40 per month in additional premiums in 2023.¹⁰³ Individuals in FFS Medicare who have prescription drug coverage pay more in premiums, on average, than individuals in MA plans who have prescription drug coverage. That is, to receive all benefits listed under Medicare Parts A and B, and prescription drug coverage, MA enrollees on average pay the cost of the Part B premium, plus \$15 per month, while FFS Medicare enrollees on average pay the cost of the Part B premium, plus \$40 per month.¹⁰⁴ Indeed, Sean Creighton, testified that MA typically covers additional prescription drug benefits over those covered by FFS Medicare, and can offer prescription drug coverage at a reduced cost to beneficiaries.¹⁰⁵

56. Third, MA plans guarantee that annual out-of-pocket expenses will not exceed a maximum threshold while FFS Medicare offers no such guarantee.¹⁰⁶ This guarantee is

See also “What is a stand-alone prescription drug plan?” *Healthinsurance.org*, available at <https://www.healthinsurance.org/glossary/stand-alone-prescription-drug-coverage>.

¹⁰⁴ Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings. Some enrollees may have a reduced Part B premium. See Section VII.C and “Medicare Advantage Program Payment System,” *MedPAC*, November 2021 (“MedPAC, Medicare Advantage Program Payment System”), p. 3, available at https://www.medpac.gov/wp-content/uploads/2021/11/medpac_payment_basics_21_ma_final_sec.pdf.

¹⁰⁵ Creighton Deposition, day 1, p. 43:7–21 (“A. The other advantage is obviously that the medical and the drug benefit are integrated typically in Medicare Advantage. So these plans are both Part C, meaning Part A plus B equals C plans, and Part D plans. And within that there is a whole other level of advantage, too, because the Part C plans can use their rebate to reduce cost sharing for drugs under Part D, and generally do, and generally have better – they typically have co-pays rather than coinsurance for drugs under Part D, particularly for preferred drugs, generics or preferred brands. So there’s a whole range of additional benefits that accrue from joining a Medicare Advantage plan for a beneficiary.”), p. 44:14–15 (“You can also use the – Part C plans can use their money to reduce Part D premium.”).

¹⁰⁶ Creighton Deposition, day 1, pp. 42:12–43:5 (“Medicare Advantage has a concept called the maximum out-of-pocket, which means that in any given year the amount that a beneficiary can spend out of pocket is capped. It was around 6,800 recently, like that; it might be a little higher now. That does not exist in fee-for-service. There’s unlimited liability. So in fee-for-service, Medicare people either have to buy a supplemental insurance to cap their liability, or a lot of people in traditional fee-for-service still have supplemental insurance through either a Medicaid program or an employer program. So about 80 percent of fee-for-service – people in fee-for-service have or must have – you know, kind of have to have some other program to control the cost. You don’t need that in Medicare Advantage because of this concept of the maximum out-of-pocket.”).

beneficial for some individuals—for example those who expect to have very high health care expenditures or who have a fixed income and are unable to afford large, unanticipated spikes in out-of-pocket health care expenditures.¹⁰⁷ In 2023, MA plans are required to provide an out-of-pocket limit for Part A and Part B services that cannot exceed \$8,300 annually for in-network services and \$12,450 annually for in-network and out-of-network services combined.¹⁰⁸ The average out-of-pocket limit observed for MA plans in 2023 is lower than what was mandated: \$4,835 for in-network services and \$8,659 for in-network and out-of-network services combined.¹⁰⁹

57. In contrast, there is no annual out-of-pocket limit for FFS Medicare, and out-of-pocket spending for FFS Medicare enrollees can exceed out-of-pocket limits set by MA plans.¹¹⁰ As discussed above, FFS Medicare enrollees may be required to bear the full cost of care for long inpatient stays and typically face coinsurance payments of 20 percent on physician visits and outpatient services, both of which can contribute to high out-of-pocket expenditures. In 2018, FFS Medicare enrollees in the top 10 percent of spenders had out-of-pocket payments that exceeded the in-network out-of-pocket limit for MA plans.¹¹¹ Consequently, out-of-pocket spending can be considerably higher under FFS Medicare than under Medicare Advantage for many individuals. A risk of high out-of-pocket expenditures is especially concerning for many

¹⁰⁷ FFS Medicare has a 20 percent coinsurance requirement for Part B coverage, so out-of-pocket spending for FFS Medicare enrollees can be substantial in cases where enrollees need frequent or costly physician services. See CMS, Medicare Costs at a Glance.

¹⁰⁸ MA implemented the out-of-pocket spending limit in 2011. Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings.

¹⁰⁹ These figures represent enrollment-weighted averages. Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings. One way that MA plans can potentially manage enrollees' out-of-pocket expenses is by controlling service use and spending through utilization-management techniques (e.g., limited provider networks or coordination of care programs to deliver appropriate services more efficiently). These savings can lower costs for enrollees through lower cost sharing or through lower premiums. See Vilsa Curto, et al., "Health Care Spending and Utilization in Public and Private Medicare," *American Economic Journal: Applied Economics*, 11(2), 2019 ("Curto et al., Health Care Spending and Utilization in Public and Private Medicare"), pp. 302–332 at pp. 302, 328.

¹¹⁰ Claire Noel-Miller, "Medicare Beneficiaries' Out-of-Pocket Spending for Health Care," *AARP Public Policy Institute*, December 2021 ("Noel-Miller, Out-of-Pocket Spending"), p. 1, available at <https://www.aarp.org/content/dam/aarp/ppi/2021/12/medicare-beneficiaries-out-of-pocket-health-care-spending.doi.10.26419-2Fppi.00105.002.pdf>.

¹¹¹ Noel-Miller, Out-of-Pocket Spending, Table 1. In 2018, MA plans were required to provide an out-of-pocket limit for Part A and Part B services that could not exceed \$6,700 for in-network services. As I explain in Section V.C, MA plan provider networks (i.e., the set of providers that provide "in-network services") can be more limited than the set of providers that accept FFS Medicare. See Gretchen Jacobson, et al., "A Dozen Facts About Medicare Advantage," *Kaiser Family Foundation*, November 13, 2018, available at <https://web.archive.org/web/20181129174017/https://www.kff.org/medicare/issue-brief/a-dozen-facts-about-medicare-advantage>.

Medicare beneficiaries since many Medicare beneficiaries have very limited and/or fixed income. For example, in 2019, half of all Medicare beneficiaries had incomes below \$29,650.¹¹²

58. Moreover, academic literature has found that MA confers surplus (i.e., utility gains) to Medicare beneficiaries. For example, Miller et al. (2023) use data from 2008–2017 to estimate a Medicare beneficiary’s willingness to pay for additional features covered by MA plans but not covered by FFS Medicare, such as dental, vision, and hearing coverage. The authors find that over the period 2008–2017, average consumer willingness to pay was \$604 per year for dental, vision, and hearing coverage packages that MA plans typically offer to beneficiaries without any additional premium.¹¹³ These results indicate that MA plans provide substantial benefits to consumers. In fact, the authors show that MA plans generated \$4.62 billion of surplus (i.e., utility benefits) to enrollees in 2017.¹¹⁴ Likewise, Curto et al. (2021) estimate that MA plans conferred approximately \$15 billion of surplus to enrollees in 2018.¹¹⁵

59. In sum, economic theory, market data, survey data, and academic literature all indicate that many Medicare beneficiaries prefer and benefit from the Medicare Advantage program.

C. MA Plans Have Often Provided Better or More Efficient Care than FFS Medicare

60. Academic literature has also found that MA plans can provide better or more efficient care than FFS Medicare. Following economic literature, I define more efficient care to be health care that provides the same patient outcomes while using fewer resources (i.e., while having lower health care utilization).¹¹⁶ As noted in one study, because CMS pays MA plans fixed, risk-

¹¹² Wyatt Koma, et al., “Medicare Beneficiaries’ Financial Security Before the Coronavirus Pandemic,” *Kaiser Family Foundation*, April 24, 2020, available at <https://www.kff.org/medicare/issue-brief/medicare-beneficiaries-financial-security-before-the-coronavirus-pandemic>.

¹¹³ Keaton Miller, et al., “The Optimal Geographic Distribution of Managed Competition Subsidies,” Working Paper, January 20, 2023 (“Miller et al., The Optimal Geographic Distribution of Managed Competition Subsidies”), p. 4, available at https://static1.squarespace.com/static/56a1484625981dd79f45da68/t/63caf1235229f06b12bda94a/1674244394942/023-01-20-Optimal_Managed_Competition_Subsidies-paper.pdf.

¹¹⁴ Miller et al., *The Optimal Geographic Distribution of Managed Competition Subsidies*, p. 5. They also estimate that the surplus for insurance companies was \$3.10 billion.

¹¹⁵ Vilsa Curto, et al., “Can health insurance competition work? Evidence from Medicare Advantage,” *Journal of Political Economy*, 129(2), 2021, pp. 570–606 (“Curto et al., Can health insurance competition work? Evidence from Medicare Advantage”) at p. 598. The paper also finds that the surplus for insurance companies was \$33 billion. While the Miller et al. (2023) and Curto et al. (2021) estimates for the surplus generated by MA plans range in value, both sets of estimates are positive and substantial.

¹¹⁶ John Wennberg, et al., “Tracking the Care of Patients with Severe Chronic Illness: The Dartmouth Atlas of Health Care 2008,” *The Dartmouth Institute for Health Policy and Clinical Practice*, 2008, p. 54, available at

adjusted payments for the total cost of care, MA plans are incentivized to “use managed care techniques to limit their costs.”¹¹⁷ A recent study of Medicare enrollees found that those enrolled in MA had a lower overall utilization of health care when compared to enrollees in FFS Medicare, while not reporting less satisfaction with the quality of their care and having similar overall health outcomes to comparable enrollees in FFS Medicare.¹¹⁸ Another study found that MA enrollees experienced lower intensity of post-acute care and fewer hospital readmissions than FFS Medicare patients, indicating more efficient care by reducing cost and maintaining or improving patient outcomes.¹¹⁹ Duggan et al. (2018) show that hospital utilization (as measured by visits, procedures, and length of stay) increased for individuals who were forced out of MA plans when MA plans completely exited the individual’s county.¹²⁰ In other words, MA plans had reduced utilization for their enrollees relative to FFS Medicare.¹²¹ Additionally, Curto et al. (2019) compared spending in MA and FFS Medicare, controlling for enrollee county, risk score, and mortality, and found that health care spending per enrollee in MA was nine percent lower than FFS Medicare in 2010.¹²² In other words, similar enrollees that would achieve similar mortality outcomes had lower spending in MA, indicating more efficient care. The study

¹²² Curto et al., *Health Care Spending and Utilization in Public and Private Medicare*, pp. 302–332 at pp. 303–304 (“Without either adjustment [for observable and unobservable characteristics], MA spending per enrollee-month is 30 percent lower than TM spending per enrollee-month. Holding county and risk score fixed, the spending difference becomes 25 percent, and adjusting for mortality differences further reduces it to 9 percent.”).

additionally found that states with higher FFS Medicare spending had greater MA “savings,” consistent with MA’s efficiency relative to FFS Medicare.¹²³

61. Consistent with this notion, former CMS Administrator Marilyn Tavenner has stated that MA is a “game-changer” which serves as an “innovative” insurance product for millions of beneficiaries.¹²⁴ During her deposition, she also emphasized why MA plans provide a “good alternative” to FFS Medicare, noting that MA allowed CMS to move toward paying for “outcomes and quality.”¹²⁵ This is consistent with MA plans providing better or more efficient care than FFS Medicare.

62. MA plans may be more efficient relative to FFS Medicare in part due to care coordination measures, such as prior authorization or limited provider networks.¹²⁶ Such

¹²³ Curto et al., *Health Care Spending and Utilization in Public and Private Medicare*, pp. 302–332 at p. 320 (“Figure 3 shows that states with higher TM spending have greater MA ‘savings’ as measured by the percentage difference between MA spending and adjusted TM spending. This is consistent with the ‘conventional wisdom’ that higher spending TM areas are less efficient or productive (e.g., Skinner 2011).”).

¹²⁴ Deposition of Marilyn B. Tavenner (CMS), February 28, 2018 (“Tavenner Deposition”), pp. 28:1–29:2, Exhibit 1000 (“‘Medicare Advantage is the game-changer. It’s the foundation for innovative, high-quality care delivery that seniors and the country demand,’ AHIP President and CEO Marilyn Tavenner said. ‘CMS should protect millions of beneficiaries who depend on Medicare Advantage and strengthen — not undermine — the program moving forward.’”), and pp. 49:19–50:4 (“Q Okay, and do you believe that Medicare Advantage is the foundation for innovative, high-quality care delivery? A Yes, sir, I do. Q And is that an opinion that you held while you were the administrator of CMS? A While I was the administrator of CMS, I probably learned what the Medicare Advantage program was about, and I felt it was a good alternative for a fee-for-service program, and I still feel that way today.”).

¹²⁵ Tavenner Deposition, pp. 49:25–50:25 (“A While I was the administrator of CMS, I probably learned what the Medicare Advantage program was about, and I felt it was a good alternative for a fee-for-service program, and I still feel that way today. Q And can you tell us why did you, why did you believe it was a good alternative to fee-for-service? A I can answer that, and the best way is to talk about what was going on with us and the Affordable Care Act at the time, which is to say that we were looking at a way to pay for – move away from fee-for-service and pay for outcomes and quality and cost, and the Medicare Advantage program offered that. Q And can you tell us in what way the Medicare Advantage service provided a superior alternative to fee-for-service? A ‘Superior alternative’ I don’t think is what I said. I just said that it offered an alternative to a fee-for-service model which tend to focus more on process, and we were trying to move toward outcomes, if that’s helpful. Q Did you believe the Medicare Advantage program allowed CMS to move toward outcomes? A I did.”).

¹²⁶ Bruce Landon, et al., “Analysis of Medicare Advantage HMOs Compared with Traditional Medicare Shows Lower Use of Many Services during 2003–2009,” *Health Affairs*, 31(12), 2012, pp. 2609–2617 at pp. 2609–10 (“Health plans may actively manage the provider networks through which they deliver care and employ programs to promote the delivery of appropriate services and avoid excessive utilization. In addition, plans use a variety of financial incentives to physicians to influence the quality and quantity of services delivered. These are all hallmarks of integrated care. In contrast, in traditional Medicare, physicians make clinical decisions for their patients with little or no oversight.”); Rajender Agarwal, et al., “Comparing Medicare Advantage And Traditional Medicare: A Systematic Review,” *Health Affairs*, 40(6), 2021, pp. 937–944 at p. 937 (“Evidence from forty-eight studies showed that in most or all comparisons, Medicare Advantage was associated with more preventive care visits, fewer hospital admissions and emergency department visits, shorter hospital and skilled nursing facility lengths-of-stay, and lower health care spending. [...] The Centers for Medicare and Medicaid Services (CMS) pays MA plans a fixed, risk-adjusted payment for the total cost of care. This payment method incentivizes MA plans to use managed care techniques to limit their costs. For example, health maintenance organizations (HMOs) require beneficiaries to use a defined network of providers, and these providers use utilization management policies and procedures (such as prior authorization) to prevent overuse.”).

provisions can require enrollees to seek approval before utilizing expensive services and encourage enrollees to use lower-cost providers.¹²⁷ Previous research has shown that MA plans save costs relative to FFS Medicare, while simultaneously generating surplus (i.e., utility gains) for enrollees even after accounting for any consumer disutility associated with having more-limited provider access.¹²⁸ In sum, evidence suggests that MA plans are more cost efficient than FFS Medicare.

63. Moreover, research shows that because MA insurers have an incentive to reduce overall health care expenditures for enrollees, MA plans with Part D coverage offer more generous prescription drug coverage than Medicare Part D prescription drug plans.¹²⁹

64. Evidence on aggregate Medicare spending also suggests that Medicare Advantage offers efficient care. Despite the steady growth in MA enrollment since 2006, as described in Section VI.B above, overall Medicare spending has not grown as rapidly as expected. In 2010, the Congressional Budget Office overestimated mandatory spending by the federal government for health care, which includes Medicare spending, in its projections for 2010–2020.¹³⁰ This overestimation was largely related to an overestimate of Medicare spending per beneficiary—the growth rate of Medicare spending per beneficiary dropped from 6.6 percent between 1987 and 2005 to 2.2 percent between 2013 and 2019.¹³¹ Indeed, growth in average Medicare spending per beneficiary has declined substantially after 2010.¹³² Furthermore, from 2010–2021, Medicare spending per beneficiary grew more slowly than per-capita private health care

¹²⁸ Curto et al, Can health insurance competition work? Evidence from Medicare Advantage, pp. 570–606 at p. 604 (“Our estimates suggest that private plans are able to obtain cost savings over traditional Medicare, sufficiently large to generate net surplus even after accounting for consumer disutility from having limited provider access.”).

¹²⁹ Amanda Starc and Robert J. Town, “Externalities and Benefit Design in Health Insurance,” *The Review of Economic Studies*, 2020, 87(6), pp. 2827–2858 at pp. 2–3 (“Stand-alone PDPs have an incentive to minimize drug expenditures, ignoring the impact on medical spending, while MA-PD plans have an incentive to minimize overall medical and drug expenditures [...] Using the detailed prescription level data with over 123 million claims, we estimate that MA-PD plan enrollees spend between 8 and 11% less on average for an identical bundle of drugs. The differences across plan type are larger for sicker enrollees. Furthermore, consistent with externalities playing a key role, the expenditure differentials are largely driven by drugs that have been explicitly identified as having large medical care offsets and treat chronic conditions like asthma, diabetes, and high cholesterol.”).

spending.¹³³ And while overall Medicare Advantage spending has grown at a faster rate than overall FFS Medicare spending in recent years, that growth appears to be closely related to the overall growth in MA enrollment.¹³⁴

65. In addition to evidence showing that MA plans are more efficient than FFS Medicare, evidence shows that MA plans benefit the Medicare program as a whole. Specifically, a study from 2013 shows that increases in Medicare Advantage enrollment are associated with lower hospitalization costs and shorter hospital stays for all seniors, even those in FFS Medicare.¹³⁵

66. In sum, there are many reasons why Medicare Advantage provides value to plan enrollees, such as those I have discussed in this section. Medicare Advantage plans provide beneficiaries with increased choice, allowing individuals to choose plans that better fit their preferences and needs. The benefit of this increased choice is confirmed by market data, surveys, and academic literature that indicate that many individuals prefer and benefit from MA plans over FFS Medicare. Additional benefits, lower premiums, and lower out-of-pocket costs for MA plans as compared to FFS Medicare are all reasons why Medicare beneficiaries may prefer MA plans over FFS Medicare. And finally, evidence indicates that MA plans may provide better, or more efficient, care, and that Medicare Advantage has positive spillovers to the Medicare program more generally.

VII. CMS Payments to MA Plans Are Based on Predicted Health Care Expenditures and Account for Enrollee Risk Profiles, Plan Quality, and Other Factors

67. In this section I explain that MA plans receive fixed payments from CMS in exchange for providing health insurance to enrollees, and that CMS adjusts these payments to account for the financial risk borne by MA plans. In particular, the fixed payment for each enrollee accounts for factors that relate to their predicted future health care expenditures such as the enrollee's health

¹³³ "The Facts About Medicare Spending," *Kaiser Family Foundation*, June 2023, available at <https://www.kff.org/interactive/medicare-spending>.

¹³⁵ Katherine Baicker, et al., "The Spillover Effects of Medicare Managed Care: Medicare Advantage and Hospital Utilization," *Journal of Health Economics*, 32(6), 2013, pp. 1289–1300 at p. 1299 ("We find that increasing MA penetration results in lower hospitalization costs and shorter lengths of stay system-wide. The magnitude of these spillovers is substantial, and taking them into account suggests higher optimal MA payments than would otherwise be the case.").

profile and demographic information. I also discuss other factors that are used to determine the fixed payment received by MA plans for each enrollee.¹³⁶

A. CMS Pays MA Plans a Fixed Fee for Each Enrollee, Exposing Insurers to Financial Risk

68. As explained in Section V, the MA program contracts with private insurers to provide health insurance to Medicare beneficiaries. Under MA, CMS pays MA plan providers (such as UnitedHealth) a fixed, pre-arranged monthly payment for each MA enrollee they cover, and this payment amount is updated based on bids provided annually by MA plans.¹³⁷ As I explain in more detail in Sections VII.B and VII.C, CMS's payment to MA plans does not depend on the actual health care expenditures incurred by plan enrollees. Instead, CMS payments to MA plans reflect an estimate of predicted health care expenditures for each enrollee in the MA plan. This predicted amount varies according to the characteristics of each enrollee.¹³⁸ For example, CMS would expect a 67-year-old woman with no known diagnoses for health conditions to have relatively low costs given her health status and relatively young age as a Medicare enrollee. As a result, CMS would predict that she would incur lower health care expenditures than another enrollee who was older or who already had known diagnoses. CMS would therefore pay less to an MA plan for insuring the 67-year-old healthy woman than for insuring an older enrollee in worse health. Sections VII.B and VII.C provide discussion on how CMS pays MA plans based on enrollees' demographics and diagnoses for health conditions.

69. Because CMS payments to MA plans do not depend on the *actual* health care expenditures of covered enrollees, MA plans are exposed to financial risk, since *actual* health care expenditures that the MA plans may have to pay for their enrollees may differ from the *estimated* health care expenditures that the MA plans receive from CMS. In the above example of the 67-year-old healthy woman, CMS would not adjust its fixed payment to the MA plan later in the year even if this enrollee experienced substantial unexpected health issues during the

¹³⁶ In total, MA plans are paid the sum of their per-enrollee payments. CMS, Medicare Managed Care Manual Chapter 8, § 80 ("Monthly payments to MA organizations reflect all beneficiaries with an effective enrollment in the MA plan in question for the month for which payment is made, including those whose enrollment was effective prior to that month, and those for whom enrollment is effective as of that month.").

¹³⁷ "Report to Congress: Risk Adjustment in Medicare Advantage," *Centers for Medicare & Medicaid Services*, December 2021 ("CMS, Report to Congress: Risk Adjustment in Medicare Advantage"), p. 3, available at <https://www.cms.gov/files/document/report-congress-risk-adjustment-medicare-advantage-december-2021.pdf>.

¹³⁸ CMS, Report to Congress: Risk Adjustment in Medicare Advantage, pp. 3–4.

year such as a serious accident requiring hospitalization. In this hypothetical, the MA plan would likely incur more expenditures associated with this enrollee's care than it would receive in payment from CMS that year.¹³⁹

70. This example illustrates why paying MA plans a fixed amount per enrollee creates a system in which MA plans assume financial risks even after CMS adjusts payments for predicted health care expenditures: this happens because actual health care expenditures can be different from predicted expenditures. That is, because enrollee expenses are not perfectly predictable and can deviate substantially from the prediction, an MA plan may not receive sufficient funds to cover its costs. This is one reason why it is particularly important that insurers are properly compensated for the risks they bear when providing insurance to Medicare enrollees.

B. CMS Uses Risk Adjustment to Ensure that Payments to MA Plans Account for the Individual Risk of Each Enrollee within the Plan

71. Payments made by CMS to MA plans reflect an estimate of future health care expenditures for the plan's enrollees, where the prediction is based on what these enrollees would cost if they were enrolled in FFS Medicare and takes into account geographic variation in costs.¹⁴⁰ These estimates are not the same for each enrollee because enrollees' expected health care expenditures vary due to differences in health status and demographics. Not surprisingly, sicker individuals are more likely to incur greater health care expenditures relative to healthier individuals,¹⁴¹ just as older individuals are more likely to incur greater health care expenditures relative to younger ones.¹⁴² As explained in Section V.C, risk adjustment is the process by which payments to MA plans are adjusted to account for the risk of future health care expenditures of

¹³⁹ MA plans consider the risk profile of the plan's population as opposed to each individual enrollee. This means that an MA plan does not consider the financial risk of taking on one enrollee, but of taking on the pool of enrollees that it insures. See "Actuarial Bid Training: Introduction to Bidding," available at [Introduction to Bidding.pdf](#) when accessing "Actuarial Bid Training (ZIP)" at "Actuarial Bid Training," *Centers for Medicare & Medicaid Services*, modified September 6, 2023 ("CMS, Actuarial Bid Training: Introduction to Bidding"), p. 6 ("Projected costs that are based on actual plan experience must reflect the risk profile of that plan's population"), available at <https://www.cms.gov/medicare/payment/medicare-advantage-rates-statistics/actuarial-bid-training>.

¹⁴² Jared Ortaliza, et al., "How do health expenditures vary across the population," *Peterson-KFF Health System Tracker*, November 12, 2021, available at <https://www.healthsystemtracker.org/chart-collection/health-expenditures-vary-across-population>.

enrollees. In its current form, risk adjustment is based on health care diagnoses and certain demographic variables, all of which are associated with different expected health care expenditures.¹⁴³

72. A central goal of risk adjustment is to ensure that insurers receive proper compensation for the risk they bear in paying for the health care expenditures that their particular pool of enrollees will incur.¹⁴⁴ Without risk adjustment, insurers may be exposed to unacceptable risks and may not have sufficient funding to cover all of the health care expenditures associated with the sicker or older beneficiaries enrolled in a plan. Risk adjustment is intended to compensate insurers for covering beneficiaries who are expected to have high health care expenditures, for example due to poor health, so that insurers will not avoid covering such beneficiaries.¹⁴⁵

73. At a high level, CMS performs the risk adjustment process by first modeling the cost of various demographic characteristics and health conditions using data from FFS Medicare to estimate the “dollar coefficients” and “relative factors” of these components. Next, CMS applies the relative factors from the model to data from the MA plans on enrollee demographic characteristics and health conditions to arrive at MA patient risk scores. In this section, I describe these components in more detail, including providing information about the model, the relative factors obtained from the model, the information used from enrollees, and the process to estimate the risk scores for MA enrollees. Then, I provide an illustrative example showing how these components fit together.

¹⁴³ CMS, Medicare Managed Care Manual Chapter 7, §§ 70.1, 70.2; MedPAC, Report to the Congress, pp. 432–433.

¹⁴⁴ Hornsby Deposition, pp. 51:16–52:4 (“Q And CMS knew when it was creating the HCC model that it was creating incentives for MAOs to find and report diagnoses that were supported by the medical records, right? A The point of choosing an additive model is to pay an MA more for people with complex medical conditions who are sicker. That’s the point; because they do have more diagnoses and because they’re sicker. Therefore, they – the MAO should be paid more for those individuals. And conversely, to pay less for the people who really have very few diagnoses or – or just very non-serious conditions. That’s the – that’s the point of an additive model.”).

¹⁴⁵ Hornsby Deposition, p. 53:16–20 (“My – the testimony – CMS’ position is that this model is meant to encourage MAOs to enroll sicker beneficiaries and care for them, and then CMS would like to pay them for – more for those sicker beneficiaries. That’s CMS’ view.”); MedPAC, Report to the Congress, p. 432 (“The purpose of risk adjustment is to ensure that plans are adequately and fairly compensated for treating all categories of enrollees—those with high medical costs as well as those with less health care utilization. If the risk-adjustment system is flawed, misaligned incentives could result in ‘favorable selection,’ in which plans have an incentive to attract certain types of beneficiaries and avoid enrolling others. Plans can achieve unwarranted profits if the risk-adjustment system overpays for some enrollees and underpays for others.”).

1. The CMS-HCC Regression Model and the Relative Factors

74. Payments to MA plans are based on estimates of the costs associated with various demographic characteristics and health conditions in the FFS Medicare population. The model CMS used to estimate the costs associated with various demographic characteristics and health conditions is called the hierarchical condition category (“CMS-HCC”) model. The CMS-HCC model estimates the average Medicare Part A and Part B costs associated with various demographic characteristics and health conditions.¹⁴⁶ In particular, the model uses data from enrollees in FFS Medicare (“FFS data”) to estimate the contribution of certain demographic characteristics (e.g., age, gender, Medicaid enrollment, and disability status) and certain health conditions to the observed health care expenditures in FFS Medicare.¹⁴⁷ The model is considered to be a multivariate regression model because it relates a dependent variable (here Medicare Part A and B expenditures) to *multiple* explanatory variables (here demographic characteristics and health conditions) and aims to isolate the incremental contribution of each of these factors to the dependent variable.¹⁴⁸ The model is prospective, meaning that the demographic and health conditions of one calendar year are used to predict Medicare Part A and B expenditures of the enrollee in a subsequent calendar year.¹⁴⁹

75. CMS estimates the CMS-HCC model using data from beneficiaries enrolled in FFS Medicare.¹⁵⁰ These FFS data include information on expenditures for Parts A and B benefits for the enrollee, enrollee demographic information (such as age, gender, Medicaid status, and disability status), and enrollee health conditions.¹⁵¹ In order to measure and identify health conditions of FFS Medicare enrollees, CMS uses the diagnosis codes associated with health care services rendered to these enrollees, which are reported to CMS on claims from medical

¹⁴⁶ CMS estimates multiple regression models for different sub-populations of Medicare beneficiaries that CMS anticipates have substantively different health care expenditures. For example, CMS estimates separate regression models for Medicare beneficiaries who live in the community, who live in long-term institutionalized settings, who are new enrollees, or who have end-stage renal disease. See CMS, Medicare Managed Care Manual Chapter 7, §§ 70.2, 70.3.

¹⁴⁷ From here on, when I discuss health care expenditures in the context of the CMS-HCC regression model, I am referring to Medicare Part A and Part B expenditures.

¹⁴⁸ CMS, Medicare Managed Care Manual Chapter 7, § 70.1.

¹⁴⁹ MedPAC, Report to the Congress, p. 433.

providers.¹⁵² Diagnosis information from medical providers is stipulated using diagnosis codes from the International Classification of Diseases (“ICD”),¹⁵³ which defines more than 10,000 unique diagnosis codes.¹⁵⁴ Rather than using all of these individual diagnosis codes directly in the regression model, CMS groups these codes into roughly 200 different hierarchical condition categories (“HCCs”) and uses a subset of those HCCs within the model.¹⁵⁵ These HCCs are broad groups of diagnosis codes “based on similar clinical characteristics and severity, and cost implications.”¹⁵⁶

¹⁵² CMS, Medicare Managed Care Manual Chapter 7, § 70.1.

¹⁵³ ICD codes are the medical standard used to classify medical conditions and procedures. See “CMS and AMA Announce Efforts to Help Providers Get Ready for ICD-10,” *Centers for Medicare & Medicaid Services*, July 6, 2015, available at <https://www.cms.gov/Medicare/Coding/ICD10/Downloads/AMA-CMS-press-release-letterhead-07-05-15.pdf>. For example, the Medicare Provider Analysis and Review Hospital Stay File, which comprises inpatient hospitalization and skilled nursing facility claims, includes “up to 10 ICD-9-CM diagnoses and 6 ICD-9-CM procedures associated with each hospital or [skilled nursing facility] stay.” The Outpatient File, which comprises “claims from institutional outpatient providers,” likewise includes ICD-9-CM diagnosis and procedure codes, though “the reporting of these codes is sporadic.” See “Analytics Issues in Using the Medicare Enrollment and Claims Data Linked to NCHS Surveys,” *National Center for Health Statistics, Office of Analysis and Epidemiology*, December 3, 2012 (“NCHS, Analytic Issues in Using the Medicare Enrollment and Claims Data”), pp. 8–9, available at https://www.cdc.gov/nchs/data/datalinkage/cms_medicare_analytic_issues_final.pdf.

¹⁵⁴ See 2022 Midyear_Final ICD-1-CM Mappings.xlsx when accessing “2022 Midyear Final ICD-10 Mappings (ZIP),” at “2022 Model Software/ICD-10 Mappings,” *Centers for Medicare & Medicaid Services* (“CMS, 2022 Midyear Final ICD-10 Mappings”), available at <https://www.cms.gov/medicarehealth-plansmedicareadvtspecratestatsrisk-adjustors/2022-model-softwareicd-10-mappings>; Hornsby Deposition, pp. 184:14–15 (“There are 15,000 ICD-9 codes. There are about 3,000 in the payment model.”). See also, Deposition of Kathleen O. Baker (UnitedHealth), May 30, 2023 (“Baker Deposition”), pp. 20:6–13, 223:16–18 (“There’s thousands – tens of thousands of diagnosis codes. About 15,000 map to HCC.”).

155 In the CMS-HCC model used prior to 2011, CMS included only 70 out of 177 (or more) possible HCCs, while the model used in 2020 included 86 out of 204 possible HCCs. CMS, Report to Congress: Risk Adjustment in Medicare Advantage, pp. 14, 17, 19; “Advance Notice of Methodological Changes for Calendar Year (CY) 2011 for Medicare Advantage (MA) Capitation Rates, Part C and Part D Payment Policies and 2011 Call Letter,” *Centers for Medicare & Medicaid Services*, February 19, 2010 (“CMS, Advance Notice of Methodological Changes for 2011”), pp. 8, 45, available at <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/Downloads/Advance2011.pdf>. See also Hornsby Deposition, pp. 183:13–17 (“The original CMS-HCC model assigned all diagnosis codes to an HCC. And then subsequently, CMS developed a payment model, and the payment model has a smaller subset of HCCs.”); Deposition of Biggs Cannon (UnitedHealth), June 6, 2023 (“Cannon Deposition”), pp. 18:8–13, 229:4–10 (“Q Okay. And you have already testified that there’s some – there are some diagnosis codes that do not map to an HCC; correct? [...] THE WITNESS: Not all diagnosis codes map to an HCC in the Medicare Advantage risk adjustment model.”); Baker Deposition, p. 47:2–3 (“About 15,000 ICD-9 codes map to 70-something HCC codes.”). The CMS-HCC model has changed over time, including different HCCs and different interactions between HCCs as regressors, and changing which diagnosis codes correspond to which HCC. For two examples of model changes, see the discussions in the 2011 and 2020 Advance Notices: CMS, Advance Notice of Methodological Changes for 2011 pp. 7–10; “Advance Notice of Methodological Changes for Calendar Year (CY) 2020 for the Medicare Advantage (MA) CMS-HCC Risk Adjustment Model,” *Centers for Medicare & Medicaid Services*, December 20, 2018, available at <https://www.cms.gov/medicare/health-plans/medicareadvtgsspecratestats/downloads/advance2020part1.pdf>.

¹⁵⁶ CMS, Medicare Managed Care Manual Chapter 7, § 70.1. For example, instead of having two different variables in the model for the “unspecified chronic bronchitis” and “interstitial emphysema” diagnoses, CMS groups these two diagnoses into one HCC named “Chronic Obstructive Pulmonary Disease” (“COPD”). The classification of diagnosis codes is exhaustive, so CMS assigns all diagnosis codes to an HCC. See CMS, 2022 Midyear Final ICD-

76. The CMS-HCC regression model estimates the average incremental (Part A and B) costs associated with each HCC.¹⁵⁷ It might be the case that many patients with one condition, say diabetes without complication, also have another condition, say a heart attack (acute myocardial infarction), which are two different HCCs. By using the data on the sum of Part A and B costs, demographics, and HCCs for a large number of FFS Medicare enrollees with various HCCs, the CMS-HCC model can estimate the average incremental Part A and B expenditures for each HCC—in this example the HCC associated with diabetes and the HCC associated with a heart attack. The estimates of the incremental costs associated with each HCC and each demographic trait are called “dollar coefficients.”¹⁵⁸

77. Once CMS estimates the CMS-HCC regression model and obtains dollar coefficient estimates associated with each demographic characteristic and HCC, it then uses the dollar coefficient estimates to calculate what are called “relative factors.” A relative factor measures the incremental predicted health care expenditure for a given HCC or demographic characteristic relative to the average spending per enrollee in FFS Medicare.¹⁵⁹ More specifically, CMS calculates relative factors by dividing the dollar coefficients for the demographic characteristics and HCCs by the average predicted health care expenditures for a FFS Medicare enrollee in a specific year (i.e., the “denominator year”).¹⁶⁰ The relative factors

10 Mappings; “Announcement of Calendar Year (CY) 2023 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies,” *Centers for Medicare & Medicaid Services*, April 4, 2022, p. 127, available at <https://www.cms.gov/files/document/2023-announcement.pdf>; “Announcement of Calendar Year (CY) 2017 Medicare Advantage Capitation Rates and Medicare Advantages and Part D Payment Policies and Final Call Letter,” *Centers for Medicare & Medicaid Services*, April 4, 2016, p. 81, available at <https://www.cms.gov/medicare/health-plans/medicareadvtspeccratestats/downloads/announcement2017.pdf>; Pope et al., *Risk Adjustment of Medicare Capitation Payments*, pp. 119–141, Figure 3; Baker Deposition, pp. 43:18–44:10 (“Q [...] HCC refers to hierarchical condition categories; is that right? A Yes. Q Okay. And what are hierarchical condition categories? A They’re the risk adjustment disease categories related for risk adjustment. Q Okay. And they’re used in the CMS HCC model to determine risk adjustment payments, correct? [...] THE WITNESS: They are used to determine appropriate payment to health plans.”); Cannon Deposition, pp. 222:24–223:6 (“Q What is a hierarchical condition category? [...] THE WITNESS: Generally speaking, within Medicare Advantage CMS creates a mapping list of diagnosis codes and HCCs, and those HCCs are how they track conditions that are present for a given Medicare Advantage beneficiary.”).

¹⁵⁷ CMS, Medicare Managed Care Manual Chapter 7, § 70.1.

¹⁵⁸ CMS, Medicare Managed Care Manual Chapter 7, § 70.1. I recognize that the coefficients from the CMS-HCC model represent correlations (or associations) and do not necessarily capture the causal impact of each HCC on Medicare expenditures. Despite this, I subsequently use causal language to describe the coefficients and relative factors, which is consistent with CMS’s description of them.

¹⁵⁹ CMS, Medicare Managed Care Manual Chapter 7, § 70.1.

¹⁶⁰ Over time, CMS changes which years of FFS Medicare enrollees’ data are used to estimate the regression coefficients of the CMS-HCC model. This process is known as re-calibration. See CMS, Medicare Managed Care Manual Chapter 7, § 70.1.

are used along with information from the MA plan enrollees to calculate MA enrollee risk scores, as described next.

2. Using MA Plan Patient Data to Calculate MA Risk Scores

78. After CMS calculates the relative factors, it then calculates a “risk score” for each MA enrollee. The risk score of a specific MA enrollee depends on their demographic characteristics (e.g., age, sex, Medicaid enrollment, and disability status) and HCCs (e.g., dementia with complications (HCC51), congestive heart failure (HCC85), diabetes without complication (HCC19)).¹⁶¹ To calculate the risk score, CMS receives data from MA plans regarding diagnosis codes and demographic information for all its plan enrollees.¹⁶² For each enrollee, CMS first determines the associated HCCs, and then sums the relative factors associated with their HCCs as well as the relative factors associated with their demographic characteristics.¹⁶³ The enrollee’s risk score is therefore equal to the sum of all of their relative factors.¹⁶⁴

79. CMS uses the enrollee’s risk score in calculating the payment to the MA plan for each enrollee, such that all else being equal, payments will be higher for MA enrollees with higher risk scores and lower for enrollees with lower risk scores.¹⁶⁵ Exhibit 2 summarizes how CMS

¹⁶¹ MedPAC, Report to the Congress, p. 432; CMS, Report to Congress: Risk Adjustment in Medicare Advantage, Table 5-20a, pp. 80–83.

¹⁶² CMS, Medicare Managed Care Manual Chapter 7, §§ 20, 40, 120.3.2.

¹⁶³ CMS, Medicare Managed Care Manual Chapter 7, Table 2.

¹⁶⁴ See Limmer Deposition, pp. 66:9–68:7 (“Q The third bullet refers to a term ‘risk scores.’ What are the risk scores? Or what does the term ‘risk score’ refer to? A Risk scores are numerical calculations that provide a gauge or a value related to the – to individual beneficiaries; so its members, you know, seeking health care. And it’s related to their – their health status. So the degree to which the cost of their health care will – would be. Where 1.0 is representing an average risk, a number greater than 1.0 is representing someone that has potentially greater costs than the average, and under 1 is less than average. Q And just to be precise, you said it reflects the health status? As stated here, it reflects both the health status and the demographics characteristics of a beneficiary, correct? A The risk score is calculated from various factors, including demographics and health status. And I thought that you were asking, like, what it reflects in terms of – it reflects expected costs or projected costs relative to these – these factors. Q Right. And so the higher the risk score for a beneficiary, the more costly they’re likely to be compared to an average beneficiary? A Correct. Q And to obtain an individual beneficiary’s risk score, one would add up the values that the risk model has calculated as the appropriate values for each of the health conditions and demographic statuses for that beneficiary, correct? A It would be based on the form and processes defined in the risk model. I think – so if that – Yes, so if that model has various factors, numerical factors, then that are added together, then based on the – and there’s – there’s a lot of different categories, right? There’s – there’s, you know, all the demographic categories, all the health status categories. But basically, you go through the specifications that are laid out for the model, and you compile that – that final numerical number.”).

¹⁶⁵ MedPAC, Report to the Congress, p. 413.

calculates MA enrollee risk scores. Details of how risk scores influence payments to MA plans are discussed in Section VII.C.

Exhibit 2
How Risk Scores Are Calculated

Source: MedPAC, Report to the Congress; CMS, Medicare Managed Care Manual Chapter 7.

Note: For a given MA plan enrollee, the risk score is the sum of the relative factors that apply to that enrollee.

3. Illustrative Example of Calculating Relative Factors and Risk Score for Hypothetical Enrollee

80. Exhibit 3 below shows the components of the risk score calculation for a hypothetical enrollee. The enrollee is a male in the 70–74-year-old age bracket who has two HCCs—diabetes with chronic complications (HCC 18) and acute myocardial infarction (i.e., a heart attack)

(HCC 86).¹⁶⁶ The example in Exhibit 3 is adopted from a CMS “clinical vignette” that is based on the CMS-HCC model used in 2020.¹⁶⁷

81. The CMS-HCC model estimates dollar coefficients associated with gender and age categories, which reflect the average Part A and B expenditures for someone in each of these categories (putting aside any particular health conditions that person may have). In the example, the coefficient associated with being a male aged 70 to 74 years is \$5,615. The dollar coefficient from the CMS-HCC model associated with HCC 18 (diabetes with chronic complications) is \$3,181 and the coefficient associated with HCC 86 (acute myocardial infarction) is \$3,534. These dollar coefficients are shown in Exhibit 3.

82. To arrive at the relative factors, CMS normalizes the dollar coefficients by dividing each dollar coefficient by the average per capita predicted health care expenditure for beneficiaries in FFS Medicare in the denominator year, as described earlier. As shown in Exhibit 3, the relative factor for a 70–74-year-old male is calculated as 0.600 ($\$5,615 / \$9,365$). Similarly, the relative factor for HCC 18 (diabetes with chronic complications) is 0.340 ($\$3,181 / \$9,365$) and for HCC 86 (acute myocardial infarction) it is 0.377 ($\$3,534 / \$9,365$).

83. This individual’s risk score is therefore 1.317, calculated by summing the three relative factors.

¹⁶⁶ The HCC for heart attack is only relevant the year in which the heart attack occurs. CMS coding guidelines indicate that the ICD-10 code for acute myocardial infarction may be used with four weeks of the event. See “Hierarchical Condition Category Coding,” *American Academy of Family Physicians*, available at <https://www.aafp.org/family-physician/practice-and-career/getting-paid/coding/hierarchical-condition-category.html> (“Risk adjustment scores reset every year. Practices need to report active diagnoses annually, even chronic conditions.”); “ICD-10-CM Official Guidelines for Coding and Reporting,” *Centers for Medicare & Medicaid Services*, available at <https://www.cms.gov/Medicare/Coding/ICD10/Downloads/2020-Coding-Guidelines.pdf>. (“For encounters occurring while the myocardial infarction is equal to, or less than, four weeks old, including transfers to another acute setting or a postacute setting, and the myocardial infarction meets the definition for “other diagnoses” (see Section III, Reporting Additional Diagnoses), codes from category I21 may continue to be reported. For encounters after the 4 week time frame and the patient is still receiving care related to the myocardial infarction, the appropriate aftercare code should be assigned, rather than a code from category I21. For old or healed myocardial infarctions not requiring further care, code I25.2, Old myocardial infarction, may be assigned.”)

¹⁶⁷ CMS, Report to Congress: Risk Adjustment in Medicare Advantage, pp. 14, 21; “Advance Notice of Methodological Changes for Calendar Year (CY) 2020 for Medicare Advantage (MA) Capitation Rates, Part C and Part D Payment Policies and 2020 Draft Call Letter,” *Centers for Medicare & Medicaid Services*, January 30, 2019, pp. 38, 41, available at <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvgtgSpecRateStats/Downloads/Advance2020Part2.pdf>; “Announcement of Calendar Year (CY) 2020 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies and Final Call Letter,” *Centers for Medicare & Medicaid Services*, April 1, 2019 (“CMS, Announcement of 2020 Medicare Advantage Capitation Rates”), p. 81, available at <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvgtgSpecRateStats/Downloads/Announcement2020.pdf>. The CMS-HCC model used in 2020 was estimated using 2014 diagnostic data and 2015 spending data, and was normalized using 2015 as the denominator year.

84. By construction, the average risk score is 1.0 for the FFS Medicare population used to estimate the relative factors.¹⁶⁸ As such, a FFS Medicare enrollee with an “average health status” has a risk score of 1.0.¹⁶⁹ The hypothetical individual in the example with a risk score of 1.317 has demographic characteristics and HCCs associated with higher than average health risk, as is evidenced by the fact that their risk score is greater than 1.0.

Exhibit 3
Hypothetical Example of Calculating a Risk Score

Demographics and health conditions	Dollar Coefficient [a]	Average per capita predicted expenditure per year [b]	Relative factors [c] = [a] ÷ [b]
1. Male, age 70–74	\$5,615	\$9,365	0.600
2. Diabetes with chronic complications (HCC 18)	\$3,181	\$9,365	0.340
3. Acute myocardial infarction (HCC 86)	\$3,534	\$9,365	0.377
Risk score			1.317

Source: CMS, “Report to Congress: Risk Adjustment in Medicare Advantage,” pp. 20–22; CMS, Announcement of 2020 Medicare Advantage Capitation Rates, p. 81.

Note: This table is based on the “clinical vignette” hypothetical example from CMS. The Dollar Coefficients [a] are from the Version 24 CMS-HCC model for the Full Benefit Dual Aged community segment, as estimated using 2014 data on diagnoses and 2015 data on expenditures provided in the source. Numbers in this table are used for illustrative purposes.

C. CMS’s Payments to Medicare Advantage Plans Are Based on Enrollee Risk Scores and Account for Plan Quality

85. In this section, I explain how CMS’s payments to MA plans relate to the risk scores of the plans’ enrollees as well as to the quality of the plans. Specifically, CMS compensates MA plans using a methodology that compares a CMS benchmark against a bid from the MA plan. This methodology also incorporates enrollee risk scores and payment adjustments to reward plans for providing high-quality services. This payment methodology is described next.

¹⁶⁸ CMS, Medicare Managed Care Manual Chapter 7, §§ 70.1, 70.5.1. When the model is used to predict risk scores for years other than the denominator year, a normalization factor for each year is calculated so that the average FFS Medicare enrollee gets a risk score of 1.0 in subsequent years. See CMS, Medicare Managed Care Manual Chapter 7, § 90.

¹⁶⁹ “Average health status” in this context includes both the health conditions and the demographic factors associated with health. For example, to the extent being in an older age group and being male is associated with greater health costs than the Medicare population as a whole, an older male enrollee’s risk score will reflect the health risks associated with his demographics.

86. Payments from CMS to MA plans depend on a benchmark, which CMS calculates for each county, and which serves as a baseline for payments to MA plans.¹⁷⁰ The benchmark is based on the average expected health care expenditures for a resident of the county with average health status (i.e., a risk score of 1.0) in FFS Medicare.¹⁷¹ This benchmark factors in average per capita Part A and Part B monthly expenditures from FFS Medicare beneficiaries residing in the county.¹⁷² By creating a benchmark for each county, CMS pays MA plans in a way that accounts for differences in health care expenditures and utilization across different geographic regions. For example, in 2023, the benchmark in Wrangell, Alaska—a county with relatively high costs and/or high utilization—is \$1,468.31; the benchmark in Miami-Dade, Florida is \$1,105.92; while the benchmark in Marshall, Iowa—a relatively low cost and/or low utilization county—is \$936.54.¹⁷³ This means that, all else equal, an MA plan in Wrangell, Alaska or Miami-Dade, Florida will be paid more per enrollee than an MA plan in Marshall, Iowa.

87. Payments from CMS to MA plans also incorporate adjustments that reward plans for providing high-quality services through what is known as “star ratings.”¹⁷⁴ CMS created the star ratings system to measure plan quality and incentivize insurers to offer high-quality plans, as

¹⁷⁰ Limmer Deposition, pp. 52:6–53:7 (“Q So the phrase ‘release of MA Rate Book,’ what is the MA Rate Book? A The MA Rate Book is – it’s basically a compilation of the various rates that CMS would pay for – for individuals that enroll in the Medicare Advantage Program. So those are – they vary across the country by geographic area. And each – each area that – that’s represented in that rate book has a unique rate. Q And those are generally by county, correct? A Correct, by county. Q And the county rate, is that also sometimes called a benchmark? A Yes. Those – those two terms are similar. Q And the benchmark that’s published in the MA Rate Book by county, is it – is it accurate to say that it’s a – a standardized benchmark? A It is standardized for risk. Yes. Basically, yes, it’s a standardized benchmark, correct. Q And so what that means, it’s the benchmark set for a 1.0 population, correct? A Yes.”).

¹⁷¹ MedPAC, Report to the Congress, p. 419.

¹⁷² The counties are organized into quartiles based on this average FFS Medicare spending. “The highest spending quartile of counties has benchmarks set at 95 percent of local FFS Medicare spending. The next highest spending quartile of county benchmarks is set at 100 percent of FFS Medicare spending, followed by the third highest quartile set at 107.5 percent of FFS Medicare spending. The lowest spending quartile has benchmarks set at 115 percent of local FFS Medicare spending. (U.S. territories are treated like counties in this low-spending quartile.) Counties can move among quartiles from year to year and in doing so receive a blended quartile factor; for example, a county moving from the 100 percent quartile in 2021 to the 107.5 percent quartile in 2022 would have a blended rate of 103.75 percent.” See MedPAC, Report to the Congress, pp. 420–421, 455.

¹⁷³ See CountyRate2023.csv when accessing “2023 MA Rate Book (ZIP),” at “2023,” *Centers for Medicare & Medicaid Services*, available at <https://www.cms.gov/medicarehealth-plansmedicareadvgtgspecratestatsratebooks-and-supporting-data/2023>.

¹⁷⁴ See Jeannie Fuglesten Biniek, et al., “Spending on Medicare Advantage Quality Bonus Payments Will Reach at Least \$12.8 Billion in 2023,” *Kaiser Family Foundation*, August 9, 2023, available at <https://www.kff.org/medicare/issue-brief/spending-on-medicare-advantage-quality-bonus-payments-will-reach-at-least-12-8-billion-in-2023/> (“To encourage Medicare Advantage plans to compete for enrollees based on quality, the Affordable Care Act (ACA) established a quality bonus program that increases payments to plans based on a five-star rating system.”).

well as to provide Medicare beneficiaries with information about the quality and performance of MA plans.¹⁷⁵ The star rating system measures five broad “domains” of plan performance: offering screenings, tests, and vaccines for staying healthy, managing chronic care, enrollee experience, enrollee complaints, and customer service.¹⁷⁶ Plans are rated up to five stars, in half star increments.¹⁷⁷

88. MA plans are incentivized to offer attractive plans to potential enrollees and to perform well on their ratings.¹⁷⁸ There are two financial incentives. First, CMS provides “Quality Bonus Payments” which increase the relevant CMS benchmark (and thus the baseline for payments to MA plans) for plans that realize at least four stars in the star rating system.¹⁷⁹ The second incentive is a higher payment, through a “rebate multiplier,” for MA plans that bid below the benchmark. The rebate multiplier is applied to the difference between the bonus-adjusted benchmark and the bid, and as a result, plans with higher star ratings can receive greater rebate payments. Specifically, the difference between the bid and the benchmark is multiplied by the rebate multiplier, which is a factor equal to 50, 65, or 70 percent, depending on the plan’s star rating.¹⁸⁰ This leads to a rebate payment from CMS, which is also risk-adjusted based on the risk

¹⁷⁵ See MedPAC, Medicare Advantage Program Payment System, p. 1; “Medicare 2022 Part C & D Star Ratings Technical Notes,” *Centers for Medicare & Medicaid Services*, October 4, 2021 (“CMS, Medicare 2022 Part C & D Star Ratings Technical Notes”), p. 1, available at <https://www.cms.gov/files/document/2022-star-ratings-technical-notes-oct-4-2022.pdf>. During the coronavirus public health emergency, CMS relaxed MA quality reporting rules, impacting 2022 star ratings and 2023 payment rates (which are based on 2022 ratings). Some plans that would not otherwise have received quality bonuses in 2023 will receive bonus payments due to the relaxation of reporting rules. See MedPAC, Report to the Congress; p. 446.

¹⁷⁶ CMS, Medicare 2022 Part C & D Star Ratings Technical Notes, pp. 3–4, 10.

¹⁷⁷ CMS, Medicare 2022 Part C & D Star Ratings Technical Notes, p. 3.

¹⁷⁸ Plans rated at four-and-a-half or five stars receive a rebate payment of 70 percent of the difference between the bid and the benchmark. Plans rated at three-and-a-half or four stars, as well as new plans, receive a rebate payment of 65 percent. Finally, plans rated at three or fewer stars receive a rebate payment of 50 percent. See CMS, Advance Notice of Methodological Changes for 2023, Table II-3 on p. 23.

¹⁷⁹ As explained in fn. 172 above, counties are organized into quartiles based on average FFS Medicare spending, with benchmarks set at a certain percentage of local FFS Medicare spending depending on the quartile. For high-rated plans, CMS adds five percentage points to the benchmark percentage. For example, a five-star plan in a county with the lowest spending quartile would have a benchmark set at 120 percent of local FFS Medicare spending (115 percent + 5 percent). By contrast, a low-rated plan within the same county would have a benchmark set at 115 percent of local FFS Medicare spending. See CMS, Advance Notice of Methodological Changes for 2023, pp. 18–20, Table II-2. Quality Bonus Payments originated in 2012 after the Affordable Care Act required CMS to incorporate star ratings into payments to MA plans. See also “Evaluation of the Medicare Quality Bonus Payment Demonstration: Final Report,” *L&M Policy Research*, February 2016, p. 4, available at <https://innovation.cms.gov/files/reports/maqbpdemonstration-finalevalrpt.pdf>.

¹⁸⁰ “Advance Notice of Methodological Changes for Calendar Year (CY) 2023 for Medicare Advantage (MA) Capitation Rates and Part C and Part D Payment Policies,” *Centers for Medicare & Medicaid Services*, February 2, 2022 (“CMS, Advance Notice of Methodological Changes for 2023”), Table II-3 on p. 23, available at <https://www.cms.gov/files/document/2023-advance-notice.pdf>.

score of the plan's enrollees.¹⁸¹ CMS requires the insurer to return these funds to its enrollees in some form, such as by providing supplemental benefits or reducing premiums.¹⁸² Most MA enrollees (71 percent) are in plans with star ratings of four or higher, which means that most MA enrollees are in plans that receive Quality Bonus Payments, as well as higher rebates (if bidding below the benchmark).¹⁸³

89. When proposing a plan for a particular county, MA plans submit a "bid" to CMS that is based on both the benefits (including financial parameters of the benefit structure such as copayments) that the plan will offer its enrollees as well as what the MA plans require as monthly compensation from CMS (based on historical trends).¹⁸⁴ To determine how much to pay the MA insurer for its plan in a particular county, CMS compares this bid against the benchmark.¹⁸⁵

90. MA plans choose both their plan benefits and their bid amount when making an offering. Both of these components can impact an insurer's prediction of future health care expenditures, and MA plans may face tradeoffs between these two components.¹⁸⁶ For example, the plan may choose to offer more benefits, but then could require a higher bid to cover any higher predicted costs. In turn, a particular bid amount would have implications for what benefits the insurer decides to cover.

¹⁸¹ MedPAC, Medicare Advantage Program Payment System, p. 3.

¹⁸² Plans can also allocate some of the rebate towards administrative expenses and margins. See MedPAC, Medicare Advantage Program Payment System, p. 3; MedPAC, Report to the Congress, p. 420.

¹⁸³ Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings.

¹⁸⁴ 42 CFR § 422.254, "Submission of bids," available at <https://www.law.cornell.edu/cfr/text/42/422.254>; Deposition of Melissa Sedor (UnitedHealth), June 29, 2023 ("Sedor Deposition"), pp. 10:8–10, 28:3–31:24; CMS, Actuarial Bid Training: Introduction to Bidding, p. 4.

¹⁸⁵ MA plans can serve one or more counties, and CMS adjusts its payments based on the county or counties in which the enrollees reside. CMS pays local MA plans and regional MA plans slightly differently. Regional plans were created to improve access to Medicare Advantage plans for rural beneficiaries. They can cover statewide or multi-state regions. See MedPAC, Medicare Advantage Program Payment System, p. 1; Meredith Freed, et al., "Medicare Advantage in 2022: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings," *Kaiser Family Foundation*, August 25, 2022, available at <https://web.archive.org/web/20230211090856/https://www.kff.org/medicare/issue-brief/medicare-advantage-in-2022-premiums-out-of-pocket-limits-cost-sharing-supplemental-benefits-prior-authorization-and-star-ratings>. In this section, I focus on local plans, though the methodology for regional plans is conceptually similar. See CMS, Actuarial Bid Training: Introduction to Bidding, pp. 12–14.

¹⁸⁶ CMS, Actuarial Bid Training: Introduction to Bidding, pp. 4–6; Sedor Deposition, pp. 28:3–31:24 ("Q Okay. And then the number you give CMS is what amount of money it needs to cover the benefits it hopes to provide assuming the average risk score is 1; correct? A Correct. The 1.0 bid is the amount of money we would need from CMS assuming the average risk score was 1 to cover the benefits we have planned for that member for each plan.").

91. Insurers compete by offering plans with different attributes.¹⁸⁷ When bidding below the benchmark, plans must use the rebate to provide additional benefits to enrollees, whether that is through reduced cost sharing, reduced premiums, or supplemental benefits, such as dental or vision benefits.¹⁸⁸ Competition between MA plans and the desire to offer these additional benefits may incentivize insurers to place bids below the benchmark. Plans may also offer additional supplemental benefits not financed by the rebate and can charge premiums to enrollees to cover those benefits.¹⁸⁹

92. MA plans cannot submit excessively high bids: they must adhere to CMS policies that limit the maximum bid they are allowed to make above the Medicare benefits they need to cover, mandatory or optional supplemental benefits, and administrative and operational costs.¹⁹⁰ When choosing plan benefits and their bid amount, MA insurers must also consider that CMS limits their profits through the Medical Loss Ratio, or MLR, as discussed in Section V.C above. Because insurers are required to spend at least 85 percent of their premium revenues on patient care, they cannot, for example, charge high premiums without providing correspondingly more generous benefits.

93. Actual payments to an MA plan depend on whether their bid is higher or lower than the benchmark. If the bid is higher, the enrollees must pay a premium, and if the bid is lower, the plans receive a rebate, which as described above, depends on the difference between the benchmark and the plan bid, and on the plan's star rating. CMS uses risk adjustment to account for the fact that some beneficiaries have higher than average costs while others have lower than average costs. The rest of this section explains the scenarios where (1) the bid is equal to or

¹⁸⁷ MA insurers in more competitive markets are incentivized to offer more generous plans to attract beneficiaries. As one study demonstrates, reduced competition among MA insurers may reduce plan generosity. See Daria Pelech, "Paying more for less? Insurer competition and health plan generosity in the Medicare Advantage program," *Journal of Health Economics*, 61, 2018, pp. 77–92.

¹⁸⁸ MedPAC, Report to the Congress, p. 420. See also, Limmer Deposition, p. 149:9–21 ("Q And so I think this is what you were talking about before, which is the plan has to take that rebate amount that it calculated and it has to allocate it between these various categories of what we're calling supplemental benefits; namely, reducing A/B cost sharing, other A/B mandatory supplemental benefits; Part B premium buydown, Part B basic premium buydown, and Part D supplemental premium buydown, correct? A Yes. And those are the only options.").

¹⁸⁹ MedPAC, Report to the Congress, p. 420.

¹⁹⁰ CMS regulates MA plan's "gain/loss margin," or the revenue margin that the MA plan can accrue above the revenue required by the plan to cover Medicare-covered benefits, mandatory or optional supplemental benefits, and costs to cover the administration and operation of the MA bid. The aggregate "gain/loss margin" across an MA insurer's plans cannot be more than 5.5 percent without CMS approval. See "Instructions for Completing the Medicare Advantage Bid Pricing Tools For Contract Year 2023," *Centers for Medicare & Medicaid Services*, February 2022, available at <https://www.cms.gov/files/document/draft-instructions-completing-medicare-advantage-bid-pricing-tools-cy2023.pdf>, pp. 13, 25–27, 31.

higher than the benchmark, and (2) the bid is below the benchmark. These scenarios are also illustrated via numerical examples below.

1. MA Plan Bid Is Equal to or Higher than the Benchmark

94. If the insurer's MA plan bid is equal to or *higher* than the benchmark, CMS sets a monthly enrollee "base rate" equal to the benchmark. This base rate is then adjusted to account for the risk score of the plan's enrollees. When the bid is higher than the benchmark, each enrollee in the plan pays the insurer the same premium,¹⁹¹ which is equal to the difference between the insurer's bid and CMS's benchmark.¹⁹² CMS then makes an additional adjustment to the payment to the MA plan for each enrollee based on their individual risk score and on the MA plan's premium amount. This adjustment is called the "enrollee premium adjustment" and compensates the insurer for any risk it bears from receiving identical (i.e., not risk-adjusted) premiums from individual enrollees.¹⁹³ The sum of the enrollee premium adjustments is zero if the average enrollee risk scores across all enrollees in the plan is 1.0.

95. Exhibit 4 shows an example for the per-enrollee monthly payment that a plan would receive if it bid above the benchmark. Consider a simplified example, where the benchmark is \$1,000. The plan enrolls two individuals, one with a risk score of 0.9, and one with a risk score of 1.1. The plan bids \$1,100 to CMS. Exhibit 4 shows the payment for two different plans, one with a star rating of 3 (Plan Alpha), and one with a star rating of 5 (Plan Beta).

96. Since Plan Alpha has a 3-star rating, it does not qualify for the Quality Bonus Payment, so CMS uses the benchmark (\$1,000) as its base rate. The plan collects \$100 in premium from each enrollee, which is the difference between its bid and the benchmark. For each individual, CMS pays Plan Alpha an amount equal to the base rate multiplied by the individual's risk score, plus or minus any necessary enrollee premium adjustment (the individual premium adjustments are offset in aggregate if the average risk score across all enrollees is 1.0). Thus, for the low-risk individual with risk score 0.9, CMS pays Plan Alpha the risk-adjusted benchmark, \$900 ($\$1,000 \times 0.9$), minus \$10 ($\$100 \times (0.9 - 1)$), the enrollee premium adjustment, for a total of \$890. The

¹⁹¹ This premium is incremental to the Part B premium that all enrollees in Medicare pay (which is \$164.90 per month in 2023). See CMS, 2023 Medicare Parts A & B Premiums and Deductibles; MedPAC, Medicare Advantage Program Payment System, p. 2.

¹⁹² MedPAC, Medicare Advantage Program Payment System, pp. 2–3.

¹⁹³ MedPAC, Medicare Advantage Program Payment System, pp. 2–3.

individual pays a premium of \$100, but the plan will receive \$90 “in premium” for this individual (from the patient and CMS combined) due to the negative premium adjustment. For the high-risk individual with risk score 1.1, CMS pays Plan Alpha the risk-adjusted benchmark, \$1,100 ($\$1,000 \times 1.1$), plus \$10 ($\$100 \times (1.1 - 1)$), the enrollee premium adjustment, for a total of \$1,110. In this case, the plan receives more than the premium paid by the individual, as CMS pays a premium adjustment of \$10. The enrollee premium adjustment means that CMS, not enrollees, pays the risk adjustment associated with the \$100 premium for that enrollee.

97. Plan Beta has a 5-star rating, so it benefits from the bonus-adjusted benchmark. The plan receives a Quality Bonus Payment that increases the benchmark by 5 percent to \$1,050.¹⁹⁴ The plan collects \$50 from each enrollee, the difference between its bid (\$1,100) and the bonus-adjusted benchmark (\$1,050). For each enrollee, CMS pays Plan Beta an amount equal to the bonus-adjusted benchmark multiplied by the individual’s risk score, plus or minus any necessary premium adjustments. So, for the low-risk individual, CMS pays Plan Beta the risk-adjusted and bonus-adjusted benchmark, \$945 ($\$1,050 \times 0.9$) minus \$5 ($\$50 \times (0.9 - 1)$), the enrollee premium adjustment, for a total of \$940. For the high-risk individual, CMS pays Plan Beta the risk-adjusted and bonus-adjusted benchmark, \$1,155 ($\$1,050 \times 1.1$) plus \$5 ($\$50 \times (1.1 - 1)$), the enrollee premium adjustment, for a total of \$1,160.

98. The total payment that Plan Alpha receives from CMS for these two enrollees, with an average risk score of 1.0, is equivalent to twice the benchmark. The payment that Plan Beta receives from CMS is equivalent to twice the bonus-adjusted benchmark.

¹⁹⁴ Counties are organized into quartiles based on average FFS Medicare spending, with benchmarks set at a certain percentage of local FFS Medicare spending depending on the quartile. For high-rated plans, CMS adds five percentage points to the benchmark percentage. For the examples throughout Section VII.C, I assume the plan is in a county in the 2nd highest quartile of FFS Medicare spending, and thus has a benchmark set at 100 percent of local FFS Medicare spending. With the Quality Bonus Payment, this means the bonus-adjusted benchmark is 105 percent of local FFS Medicare spending. See fn. 179 above.

Exhibit 4**Illustration of Medicare Advantage Plan Payment for Plans Bidding Above the Benchmark**

		Plan Alpha Lower Quality Plan, 3 Stars		Plan Beta Higher Quality Plan, 5 Stars	
		Low Risk	High Risk	Low Risk	High Risk
1.	CMS Plan Benchmark	[a]	\$1,000	\$1,000	\$1,000
2.	Plan Star Rating Bonus Percentage	[b]	0%	5%	5%
3.	Quality Bonus Payment	[c] = [a] x [b]	\$0	\$50	\$50
4.	Bonus-Adjusted Benchmark	[d] = [a] + [c]	\$1,000	\$1,050	\$1,050
5.	Bid	[e]	\$1,100	\$1,100	\$1,100
6.	CMS Base Rate	[f] = [d]	\$1,000	\$1,050	\$1,050
7.	Risk Score	[g]	0.9	1.1	1.1
8.	Risk Adjusted Payment	[h] = [f] x [g]	\$900	\$1,100	\$1,155
9.	Enrollee Premium	[i] = [e] - [f]	\$100	\$50	\$50
10.	CMS Enrollee Premium Adjustment	[j] = ([g]-1) x [i]	-\$10	-\$5	\$5
11.	Total CMS Payment to Plan	[k] = [h] + [j]	\$890	\$940	\$1,160
12.	Total Payment to Plan	[l] = [i] + [k]	\$990	\$990	\$1,210

Source: MedPAC, Medicare Advantage Program Payment System; CMS, Advance Notice of Methodological Changes for 2023.

Note: In this example, there are two plans, one with a 3-star rating, and one with a 5-star rating. Each plan has two enrollees, one with a risk score of 0.9, and one with a risk score of 1.1. Since both plans are bidding above the bonus-adjusted benchmark, neither qualifies for rebates.

2. MA Plan Bid Is Lower than the Benchmark

99. If, the insurer's MA plan bid is *lower* than the benchmark, CMS sets the monthly enrollee base rate equal to the bid. The plan enrollees will not have an incremental premium to the Part B premium, and in some cases they may pay a reduced Part B premium.¹⁹⁵ One report indicates that over 7 in 10 MA enrollees pay no incremental premium, indicating that the insurer bids are often at or below CMS's benchmark.¹⁹⁶ CMS also adjusts the base rate to account for the risk scores of the plan's enrollees. In addition, when the MA plan bid is lower than the benchmark, CMS provides the MA plan with a rebate, as explained earlier, which depends on the plan's star rating and is also adjusted based on enrollees' risk scores.¹⁹⁷

100. Exhibit 5 shows an example of the per-enrollee monthly payment that a plan would receive if it bid below the benchmark. As in the previous example, the benchmark is \$1,000 and the plan enrolls two individuals, one with a risk score of 0.9, and one with a risk score of 1.1. Similar to the prior exhibit, Exhibit 5 shows two plans, one with a 3-star rating (Plan Gamma),

¹⁹⁵ MedPAC, Medicare Advantage Program Payment System, p. 3.

¹⁹⁶ Ochieng et al., Medicare Advantage in 2023: Premiums, Out-of-Pocket Limits, Cost Sharing, Supplemental Benefits, Prior Authorization, and Star Ratings.

¹⁹⁷ MedPAC, Medicare Advantage Program Payment System, p. 3.

and one with a 5-star rating (Plan Delta). Plan Gamma has a 3-star rating and does not qualify for a Quality Bonus Payment, so its benchmark is not adjusted. Here, the plans bid \$900. CMS uses the bid as its base rate. For each enrollee, CMS pays Plan Gamma an amount equal to the base rate multiplied by the individual's risk score. So, for the low-risk enrollee with a risk score of 0.9, CMS pays Plan Gamma \$810 ($\900×0.9). For the high-risk individual with a risk score of 1.1, CMS pays Plan Gamma \$990 ($\900×1.1). Since Plan Gamma bids below the benchmark, it also receives a rebate from CMS for each enrollee (which the plan must redistribute to enrollees as additional benefits or as a reduced Part B premium).¹⁹⁸ As a 3-star plan, Plan Gamma's per-enrollee rebate multiplier is 50 percent.¹⁹⁹ For the low-risk individual, the rebate is equal to \$45, the difference between the risk-adjusted bid and the risk-adjusted benchmark, multiplied by the rebate multiplier $[(\$1,000 - \$900) \times 0.9] \times 0.5$. Plan Gamma receives a rebate of \$55 for the high-risk enrollee $[(\$1,000 - \$900) \times 1.1] \times 0.5$.

101. Plan Delta has a 5-star rating, so receives the Quality Bonus Payment. As in the previous example, the benchmark is increased five percent. For each enrollee, CMS pays Plan Delta an amount equal to the base rate (i.e., the bid) multiplied by the individual's risk score. Thus, for the low-risk individual, with risk score 0.9, CMS pays Plan Delta \$810 ($\900×0.9). For the high-risk individual, with risk score 1.1, CMS pays Plan Delta \$990 ($\900×1.1). Plan Delta also receives a rebate from CMS but is eligible for a 70 percent rebate multiplier due to its quality rating.²⁰⁰ For the low-risk individual, the rebate is equal to \$94.50, the difference between the risk-adjusted and bonus-adjusted benchmark and the risk-adjusted bid multiplied by the rebate multiplier $[(\$1,050 - \$900) \times 0.9] \times 0.7$. After a similar calculation, CMS pays Plan Delta \$115.50 as a rebate for the high-risk individual $[(\$1,050 - \$900) \times 1.1] \times 0.7$.

102. The total payment that Plan Gamma receives from CMS for these two enrollees is below twice the benchmark but above twice the bid due to the rebate (average payment of \$950). The total payment that Plan Delta receives from CMS for these two enrollees is above twice the benchmark (average payment of \$1,005) due to the rebate and the Quality Bonus Payment. And because the bid is below the benchmark, enrollees do not pay a premium.

Note: In this example, there are two plans, one with a 3-star rating, and one with a 5-star rating. Each hypothetical plan has two enrollees, one with a risk score of 0.9, and one with a risk score of 1.1. Since both plans are bidding below the bonus-adjusted benchmark, both qualify for rebates.

D. Reporting Complete Diagnosis Information Is Important for Medicare Advantage Insurers

103. As explained earlier in this report and is further detailed above in Sections VII.A–C, enrollees’ diagnosis codes (i.e., ICD codes) affect risk scores, and these affect CMS payments to MA plans. These CMS payments ensure that plans can offer the full array of health care services to plan members. If the diagnosis information that determines payments to MA plans is incomplete, MA plans risk not being reimbursed sufficiently to cover their expected costs, and MA insurers might attempt to avoid providing insurance for those who are very sick. Because of this, MA insurers are incentivized to provide complete enrollee diagnosis information to CMS.²⁰¹ Additionally, having complete information about enrollee health status can be helpful in providing more efficient and/or better care.²⁰² For example, knowing that an enrollee has

²⁰¹ MedPAC, Report to the Congress, p. xxviii (“MA plans have a financial incentive to ensure that their providers record all possible diagnoses: Each diagnosis documented raises an enrollee’s risk score, and higher enrollee risk scores result in higher payments to the plan.”).

²⁰² “Importance of Documentation” *U.S. Department of Health & Human Services, Office of Inspector General*, January 30, 2012, available at <https://oig.hhs.gov/newsroom/oig-podcasts/importance-documentation> (“Good documentation is important to protect your patients. Good documentation promotes patient safety and quality of care. Complete and accurate medical recordkeeping can help ensure that your patients get the right care at the right time. At the end of the day, that’s what really matters.”).

diabetes before they develop significant complications can help MA plans and enrollees better manage care and can lead to better health outcomes.

104. Given these incentives to ensure a complete record of enrollee diagnosis information, MA plans, such as UnitedHealth, often take actions to capture complete diagnosis information for their plan enrollees.²⁰³ For example, MA plans have taken steps to review medical records and report all diagnoses that are supported in the medical record, even those that were not previously reported in claim submissions.²⁰⁴ MA plans have also used home visits to conduct health assessments of enrollees and report diagnoses that are found.²⁰⁵ Without this type of additional review, the plan's information about its enrollees' health conditions may not be complete.

105. MA insurers and FFS Medicare have different incentives concerning the submission of diagnosis codes to CMS. As explained above, MA insurers have an incentive to identify and record all relevant diagnoses so that they can receive adequate compensation for the risk they bear. In contrast, physicians billing to FFS Medicare are compensated by CMS for each procedure performed so long as there is a *single* diagnosis that supports a need for the services provided. Therefore, these physicians do not have the same incentives to submit complete diagnosis information.²⁰⁶ Indeed, information on diagnoses for claims submitted for FFS Medicare enrollees through Medicare Part B can be "sporadic," potentially reflecting these providers' diminished incentive to submit complete information on diagnoses.²⁰⁷

²⁰³ MedPAC, Report to the Congress, p. 437 ("MA plans use several mechanisms that do not exist in FFS Medicare to document diagnoses for their enrollees.").

²⁰⁴ MedPAC, Report to the Congress, p. 437 ("MA plans often identify enrollees with additional HCCs by using an enrollee's historical information (e.g., electronic health records, claims, or risk score data), when it is available, or by identifying likely diagnoses in data that are not used in MA risk adjustment, such as prescription drug data (e.g., a prescription for insulin likely indicates a diabetes diagnosis). Plans then need to ensure that all diagnoses are appropriately documented in the current year to count toward MA payment.").

²⁰⁵ Richard Kronick and Pete Welch, "Measuring Coding Intensity in the Medicare Advantage Program," *MMRR*, 4(2), 2014 ("Kronick and Welch, Measuring Coding Intensity"), p. E3; MedPAC, Report to the Congress, p. 438.

²⁰⁶ Kronick and Welch, Measuring Coding Intensity, p. E3 ("If, for example, a FFS patient with quadriplegia and a urinary tract infection (UTI) has an office visit for treatment of the UTI, the payment to the physician will be no more if both the UTI and quadriplegia are reported on the claim than if only the UTI is reported. Coding guidelines specify that the quadriplegia can legitimately be coded if it contributes to the complexity of care, but unlike the situation for MA plans, in FFS there is no incentive to report more than one diagnosis.").

²⁰⁷ NCHS, Analytic Issues in Using the Medicare Enrollment and Claims Data, p. 9.

106. This difference in incentives to report information on diagnoses led Congress to become concerned about a potential overpayment of MA plans.²⁰⁸ Specifically, in the Deficit Reduction Act of 2005, Congress instructed CMS to measure and adjust for the difference in diagnosis coding patterns between MA plans and FFS Medicare.²⁰⁹ This is explained next.

E. CMS Adjusts the Fixed Payments to MA Plans to Account for Differences in Diagnosis Coding Patterns between MA Plans and FFS Medicare

107. Analyses done by CMS have indicated that there is a difference in coding patterns between MA plans and FFS Medicare. Specifically, CMS observed that risk scores for MA enrollees were growing faster than risk scores for FFS Medicare enrollees.²¹⁰ In the course of its analysis, CMS noted that “we do not assume that the coding pattern differences that we found in our study are the result of improper coding.” Rather, it noted the need for an adjustment in cases where there is a “difference in coding patterns” between MA and FFS Medicare.²¹¹ This difference in coding patterns could be the result, for example, of the stronger incentive to record enrollee diagnosis information in MA when compared to FFS Medicare, as I discussed above in Section VII.D. As a result of this difference in coding patterns, the risk score of a beneficiary in an MA plan could be different when using the diagnosis codes recorded in an MA plan rather than the diagnoses that would be coded for the same beneficiary if they were enrolled in FFS Medicare.

108. As explained by Kronick and Welch (2014), “[i]f, for example, Jane Doe would have a risk score of 1.0 if she were in FFS, the implicit assumption in the design of the MA payment

²⁰⁸ United States Government Accountability Office, “Medicare Advantage: CMS Should Improve the Accuracy of Risk Score Adjustments for Diagnostic Coding Practices,” Report to Congressional Requesters GAO-12-51, January 2012 (“GAO, Report to Congressional Requesters”), available at <https://www.gao.gov/assets/gao-12-51.pdf> (“Policymakers raised concerns that differences in diagnostic coding between MA plans and Medicare FFS could lead to inappropriately high MA risk scores and payments to MA plans.”). See also Kronick and Welch, Measuring Coding Intensity, p. E2 (“Concerns about overpayment as a result of favorable risk selection have confronted the Medicare program throughout the history of Medicare contracting with health maintenance organizations and other private plans.”).

²¹¹ “Announcement of Calendar Year (CY) 2010 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies,” *Centers for Medicare & Medicaid Services*, April 6, 2009 (“CMS, Announcement of 2010 Medicare Advantage Capitation Rates”), p. 20, available at <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvSpecRateStats/Downloads/Announcement2010.pdf>.

system is that she would have the same risk score of 1.0 if enrolled in MA.”²¹² However, due to the differences in coding patterns between MA and FFS Medicare, this assumption may not hold. Thus, the asymmetry of having a higher risk score in MA than the same individual would have in FFS Medicare could lead to payments to MA plans that are too high relative to FFS Medicare.²¹³

109. In response to the different observed coding patterns, in 2010, CMS first implemented a “coding adjustment,” commonly referred to as the “coding intensity adjustment.”²¹⁴ The coding intensity adjustment scales MA enrollee risk scores downward, amounting to an across-the-board reduction in risk-adjusted payments to an MA plan.²¹⁵ The coding intensity adjustment has been approximately 5.9 percent since 2018.²¹⁶ This means that since 2018, CMS has reduced MA risk scores—and therefore an individual enrollee’s payment to an MA plan—by

²¹² Kronick and Welch, Measuring Coding Intensity, p. E4.

²¹³ Hornsby Deposition, pp. 45:21–46:3 (“Q. And when you say that plans should be coding as fee-for-service coding occurs, the payments to plans are correct to the extent that the plans are coding similarly to fee-for-service as opposed to differently from fee-for-service, right? A. That is correct. And if plans code more intensely, then they are being overpaid under the model.”).

See also CMS, Advance Notice of Methodological Changes for 2010, pp. 7, 9; “Announcement of Calendar Year (CY) 2009 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies,” *Centers for Medicare & Medicaid Services*, April 7, 2008, p. 18, available at <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2009.pdf>; Hornsby Deposition, p. 116:10–12 and p. 89:2–11 (“Q. Okay. M—Ms. Hornsby, what was the impetus behind the coding intensity adjustment? A. Congress. Congress passed the requirement in the Deficit Reduction Act of 2005 for CMS to conduct research to determine whether there was more intense coding or a higher volume of coding in the Medicare Advantage program compared to fee-for-service. And if CMS found such a difference, CMS was to develop an adjustment to adjust risk scores for the coding intensity.”).

²¹⁵ The coding intensity adjuster is applied to risk scores for MA enrollees. All MA enrollees risk scores are scaled down by a percentage intended to capture faster increases in the number of diagnoses submitted by MA insurers compared to FFS Medicare providers. See CMS, Advance Notice of Methodological Changes for 2010, pp. 9–10. See also CMS, Medicare Managed Care Manual Chapter 7, § 100.

²¹⁶ The coding intensity adjustment was 5.91 percent in 2018 and has been 5.90 percent since 2019. See Kronick and Welch, Measuring Coding Intensity, p. E4; CMS, Advance Notice of Methodological Changes 2023, p. 60; “Announcement of Calendar Year (CY) 2022 Medicare Advantage (MA) Capitation Rates and Part C and Part D Payment Policies,” *Centers for Medicare & Medicaid Services*, January 15, 2021, p. 105, available at <https://www.cms.gov/files/document/2022-announcement.pdf>; “Advance Notice of Methodological Changes for Calendar Year (CY) 2021 for Medicare Advantage (MA) Capitation Rates and Part C and Part D Payment Policies – Part II,” *Centers for Medicare & Medicaid Services*, February 5, 2020, p. 34, available at <https://www.cms.gov/files/document/2021-advance-notice-part-ii.pdf>; CMS, Announcement of 2020 Medicare Advantage Capitation Rates, p. 5; “Announcement of Calendar Year (CY) 2019 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies and Final Call Letter,” *Centers for Medicare & Medicaid Services*, April 2, 2018, p. 4, available at <https://www.cms.gov/medicare/health-plans/medicareadvtspecratestats/downloads/announcement2019.pdf>; “Advance Notice of Methodological Changes for Calendar Year (CY) 2018 for Medicare Advantage (MA) Capitation Rates, Part C and Part D Payment Policies, and 2018 Call Letter,” *Centers for Medicare & Medicaid Services*, February 1, 2017, p. 28, available at https://www.hhs.gov/guidance/sites/default/files/hhs-guidance-documents/advance2018_119.pdf.

approximately 5.9 percent. CMS performs this adjustment for all payments it makes to MA plans.

110. The minimum coding intensity adjustment has been set by congressional mandate since 2010.²¹⁷ The minimum adjustment was 3.4 percent in 2010–2013, 4.9 percent in 2014, and then was gradually increased until it reached its current level of approximately 5.9 percent in 2018.²¹⁸ Since its inception in 2010, CMS has never increased the coding intensity adjustment by any amount other than the legislative minimum.²¹⁹

111. CMS has stated that its “methodology results in an accurate measure of the coding differential between FFS and MA,” and that it “continually develops its understanding of coding trends and makes an assessment for each payment year regarding the appropriate adjustment based on specific considerations of both coding trends and other market changes.”²²⁰ As noted, CMS set the 2023 coding intensity adjustment at the statutory minimum of 5.9 percent, suggesting that CMS believes this level is the appropriate amount to adjust for any coding differences between MA and FFS Medicare.²²¹

112. In describing the need for the coding intensity adjustment, CMS stated that “MA plans must code the way Medicare Part A and B providers do for risk adjustments to be valid. This means that MA organizations are coding ‘accurately’ when they are coding in a manner similar to fee-for-service coding used on the beneficiaries to whom MA plan enrollees are being compared.”²²² CMS’s use of the coding intensity adjustment to determine payments to MA plans indicates that, when coding practices are distinct between MA plans and FFS Medicare, CMS attempts to restore coding symmetry (or to ensure that “MA organizations are coding ‘accurately,’” as described by CMS).²²³

VIII. Requiring MA Plans to Delete Unsupported Diagnosis Codes without FFS Medicare Doing the Same Would Result in Improper Compensation to MA Plans

113. In this matter, Plaintiffs allege that UnitedHealth “failed to delete in the RAPS system the invalid diagnoses [...] or knowingly and improperly failed to otherwise return to the Medicare Program the overpayments based on the invalid diagnoses.”²²⁴ In this section, I assess the consequences for payments to MA plans of requiring MA plans to remove unsupported diagnosis codes without FFS Medicare doing the same.

114. I first consider the situation in which an MA plan and FFS Medicare have an identical pool of enrollees and identical unsupported diagnosis codes.²²⁵ An identical pool of enrollees means that the MA plan and FFS Medicare have enrollees with the same demographic and diagnosis codes prior to any auditing being done. Identical unsupported diagnosis codes means that the probability that a diagnosis code is unsupported is the same in the MA plan and in FFS Medicare. In this situation, requiring MA plans to delete unsupported diagnosis codes without requiring FFS Medicare to do the same would lead MA plans to be undercompensated relative to FFS Medicare.

115. I then consider situations in which an MA plan and FFS Medicare have different populations or different rates of unsupported codes. I explain that in these situations, requiring MA plans to remove unsupported codes without FFS Medicare doing the same would result in improper compensation to MA plans.

compare the risk scores of MA plan enrollees to other plan enrollees and beneficiaries not enrolled in MA plans, for this comparison to be valid, MA plans must code the way Medicare Part A and B providers do in order for risk adjustments to be valid. This means that MA organizations are coding ‘accurately’ when they are coding in a manner similar to fee-for-service coding used on the beneficiaries to whom MA plan enrollees are being compared.”).

²²⁴ Complaint, ¶ 342.

²²⁵ I understand that in this matter an unsupported diagnosis code is a code that is not supported by the underlying medical records of an enrollee.

A. Requiring MA Plans to Identify and Delete Unsupported Diagnosis Codes Would Result in CMS Undercompensating MA Plans Relative to FFS Medicare when MA Plans and FFS Medicare Have an Identical Pool of Enrollees and Identical Unsupported Diagnosis Codes

1. Defining What It Means for an MA Plan to Be Undercompensated Relative to FFS Medicare

116. I first discuss the situation where MA plans and FFS Medicare have an identical pool of enrollees and identical unsupported diagnosis codes. Although the pool of enrollees and probabilities of unsupported diagnosis codes are unlikely to be identical between a given MA plan and FFS, analyzing the situation in which they are both identical allows one to isolate the impact of deleting unsupported codes in the MA data on payments to MA plans. To understand whether a given policy results in proper compensation to MA plans in this situation, I first introduce the concept of being undercompensated relative to FFS. I define this as follows: MA plans are undercompensated relative to FFS Medicare when MA plans are paid less than what these same enrollees would be expected to cost if they were enrolled in FFS, while also accounting for the plan's MA bid (i.e., accounting for the fact that if a plan's bid is below the benchmark, CMS sets the base rate to be below the benchmark).

117. This definition means that for an insurer that bids at or above the benchmark for a plan with an average risk score of 1.0, an MA plan is undercompensated if it receives less than the benchmark amount, which is the maximum that the MA plan is entitled to receive from CMS for insuring this pool of enrollees. As I explained in Section VII.C, the benchmark is based on the expected health care expenditures that an average enrollee (with a risk score of 1.0) would incur in FFS Medicare (in a given county). Thus, when an MA insurer bids at or above the benchmark, CMS pays the plan the risk-adjusted benchmark, which is equivalent to the total expected cost of treating these same enrollees in FFS Medicare (with identical risk scores). The MA plan would be undercompensated in this scenario if the total payment it received from CMS were less than this total expected cost.²²⁶

²²⁶ MA plans cannot be overcompensated in this scenario, as model coefficients and thus relative factors are constrained to be positive. That is, risk scores for MA enrollees will mechanically decline as MA plans are required to remove codes. See Pope et al., Risk Adjustment of Medicare Capitation Payments, pp. 119–141 at pp. 121–122.

118. When an insurer bids below the benchmark for a plan, determining whether a plan is undercompensated will not be based on a direct comparison to the benchmark. This is because the plan expects to be paid below the benchmark (and thus below expected FFS Medicare costs for the same pool of enrollees) consistent with its bid for an average enrollee. When insurers bid below the benchmark, MA plans are undercompensated if the total payment they receive is less than the amount to which they are entitled, based on the plan's quality rating and the insurer's bid. Note that I apply this definition of undercompensation only to situations where MA plans and FFS Medicare have an identical pool of enrollees and identical probabilities of unsupported diagnosis codes.

119. Examining situations where MA plans and FFS Medicare have an identical pool of enrollees and identical probabilities of unsupported diagnosis codes is consistent with the origins of the CMS-HCC model.²²⁷ First, the basis of the CMS-HCC model is that, for an enrollee, CMS should pay MA plans the expected cost of covering that enrollee in FFS Medicare. For example, the 2003 MMA (described above in Section V.C) increased payments to plans to 100 percent of FFS Medicare costs, rather than 95 percent: "The 100 percent provision ensured that all plans were at least immediately brought to equality with [FFS Medicare]."²²⁸

120. Second, because the model relies on FFS Medicare enrollees to predict expenditures that are associated with each HCC for MA enrollees, it implicitly assumes that, for each HCC, the relative cost to treat enrollees is the same in FFS Medicare and MA plans.²²⁹ This assumption is only true when the distribution of unsupported diagnosis codes (and thus HCCs) is identical in

²²⁷ Gregory Pope, et al., "Principal Inpatient Diagnostic Cost Group Model for Medicare Risk Adjustment" *Health Care Finance Review*, 21(3), 2000 ("Pope et al., Principal Inpatient Diagnostic Cost Group Model"), pp. 93–118 at p. 93 ("The goal of implementing health-status-based risk adjustment for Medicare capitation payments is to fairly compensate the health plans for the expected cost associated with the disease burden of their enrollees.").

²²⁸ As I explained in Section VII.C, when an MA plan submits a bid equal to or higher than the benchmark, CMS pays the plan the expected cost of covering the same beneficiaries (with the same diagnosis codes) in FFS; when plans bid below the benchmark CMS will pay less than this expected cost. See Pope et al., Principal Inpatient Diagnostic Cost Group Model, pp. 93–118 at p. 97 ("The PIPDCG model has been developed and calibrated with data from the traditional Medicare fee-for-service (FFS) program, reflecting the legislative mandate that Medicare capitation be based on 95 percent of what a beneficiary is expected to cost in the FFS program, as it was under the previous AAPCC methodology. Risk adjustment factors developed from FFS data are in this sense consistent with the historical basis of Medicare's capitation payment methodology."); McGuire et al., *Economic History of Medicare Part C*, pp. 289–332 at p. 314.

²²⁹ Pope et al., Principal Inpatient Diagnostic Cost Group Model, pp. 93–118 at p. 98 ("The implicit assumption is that the relative cost of patients with specified levels of disease burden are similar in the FFS and managed care sectors.").

FFS Medicare and MA plans. Thus, the model is unlikely to accurately predict expenditures for MA enrollees unless the distribution of unsupported diagnosis codes (and thus HCCs) is identical in the FFS Medicare and MA populations (so that the incremental cost of an HCC is the same across the two populations).

2. MA Plans Would Be Undercompensated Relative to FFS Medicare If They Were Required to Identify and Delete Unsupported Diagnosis Codes without FFS Medicare Doing the Same when the Enrollee Populations and Unsupported Diagnosis Codes Are Identical

121. As discussed in Section VIII.A.1, when an MA plan has an identical enrollee population and identical probabilities of unsupported diagnosis codes as FFS Medicare, the MA plan would be properly compensated if CMS paid it the amount that the MA plan is entitled to receive based on the bid and the benchmark amount. As I explain below, in this scenario, requiring MA plans to delete unsupported diagnosis codes that result in the removal of HCCs, without making any other changes to CMS's payments to those plans, reduces payments to MA plans for a given enrollee without reducing the expected cost of that enrollee. Therefore, such a requirement would result in CMS undercompensating MA plans with an identical enrollee population as FFS Medicare.

122. Specifically, requiring MA plans to identify and delete unsupported diagnosis codes, while maintaining the coefficients from the CMS-HCC model estimated on FFS data with unsupported diagnosis codes, mechanically reduces payments to MA plans. This is because removing unsupported diagnosis codes would reduce the risk score for each MA plan enrollee.²³⁰ Hence, the total risk-adjusted payment that the MA plan would receive would decrease.

123. On the other hand, the expected costs to CMS of providing care for the identical population as an MA plan with identical diagnosis codes remains unchanged when the MA plan removes diagnosis codes. This is because removing diagnoses recorded for this hypothetical pool of FFS Medicare enrollees does not change their FFS Medicare expenditures in any way. That is, regardless of whether an FFS Medicare enrollee is designated as having a given

²³⁰ As discussed in Section VII.B.1, CMS groups related diagnosis codes into HCCs. Removing unsupported diagnosis codes can remove an HCC code for a patient if the remaining diagnosis codes for the patient in that calendar year do not support inclusion of that HCC.

diagnosis (for example, Type 1 diabetes mellitus without complications²³¹), services were rendered to the FFS Medicare enrollee that CMS paid for and that would factor into expected costs for the enrollee. Put another way, removing diagnosis codes for FFS Medicare enrollees would not change the benchmark against which plans bid.

124. The previous two paragraphs mean that when an MA plan has an identical enrollee population as FFS Medicare with an identical distribution of both supported and unsupported diagnosis codes, requiring that MA plans delete unsupported codes while not requiring CMS to do the same means that the MA plan would be undercompensated relative to FFS Medicare. As explained above, this is because when the MA plan has identical enrollees and an identical distribution of unsupported diagnosis codes as in the FFS data, it should receive as payment (when bidding at or above the benchmark) the total expected cost for the FFS Medicare enrollees. When the MA plan deletes unsupported codes, it receives less than this amount.

125. For clarity of exposition, consider the following example in which the total expected costs for the FFS Medicare population are \$100,000.²³² Then the CMS-HCC model, estimated on an FFS dataset that contains unsupported diagnosis codes, would distribute this \$100,000 across the set of supported and unsupported diagnosis codes to generate relative factors. Now suppose that an MA plan has an identical population with an identical set of both supported and unsupported diagnosis codes as FFS. This MA plan should receive \$100,000 in compensation (assuming it bid the benchmark). Requiring the MA plan to identify and delete unsupported diagnosis codes, without making any additional changes to how CMS pays the plan, mechanically means the plan receives less than \$100,000 (because the risk scores for its enrollees decline when it removes codes, as model coefficients and relative factors can never be negative). Hence, CMS would pay the MA plan less than what CMS would pay for these same enrollees under FFS, and therefore the MA plan would be undercompensated relative to FFS.

²³¹ “ICD-10-CM/PCS MS-DRGv33 Definitions Manual: MDC 10 Endocrine, Nutritional, & Metabolic Diseases & Disorders,” *Centers for Medicare & Medicaid Services*, available at https://www.cms.gov/icd10manual/version33-fullcode-cms/fullcode_cms/P0240.html.

²³² This example is intended to illustrate what it means to undercompensate or overcompensate a MA plan relative to FFS Medicare. As such, it does not consider instances in which MA plans code more intensely than FFS Medicare, as that type of difference in coding patterns is meant to be corrected for by the coding intensity adjuster. See Section VII.E for further discussion.

B. When an MA Plan and FFS Medicare Have Different Pools of Enrollees or Different Probabilities of Unsupported Codes, Requiring MA Plans to Remove Unsupported Codes without FFS Medicare Doing the Same Would Result in Improper Compensation to MA Plans

126. I now discuss situations in which an MA plan and FFS Medicare have different pools of enrollees or have different probabilities of unsupported codes. In these situations, MA plans that are required to remove unsupported codes would be properly compensated when FFS Medicare also removes its unsupported codes. Only when this happens will the coefficients from the CMS-HCC model reflect the true incremental cost of each HCC, resulting in proper compensation when MA plans remove their unsupported codes.

127. CMS has recognized that unsupported diagnosis codes exist in the FFS data. Additionally, I understand that Michael Salve, who has been retained by UnitedHealth in this matter, has conducted an analysis of 2013 FFS data and determined that 31.6 percent of HCCs are unsubstantiated.²³³ Consistent with this, a CMS document from 2009 explains that it is reasonable to expect that the FFS data used to estimate the CMS-HCC model contains unsupported diagnoses.²³⁴ Yet, CMS generally does not audit the FFS data for such unsupported diagnosis codes. Connie Leonard, Director of the Provider Compliance Group at the Center for Program Integrity at CMS, testified that CMS audits less than one percent of FFS Medicare claims.²³⁵ Of the FFS Medicare claims that are subject to a medical record review, diagnosis

²³³ Expert Report of Michael P. Salve, Ph.D., September 29, 2023, § I.

²³⁴ USBP001729882-4 at USBP001729882 (“As a consequence, it is reasonable to expect that there would be some inherent level of unsupported diagnoses in the FFS claims. Thus, that level of unsupported diagnoses would be calibrated into the model. Hence, the MA industry believes that their payments are subject to error inherent in FFS coding patterns.”).

²³⁵ Deposition of Connie Lynn Leonard (CMS), May 26, 2023 (“Leonard Deposition”), pp. 10:15–21, 24:20–25:10 (“Q. So for all of the auditing of fee for service claims that CMS conducts, it’s looking at less than 1 percent of this whole fee for service claim? [...] THE WITNESS: Okay. So from a claim perspective, when we conduct claim review and medical record, when we request medical records, then we typically do review less than 1 percent of all claims.”), p. 200:5–20 (“Q. Okay. And for 99 percent of the claims from which that data comes from, they have not been audited at all by CMS through a medical record review; correct? [...] THE WITNESS: CMS has stated that we only review less than 1 percent of all Medicare fee for service claims. So the majority of the claims in that data sample have not been audited by a medical records review, that is correct BY MR. MARTINEZ: By ‘majority,’ you mean more than 99 percent of the claims; right? A. Give or take 99 percent of the claims, yes.”).

codes are not always reviewed and audited.²³⁶ Thus, the overall rate of unsupported codes in the FFS data is unknown to MA plans.²³⁷

128. The existence of unsupported diagnosis codes in the FFS data affects the payments to MA plans because such unsupported diagnosis codes in the FFS data affect the size of the estimated dollar coefficients and relative factors from the CMS-HCC model. Indeed, a 2009 CMS document notes that “diagnostic error[s] [are] calibrated into the risk adjustment model that formulates MA payment.”²³⁸ This is also supported by CMS’s Addendum to its FFS Adjuster Study (“FFS Adjuster Study Addendum”), as described in more detail in Section IX below, which indicates that the average estimated dollar coefficient in the CMS-HCC model increases when unsupported codes are removed from the FFS data.²³⁹

²³⁶ Leonard Deposition, pp. 59:2–13 (“So just take a step back about how Medicare fee for service reviews. We review claims. Now, each claim has several—could, not all, could have several claim lines. Those lines could have several diagnosis codes. When we conduct medical record review, we’re reviewing that claim. During that medical record, we could or could not, maybe not, make it down to that diagnosis code. We may not. It would depend on the claim.”) and pp. 85:15–86:16 (“Q. So from time to time the government will conduct audits of diagnosis codes in the fee for service data; correct? [...] THE WITNESS: What we will do in the Medicare fee for service program is we will review a claim, the care, some type of benefit and during that review bringing the claim and the claim line and we may actually review the diagnosis code and compare it to the medical documentation in the medical record. [...] Q. In the auditing of claims that the government does, sometimes it will audit diagnosis codes as part of that process, but not always? [...] THE WITNESS: That is correct, that sometimes a claim audit will include a diagnosis code review, and sometimes it will not.”).

²³⁷ See Leonard Deposition, p. 229:2–5 (“[W]e do not calculate a diagnosis code error rate, improper payment rate, percentage of diagnosis codes that were incorrect on the claims. We do not track that in any way.”) and pp. 232:16–233:10 (“Q. So my question then is with that understanding, because CMS doesn’t track this information and doesn’t have this information, am I correct that CMS has not determined what the rate of unsupported diagnosis codes are in the fee for service data that’s been used to calibrate the risk adjustment model? [...] THE WITNESS: CMS does not track the diagnosis code error rates for claims that have been reviewed and presented based on unsupported documentation, and they would not have it before they ran the data to do the risk adjustment model.”).

²³⁸ USBP001729882–4 at USBP001729882 (“In fact, there is a certain level of diagnostic error calibrated into the risk adjustment model that formulates MA payment. The FFS claims from which the CMS-HCC model is estimated are not subject to RADV audit. As such, there is an error rate calibrated into the model, and as a consequence, factored into current payments to MA plans.”). See also DC027431–40 at DC027433 (“Medicare Advantage (MA) payment model (CMS-HCC model) is calibrated on diagnoses from FFS claims data, which contain a level of error due to diagnoses not supported by medical record documentation in FFS.”).

²³⁹ “Addendum to the Fee-For-Service Adjuster Study,” *Centers for Medicare & Medicaid Services*, June 2019, available at [Addendum to the Fee-for-Service Adjuster Study.pdf](#) when accessing “RADV Provision CMS 4185-N4 Data Release June 2019 (ZIP)” at “Medicare Risk Adjustment Data Validation Program Resources,” *Centers for Medicare & Medicaid Services* (“CMS, FFS Study Addendum”), modified September 6, 2023, p. 8, steps (3–6), available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/Medicare-Risk-Adjustment-Data-Validation-Program/Resources> (“ $\bar{b} > \bar{b}$ ”). Note that $\bar{b}$ represents the average estimated dollar coefficient in the CMS-HCC model after auditing the FFS data, and $\bar{b}$ represents the average estimated dollar coefficient before auditing. In the FFS Adjuster Study, CMS applies an Inflated Post-Audit Risk Score (“IPARS”) adjustment to support its claim that unsupported HCC codes in the FFS data do not impact payments to MA plans. As I discuss in Section IX, I disagree with CMS’s use of an IPARS adjustment, and I disagree with CMS’s claim that unsupported codes in the FFS data do not impact payments to MA plans.

129. When an MA plan and FFS Medicare have different pools of enrollees or different probabilities of unsupported codes, requiring an MA plan to remove unsupported codes while failing to also remove unsupported codes from the FFS data used to estimate the CMS-HCC model would result in improper compensation to MA plans. In particular, if unsupported codes are removed from the data submitted by MA plans, proper compensation requires that the relative factors applied to each HCC in the audited MA plan data reflect the true incremental cost of the HCC according to similarly audited FFS data. However, when the CMS-HCC model is estimated on FFS data that contain unsupported codes, this will not be the case. In fact, CMS's FFS Adjuster Study Addendum indicates that the average of the estimated dollar coefficients (and thus relative factors) in the CMS-HCC model increases when unsupported codes are removed from the FFS data.²⁴⁰ CMS also found that for any given HCC, estimating the CMS-HCC model using FFS data with unsupported codes will result in a dollar coefficient that may be larger or smaller than the true incremental costs of the HCC under audited FFS data, depending on the relative likelihood that the HCC is unsupported in the FFS data.²⁴¹ Likewise, the estimated value of the relative factor for a given HCC may be larger or smaller relative to its true value based on audited FFS data. This means that if MA plans are required to remove unsupported codes, the FFS data used to estimate the CMS-HCC model must also remove unsupported codes in order for MA plans to be properly compensated.

130. The resulting impact of estimating the CMS-HCC model using unaudited FFS data versus audited FFS data on payments to the MA plan depends on the pool of enrollees and distribution of unsupported codes in the MA plan data relative to the FFS data. For example, if unsupported codes in the FFS data lead the CMS-HCC model to underestimate the dollar coefficient and relative factor for a particular HCC, and an MA plan has a relatively large number of enrollees for whom this HCC is supported, original payments to the MA plan could have been too low. In

²⁴⁰ CMS, FFS Study Addendum, p. 8, steps (3–6).

²⁴¹ Deposition of Sean Creighton (CMS), October 4, 2022 (“Creighton Deposition, day 2”), pp. 30:17–34:10. (“[...] Q. And going back to that notion of removing from the population the erroneous diagnosis codes so that you have the true population that suffer from the conditions, you would expect the costs, the incremental costs, of caring for that condition to rise? [...] THE WITNESS: That – that has been my expectation. The – our study showed that it was a bit more complicate than that. So, yeah, that’s normally the expectation [...] However, it turns out it’s not, like a lot of statistical stuff, it’s not quite as simple as that. So we found in our studies, sometimes they rise, sometimes they go down. But on—on average what you do know is they’re gonna be different, they’re... You know. So I agree with your initial hypothesis, it was my hypothesis, too. Turns out it’s not true for all conditions across the model. [...])”).

this case, removing unsupported codes from the FFS data and re-estimating the CMS-HCC model on the audited FFS data would lead the dollar coefficient and the relative factor for this HCC to increase. As a result, payments to the MA plan would likely increase because the risk scores of enrollees with this HCC would increase, due to the now higher relative factor from the higher CMS-HCC dollar coefficient (estimated using the audited FFS data) for this HCC. This example demonstrates that in cases where the MA plan and FFS Medicare have different pools of enrollees or different probabilities of unsupported codes, requiring MA plans to remove unsupported codes without FFS Medicare doing the same would result in improper compensation to MA plans.

131. Moreover, in order to determine whether CMS's payments based on unaudited FFS data constitute proper compensation to the MA plan, one would need to determine the extent to which the pool of enrollees and the probabilities of unsupported codes differed between the MA plan and the FFS Medicare population.²⁴² CMS, however, does not track the rate of unsupported codes in the FFS Medicare population.²⁴³ Without this information, neither the MA plan nor CMS can determine whether CMS has properly compensated the MA plan.

IX. CMS's FFS Adjuster Study Is Flawed

132. In February 2012, CMS released a notice presenting the mechanics of its contract-level audits of MA plans known as Risk Adjustment Data Validation ("RADV") audits.²⁴⁴ CMS has described the RADV audits as its "main corrective action for overpayments made to Medicare Advantage organizations [...] when there is a lack of documentation in the medical record to

²⁴² See Deposition of Jonathan D. Morse (CMS), August 17, 2022, pp. 25:15–27:6, 177:22–178:3 ("And so in order to know whether a particular plan would—would have an overpayment or an underpayment problem when you go and remove unsupported codes, you would need to know the distribution of that plan's particular disease and demographic characteristics— A. Right.").

²⁴³ See Leonard Deposition, p. 229:2–5 ("[W]e do not calculate a diagnosis code error rate, improper payment rate, percentage of diagnosis codes that were incorrect on the claims. We do not track that in any way.").

²⁴⁴ "Notice of Final Payment Error Calculation Methodology for Part C Medicare Advantage Risk Adjustment Data Validation Contract-Level Audits," *Centers for Medicare & Medicaid Services*, February 24, 2012 ("CMS, Notice of Final Payment Error Calculation Methodology"), p. 1, available at <https://www.cms.gov/Research-Statistics-Data-and-Systems/Monitoring-Programs/recovery-audit-program-parts-c-and-d/Other-Content-Types/RADV-Docs/RADV-Methodology.pdf>.

support the diagnoses reported for risk adjustment.”²⁴⁵ I note that by describing “corrective action for overpayments,” CMS is using the term “overpayments” to refer to what it considers to be excess compensation to MA plans when MA plans have not deleted any unsupported diagnosis codes.

133. In its notice, CMS stated that it would “apply a Fee-for-Service Adjuster (FFS Adjuster) amount as an offset to the preliminary recovery amount” in the RADV audits.²⁴⁶ The FFS adjuster was intended to account for the fact that the preliminary recovery amount resulting from RADV audits account for unsupported diagnosis codes from only MA enrollees, even though there are also unsupported diagnosis codes in the FFS data that are used in the CMS-HCC model.²⁴⁷ The presence of unsupported diagnosis codes in the FFS data implies that the coefficients from the CMS-HCC model do not accurately measure the incremental cost of HCCs in the FFS data,²⁴⁸ which can result in payments to MA plans that are too low if MA plans are required to remove unsupported diagnosis codes but FFS Medicare is not required to do so. Applying an FFS adjuster would decrease preliminary RADV audit recovery amounts to reflect the presence of unsupported codes in FFS data.²⁴⁹

134. In 2023, CMS adopted a Final Rule which indicated it would not apply an FFS adjuster.²⁵⁰ Prior to adopting this Final Rule, CMS released several documents related to its analysis of the impact of unsupported diagnosis codes in the FFS data on payments to MA

²⁴⁵ CMS Final Rule. See also Deposition of Christopher Gile Bresette (OIG), May 31, 2023, pp. 17:16–18:6, 42:14–25 (“The objective of our audit was to determine whether the diagnosis codes that – that they submitted to CMS complied with federal requirements. Q. And as part of the explanation for why [U.S. Department of Health & Human Services, Office of Inspector General (“OIG”)] did this – this audit, it notes in the second paragraph there that – that OIG was assessing whether MAOs had received improper payments. Is that right? A. If – if an MAO submits incorrect diagnosis, it will lead to improper payments. So – it could lead to improper payments; I clarify.”).

²⁴⁶ CMS, Notice of Final Payment Error Calculation Methodology, pp. 4–5 (“The FFS adjuster accounts for the fact that the documentation standard used in RADV audits to determine a contract’s payment error (medical records) is different from the documentation standard used to develop the Part C risk-adjustment model (FFS claims).”). See also, Deposition of Thomas Kornfield (CMS), March 10, 2022 (“Kornfield Deposition”), pp. 20:21–21:1, 196:23–197:12.

²⁴⁷ See discussion in Section VIII; CMS, Notice of Final Payment Error Calculation Methodology, pp. 1, 4–5.

²⁴⁸ See further discussion in Section IX.B.2.

²⁴⁹ Deposition of Carolyn Kapustij (CMS), August 25, 2023, pp. 14:2–20, 161:5–23 (“Q. Okay. And if a fee-for-service adjuster had been applied to that \$98 million figure, that figure would have been even lower; correct? [...] THE WITNESS: It seems that the fee-for-service adjuster would reduce that amount. [...] Q. Assuming it’s a positive fee-for-service adjuster; correct? [...] THE WITNESS: Correct”) and pp. 214:21–215:5 (“Q. Okay. So if that’s what preliminary means according to CMS, then the recovery amounts that are listed in Exhibit 1187-1. Those recovery amounts are only going to decrease through the application of a fee-for-service adjuster or any appeals process; right? [...] THE WITNESS: That would seem to be the case.”).

²⁵⁰ CMS Final Rule.

plans. In October 2018, CMS put forth a study (the “FFS Adjuster Study”) in which it claimed that applying an FFS adjuster would not be “appropriate.”²⁵¹ Specifically, the study stated that “errors in FFS claims data do not have any systematic effect on the risk scores calculated by the CMS-HCC risk adjustment model, and therefore do not have any systematic effect on the payments made to MA organizations.”²⁵² That is, CMS claimed that unsupported codes in FFS data do not “systematically” impact CMS’s payments to MA plans, and therefore that there is no need for CMS to account for such unsupported codes when assessing whether MA plans were overpaid. In November 2018, CMS released a “Proposed Rule” which included a proposal to not apply an FFS adjuster when assessing potential overpayments to MA plans.²⁵³ CMS subsequently published a technical addendum to the FFS Adjuster Study in 2019,²⁵⁴ and the Final Rule was adopted in 2023.²⁵⁵

135. As I explain in detail below, I disagree with CMS’s conclusion that unsupported diagnosis codes in the FFS data do not have a systematic effect on CMS’s payments to MA plans. CMS’s FFS Adjuster Study exhibits a number of methodological flaws that render it unreliable, and as a result, the Study fails to demonstrate that an FFS adjuster is unnecessary.

136. In this section, I first describe the methodological framework that CMS adopted in the FFS Adjuster Study to evaluate the impact of unsupported codes in FFS data on payments to MA plans. I then describe critical errors in CMS’s methodology, and, as a result, in CMS’s conclusion that unsupported codes in FFS data do not impact payments to MA plans. I then explain why the data that CMS used to calculate the FFS adjuster are inadequate to evaluate the impact of unsupported codes in FFS data on payments to MA plans. Finally, I explain that contrary to CMS’s conclusion, unsupported diagnosis codes in the FFS data likely impact payments to MA plans, and thus an FFS adjuster is necessary.

²⁵⁴ CMS replicated the initial study within this June 2019 addendum (the “FFS Adjuster Study Addendum”), finding results consistent with the initial implementation. See CMS, FFS Study Addendum, p. 1.

²⁵⁵ CMS Final Rule.

A. Overview of CMS Methodology to Estimate the Impact of Unsupported Codes in FFS Data on Payments to MA Plans

137. At a high level, CMS's methodology seeks to understand how removing unsupported codes from the FFS data would impact the dollar coefficients and relative factors estimated by the CMS-HCC model, and as a consequence, the risk scores used to determine payments to MA plans.²⁵⁶ CMS calculates for each MA enrollee the percentage difference between the risk score resulting from the model estimated with audited FFS data relative to the risk score resulting from the model estimated with unaudited FFS data. CMS then calculates the average of these percentage differences across MA enrollees in their study. According to CMS's framework, if this average percentage difference in risk scores is not a "large, positive percentage," then expected payments are not impacted and no FFS adjuster is needed.²⁵⁷ Thus, to evaluate the need for an FFS adjuster, CMS needs to understand how the dollar coefficients and the relative factors from the CMS-HCC model change when the FFS data are audited.

138. Because a comprehensive audit of all diagnosis codes in the FFS data is not feasible, CMS audits the diagnosis codes in only a sample of the FFS data in its FFS Adjuster Study, and then extrapolates the results from the sample to the overall FFS data.²⁵⁸ Using this sample, CMS seeks to implement the following methodology to estimate the impact of removing unsupported codes from the FFS data:²⁵⁹

- First, estimate the probability each HCC is unsupported at the patient level in a given year within the sample.
- Second, use these sample probabilities to estimate the probability that each HCC is unsupported at the patient level in that year for the overall FFS Medicare population.
- Third, apply these estimated FFS Medicare population-wide probabilities to the unaudited FFS data to simulate audited FFS data in which unsupported diagnosis codes are removed.

²⁵⁸ CMS, FFS Adjuster Study Technical Appendix, pp. 6–12.

²⁵⁹ CMS, FFS Adjuster Study Technical Appendix, p. 6–16. For this discussion, I do not address whether the framework used by the CMS FFS Adjuster Study is appropriate.

- Fourth, re-estimate the CMS-HCC model on the simulated audited data to estimate simulated audited relative factors.
- Fifth, compare the implied MA plan risk scores using simulated audited relative factors to the corresponding risk scores using unaudited relative factors from estimating the CMS-HCC model on the original, unaudited FFS data.

139. I now explain some of the critical methodological flaws leading CMS to conclude that unsupported codes in FFS data do not impact payments to MA plans.

B. CMS Uses a Flawed Methodology to Determine Whether an FFS Adjuster Is Necessary

140. In this sub-section, I address two errors that bias CMS's estimate of the impact of unsupported codes in the FFS data on the audited relative factors and the resulting MA risk scores, leading CMS to incorrectly conclude that payments to MA plans are unaffected: (1) CMS incorrectly estimates the beneficiary-level probability that an HCC is unsupported in the FFS data; and (2) CMS inappropriately adjusts for the effects of the auditing process on FFS Medicare costs, despite actual FFS Medicare costs being unaffected. Both of these errors bias CMS's estimate of the average audited relative factors and resulting MA risk scores downwards, and lead to incorrect conclusions regarding the impact of removing unsupported codes from the FFS data on payments to MA plans.

1. CMS's Methodology for Estimating the Probability That an HCC Is Unsupported Is Flawed

141. The FFS Adjuster Study relies on incorrect assumptions to estimate the probability that each HCCs is unsupported (the first two steps in the methodology outlined in Section IX.A).²⁶⁰ As a result, CMS's estimates of these probabilities are unreliable, as are its estimates of the resulting audited dollar coefficients, audited relative factors, and resulting MA risk scores.

²⁶⁰ For clarity of exposition, when I refer to HCCs being unsupported, it means the HCC is unsupported for a patient in a year. In addition, CMS defines an HCC as unsupported when none of the associated claims have a diagnosis code that maps to the HCC and that is supported by the medical record. CMS, FFS Adjuster Study, p. 3 ("The correctness of the status of an HCC in the profile is determined by the presence of at least one claim that both has a diagnosis that maps to that HCC and is supported by medical record documentation. For this reason, the impacts of the unsupported diagnoses in the claims on the model parameter estimates are driven by the number of HCCs in each beneficiary's profile that do not have at least one claim supported by medical record documentation.").

142. To estimate the probability that an HCC is unsupported, CMS relies on a sample from the 2008 Comprehensive Error Rate Testing (“CERT”) data containing 8,630 unique outpatient FFS Medicare claims and the underlying medical records that CMS uses to assess whether the diagnosis codes for each of these claims are supported.²⁶¹ These data do not include all claims for a beneficiary in a year, and thus, CMS cannot directly determine from these data whether an HCC is unsupported for a beneficiary in that year.²⁶² Instead, CMS estimates the probability that a particular HCC is unsupported for a given *claim* (i.e., the “claim-level probability”) by estimating the number of claims that are associated with the HCC but do not support the HCC, as a share of all the claims that are associated with the HCC (i.e., both claims with and without diagnosis codes and medical records that support the HCC).²⁶³

143. CMS uses these claim-level probabilities to estimate the likelihood that each HCC is unsupported for a given beneficiary. Specifically, for each HCC, CMS first estimates the average number of claims that include a diagnosis code within the HCC across beneficiaries. CMS estimates this average using a different dataset, namely a 2004 sample of FFS Medicare beneficiaries and their claims.²⁶⁴ For example, if there were two beneficiaries with diagnosis codes that indicate a particular HCC, one with two claims that have a diagnosis code associated with the HCC and the other with four claims that have a diagnosis code associated with the HCC, then the per-beneficiary average number of claims indicating the HCC would be three. CMS then estimates the probability that an HCC is unsupported at the beneficiary level as equal to the claim-level probability that an HCC is unsupported raised to an exponent equal to the average number of claims per beneficiary indicating that HCC.²⁶⁵ So, for example, if on average each beneficiary has three claims with an HCC, CMS would raise the claim-level probability that the HCC is unsupported to the power of three to account for the fact that the HCC would only be unsupported if all three claims were unsupported.

²⁶¹ CMS, FFS Adjuster Study Technical Appendix, p. 6.

²⁶² I further address issues with the adequacy of CMS’s data in Section IX.C.

²⁶³ CMS, FFS Adjuster Study Technical Appendix, p. 6, Table 2a. CMS provides its estimates of the claim-level probability that an HCC is unsupported in Table 2a of the FFS Adjuster Study Technical Appendix. CMS uses the term “sampled” to refer to the number of sampled claims associated with the HCC and the term “discrepant” to refer to the number of claims associated with the HCC that are unsupported. CMS estimates “%Discrepant” as the percent of “sampled” claims that are “discrepant.”

²⁶⁴ Specifically, CMS uses these data to identify all beneficiaries with claims indicating a given HCC and, among these beneficiaries, calculates the average number of claims indicating that HCC. CMS, FFS Adjuster Study, p. 3; CMS, FFS Adjuster Study Technical Appendix, pp. 9–11.

²⁶⁵ CMS, FFS Adjuster Study Technical Appendix, p. 9.

144. For CMS’s calculation to yield a correct estimate of the probability that an HCC is unsupported at the beneficiary level, two assumptions must hold. First, it must be the case that using the average number of claims per HCC among beneficiaries in the FFS sample data does not bias the calculation of the relevant probability. Second, it must be the case that the probability that a claim has an unsupported HCC is independent across claims within a beneficiary.²⁶⁶ As I discuss below, both of these assumptions likely do not hold, and both can bias downward the probability that an HCC is unsupported in the FFS data.

145. First, CMS’s use of the average number of claims per HCC would lead it to underestimate the probability an HCC is unsupported for a beneficiary.²⁶⁷ Using the average number of claims per HCC among beneficiaries implicitly assumes that every beneficiary with that HCC has the average number of claims. To see why this is not always the case, consider the following stylized example. Suppose that half of the beneficiaries with a given HCC have exactly one claim indicating that HCC and the other half have exactly five claims indicating that HCC. The average number of claims for the HCC among beneficiaries is three. Suppose further that each claim has a 30 percent probability of being unsupported and, for simplicity, that this probability does not vary across beneficiaries and is independent across claims.²⁶⁸ CMS’s approach would estimate that the probability that the HCC is unsupported for a beneficiary is 2.7 percent.²⁶⁹ In reality, the true probability would be much higher. Specifically, the probability of an unsupported HCC is 30 percent for beneficiaries with one claim and 0.243 percent for beneficiaries with five claims.²⁷⁰ Thus, the correct estimate for the probability that a randomly drawn beneficiary has the HCC is the weighted average of these two probabilities, where the weights are the proportions of beneficiaries with the given number of claims indicating the

²⁶⁶ Two events are independent if the occurrence of one event does not affect the probability of the occurrence of the other event. See, e.g., James H. Stock and Mark Watson, *Introduction to Econometrics, Second Edition*, (Boston: Addison Wesley, 2006), p. 34 (“Two random variables X and Y are independently distributed, or independent, if knowing the value of one of the variables provides no information about the other.”).

²⁶⁷ The findings of the Lambert Report also support this assertion. See Julia Lambert, “Actuarial Report on Medicare Advantage FFS Adjuster,” *Wakely*, August 28, 2019 (“Lambert Report”), pp. 26–29.

²⁶⁸ The assumption that each claim has the same probability of being unsupported is unlikely to hold. The probability a claim is unsupported is likely to decrease with the number of claims with a given diagnosis. For example, an individual that only has one claim with a diagnosis code for diabetes is likely to have a higher probability that the diabetes diagnosis is unsupported than an individual with five claims including a diagnosis code for diabetes.

²⁶⁹ $0.3^3 = 0.3 \times 0.3 \times 0.3 = 0.027$.

²⁷⁰ $0.3^1 = 0.3$, and $0.3^5 = 0.3 \times 0.3 \times 0.3 \times 0.3 \times 0.3 = 0.00243$.

HCC. In the example, this weighted average would be 15.12 percent—more than 5 times greater than the estimate derived from CMS’s methodology.²⁷¹

146. This example applies more generally. Specifically, as I describe in the example above, the correct method of calculating the probability that an HCC is unsupported for a beneficiary would use the actual distribution of claims underlying HCCs across beneficiaries instead of just the average number of claims associated with a particular HCC. Mathematically, the correct method will estimate a higher probability that an HCC is unsupported relative to CMS’s use of the average number of claims.²⁷² Likewise, Ms. Lambert, a health actuary retained by UnitedHealth to evaluate the CMS FFS Adjuster Study, demonstrates this flaw in CMS’s calculation.²⁷³ Underestimating the probability that an HCC is unsupported leads to lower estimates of the average audited relative factors,²⁷⁴ and contributes to CMS’s incorrect conclusion that unsupported codes in the FFS data have no impact on payments to MA plans. Thus, this error by CMS leads it to incorrectly conclude that an FFS adjuster is not needed.

147. Second, the probability that a claim does not support an HCC is not independent across claims within a beneficiary or across beneficiaries, and this assumption can also bias downward CMS’s estimates of the beneficiary-level probability that an HCC is unsupported, again biasing the average estimates of the audited relative factors downwards. Whether a claim supports an HCC for a given beneficiary is likely correlated across claims due to the types of diagnoses the beneficiary has and variation in physician coding practices that would similarly affect all claims

²⁷¹ 0.1512 ($0.5 \times 0.3 + 0.5 \times 0.00243$) is the weighted average of 30 percent and 0.243 percent, where the weights correspond to the fraction of beneficiaries with one claim indicating the HCC and five claims indicating the HCC, respectively. In my example, both weights are 50 percent.

²⁷² It is a mathematical fact known as the “Jensen’s Inequality” that raising a probability to the average of k numbers is higher than the average of that probability raised to each of the k numbers. See, for example, Patrick Billingsley, *Probability and Measure, Third Edition*, (New Delhi: Wiley India Edition, 1995), p. 80. To see why, consider two points on the graph of a convex function (an example of a convex function is a U-shaped curve). The average of the function values at those two points is greater than the value of the function at the average of the two points.

²⁷³ Ms. Lambert estimated a beneficiary-level HCC discrepancy rate of 13.716 percent, compared to CMS’s calculation of 2.115 percent. See Lambert Report, pp. 26–29. See also, Letter from Matthew Eyles (AHIP) to Seema Verma (CMS), “RE: Medicare and Medicaid Programs; Policy and Technical Changes to the Medicare Advantage, Medicare Prescription Drug Benefit, Program of All-inclusive Care for the Elderly (PACE), Medicaid Fee-For-Service, and Medicaid Managed Care Programs for Years 2020 and 2021 (‘Proposed Rule’),” August 27, 2019 (“Letter from Matthew Eyles to Seema Verma”), p. 20, available at https://ahiporg-production.s3.amazonaws.com/documents/AHIP_RADV_comments_FINAL_8_27.pdf.

²⁷⁴ CMS, FFS Study Addendum, p. 8, step (6).

for a beneficiary from the same physician.²⁷⁵ For example, if a given physician was systematically less accurate at medical coding than another physician, all of the first physician's claims would be more likely to have unsupported diagnosis codes. Deposition testimony from Thomas Kornfield, who was the Director of Payment Systems at CMS and a former Vice President at America's Health Insurance Plans ("AHIP"), supports this point: "CMS is assuming that [diagnoses are] independent when they probably aren't, meaning a provider that codes an error is probably going to code an error."²⁷⁶

148. Because claim-level probabilities are not independent, CMS cannot simply multiply them to estimate the probability that an HCC is unsupported. This is a fundamental law of probability.²⁷⁷ Instead, CMS would need to estimate how the presence of one unsupported diagnosis for a beneficiary impacts the likelihood that other diagnosis codes are unsupported for that beneficiary. CMS has not done so.

149. To see why this matters, consider the following simple example. There are 100 beneficiaries with a given HCC, and each beneficiary has 2 claims associated with the HCC. Two physicians, doctor A and doctor B, each treat 50 Medicare beneficiaries. Doctor A keeps high-quality medical records, and all of the claims—and thereby the HCCs associated with these claims—for the beneficiaries they treat are supported. By contrast, none of the claims for the beneficiaries treated by doctor B are supported. Thus, the data contain a total of 200 claims: 100 supported claims (i.e., 2 claims for each of doctor A's 50 patients) and 100 unsupported claims (i.e., 2 claims for each of doctor B's 50 patients). The FFS Adjuster Study methodology would estimate a 50 percent probability that a claim is unsupported (i.e., 100 unsupported claims divided by 200 total claims). Furthermore, each beneficiary has 2 claims, so the average number of claims per beneficiary is 2. Thus, the FFS Adjuster Study methodology would estimate a 25 percent probability that the HCC is unsupported for an FFS Medicare beneficiary

²⁷⁵ Correlation in the accuracy of a patient's claims may arise if there are common factors impacting the coding of patients' diagnoses. For example, physician qualities such as experience play a role in coding accuracy and hospitals differ in their rates of diagnosis code accuracy. See Kimberly O'Malley, et al., "Measuring Diagnoses: ICD Code Accuracy," *Health Services Research*, 40(5 Pt. 2), October 2005, pp. 1620–1639 at pp. 1627–1628; Pavani Rangachari, "Coding for Quality Measurement: the Relationship Between Hospital Structural Characteristics and Coding Accuracy from the Perspective of Quality Measurement," *Perspectives in Health Information Management*, 4(3), 2007.

²⁷⁶ Kornfield Deposition, pp. 19:18–21:22, 218:22–25.

²⁷⁷ See, e.g., Morris DeGroot and Mark Schervish, *Probability and Statistics, Fourth Edition*, (Boston: Addison Wesley, 2012), pp. 66–67.

(i.e., claim level probability of 50 percent raised to the power of 2). However, in this example, the actual probability that the HCC is unsupported for an FFS Medicare beneficiary is 50 percent: the HCC is unsupported for the 50 beneficiaries treated by doctor B, out of 100 beneficiaries total. In this example, CMS's methodology underestimates the probability that an HCC is unsupported for an FFS Medicare beneficiary because it fails to take into account potential correlation that claims could be supported (or unsupported) within beneficiaries (because of the systematic difference in coding patterns between doctor A and doctor B). If, as in the example above, CMS underestimates the probability that an HCC is unsupported, CMS's conclusions that the audited relative factors and resulting MA risk scores are unaffected and that an FFS adjuster is unnecessary will be incorrect.

2. No IPARS Adjustment Is Needed, and Its Use Biases the Impact of Unsupported Codes in the FFS Data on Audited Coefficients, Audited Relative Factors, and MA Risk Scores towards Zero

150. In its Addendum to the FFS Study, CMS shows that the removal of unsupported codes from the FFS data impacts the dollar coefficients estimated in its CMS-HCC model.²⁷⁸ However, CMS then makes a fundamental conceptual error—it reasons that “diagnoses cannot soundly be deleted in the CMS-HCC modeling context without making adjustments to account for the bias that the deletion procedure itself creates in expenditures.”²⁷⁹ In other words, CMS states that if it removes diagnosis codes from the FFS data, it also needs to adjust the observed expenditures under FFS Medicare when estimating the CMS-HCC model. Based on this fundamental misconception that FFS Medicare expenditures should be reduced, CMS makes an adjustment to the audited dollar coefficients, called an Inflated Post-Audit Risk Score (“IPARS”) adjustment.²⁸⁰ Mechanically, CMS calculates the IPARS adjustment by calculating a ratio of predicted average FFS Medicare expenditures.²⁸¹ Specifically, the numerator of this ratio is equal to the average predicted FFS Medicare expenditures estimated using *audited* dollar

²⁷⁸ CMS, FFS Study Addendum, p. 8, steps (3)–(6). As described in Section VIII.B, CMS's FFS Study Addendum notes that “ $\bar{b} > \bar{b}$,” where $\bar{b}$ represents the average of the dollar coefficient obtained from estimating the CMS-HCC model on audited FFS data, and $\bar{b}$ represents the average of the dollar coefficient obtained from estimating the model on unaudited FFS data.

²⁷⁹ CMS, FFS Study Addendum, p. 5.

²⁸⁰ CMS, FFS Study Addendum, pp. 5, 10.

²⁸¹ CMS, FFS Study Addendum, p. 10.

coefficients and *unaudited* FFS data. The denominator of this ratio is the average predicted FFS Medicare expenditures using *unaudited* dollar coefficients and *unaudited* FFS data, which equals the realized average FFS Medicare expenditures.²⁸² The IPARS adjustment is:

$$\frac{\text{Audited coefficients} \times \text{unaudited data}}{\text{Unaudited coefficients} \times \text{unaudited data}}$$

151. This ratio is always greater than one because, as CMS shows in the FFS Study Addendum, the average *audited* dollar coefficient is larger than the average *unaudited* dollar coefficient.²⁸³

152. CMS then divides the *audited* dollar coefficients by the IPARS adjustment, thereby deflating these dollar coefficients, the relative factors, and the subsequent risk scores in the MA data.²⁸⁴ CMS's use of the IPARS adjustment therefore systematically biases the impact of unsupported codes in the FFS data on average audited dollar coefficients, average audited relative factors, and subsequent MA risk scores towards zero. That is, this IPARS adjustment removes the very change in the dollar coefficients that CMS intends to measure. Indeed, Sean Creighton testified that the IPARS adjuster methodology was circular.²⁸⁵

153. To illustrate, first consider the impact of removing unsupported codes from the FFS data on the payments to MA plans, before applying any IPARS adjustment. Exhibit 6 provides a simplified example where there is a single HCC and no other regressors in the CMS-HCC model. Suppose there are 100 FFS Medicare beneficiaries that generated \$10,000 in FFS Medicare costs and suppose that the *unaudited* FFS data indicates that 50 of these beneficiaries have the HCC. Then the *unaudited* dollar coefficient for the HCC is \$200 (\$10,000 / 50). Now

²⁸² CMS, FFS Study Addendum, p. 10; Lambert Report, p. 18.

²⁸³ CMS, FFS Study Addendum, p. 8. See Steps (5) and (6). See also CMS, FFS Study Addendum, Figure 2.

²⁸⁴ Lambert Report, p. 18 ("A review of CPI's provided SAS code indicates that as part of the normalization process, before converting the revised dollar coefficients to relative factors (like in the baseline model), it first made a reduction to the resulting dollar coefficients by dividing them by an IPARS adjustment."). See also CMS, FFS Study Addendum, pp. 8–9, step (13) and p. 10. Elsewhere in the FFS Study Addendum, CMS defines the IPARS "adjustment factor" as the ratio of average realized expenditures to average predicted expenditures, or the inverse of the ratio shown in the text of the current report. For this definition, CMS indicates that the dollar coefficients would be multiplied, rather than divided, by the IPARS adjustment. This alternative process is mathematically equivalent to the process described in the text of the current report. See CMS, FFS Study Addendum, pp. 8–9.

²⁸⁵ Creighton Deposition, day 2, pp. 36:10–39:1. ("Q And you wrote [...] 'If CMS had found that the different [sic] was 10 percent, it would have divided all coefficients by 1.1 (in other words, in effect, CMS's approach is similar to multiplying a number by 10 and then dividing by 10).' A Correct. Q And am I correct in saying that—or what you said here is that the CMS methodology was circular? A Absolutely.").

suppose that after auditing these data, only 40 of these FFS Medicare beneficiaries have the HCC. Then the *audited* dollar coefficient for the HCC is \$250 ($\$10,000 / 40$). Assuming there are 100 MA beneficiaries, 40 of whom have the HCC after the MA data are audited, MA plans would have received \$8,000 ($\200×40) when payments were based on CMS-HCC model calibrated on *unaudited* FFS data. However, when the FFS data used to calibrate the model is *audited*, payment to MA plans would increase to \$10,000 ($\250×40).

Exhibit 6
Example of FFS Data Audits on Payments to MA Plans

		Unaudited FFS Data	Audited FFS Data
FFS			
Total FFS expenditure for 100 patients	[a]	\$10,000	\$10,000
FFS patients with HCC	[b]	50	40
Dollar coefficient	[c] = [a] / [b]	\$200	\$250
MA Plan			
MA patients with HCC (audited)	[d]	40	40
Total payment to MA plan	[e] = [c] x [d]	\$8,000	\$10,000

154. This simplified example provides two key results, which extend readily to the full CMS-HCC model: (1) removing unsupported HCCs from FFS enrollee data has the effect of spreading the same amount of expenditures incurred by CMS for FFS Medicare enrollee health care over fewer enrollees per HCC, and so per-enrollee payments per HCC—i.e., the dollar coefficient—must on average increase; and (2) MA plans that have enrollees for whom the payments per HCC increase would be paid more by CMS if CMS audited the FFS data. This intuition and the logic of this example are entirely consistent with the mathematics outlined in CMS’s FFS Study Addendum.²⁸⁶

155. CMS’s motivation for applying the IPARS adjustment derives from its claim in the FFS Study Addendum that it must “maintain coefficient values such that predicted FFS expenditures do not increase.”²⁸⁷ That is, CMS claims that the total predicted expenditures derived using *audited* dollar coefficients and unaudited data ($\$12,500 = \250×50 beneficiaries with the HCC,

²⁸⁶ CMS, FFS Study Addendum, p. 8, steps (3–7).

²⁸⁷ CMS, FFS Study Addendum, p. 9, step (11).

in the above example) should equal the total predicted expenditures derived using *unaudited* dollar coefficients and *unaudited* data (\$10,000 = \$200 x 50 beneficiaries with the HCC in the above example).²⁸⁸ As a practical matter, this statement would only be true if the *audited* and *unaudited* dollar coefficients were identical because both predicted expenditures are estimated using the same *unaudited* data. However, as the simplified example above demonstrates, removing unsupported codes from FFS data for a particular HCC would increase the average of the dollar coefficients estimated from the CMS-HCC model for that HCC. As CMS has shown, removing unsupported codes from FFS data increases the average of the dollar coefficients estimated from the CMS-HCC model.²⁸⁹ Thus, CMS's claim that these two predicted expenditures should be equal is incorrect. However, based on this incorrect claim, CMS applies an IPARS adjustment. Specifically, as explained above, the IPARS adjustment is the ratio of the average predicted FFS Medicare expense calculated using *audited* dollar coefficients multiplied by *unaudited* data to the average FFS Medicare expenditure using *unaudited* dollar coefficients and *unaudited* FFS data. CMS then divides the *audited* dollar coefficients by the IPARS adjustment (which is greater than one), thus deflating these coefficients and effectively cancelling out the increase in the average of the dollar coefficients that results from removing unsupported codes from the FFS data. That is, the IPARS adjustment incorrectly biases downward the dollar coefficients used to estimate the HCC relative factors and the MA risk scores.

156. The intuition for why this is the case is most easily seen in the example in Exhibit 7. In this example, CMS would calculate the IPARS adjustment as 1.25 $[(\$250 \times 50) / (\$200 \times 50)]$. CMS would then divide the *audited* coefficient of \$250 by this ratio and derive the exact same value as the *unaudited* coefficient: \$200. CMS would label this final value as the “audited”

²⁸⁸ This claim is clear by examining steps (2) through (12) in the FFS Study Addendum justifying a “General Expenditure Adjustment to Offset Deletion Bias.” CMS writes that “To maintain coefficient values such that predicted FFS expenditures do not increase, we need a factor Z such that [...] the total using the ‘new’ coefficients [is not] greater than the original predicted expenditures,” see steps (9) and (11). CMS estimates this “total using the ‘new’ coefficients” by multiplying the *audited* dollar coefficients by the “original number of ones” or, equivalently, the *unaudited* data, see step (7). CMS compares this with the “original predicted expenditures” calculated by multiplying the *unaudited* dollar coefficients by the *unaudited* data. See CMS, FFS Study Addendum, pp. 8–9.

²⁸⁹ See CMS, FFS Study Addendum, p. 8, steps (3–6).

coefficient despite their flawed, circular logic. Indeed, Mr. Kornfield testified that the CMS methodology “divided away the difference” it found in the coefficients.²⁹⁰

Exhibit 7
The IPARS Adjustment Is Circular

		Unaudited FFS Data	Audited FFS Data
FFS			
Total FFS expenditure for 100 patients	[a]	\$10,000	\$10,000
FFS patients with HCC	[b]	50	40
Dollar coefficient	$[c] = [a] / [b]$	\$200	\$250
MA Plan			
MA patients with HCC (audited)	[d]	40	40
Total payment to MA plan	$[e] = [c] \times [d]$	\$8,000	\$10,000
IPARS Payment Adjustment			
Audited Coefficient	[c (audited)]		\$250
CMS Claimed Expenses	$[f] = [b \text{ (unaudited)}] \times [c \text{ (audited)}]$		\$12,500
IPARS Adjustment	$[g] = [f] / ([b \text{ (unaudited)}] \times [c \text{ (unaudited)}])$		1.25
IPARS Adjusted Coefficient	$[h] = [c \text{ (audited)}] / [g]$		\$200
Total payment to MA plan after IPARS Adjustment	$[i] = [h] \times [d]$		\$8,000

157. As this example makes clear, through its use of the IPARS adjustment, CMS does not estimate the impact of unsupported codes in FFS data on the CMS-HCC model but rather uses a methodology that effectively assumes the presence of unsupported codes have no impact.

158. I note that CMS’s flawed reasoning leading to the IPARS adjustment is based on its incorrect claim in the FFS Study Addendum that the total predicted expenditures derived using *audited* dollar coefficients and *unaudited* FFS data (\$12,500 = \$250 x 50 FFS Medicare beneficiaries with the HCC, in the above example) should equal the total predicted expenditures derived using *unaudited* dollar coefficients and *unaudited* FFS data (\$10,000 = \$200 x 50 FFS Medicare beneficiaries with the HCC in the above example). This IPARS adjustment undoes the entire premise of deriving new coefficients based on audited data. Instead, total predicted expenditures derived using *audited* dollar coefficients and *audited* FFS data should be equal to total predicted expenditures derived using *unaudited* dollar coefficients and *unaudited* FFS data.

²⁹⁰ Kornfield Deposition, pp. 217:21-218:4 (“Q Do you agree that CMS’s methodology appears to be designed to minimize differences in payments under the two models? A Yeah, I don’t—I don’t remember the specifics of—of exactly how CMS did this, but—but if memory serves, the study that they did, there was a difference, but then they essentially divided away the difference to show that there wasn’t a difference. So yes, I agree with that.”).

As the simple example demonstrates, the total predicted expenditures are indeed equivalent—\$10,000 in both cases.

159. Moreover, there is no conceptual reason for CMS to “make adjustments” to FFS Medicare expenditures. The exercise of determining whether an FFS adjuster is necessary requires keeping FFS Medicare expenditures *constant* while removing unsupported diagnosis codes to derive audited dollar coefficients and audited relative factors. As discussed in Section VIII.A, the basis of the CMS-HCC model is that CMS should pay MA plans for a beneficiary the expected cost of covering that beneficiary in FFS Medicare. MA plans should not be paid less than what their enrollees would be expected to cost if they were enrolled in FFS Medicare, while also accounting for the plan’s MA bid.²⁹¹ The expected cost of covering a beneficiary in FFS Medicare includes expenditures that CMS incurs for claims with unsupported diagnosis codes.²⁹² Thus, the CMS-HCC model should compensate MA plans for these codes to preserve 100 percent parity to FFS Medicare. This also mirrors the fact that MA plans pay providers that provide services to the plans’ enrollees for claims with unsupported diagnosis codes.²⁹³ CMS’s use of an IPARS adjustment to reduce FFS Medicare expenditures in the audited data assumes that Medicare did not pay expenditures reported in the FFS data for claims with unsupported diagnosis codes and that MA plans *never* pay providers for claims with unsupported diagnosis codes, which is implausible.²⁹⁴

²⁹¹ As noted in Section VIII.A, when insurers bid below the benchmark, MA plans are undercompensated if the total payment they receive is less than the amount to which they are entitled, based on the plan’s quality rating and how far below the benchmark the insurer bid.

²⁹² In 2021, FFS Medicare found a 6.26 percent improper payment rate from claims submitted from July 2019 through June 2020, with 79.5 percent of improper payments attributed to incorrect coding or insufficient or no documentation. See “2021 Medicare Fee-for-Service Supplemental Improper Payment Data,” *U.S. Department of Health & Human Services*, December 7, 2021, pp. 1–2, available at <https://www.cms.gov/files/document/2021-medicare-fee-service-supplemental-improper-payment-data.pdf>.

²⁹³ In 2012, the Federal Bureau of Investigation reported that “fraudulent billings to health care programs, both public and private, are estimated between three and ten percent of total health care expenditures.” See “Financial Crimes Report To the Public, Fiscal Years 2010–2011,” *Federal Bureau of Investigation*, February 27, 2012, p. 16, available at <https://www.fbi.gov/file-repository/stats-services-publications-financial-crimes-report-2010-2011-financial-crimes-report-2010-2011.pdf/view>.

²⁹⁴ As noted above, CMS should not “make adjustments” to FFS Medicare expenditures through the IPARS adjustment. However, even setting this aside, CMS’s methodology to estimate the impact of removing unsupported codes in the FFS data is incorrect. Specifically, the IPARS adjustment assumes an equivalent expenditure reduction regardless of which diagnosis codes were removed, but this is unlikely to be the case. For example, diagnosis codes associated with outpatient services in FFS Medicare would not necessarily lead to a reduction in FFS Medicare expenditures because outpatient services are reimbursed based on health care services conducted, not solely on patient diagnoses. See Cubanski et al., *A Primer on Medicare*. It is possible that CMS believes that some of the unsupported codes they identified in the FFS data indicate that CMS should never have paid providers for those

160. In sum, CMS's reasoning for an IPARS adjustment is flawed. No such adjustment is needed.

C. CMS Uses Data Wholly Inadequate for the Task of Estimating the Impact of Unsupported Codes in FFS Data on the CMS-HCC Model

161. I now explain why the data that CMS used in the FFS Adjuster Study is inadequate for estimating the impact of unsupported codes in FFS data on MA risk scores and, as a result, payments to MA plans. Specifically, CMS uses a sample of 2008 CERT data in its FFS Adjuster Study to estimate the probability that an HCC is unsupported in the FFS data.²⁹⁵ However, using this CERT data sample is problematic, and its use for estimating the probability that an HCC is unsupported requires making assumptions that likely do not hold.

162. I discuss three key shortcomings of using the CERT data sample for estimation of the FFS Adjuster:

- First, the sample includes claims from only the year 2008;
- Second, the sample is unlikely to be nationally representative; and
- Third, the sample contains many HCCs with very few claims, in part because it relies only on claims for outpatient services.

163. CMS's methodology cannot overcome these shortcomings and so cannot recover credible estimates for the true probability that an HCC is unsupported. This renders CMS's conclusions that unsupported diagnosis codes in FFS data do not affect payments to MA plans unfounded and unreliable. I discuss each of these shortcomings further below.

164. First, the CERT data sample includes claims from only 2008—a single calendar year.²⁹⁶ Thus, CMS's estimates of the probability that an HCC is unsupported and of the impact of unsupported codes in the FFS data apply to only 2008. For CMS to extrapolate these estimates to all years after 2008 requires CMS to assume that there have been no changes in the coding accuracy in FFS or MA data for any HCC over time. Such an assumption is implausible for several reasons.

services. If that is the case, correctly calculating an FFS adjuster requires a comprehensive audit of all FFS Medicare claims to determine which claims do not support diagnoses and whether the expenditures on those claims need to be refunded to the government. Such an exercise is well beyond anything that CMS has done.

²⁹⁵ CMS, FFS Adjuster Study Technical Appendix, p. 6.

²⁹⁶ CMS, FFS Adjuster Study Technical Appendix, p. 6.

- CMS has added new HCCs and significantly changed the structure of the HCCs since 2008.²⁹⁷ CMS's FFS Adjuster Study has not investigated whether new HCCs or changes to groups of diagnoses in a given HCC would impact the probability that an HCC is unsupported for a given beneficiary in a year and, hence, the need for an FFS Adjuster.
- Since 2008 there has been an increase in the use of health information technology that could impact the accuracy of coding,²⁹⁸ as well as changes in diagnostic practices that could impact the probability that an HCC is unsupported.²⁹⁹
- When the underlying diagnoses that indicate a given HCC vary with respect to their probabilities of being unsupported, an increased share of beneficiaries with a diagnosis that has a higher probability of being unsupported would increase the probability that the HCC is unsupported. When using data only from 2008 to form its conclusions, CMS is ignoring all such possible changes that could have occurred since 2008.
- Finally, as discussed in Section VI.B, there has been a steady increase in the fraction of Medicare beneficiaries enrolled in MA over time. It is plausible that the average characteristics of these beneficiaries is changing over time (e.g., with sicker beneficiaries with a different distribution of HCCs enrolling in MA over time, or with beneficiary take-up of MA spreading across geographic regions in the United States so that newer beneficiaries are more likely to live in certain states, etc.).³⁰⁰ What this means is that the probability that HCCs are unsupported among remaining FFS Medicare patients would likewise change over time.

²⁹⁷ See fn. 155 above.

²⁹⁸ See, e.g., Jinhyung Lee and Jae-Young Choi, "Improved efficiency of coding systems with health information technology," *Scientific Reports*, 11, Article No. 10294, 2021, p. 1.

²⁹⁹ For instance, more advanced big data approaches can improve accuracy of diagnosis. See, e.g., "AI Improves Accuracy of Heart Condition Diagnosis," *Cedars-Sinai*, October 27, 2022, available at <https://www.cedars-sinai.org/newsroom/ai-improves-accuracy-of-heart-condition-diagnosis>. Similarly, there is evidence that the transition to the ICD-10 in 2015 impacted coding, improving accuracy over time in some settings. See Cindy Cai, et al., "Effect of ICD-9 to ICD-10 Transition on Accuracy of Codes for Stage of Diabetic Retinopathy and Related Complications: Results From the CODER Study," *Ophthalmology Retina*, 5 (4), April 2021, pp. 374–380.

³⁰⁰ One study found an increase in the share of Medicare Advantage enrollees who are young, black, and dually enrolled in Medicaid between 2011 and 2019. See William Weeks, et al., "Trends in Characteristics of Adults Enrolled in Traditional Fee-for-Service Medicare and Medicare Advantage, 2011–2019," *Medical Care*, 60(3), March 2022, pp. 227–231 at p. 227.

165. Second, the 2008 CERT data sample may not be nationally representative of the FFS Medicare population, and CMS has not provided any evidence that it is. Indeed, CMS conceded that the CERT data sample was “not designed to produce a representative sample of diagnoses.”³⁰¹ Without a representative sample, CMS must assume that the probability that an HCC is unsupported for the entire FFS Medicare population is the same as the probability estimated using the 2008 CERT data sample. This is an unsupported and implausible assumption. For example, the CERT data sample could oversample a healthier population, a younger population, or a wealthier population. Relatedly, the CERT data sample includes only outpatient claims, which may lead to bias in both the set of beneficiaries included in the sample and in the claim-level probability that a diagnosis code is unsupported, to the extent that the probability of unsupported codes is different between outpatient and inpatient claims.³⁰² In sum, any systematic differences between the 2008 CERT data sample and the overall FFS Medicare population (in terms of both demographic characteristics and HCCs) would result in differences between the estimated probability that an HCC is unsupported in the 2008 CERT data sample (and thus the FFS Adjuster Study) and in the overall FFS Medicare population.

166. Third, the 2008 CERT data sample contains many HCCs with an extremely small number of claims. CMS acknowledges that “for many of the diagnoses and by extension, the HCCs, we have an insufficient sample size to develop reliable discrepancy rates at the HCC level.”³⁰³ For example, the data sample includes only one claim with a diagnosis of extensive third-degree burns, and only two claims with a diagnosis of severe head injury.³⁰⁴ CMS admits that “[v]ariation [in HCC discrepancy rates] due to insufficient sample size confounds the analysis.”³⁰⁵ A fundamental principle of statistics (i.e., the Law of Large Numbers) is that statistics estimated on larger sample sizes are likely to be closer to the population value of the statistic (since the variance of an estimate declines with sample size).³⁰⁶ Thus, conclusions about population statistics drawn from small samples are inherently less reliable. Because of this, estimates of the probability that an HCC is unsupported based on a very small set of claims

³⁰¹ CMS, FFS Adjuster Study Technical Appendix, p. 8.

³⁰² CMS, FFS Adjuster Study Technical Appendix, p. 6.

³⁰³ CMS, FFS Adjuster Study Technical Appendix, p. 8.

³⁰⁴ CMS, FFS Adjuster Study Technical Appendix, p. 8.

³⁰⁵ CMS, FFS Adjuster Study Technical Appendix, p. 8.

³⁰⁶ Morris DeGroot and Mark Schervish, *Probability and Statistics, Fourth Edition*, (Boston: Addison Wesley, 2012), pp. 348–353.

from the 2008 CERT data sample would be unreliable. Thus, CMS's conclusions derived from the 2008 CERT data sample would be unreliable.

167. As further examples of the small number of claims in the 2008 CERT data sample, the data contain only one observation each for HCCs 70 (muscular dystrophy), 107 (cystic fibrosis), 150 (extensive third-degree burns), and 177 (amputation status, lower limb/amputation complications). For HCCs 70 and 150, the single claim is supported, and CMS estimates a probability of being unsupported of 0 percent. For HCCs 107 and 177, the single claim is unsupported, and CMS estimates a probability of being unsupported of 100 percent.³⁰⁷ These two estimates likely suffer from the small sample bias described above. CMS attempts to “mitigate” the impact of small sample size by replacing observed probabilities with “effective” probabilities. Specifically, CMS assigns all four of these HCCs a probability of being unsupported of 33.8 percent based on the overall probability in the entire CERT data sample.³⁰⁸ However, there is no reason to believe the actual probabilities of being unsupported for these HCCs are all equal to overall probability of 33.8 percent.

168. Further, the CERT data sample had no claims with HCC 77 (respirator dependence/tracheostomy status).³⁰⁹ In this case, CMS has no data with which to estimate the actual probability of being unsupported for this HCC. Again, CMS simply assigns a claim level probability of 33.8 percent to this HCC.³¹⁰ But again, there is no reason to believe that this 33.8 probability rate is accurate.

169. In sum, for all of the reasons discussed in this sub-section, the data that CMS used in the FFS Adjuster Study is inadequate for estimating the impact of unsupported codes in Medicare FFS data on audited relative factors, MA risk scores, and as a consequence, payments to MA plans. As such, CMS cannot use the FFS Adjuster Study to conclude that payments to MA plans are not systematically affected by unsupported codes in the Medicare FFS data.

³⁰⁷ CMS, FFS Adjuster Study Technical Appendix, pp. 7–8.

³⁰⁸ In general, CMS bucketed HCCs into high, baseline, and low probabilities of being unsupported based on the probability they estimated in the sample. HCCs were assigned to the high or low categories if they had a discrepancy rate that was statistically different from the overall discrepancy rate (at a 95 percent confidence level) and were assigned to the baseline category otherwise. For the four HCCs discussed in the text, because there was only one claim for each HCC in the sample, the probability that the HCC was unsupported was indistinguishable from the mean. These HCCs were therefore assigned to the baseline category, with a rate of being unsupported of 33.8 percent. See CMS, FFS Adjuster Study Technical Appendix, pp. 8–11.

³⁰⁹ CMS, FFS Adjuster Study Technical Appendix, p. 7.

³¹⁰ CMS, FFS Adjuster Study Technical Appendix, pp. 9–11.

D. Contrary to the Conclusion of CMS’s Flawed FFS Adjuster Study, an FFS Adjuster Is Necessary and Unsupported Diagnosis Codes that Exist in FFS Data Likely Impact Payments to MA Plans

170. Although CMS’s 2023 Final Rule indicated that CMS would not apply an FFS adjuster, CMS’s conclusion in its FFS Adjuster Study that unsupported codes in FFS data have no impact on payments to MA plans under the CMS-HCC model is incorrect. As I have explained in this section, CMS’s FFS Adjuster Study is based on unfounded assumptions, follows a deeply flawed methodology, and relies on problematic data. Accordingly, CMS’s analysis is unreliable and cannot be used to determine whether unsupported diagnosis codes in the FFS data impact payments to MA plans and if so, by how much. Also as discussed in this report, CMS’s methodology biases its estimate of the impact of unsupported diagnosis codes in the FFS data towards zero due to: (1) CMS likely underestimating the probability that an HCC is unsupported in the FFS Medicare population, which would lead it to underestimate audited relative factors on average; and (2) CMS inappropriately deflating the audited relative factors by the IPARS adjustment, which incorrectly adjusts FFS Medicare expenditures despite actual FFS Medicare expenditures being unaffected.

171. As I explained above, using FFS data with unsupported codes to estimate the CMS-HCC model leads to lower estimated dollar coefficients, on average, relative to using FFS data in which such unsupported codes are removed. Thus, removing such unsupported codes in FFS data increases, on average, the dollar coefficients estimated by the CMS-HCC model. Therefore, had CMS defined an FFS adjuster in a manner consistent with this increase in the average of the dollar coefficients, such an FFS adjuster would lead to increased payments to MA plans relative to the situation where only MA plans remove unsupported codes. Consistent with this, Hans Dutt, President and Principal Economist at Stat Analytics and author of the CMS FFS Adjuster Study, testified in his deposition that if diagnoses are deleted from the FFS data, the coefficients in the CMS-HCC model will increase.³¹¹ And as further supported by the evidence below, this contradicts CMS’s conclusion that the FFS Adjuster is unnecessary.

³¹¹ Deposition of Hans Dutt (Stat Analytics), September 28, 2022, pp. 34:9–12, 118:11–21 (“Q. And Dr. Dutt, do you agree with that mathematical phenomenon, that if you don’t adjust the expenditures but you delete certain diagnoses codes, the coefficients go up? A. Yes, so—so that is—I think you articulated it well. It is a mathematical certainty, right? It’s a phenomenon that’s going to happen, is if you have the expenditures staying the same, and you know, you basically delete the—make the—the denominator smaller, the coefficients are going to go up. That is going to happen.”).

172. In the remainder of this section, I highlight testimony in this matter as well as other sources that indicate that the removal of unsupported diagnosis codes from FFS data would impact payments to MA plans, and that an FFS adjuster is necessary.

173. First, officials have testified that the removal of unsupported diagnosis codes from FFS would impact payments to MA plans by changing the coefficients of the CMS-HCC model. For instance, Thomas Kornfield testified that the coefficients would be different if the FFS data did not have unsupported diagnoses.³¹² Sean Creighton also explained in his deposition that if CMS removes unsupported diagnosis from the FFS data used to estimate the dollar coefficients from the CMS-HCC risk adjustment model, the average of the dollar coefficients would change.³¹³ Thomas Hutchinson, former Director of Medicare Plan Payment Group at CMS, testified that an FFS adjuster was necessary to improve the accuracy of CMS's assessment as to whether MA plans were overpaid.³¹⁴

174. Additionally, CMS has performed or commissioned studies which have found that unsupported codes in the FFS data impact the dollar coefficients and relative factors from the CMS-HCC model, and consequently impact MA risk scores and payments to MA plans.³¹⁵ Specifically, a 2009 study suggested that a "proxy" for the FFS adjuster is equal to 3.9 percent.³¹⁶ A 2010 study proposed that an adjustment of approximately 4.9 percent be applied to MA risk scores when assessing compensation to MA plans, based on the estimated impact of

³¹² Kornfield Deposition, pp. 198:24–199:12.

³¹³ Creighton Deposition, day 2, pp. 30:17–34:10. ("[...] Q. And going back to that notion of removing from the population the erroneous diagnosis codes so that you have the true population that suffer from the conditions, you would expect the costs, the incremental costs, of caring for that condition to rise? [...] THE WITNESS: That – that has been my expectation. The – our study showed that it was a bit more complicate than that. So, yeah, that's normally the expectation [...] However, it turns out it's not, like a lot of statistical stuff, it's not quite as simple as that. So we found in our studies, sometimes they rise, sometimes they go down. But on—on average what you do know is they're gonna be different, they're... You know. So I agree with your initial hypothesis, it was my hypothesis, too. Turns out it's not true for all conditions across the model. [...]").

³¹⁴ Deposition of Thomas Hutchinson (CMS), January 26, 2022, pp. 18:12–19, 59:10–17 ("When I refer to 'accurate amount' or when I referred to 'accurate amount,' I meant the amount to—the amount of payment error that CMS measured in a RADV audit at a plan level. The accurate calculation of that payment amount needs to have a fee-for-service adjuster built into it to be maybe more accurate, we will say, rather than the perfect accuracy.")

³¹⁵ Hornsby Deposition, p. 83:9–20 ("Q. [...] Are you aware of a single document before 2016 where the government determined that using unaudited fee-for-service claims data really has no impact or an indeterminate impact on the calculation of coefficients and risk scores in the risk adjustment model? [...] A. I am not aware of any MPPG document that says there is no impact.").

³¹⁶ USBP001706860–63 at USBP001706861. This 3.9 percent "proxy" for the FFS Adjuster was based on a November 2008 "FFS CERT National Paid Claims Error Rate" of 3.9 percent.

removing unsupported codes from the FFS data.³¹⁷ Similarly, a 2011 document suggested that the average risk score in MA plans be adjusted upward by 5 percent to account for the impact of unsupported diagnosis codes in the FFS data when assessing overpayments to MA plans.³¹⁸ Around the time when CMS announced the RADV audits for MA plans in 2012, a CMS study proposed that an FFS adjuster be 8.1 percent.³¹⁹

175. Since the CMS FFS Adjuster Study was published in 2018, three separate studies published in 2019 by Avalere, Milliman, and the Wakely Consulting Group also concluded that an FFS adjuster is necessary.³²⁰ In particular, Avalere tested three alternatives to the assumptions made by CMS and concluded that the presence of coding errors in FFS claims data results in underpayments of nearly 8 percent to MA plans.³²¹ The Milliman study also found that the CMS FFS Adjuster Study cannot be used to conclude that the FFS adjuster is not necessary.³²² In contrast to CMS's findings, Milliman's estimates suggest that the audited CMS-HCC model increases risk scores for the MA population by 10–32 percent relative to the model run with unaudited FFS data.³²³ Likewise, a study conducted by the Wakely Group concluded that, after correcting errors in the FFS Adjuster Study, failing to use an FFS Adjuster would lead to underpayments to MA of almost 10 percent.³²⁴

³¹⁹ CMS, Notice of Final Payment Error Calculation Methodology; Deposition of Cheri Rice (CMS), August 3, 2022, pp. 16:2–7, 101:7–17; USBP001565703–8 at USBP001565706 (“Based on this CERT RADV audit, we estimate the FFS adjuster to be 8.1%”).

³²⁰ Letter from Matthew Eyles to Seema Verma, p. 6 (“Since CMS published the Proposed Rule, two independent analyses – one by Avalere (the Avalere study) and one by Milliman (the Milliman study) – clearly demonstrate the need for a FFS adjuster. Importantly, neither analysis estimates the appropriate amount of the FFS adjuster. Rather, each study demonstrates that CMS’s methodology, after adjusting for methodological flaws, would lead to a FFS adjuster that is **not zero**.”).

³²¹ “Eliminating the FFS Adjuster from the RADV Methodology May Affect Plan Payment,” *Avalere Health*, March 2019, available at <https://avalere.com/wp-content/uploads/2019/03/20190318-FFS-Adjuster-Analysis-Final-.pdf> (“Avalere tested 3 alternatives to the assumptions made by CMS, comparing the results. Avalere’s analysis finds that audit miscalibration bias yields underpayments of nearly 8%.”).

³²² Letter from Matthew Eyles to Seema Verma, p. 2 (“Milliman finds that the CMS technical analysis ‘cannot appropriately be used to conclude a FFS adjuster is not required.’ Milliman adjusts for errors in CMS’s methodology to find that an FFS adjuster is both positive and material. As such, Milliman’s study refutes CMS’s conclusion that a FFS adjuster is not necessary.”). See also, Rob Pipich, “Medicare Advantage RADV FFS adjuster: White paper,” *Milliman White Paper*, August 23, 2019 (“Milliman White Paper”), pp. 1, 4, available at https://assets.milliman.com/ektron/Medicare_Advantage_RADV_FFS_adjuster_8-23-2019.pdf (“Further analysis must be completed to calculate an accurate FFS adjuster. In any case, the range is wide and even the bottom end is material and significant.”).

³²³ Milliman White Paper, p. 21.

³²⁴ Lambert Report, p. 6.

176. In sum, contrary to the findings of the CMS FFS Adjuster Study, other studies have shown that the removal of unsupported diagnosis codes from the FFS data would impact assessment of the proper compensation to MA plans and that an FFS adjuster is needed. Indeed, these studies indicate that CMS's payments to MA plans would be too low if MA plans were required to remove unsupported diagnosis codes from their data, but FFS Medicare was not required to do the same.

X. Economic Theory and Historical Evidence Indicate that Requiring MA Plans to Remove Unsupported Diagnosis Codes Would Result in Higher Prices or Less Generous Plans

177. CMS alleges that UnitedHealth failed to delete unsupported codes.³²⁵ Removing unsupported diagnosis codes associated with certain MA enrollees lowers those enrollees' risk scores, thereby—all else equal—lowering CMS's payments to the MA plan. This, however, does not reduce the enrollees' actual health care expenditures. Hence, requiring that MA plans remove unsupported diagnosis codes, relative to the current world and making no other changes to the way MA plans are paid, would reduce MA plans' revenues while the costs associated with providing care to their enrollees would remain unchanged.

178. Economic theory predicts that a firm faced with falling revenues and similar costs would adjust their behavior.³²⁶ Indeed, both economic theory and historical evidence indicate that MA plans in a similar situation would act in one or more of the following ways: (1) increase their plan bids, with the consequence of increasing government or enrollee expenses, or increase

³²⁵ Complaint, ¶ 342.

³²⁶ It is possible that in the short run, a firm faced with falling revenues and similar costs (i.e., falling profits) may not alter its behavior. For example, suppose all firms in an industry face falling profits due to a short-term industry-wide shock. In this context, firms face an opportunity cost by remaining in the industry—they could gain higher returns on investments, capital, and labor in other industries or sectors. In the short run, these firms may also face costs to switching their resources to alternate uses and so may not change their behavior. In the long run, these same firms would alter their behavior: economic theory tells us that firms facing systematically better opportunities (i.e., better returns on investing its resources) by allocating these resources differently will do so. MA insurers are particularly unlikely to absorb profit losses without altering their behavior because MA plan profits are capped through the MLR. As discussed in ¶ 43, MLR is the proportion of premium revenues that a health insurance company spends on clinical services and quality improvement. MA insurers are required to have an MLR of at least 85 percent, meaning that only the remaining 15 percent of premium revenues can be spent on administrative costs and profits. Due to this constraint on how an MA plan can allocate its revenues, MA plans are likely to adjust their behavior. See CMS, Medical Loss Ratio. See also, "Medical Loss Ratio," *Centers for Medicare & Medicaid Services*, modified September 6, 2023, available at <https://www.cms.gov/marketplace/private-health-insurance/medical-loss-ratio>; Pindyck and Rubinfeld, *Microeconomics*, p. 205.

enrollee cost sharing; (2) reduce the quality and/or number of benefits associated with their plans; and/or (3) exit the market altogether, with the consequence of reducing the options available to Medicare beneficiaries and thereby reducing consumer welfare. I discuss each of these potential responses by MA plans in Sections X.A–C below.

179. As a matter of economics, accurately estimating the change in government payments to UnitedHealth or the change in consumer welfare when requiring UnitedHealth to remove unsupported codes necessitates accounting for such dynamic effects. I discuss this further in Section X.D below.

A. If Payments to MA Plans Decline, Some MA Plans Would Increase Their Bids, Thereby Increasing Government and Enrollee Expenses, or Increase Enrollee Cost Sharing

180. Requiring MA plans to identify and delete unsupported codes would lead to lower payments from CMS to MA plans. In turn, MA plans would have an incentive to increase their bids to compensate for these lower payments. MA plans would also have an incentive to increase enrollee cost sharing to compensate for lower payments.

181. As discussed in Section VII.C, CMS compensates an MA plan based on a comparison between a CMS benchmark and the bid from the MA plan, while incorporating the risk scores of the MA plan enrollees and the quality of the MA plan. When an MA plan anticipates a reduction in risk scores (which would reduce payments to the MA plan, all else equal), the plan can increase its bid and thereby compensate for the impact that this reduction in risk scores would have on payments to the plan.

182. If an MA plan were to increase its bid, there are three scenarios to consider: (1) a plan that would bid *below* the benchmark both before and after the rule change; (2) a plan that would bid *below* the benchmark before the rule change but *above* the benchmark after; and (3) a plan that would bid *above* the benchmark both before and after the rule change.

- If the plan's bid is originally below the benchmark, and the plan increases its bid to a value that remains below the benchmark, then CMS would pay more for each of this plan's enrollees via a higher agreed-upon payment for an enrollee with the average health status. As the plan's bid is now closer to the benchmark, CMS would provide a smaller rebate to the MA plan for each enrollee, mechanically leading to lower

incremental benefits for its enrollees.³²⁷ As discussed in Section VI.B, these benefits can include eye exams and glasses, dental and fitness benefits, and hearing aids. It is thus likely that such benefits would become less widely available following an increase in plan bids.

- If the plan's bid is originally below the benchmark, and the plan increases its bid to a value above the benchmark, then CMS would pay more for each of this plan's enrollees *and* the plan's enrollees would now be required to pay the MA plan premiums to cover the shortfall between the benchmark and the plan's bid.³²⁸ In this case, the plan would no longer receive any rebates from CMS. The elimination of the rebate would reduce incremental benefits for plan enrollees. Enrollees might leave the plan due to the absence of incremental benefits or due to the additional cost of an incremental premium.
- If the plan's bid is originally above the benchmark, and the plan further increases its bid, then the plan's enrollees would need to pay the MA plan higher premiums for the same insurance product and benefits. Enrollees might leave the plan rather than pay these higher premiums.

183. From the perspective of the MA plan's enrollees, an increase in an MA plan's bid results in either reduced incremental benefits, higher premiums, or both. In all cases, there is a loss to the enrollee. Moreover, in the first two cases discussed above, any savings realized by CMS from removing unsupported codes and decreasing the risk scores for some MA plan enrollees could be partially or even fully offset by the resulting increase in the plan bids, and thus result in some additional payments to the MA plans.

184. Additionally, some MA insurers would increase enrollee cost sharing (e.g., drug copayments) for their MA plans in response to a reduction in payments from CMS. As I discuss below, in order to ensure that the plan can cover enrollee health care expenditures, a plan could require enrollees to pay a larger share of some of their procedures out-of-pocket. Such a change

³²⁷ MA plan rebates can be used to add additional benefits or to reduce plan premiums or cost-sharing requirements. I use the expression "incremental benefits" to refer to the variety of uses plans have for rebates. See MedPAC, Medicare Advantage Program Payment System, p. 3.

³²⁸ For examples of how plans are compensated when bidding at or above the benchmark, see Section VII.C.1.

would directly reduce the welfare of MA enrollees and potentially drive MA enrollees to leave the plan.

185. Historical evidence confirms that MA insurers have responded to legislated changes in the generosity of CMS payments to MA plans by adjusting cost-sharing requirements and premiums. As discussed in Section V, two major changes in Medicare law, first the BBA (passed in 1997) and later the MMA (passed in 2003), impacted the size of the payments CMS provided to MA plans. The BBA first imposed a cap on payments, and the MMA went on to remove this cap and increase payments.³²⁹ Following the MMA, CMS contracted a study to assess the effects of these legislated changes in payment provisions.³³⁰ The CMS study noted that “plans responded to the payment update restrictions of the BBA and rising medical cost inflation by attempting to raise revenue through higher premiums.”³³¹ It also noted that “[c]ost sharing increased substantially in the early years of the decade, then declined or stabilized post MMA.”³³²

186. Other academic research affirms this point as well. A paper by Cabral and coauthors (2018), for example, shows that an increase in payments to private plans reduced both premiums and enrollee cost sharing.³³³ Duggan et al. (2016) also find suggestive evidence that increases in payments to MA plans pass through to consumers, especially in the most competitive markets.³³⁴ Similarly, Pelech and Song (2023) find that the ACA-induced reductions

³²⁹ See ¶¶ 39–42.

³³¹ Pope et al., Impact of Increased Financial Incentives to Medicare Advantage Plans, p. 3.

³³² Pope et al., Impact of Increased Financial Incentives to Medicare Advantage Plans, p. 4. See also, Daria Pelech and Zirui Song, “Pricing and Pass-Through in Response to Subsidies and Competition: Evidence from Medicare Advantage Before and After the Affordable Care Act,” Working Paper, January 12, 2023 (“Pelech and Song, Pricing and Pass-Through in Response to Subsidies and Competition”), p. 4, available at [https://hcp.hms.harvard.edu/sites/default/files/assets/users/Working Papers/Pricing_Pass-through_MA_1-12-23.pdf](https://hcp.hms.harvard.edu/sites/default/files/assets/users/Working%20Papers/Pricing_Pass-through_MA_1-12-23.pdf) (“High benchmarks, combined with the new bidding mechanism, also changed how insurers allocated resources between enrollee benefits and premiums. Because benchmarks were high, few insurers charged additional premiums beyond the standard Medicare premium paid by all beneficiaries, and instead competed by providing additional covered benefits and reduced cost sharing.”).

³³³ Marika Cabral, et al., “Do Larger Health Insurance Subsidies Benefit Patients or Producers? Evidence from Medicare Arbitrage,” *American Economic Review*, 108(8), 2018 (“Cabral et al., Evidence from Medicare Arbitrage”), pp. 2048–2087 at pp. 2049, 2063–2068, 2085. The authors also describe that decreased payments might result in an increase in premiums or less generous benefits (“Naturally, the lines of argument are reversed when a reduction in payments is proposed.”).

³³⁴ Duggan et al., Who Benefits when the Government Pays More, p. 62.

in benchmarks, and the associated decrease in payments to plans, are associated with a decrease in the rebates offered to prospective enrollees.³³⁵

187. Finally, evidence in the current matter is also consistent with this academic research. In particular, Melissa Sedor, Vice President of Finance of Medicare & Retirement for UnitedHealthcare, provided testimony related to UnitedHealth's MA bids.³³⁶ Ms. Sedor testified that UnitedHealth, following discussion with CMS in 2014, discontinued its claim verification process, which she testified typically led UnitedHealth to delete diagnosis codes associated with their MA plan enrollees.³³⁷ Ms. Sedor testified that the discontinuation of claims verification led to an increase in risks scores for its MA plans and, as a result, to an increase in the payments received by its MA plans.³³⁸ As part of the MA bid process for payment years 2015 and later, however, UnitedHealth used most of the increase in payments to reduce MA plan enrollee premiums or to offer supplemental benefits to MA plan enrollees.³³⁹ That is, when UnitedHealth received more payments from CMS for its MA plans, it reduced the cost sharing faced by its MA plan enrollees and provided additional benefits to those enrollees. For example, for payment year 2015, UnitedHealth estimated that changing the claims verification process resulted in an expected increase in payments of \$140 million, but that roughly \$135 million of that was reinvested back into health plans, with lower premiums and better Part D benefits.³⁴⁰

³³⁵ Pelech and Song, Pricing and Pass-Through in Response to Subsidies and Competition, pp. 5–6 (“For each dollar decrease in the benchmark post-ACA, plans reduced their bids by roughly the same amount—57 cents on average—while passing through an average cut of 26 cents in rebates to beneficiaries. Within this change in rebates, plans reduced cost-sharing and covered benefits by about twice as much on the margin after the ACA as they had increased those buy-downs and coverage before the ACA – perhaps suggesting that insurers allocate cuts towards plan characteristics that are less salient to beneficiaries.”)

³³⁶ Sedor Deposition, p. 19:14–18.

³³⁷ Sedor Deposition, p. 32:1–10 (“Q. [...] And I'm not going to ask you what the claims verification program did or how it worked. But in general, it tended to delete more codes than it added; is that correct? [...] THE WITNESS: The claims verification process generally resulted in deleting of codes. [...] Q. And hence lower risk scores? A. Yes.”), p. 35:10–22.

³³⁸ Sedor Deposition, pp. 32:19–33:8 (“Q. [...] Did the cancellation of the claims verification program affect United's bids? A. Yes, it did. Q. How so? A. When the claims verification process ceased, we were towards the end of pricing for 2015, and the cessation of that process resulted in the 2014 risk scores being higher, which went into the bids, which they then would have projected to also have a higher risk score in 2015. As a result of that higher risk score in 2015, we were able to change our bids around and pass that benefit back to the member by lowering the premiums we received from the members or by adding supplemental benefits to those bids.”).

³³⁹ Sedor Deposition, pp. 33:18–34:3 (“Q. Okay. So the thing that happened was the bid amount stayed the same, the risk score went up, and that money was redistributed to things like supplemental benefits? A. Correct. Q. Or lowering— A. Or lower premiums. Q. And when you say ‘premiums’ in this context, you mean collected from the beneficiaries, not CMS? A. Yes.”).

³⁴⁰ Sedor Deposition, pp. 46:8–48:13, Exhibit 732.

B. If Payments to MA Plans Decline, Some MA Plans Would Reduce the Quality of Benefits Provided

188. In addition to increasing bids and enrollee cost sharing to account for reduced payments, some MA plans would reduce their costs by reducing the quality of the experience enrollees have with their plan. For example, managed care plans, such as MA plans, rely on a network of health care providers and negotiate rates with these providers to help manage costs.³⁴¹ MA plans may reduce the quality of their network as a cost-saving measure when the payments they receive decline, for example by relying more on lower-quality providers.

189. Historical evidence from proposed payment cuts to Medicare Advantage in the last decade supports this conclusion. In 2014, proposed decreases to payments to Medicare Advantage plans were rolled back due to pressure from insurers and lawmakers, who claimed that the cuts would hurt seniors by increasing costs or limiting their provider networks.³⁴² This is consistent with declining payments to MA plans having a negative impact on the quality of plans provided and the patient experience.

190. Academic research confirms these points, as does the evidence in this matter. As discussed above, Cabral and coauthors (2018) find that an increase in payments to private plans increased the generosity of MA plans, and they similarly note that a decrease in payments may result in less generous benefits.³⁴³ As also discussed above, UnitedHealth increased supplemental benefits to its MA plan enrollees when payments to its MA plans from CMS increased.³⁴⁴

³⁴¹ See ¶ 35.

³⁴² Caroline Humer and David Morgan, “U.S. Government Rolls Back Proposed Medicare Advantage Cut,” *Reuters*, April 7, 2014, available at <https://www.reuters.com/article/us-usa-healthcare-medicare/u-s-government-rolls-back-proposed-medicare-advantage-cut-idINBREA361R520140407> (“‘In many parts of the country, including New York, Medicare Advantage works very well. They’ve shouldered their share already and this proposed cut would have been disproportionate, hurting seniors who would lose doctors or pay more. We’re glad the administration heeded our call and reversed the policy,’ Democratic Senator Charles Schumer said in a statement.”).

³⁴⁴ Sedor Deposition, pp. 32:1–34:2.

C. If Payments to MA Plans Decrease, Some MA Plans Would Exit the Market, Reducing the Number of Options Available to Consumers

191. If MA plans were to receive less in payments from CMS, some MA plans would cease to provide MA insurance (in certain, or even all, counties). In this case, Medicare beneficiaries in the affected counties would face reduced choice in Medicare insurance products.

192. Historical evidence confirms that when MA plans receive less payments, some plans exit. For example, the BBA capped payments to MA plans. Specifically, in 1997, the BBA limited plans' reimbursements to be at most 2 percent higher than the prior year's reimbursement,³⁴⁵ yet between 1999 and 2003, overall Medicare expenditures per enrollee grew between 4.2 and 9.0 percent per year, meaning that many plans were not able to fully cover their costs.³⁴⁶ Plans responded to these reimbursement caps by "reduc[ing] the number of covered services, such as prescription drug coverage, and rais[ing] their cost-sharing requirements."³⁴⁷ In addition, some plans withdrew from certain counties and enrollment in Part C started to decline in 1999. The number of MA contracts fell from 264 to 154 within the first two years following the full implementation of the BBA caps.³⁴⁸ Between 1999 and 2003, more than two million beneficiaries were involuntarily disenrolled from the MA plans that withdrew.³⁴⁹

193. A 2006 report to CMS indicated that following the implementation of the MMA in 2003 and the associated increase in payments in 2004, the number of MA plans available increased by approximately 62 percent in 2005.³⁵⁰ The conclusions of this report to CMS are consistent with other academic work that has studied plan entry in response to increased payments to MA plans.³⁵¹ For example, Duggan et al. (2016) find that relative to comparable counties, those with

³⁴⁵ McGuire et al., *Economic History of Medicare Part C*, pp. 289–332 at pp. 306, 309.

³⁴⁶ See Workpaper 1. Medicare expenditure data available at NHE2021.xlsx when accessing "National Health Expenditures by type of service and source of funds, CY 1960-2021 (ZIP)" at "Historical," *Centers for Medicare & Medicaid Services*, available at <https://www.cms.gov/data-research/statistics-trends-and-reports/national-health-expenditure-data/historical>. ³⁴⁹ McGuire et al., *Economic History of Medicare Part C*, pp. 289–332 at p. 310.

³⁵⁰ Pope et al., *Impact of Increased Financial Incentives to Medicare Advantage Plans*, pp. 11, 29–30.

³⁵¹ Duggan et al., *Who Benefits when the Government Pays More*, pp. 50–67 at p. 50 ("Our results demonstrate that the additional reimbursement leads more private firms to enter this market."). I note that other papers—including Cabral et al., *Evidence from Medicare Arbitrage*, pp. 2048–2087 at pp. 2070–2071—have found more muted responses in terms of entry in response to changes in reimbursement rates. They observe no evidence of increased

a 10.5 percent higher reimbursement floor (due to being located in a metropolitan statistical area with a population of 250,000 or more) had an average of 1.8 more MA insurers.³⁵²

194. If MA plans were to exit, Medicare beneficiaries would be less likely to choose an MA plan, as they would consequently have fewer MA plan options from which to choose. As a result, a decline in reimbursements to MA plans will not only reduce plan availability; it would also be expected to reduce total enrollment in MA. Between 1999 and 2004, enrollment in MA fell from 6.9 million (18 percent of all Medicare enrollees) to 5.3 million (13 percent of all enrollees).³⁵³ The timing of this decline directly followed the capped growth in MA reimbursement under the BBA, up through the point where plans were able to re-contract under the more generous terms of the MMA.³⁵⁴ Following the passage of the MMA and the subsequent increase in plan entry, the share of beneficiaries enrolled in MA continued to grow from 2003 to present day.³⁵⁵

195. The academic literature also shows that MA plan enrollment responds to plan reimbursement. Duggan et al. (2016) also find that average share of Medicare enrollees electing MA plans was 13.1 percentage points higher in counties where plans were reimbursed an amount 10.5 percent higher than in other counties.³⁵⁶ In a separate paper, Duggan et al. (2018) find that an additional \$100 per person, per month in MA reimbursement is associated with a 5.1 percent increase in the share of Medicare recipients enrolled in MA.³⁵⁷ Curto et al. (2021) use data from 2006-2011 to estimate an equilibrium model of optimal bidding in the context of MA. They estimate that an increase of \$100 in the risk-adjustment benchmark would increase the share of Medicare beneficiaries enrolled in MA by approximately 10 percentage points, and

payments increasing either the number of counties with at least one plan or the number of plans per county more generally. In regards to the former, the authors attribute this to the small additional revenue that could have been earned by insurers entering zero-plan counties that received more payments.

³⁵² Duggan et al., Who Benefits when the Government Pays More, pp. 50–67 at p. 51.

³⁵³ The total number of Medicare enrollees calculated as the total number of Medicare beneficiaries enrolled in Part A and/or Part B. Freed et al., A Dozen Facts About Medicare Advantage in 2020; Ochieng et al., Medicare Advantage in 2023: Enrollment Update and Key Trends.

³⁵⁶ Duggan et al., Who Benefits when the Government Pays More, pp. 50–67 at p. 51.

³⁵⁷ Mark Duggan, et al., “The Consequences of Health Care Privatization: Evidence from Medicare Advantage Exits,” *American Economic Journal: Economic Policy*, 10(1), 2018, pp. 153–186 at p. 181 (“Consistent with the existing literature (Afendulis, Chernew, Kessler 2013; Cawley, Chernew, and McLaughlin 2005; Pope et al. 2006) we find that an additional \$100, per person month, in MA reimbursement (or about a 20 percent increase, relative to average reimbursement) is associated with a 5.1 percent increase in the share of nationwide Medicare recipients in MA.”).

that conversely, reducing the benchmark decreases the MA enrollment share as well as consumer surplus.³⁵⁸

D. Correctly Estimating the Change in Government Payments to UnitedHealth, If UnitedHealth Were Required to Identify and Delete Unsupported Codes, Requires Accounting for Behavioral Responses from MA Plans

196. As I discuss in Sections X.A–C, economic theory and historical evidence indicate that MA plans would alter their behavior were they required to identify and delete unsupported diagnosis codes. As a matter of economics, then, any credible estimate of the change in government payments to an MA plan that was required to identify and delete unsupported codes would need to account for changes in the behavior of MA plans and of Medicare beneficiaries. Failure to do so would ignore the full ramifications of a policy requiring MA plans to identify and delete unsupported codes and would ignore the potential for the government (and enrollees) to pay more due to higher bids (and higher cost sharing, in the case of enrollees).

Executed this 29th of September, 2023

MARK DUGGAN, Ph.D.

Work Experience

The Trione Director, Stanford Institute for Economic Policy Research (SIEPR), 2015 - present.

The Wayne and Jodi Cooperman Professor of Economics, Stanford University, 2014 – present.

Senior Fellow, Stanford Institute for Economic Policy Research, 2014 - present.

Chair, Department of Business Economics and Public Policy, the Wharton School, University of Pennsylvania, 2012 – 2014.

Rowan Family Foundation Professor, Wharton School, University of Pennsylvania, 2012 - 14.

Faculty Director, Penn Wharton Public Policy Initiative, 2012 – 2014.

Professor, Department of Business Economics and Public Policy, Department of Health Care Management, the Wharton School, University of Pennsylvania, 2011 – 2014.

Professor, University of Maryland, Department of Economics, 2007 - 2011.

Senior Economist, Council of Economic Advisers, Executive Office of the President, 2009 - 2010.

Associate Professor, University of Maryland, Department of Economics, 2003 – 2007.

Visiting Fellow, Brookings Institution, 2006 – 2007.

Assistant Professor, University of Chicago, Department of Economics, 1999 – 2003.

Visiting Assistant Professor, MIT, Department of Economics, 2001 – 2002.

Teaching Fellow, Harvard University, Department of Economics, 1996 - 1998.

Research Assistant, Harvard University, Department of Economics, 1994 - 1996.

Teaching Assistant, M.I.T. Department of Electrical Engineering and Computer Science, 1993-94.

Education

Ph.D., Economics, June 1999, Harvard University.

M.S., Electrical Engineering, June 1994, M.I.T.

B.S., Electrical Engineering, June 1992, M.I.T.

Professional Activities

American Economic Association 2022 Annual Meeting Program Committee, 2020 – 2022.

Program Area Coordinator, Econometric Society World Congress, 2020.

Chair, Bay Area Council Economic Institute, 2019 - present.

Member of Committee to select Editor of *American Economic Journal: Economic Policy*, 2018.

Affiliated Expert, Cornerstone Research, 2015 – present.

Advisory Board, Nuna Health, 2015 – 2019.

National Institutes of Health, Health and Retirement Study Data Monitoring Committee, 2014 - 2020.

American Economic Association, Committee on Government Relations, 2013 – 2017.

National Bureau of Economic Research IRB Committee, 2012 – 2015.

U.S. Bureau of Economic Analysis, Health Experts Advisory Group, 2012 – 2016.

Leonard Davis Institute, Senior Fellow, 2011 – 2014.

Social Security Advisory Board, Technical Panel on Assumption and Methods, 2010 – 2011.

Food and Drug Administration, Special Government Employee, 2011.

Advisory Board Member, McKinsey Center for U.S. Health System Reform, 2010 - 2012.

Research Associate, National Bureau of Economic Research, 2007–present.

Faculty Research Fellow, National Bureau of Economic Research, 2000-2007

Research Associate, Maryland Population Research Center, 2003-2011.

Co-organizer (with Amy Finkelstein) of NBER Public Economics Program meeting, Spring 2007.

Organizer of NBER Health Care meeting, Autumn 2007.

Member of Committee to Select Editor of *American Economic Journal: Applied Economics*, 2006-07.

Member of Social Security Administration's Technical Advisory Panel for Modeling the Effect of Social Security Reform on the SSDI Program, 2004-05.

Program Committee Member for the Econometric Society's 2005 World Congress.

Co-organizer (with Steven Levitt) of NBER Universities' Research Conference "The Economic Analysis of Government Expenditure Programs," 2002.

Member of American Economic Association, American Society of Health Economists, and National Academy of Social Insurance.

Fellowships and Awards

Stanford University Economics Department Distinguished Faculty Teaching Award, 2021-2022.

National Institute for Health Care Management Research Award (with Fiona Scott Morton), 2011.

ASHEcon Medal awarded once every two years to "Economist Age 40 and under who has Made the Most Significant Contributions to the Field of Health Economics", 2010.

Raymond Vernon Prize (with Melissa Kearney) for Best Article in the *Journal of Policy Analysis and Management*, 2007.

University of Maryland Undergraduate Student Teaching Award, 2006.

University of Maryland Graduate Student Teaching Award, 2005, 2006.

Alfred P. Sloan Foundation Research Fellow, 2004 - 2006.

Journal of Political Economy Griliches Award, Honorable Mention, 2002.

University of Chicago Faculty Appreciation Award, 2000 (awarded by economics Ph.D students)

Alfred P. Sloan Foundation Doctoral Dissertation Fellowship, 1998-99.

Harvard's Derek Bok Center Award for Excellence in Undergraduate Teaching, 1997 and 1998.

NBER Not-for-Profit Fellowship, 1997-98.

Harvard University Positive Political Economy Fellowship, 1996-97.

Harvard University Economics Department Fellowship, 1994-98.

Harvard University Albert J. Lynch Fellowship, 1994-98.

M.I.T. Frederick Hennie Award for Excellence in Undergraduate Teaching, 1994.

William T. Grant Foundation Fellowship, 1993-94.

Tau Beta Pi, 1991.

Editorial and Referee Service

Board of Editors, *Journal of Policy Analysis and Management*, 2021 – present.

Board of Editors, *American Economic Journal: Economic Policy*, 2007-2012, 2015 – 2021.

Co-Editor, *American Economic Journal: Economic Policy*, 2012 – 2015.

Co-Editor, *Journal of Public Economics*, 2010-2013.

Associate Editor, *Journal of Public Economics*, 2007-2010.

Referee for: *American Economic Journal: Applied Economics*, *American Economic Journal: Economic Policy*, *American Economic Review*, *B.E. University of Chicago Ph.D. Advisees (with first job placement)

Rodrigo Garcia-Verdu, 2000, Mexico Central Bank
Rena Rosenberg, 2000, McKinsey and Company
Joseph Doyle, 2001, M.I.T. Sloan School
Ming-Jen Lin, 2001, National Taiwan University
Deborah Healy, 2002, U.S. Department of Justice
Grecia Marrufo, 2002, Stanford post-doctoral fellowship
Raphael de Coninck, 2003, NYU post-doctoral fellowship
Damien de Walque, 2003, World Bank
Chris Rohlfs, 2006, Syracuse University

University of Maryland Ph.D. Advisees (with first job placement, ** indicates Chair or Co-Chair)

Jennifer Goodwin, 2004, Duke post-doctoral fellowship
Rubiana Chamarbagwala, 2005, Indiana University
Julian Cristia, 2006, Congressional Budget Office
Beomsoo Kim, 2006, University of North Carolina at Greensboro
Gaobo Pang, 2006, Watson Wyatt
Heng Wei, 2006, Price Waterhouse Coopers
Alex Whalley, 2006, University of California at Merced
Janet Hao, 2007, Conference Board
Scott Imberman **, 2007, University of Houston
Emily Owens, 2007, Cornell University, Public Policy and Management
Perry Singleton **, 2007, Syracuse University
Aparajita Goyal **, 2008, World Bank
Melissa Powell McInerney, 2008, College of William and Mary
Melinda Sandler, 2008, North Carolina State University
Meltem Daysal, 2009, Tillburg University
Craig Garthwaite **, 2009, Northwestern University (Kellogg)
Tamara Hayford **, 2009, Congressional Budget Office
Jessica Hennessey, 2009, Furman University
Yeon Soo Kim, 2010, Korea Development Institute
Lingsheng Meng **, 2010, Tsinghua University
Quynh Nguyen, 2010, World Bank
Li Tang, 2010, Inter-American Development Bank
Abby Alpert **, 2011, RAND
Diether Beuermann **, 2011, IADB
Keith Kranker **, 2011, Mathematica
Timothy Moore, 2012, George Washington University

University of Pennsylvania Ph.D. Advisees (with first job placement, ** indicates Chair or Co-Chair)

Adam Isen, 2013, U.S. Department of the Treasury
Jillian Popadak, 2014, Duke University (Fuqua)

Daniel Sacks, 2014, Indiana University (Kelley)
Victoria Perez, 2015, Indiana University (SPEA)
Boris Vabson **, 2016, Nuna Health
Andrew Johnston **, 2016, University of California at Merced

Stanford Ph.D. Advisees (with first job placement, ** indicates Chair or Co-Chair)

Joe Orsini, 2016, Nuna Health
Pietro Tebaldi, 2016, University of Chicago
Monica Bhole, 2017, Pandora
Atul Gupta, 2017, University of Pennsylvania (Wharton)

I. INTRODUCTION AND QUALIFICATIONS

A. Qualifications

1. My name is Craig Garthwaite. I am the Herman Smith Research Professor in Hospital and Health Services and a tenured Professor of Strategy at the Kellogg School of Management, Northwestern University. I am also the Director of the Program on Healthcare at Kellogg, and I organize Kellogg's healthcare business curriculum. At Kellogg, I teach courses in health care strategy, the economics of strategy, and value creation in biopharmaceuticals.
2. I am a Research Associate at the National Bureau of Economic Research, and a Faculty Associate at the Institute for Policy Research at Northwestern University. I received a Ph.D. in Economics from the University of Maryland at College Park, a Master's in Public Policy from the Gerald R. Ford School of Public Policy at the University of Michigan, and a B.A. in Political Science from the University of Michigan.
3. Prior to my graduate studies, I was an Economist at Public Sector Consultants in Lansing, Michigan, and the Director of Research and Chief Economist at the Employment Policies Institute in Washington, DC.
4. My research focuses on a variety of issues, including the potential impacts of health policy and the changing health care market on the operations of private health firms such as hospitals and insurers. In my academic research, I have worked with a variety of large and complex datasets, including insurer claims datasets,¹ hospital discharge datasets,² and hospital financial reports.³ My research has been published in journals such as the *Quarterly Journal of Economics*, the *American Economic Review*, the *Review of Economics and Statistics*, the *Journal of Health Economics*, the *New England Journal of Medicine*, the *Annals of Internal Medicine*, and *Health Affairs*, and has been profiled in

¹ Craig Garthwaite, David Dranove, and Christopher Ody, "The Economic Downturn And Its Lingering Effects Reduced Medicare Spending Growth By \$4 Billion In 2009–12," *Health Affairs*, Vol. 34, No. 8, August 2015, pp. 1368-1375, <https://www.healthaffairs.org/doi/10.1377/hlthaff.2015.0100>.

² Mark Duggan, Craig Garthwaite, and Adelina Yanyue Wang, "Heterogeneity in the Impact of Privatizing Social Health Insurance: Evidence from California's Medicaid Program," *NBER Working Paper Series*, No. 28944, June 2021.

³ Craig Garthwaite, Christopher Ody, and Amanda Starc, "Endogenous Quality Investments in the U.S. Hospital Market," *Journal of Health Economics*, Vol. 84, No. 102636, May 14, 2022.

media outlets such as *The New York Times*, *The Wall Street Journal*, and *The Washington Post*. I have testified before the United States House of Representatives and the United States Senate on matters related to health care markets, prescription drugs, and health care reform.

5. A copy of my Curriculum Vitae, including a list of all publications I have authored in the last ten years, is attached as **Appendix A**. A list of my prior testimony from the last four years is attached as **Appendix B**.

B. Assignment

6. The United States of America (“United States”) and Relator Benjamin Poehling (together, “Plaintiffs”) allege that, in relation to their Medicare Advantage and Medicare Advantage prescription drug plans, UnitedHealth Group Inc. and its subsidiaries (collectively, “Defendants”) knowingly and improperly avoided or decreased an obligation to repay risk adjustment payments to the Medicare program administered by the Centers for Medicare and Medicaid Services (“CMS”) by retaining risk adjustment payments to which they were not entitled.⁴
7. I have been engaged by counsel for Plaintiffs to provide expert testimony in this matter. Specifically, I have been asked to (1) identify diagnosis codes from service years 2008 through 2016 that Defendants submitted to CMS for risk adjustment payments covering payment years 2009 through 2017, where Defendants reviewed the medical records associated with those diagnosis codes as part of their Chart Review Program and did not find support for the diagnosis codes, and those diagnosis codes affected payment; (2) calculate the financial impact on Defendants’ Medicare Advantage and Medicare Part D risk adjustment payments that would have resulted had Defendants deleted the diagnosis codes I identified;⁵ and (3) determine the number of beneficiaries in each payment year for

⁴ United States’ Amended Complaint-In-Partial-Intervention and Demand for Jury Trial, *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. CV 16-08697 MWF (SSx), November 17, 2017 (“US vs UHG Amended Complaint”).

⁵ I was also asked to separately calculate the portion of this impact that is associated with diagnosis codes reviewed by Defendants in Second Level Review as part of the Chart Review Program.

whom Defendants would have received reduced risk adjustment payments from CMS had Defendants deleted the diagnosis codes I identified.

8. I have also been asked to separately calculate the financial impact on Defendants' Medicare Advantage and Medicare Part D risk adjustment payments resulting from their failure to delete the diagnosis codes included on two spreadsheets produced by Defendants, which contain diagnosis codes that Defendants identified as having been included in their Claims Verification program but not having completed all the steps of the program (hereinafter referred to as "Defendants' CV Pipeline Lists").
9. For my work on this case, I am being compensated at my standard hourly billing rate of \$900. Staff at Analysis Group, a consulting firm, worked under my direction and helped me prepare my report. I also receive compensation from Analysis Group based on its collected staff billings for its support of me in this matter. Neither my compensation in this matter nor my compensation from Analysis Group is in any way contingent or based on the content of my opinions or the outcome of this or any other matter.
10. I have reviewed documents, data, testimony, and other materials provided through discovery or obtained from public sources. The documents, data, testimony, and other materials that I have relied upon as a basis for my opinions are listed in **Appendix C**.
11. **Appendix D** contains more detailed descriptions of the data I relied upon and the methods I used for my analyses, as well as illustrative examples of the data and methods.
12. My opinions are based on the research and analyses that I undertook during this period and the information available to me as of the date of this report. Should additional relevant materials including documents, data, testimony, declarations or reports of other experts, or other information be made available to me, I may adjust or supplement my opinions as appropriate.

II. SUMMARY OF OPINIONS

13. I have identified in **Attachment 1** a set of diagnosis codes that Defendants submitted to CMS for risk adjustment purposes. According to my analysis, Defendants reviewed the medical records that were the source of these diagnosis codes as part of their Chart Review Program and their review found no support for these diagnosis codes or their associated

Hierarchical Condition Categories or Rx Hierarchical Condition Categories. In addition, I found no other instances of these diagnosis codes nor did I find other diagnosis codes associated with the same Hierarchical Condition Categories or Rx Hierarchical Condition Categories that Defendants may have submitted for that beneficiary in the same year.⁶ I have calculated that the risk adjustment payments Defendants received from CMS would have been reduced if Defendants had deleted these diagnosis codes.

14. I have concluded that:

- i. The total financial impact on Defendants' Medicare Advantage and Medicare Part D risk adjustment payments resulting from Defendants' failure to delete the diagnosis codes in **Attachment 1** is \$2,135,252,375 for payment years 2009-2017.
- ii. The total number of affected beneficiaries counted year-by-year across payment years 2009-2017 is 1,132,418.⁷
- iii. The total financial impact on Defendants' Medicare Advantage and Medicare Part D risk adjustment payments resulting from Defendants' failure to delete the diagnosis codes listed in Defendants' CV Pipeline Lists is \$188,402,348.

III. BACKGROUND

15. In this section, I provide a description of Medicare Advantage, which is based on my professional understanding and my review of the documents cited herein. My intent is to provide background and context relevant to understanding the analyses I have performed.

⁶ Specifically, the diagnosis codes in **Attachment 1** do not share an HCC with any other submitted diagnosis code, do not share an HCC with any other risk adjustment-eligible but unsubmitted diagnosis code, *and* do not map to an HCC recorded in the Claims Verification program, as further explained in Section **VI.E**.

⁷ Each beneficiary is counted once for each payment year in which their risk adjustment payments are affected. If a beneficiary's Medicare Advantage and Medicare Part D risk adjustment payments are affected in a single year, that beneficiary is counted only once in that year.

A. Medicare Overview

16. Medicare provides health insurance for people aged 65 or older, younger people with a disability, end-stage renal disease, or amyotrophic lateral sclerosis, and certain railroad retirement beneficiaries.⁸
17. Medicare beneficiaries have the option to enroll in “Traditional Medicare,” which is largely administered by CMS,⁹ or “Medicare Advantage,” which is administered by commercial insurers known as Medicare Advantage Organizations (“MAOs”).¹⁰
18. Traditional Medicare includes two types of coverage, called “Parts.” **Part A** generally covers inpatient care in hospitals, care in nursing facilities, care in hospice facilities, and home health care.¹¹ **Part B** generally covers outpatient services from doctors and other health care providers, durable medical equipment, and other preventative services.¹² Under Traditional Medicare, healthcare providers submit claims for services to CMS for payment by CMS on a claim-by-claim basis (sometimes called “fee-for-service”).¹³ Traditional Medicare beneficiaries may also purchase prescription drug coverage under Medicare Part D.
19. Medicare Advantage, or **Part C**, is an alternative to Traditional Medicare through which MAOs offer Medicare-approved plans that bundle coverage normally provided by CMS in Part A and Part B to beneficiaries enrolled in Part C. MAOs may also offer plans that include prescription drug coverage under Medicare **Part D**.¹⁴ A Medicare Advantage plan that includes Part D coverage is called a Medicare Advantage Prescription Drug (“MA-

¹¹ 42 USC § 1395c.

¹² *Ibid.*

¹³ 42 USC § 1395c et seq.

¹⁴ 42 USC § 1395w et seq.

PD”) plan.¹⁵ MAOs can, and generally do, operate a large number of Medicare Advantage plans.

20. Under Medicare Advantage, beneficiaries and/or their healthcare providers submit claims to Medicare Advantage plans and, instead of receiving payment from CMS on a “fee-for-service” basis, receive payment from the MAO.¹⁶ MAOs that participate in the Medicare Advantage program receive monthly premium payments for each beneficiary enrolled in their plans.¹⁷ These “per member per month” payments are calculated in accordance with a method for determining anticipated medical costs, called risk adjustment.¹⁸

B. Risk Adjustment for Medicare Advantage

i. Payments to Medicare Advantage Plans

21. Under Part C, each MAO receives per member per month payments from CMS for each beneficiary enrolled in its Medicare Advantage plans.
22. The per member per month payments that MAOs receive from CMS are calculated as a plan-specific “bid,” or base rate,¹⁹ which is adjusted based on geography but otherwise the same for every beneficiary in the plan, multiplied by a risk score, which is beneficiary-specific and calculated based on the beneficiary’s health status and demographics, such as age and sex.²⁰ The base rate is meant to reflect the average cost of coverage for a beneficiary in the plan.²¹ The risk score is designed to broadly account for anticipated

¹⁵ *Ibid.*

¹⁶ *Ibid.*

¹⁷ 42 USC § 1395w-23(a)(1)(C); 42 CFR § 422 et seq.

¹⁸ 42 USC § 1395w-23(a)(1)(C); 42 CFR § 422 et seq.

¹⁹ Each MAO plan submits bids to CMS indicating the premium amount that would be required to cover an average beneficiary’s expenses. There is a maximum premium CMS will pay for an average beneficiary based on geography (the “benchmark”). If a plan’s bid falls below the benchmark, it receives a rebate. If the plan’s bid exceeds the benchmark, the plan collects that difference from its beneficiaries. See 42 USC § 1395w-23(a)(1)(B); *Ibid.*(b)(1)(B).

²⁰ Other factors, such as the congressionally mandated coding adjustment (see *Ibid.*(a)(1)(C)(ii)) and the normalization factor (see 42 CFR § 422.308(a)) also affect the amount CMS pays MAOs.

²¹ See 42 USC § 1395w-24 et seq; 42 CFR § 422.254 et seq.

differences in the cost of coverage between beneficiaries.²² In general, CMS pays MAOs higher per member per month amounts to cover beneficiaries who are expected to incur more medical costs because of their poor health status.

23. CMS calculates the risk score using the CMS Hierarchical Condition Category Risk Adjustment Model (“CMS HCC Model”),²³ which assigns weighted numeric values to various factors that affect the expected costs to cover a beneficiary, including health status and demographics (e.g., sex, age, disability, whether institutionalized, and whether enrolled in Medicaid).²⁴ CMS makes publicly available on its website computer programs for calculating risk scores.²⁵ These programs take beneficiary health status information and demographics as inputs, and automatically calculate a risk score for each beneficiary based on the weighted numeric values assigned to the various factors in the CMS HCC Model.
24. The health status portion of a beneficiary’s risk score depends upon the medical diagnosis codes that an MAO submits to CMS for that beneficiary. CMS requires MAOs to submit beneficiary diagnosis codes using the International Classification of Diseases (“ICD”) system established by the World Health Organization.^{26, 27}

²⁴ “CMS Manual System Transmittal 118,” Department of Health & Human Services and Centers for Medicare & Medicaid Services, September 19, 2014, <https://www.cms.gov/Regulations-and-Guidance/Guidance/Transmittals/Downloads/R118MCM.pdf>, accessed June 30, 2022 (“In order to use the risk adjustment model to calculate risk scores for payment, CMS creates a relative factor for each demographic factor and HCC in the model.”).

²⁵ “Medicare risk adjustment information,” Centers for Medicare & Medicaid Services, <https://www.cms.gov/medicare/payment/medicare-advantage-rates-statistics/risk-adjustment>, downloaded on June 16, 2023.

²⁶ During the time period at issue in this matter, diagnosis codes were coded using the ICD-9-CM coding system until the Centers for Disease Control and Prevention fully transitioned diagnosis codes to the ICD-10-CM coding system on October 1, 2015. See “Announcement of Calendar Year (CY) 2015 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies and Final Call Letter,” Centers for Medicare & Medicaid Services, April 7, 2014, <https://www.cms.gov/medicare/health-plans/medicareadvtspecratestats/downloads/announcement2015.pdf>, accessed September 14, 2023 Section N.

²⁷ “CMS Manual System Transmittal 118,” Department of Health & Human Services and Centers for Medicare & Medicaid Services, September 19, 2014, <https://www.cms.gov/Regulations-and-Guidance/Guidance/Transmittals/Downloads/R118MCM.pdf>, accessed June 30, 2022, p. 4.

25. Each year, CMS calculates a new risk score for each beneficiary based on diagnosis codes documented for that beneficiary in the previous year.²⁸ For example, the health status component of a beneficiary's final risk score used for payment in 2011 (the "payment year") is determined only by the diagnosis codes documented during medical encounters with their providers in 2010 (the "service year"). Diagnosis codes from encounters that occurred outside of the service year do not affect the calculation of the beneficiary's final risk score for the associated payment year.
26. During payment years 2009-2017 (corresponding to service years 2008-2016), which is the time period at issue in this matter, CMS had specific rules governing MAO submissions of diagnosis code data (also called "risk adjustment data"). For example, diagnosis codes used to determine payments for a particular payment year (*e.g.*, 2011) must be supported by the beneficiary's medical records and must generally result from face-to-face encounters²⁹ between beneficiaries and providers with an acceptable specialty³⁰ that occurred during the corresponding service year (*e.g.*, 2010). Furthermore, for every date of service (*e.g.*, a medical encounter that took place on January 1, 2010) included within a medical record ("Chart") and used as the basis for submission of a given diagnosis code, the Chart must be signed and include the provider's credentials.³¹ In this Report, I refer to encounters that meet CMS' rules as risk adjustment-eligible encounters, and I refer to the diagnosis codes associated with these encounters as risk adjustment-eligible diagnosis codes.
27. The CMS HCC Model maps some, but not all, diagnosis codes to one of 70 or 79 (depending on the time period)³² Hierarchical Condition Categories ("HCCs"), which

²⁸ 42 CFR § 422.304 et seq.

²⁹ For example, labs and diagnostic radiology encounters are not considered valid sources for diagnosis codes used to determine payment. See *2008 Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide*, Centers for Medicare & Medicaid Services, January 1, 2008, <https://www.hhs.gov/guidance/document/2008-risk-adjustment-data-technical-assistance-medicare-advantage-organizations>, accessed September 5, 2023, at Section 3.2.3. There are limited exceptions to the face-to-face requirements, such as diagnoses made by pathologists. See also 42 CFR 422.310(d)(1); 45 CFR 162.1002(c)(2) and (c)(3).

³⁰ A list of acceptable physician specialties is found in *Ibid.*, at Table 3H.

³¹ *Ibid.* at Section 7.2.4.2.

³² For service years 2008-2012, CMS used version 12 of the CMS HCC Risk Adjustment Model, which included 70 HCCs. Starting with service year 2013, CMS began phasing in version 22 of the model, which included 79 HCCs. Full implementation of version 22 began with service year 2016. See "Announcement of Calendar Year

represent groups of diagnosis codes that define major health conditions.³³ For example, diagnosis code 25000, *Diabetes mellitus without mention of complications*, diagnosis code 24900, *Secondary diabetes mellitus without mention of complication, not stated as uncontrolled, or unspecified*, and diagnosis code 25003, *Diabetes mellitus without mention of complication, type I, uncontrolled - as a primary diagnosis code* all map to HCC 19, *Diabetes without complications*.³⁴

28. If an MAO does not submit any diagnosis codes for a particular beneficiary during the service year, the beneficiary's risk score for the payment year is based solely on the beneficiary's demographic factors. For example, in service year 2010, a beneficiary who is female, 65 years old, not disabled, not institutionalized, and not dually enrolled in Medicaid would have a demographic factor of 0.298.³⁵ If the MAO did not report any diagnosis codes for this beneficiary in service year 2010, the associated per member per month payment in payment year 2011 would be 29.8% of the plan's base rate. Thus, if the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$29.80 for this beneficiary.
29. If an MAO submits a diagnosis code for a beneficiary mapping to an HCC, the CMS HCC Model incorporates that HCC into its calculation of the beneficiary's risk score. For

(CY) 2014 Medicare Advantage Capitation Rates and Medicare Advantage and Part D Payment Policies and Final Call Letter,” Centers for Medicare & Medicaid Services, April 1, 2013, <https://www.cms.gov/medicare/health-plans/medicareadvtspecratestats/downloads/announcement2014.pdf>, accessed September 14, 2023 at Table 5; *Report to Congress: Risk Adjustment in Medicare Advantage*, Centers for Medicare & Medicaid Services, December 2021, <https://www.cms.gov/files/document/report-congress-risk-adjustment-medicare-advantage-december-2021.pdf>, accessed June 30, 2022, at 7. CMS determines which diagnosis codes map to which HCCs each year.

³³ In the CMS HCC Model, diagnosis codes are grouped with other clinically similar diagnosis codes and the diagnosis groupings are mapped to condition categories based on similar clinical characteristics and severity, and cost implications. Hierarchies are imposed on the condition categories included in the model (then called “Hierarchical Condition Categories or “HCCs”). “CMS Manual System Transmittal 118,” Department of Health & Human Services and Centers for Medicare & Medicaid Services, September 19, 2014, <https://www.cms.gov/Regulations-and-Guidance/Guidance/Transmittals/Downloads/R118MCM.pdf>, accessed June 30, 2022, at § 70.1.

³⁴ The illustrative examples presented in my Report and in **Appendix D** use ICD-9 codes, but the same concepts apply to ICD-10 diagnosis codes.

³⁵ The factors presented in the examples in my Report are from CMS’ “Announcement of Calendar Year (CY) 2008 Medicare Advantage Capitation Rates and Payment Policies,” Centers for Medicare & Medicaid Services, April 2, 2007, <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2008.pdf>, accessed September 5, 2023 at Table 1-4.

example, assume that the beneficiary described above had only one risk adjustment-eligible medical encounter in 2010, with Provider A, and that Provider A reported diagnosis code 25000 to the MAO for this encounter. Assume that in turn, the MAO submitted this diagnosis code to CMS. As noted above, diagnosis code 25000 maps to HCC 19, *Diabetes without complication*, which is assigned a factor of 0.181. When the demographic risk factor (0.298) and HCC 19 risk factor (0.181) are combined, the resulting total risk score for this beneficiary would be 0.479.³⁶ If the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$47.90 for this beneficiary.

30. Some HCCs are strictly additive, such that multiple diagnosis codes mapping to different HCCs will have a numerical value assigned to each HCC and each HCC will be included in the risk score and payment calculation. For example, consider Beneficiary 1 in **Exhibit 1** below. Assume that she has the same demographic factor as the hypothetical beneficiary described above (0.298) but that Provider A reported two diagnosis codes for her based on the 1/1/2010 medical encounter. In this hypothetical, Provider A reported diagnosis codes 25000 and 82100, which map to HCC 19, *Diabetes without complication* and HCC 158, *Hip fracture/dislocation*, respectively. HCC 19 is assigned a factor of 0.181 and HCC 158 is assigned a factor of 0.450, resulting in a total risk score of 0.929 for this beneficiary.³⁷ If the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$92.90 for this beneficiary.

³⁶ $0.479 = 0.298 \text{ demographic factor} + 0.181 \text{ HCC 19 factor}.$

³⁷ $0.929 = 0.298 \text{ demographic factor} + 0.181 \text{ HCC 19 factor} + 0.450 \text{ HCC 158 factor}.$

Exhibit 1
Risk Score Calculation for Hypothetical Beneficiary 1

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
1	1/1/2010	A	Claims	25000	19	0.181
1	1/1/2010	A	Claims	82100	158	0.450
Demographic Factor						0.298
Total Risk Score						0.929
x Base Rate						\$100
Per Member Per Month Payment						\$92.90

31. If an MAO submits multiple diagnosis codes mapping to the same HCC for a beneficiary, the beneficiary's risk score does not depend on which specific diagnosis code was reported. Nor does the risk score depend on how many times a particular diagnosis code is reported within a service year.
32. This principle can be observed in **Exhibit 2** below. Like Beneficiary 1, Beneficiary 2 had her first encounter in 2010 with Provider A on 1/1/2010. Again, Provider A reported diagnosis codes 25000 and 82100, which map to HCC 19 and HCC 158, respectively. Beneficiary 2 then had three subsequent encounters with Provider A in the same year, for which Provider A only reported diagnosis code 25001. Diagnosis code 25001, like diagnosis code 25000, maps to HCC 19. In service year 2010, Beneficiary 2 has the same two distinct HCCs as Beneficiary 1 (HCC 19 and HCC 158). As a result, despite having a greater number of submitted diagnosis codes, Beneficiary 2 has the same risk score as Beneficiary 1 (0.929). Likewise, if the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$92.90 for this beneficiary.³⁸

³⁸ 0.929 = 0.298 demographic factor + 0.181 HCC 19 factor + 0.450 HCC 158 factor.

Exhibit 2
Risk Score Calculation for Hypothetical Beneficiary 2

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
2	1/1/2010	A	Claims	25000	19	0.181
2	1/1/2010	A	Claims	82100	158	0.450
2	4/1/2010	A	Claims	25001	19	0.181
2	5/1/2010	A	Claims	25001	19	0.181
2	6/1/2010	A	Claims	25001	19	0.181
2	7/1/2010	A	Claims	25001	19	0.181

Distinct HCCs	HCC Factor
19	0.181
158	0.450
Demographic Factor	0.298
Total Risk Score	0.929
x Base Rate	\$100
Per Member Per Month Payment	\$92.90

33. While some HCCs are strictly additive, certain HCCs represent more or less severe cases of the same condition or related conditions, and these are not strictly additive.³⁹ In these cases, the model utilizes a hierarchy such that only the most severe case of the condition is included in the risk score. For example, HCCs 15 through 19 are related to diabetes and defined by CMS as belonging to a single hierarchy.⁴⁰ If a beneficiary has a diagnosis code mapping to HCC 15 and a different diagnosis code mapping to HCC 19, only the more severe condition will be used for calculating that beneficiary's risk score.⁴¹ Within a hierarchy, more severe conditions map to lower HCCs,⁴² so in this example, HCC 15 would be included in the beneficiary's risk score and HCC 19 would not.

³⁹ "Announcement of Calendar Year (CY) 2008 Medicare Advantage Capitation Rates and Payment Policies," Centers for Medicare & Medicaid Services, April 2, 2007, <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2008.pdf>, accessed September 5, 2023.

⁴⁰ The five diabetes-related HCCs are defined as follows: Diabetes with renal or peripheral circulatory manifestation (HCC 15), Diabetes with neurologic or other specified manifestation (HCC 16), Diabetes with acute complications (HCC 17), Diabetes with ophthalmologic or unspecified manifestation (HCC 18), and Diabetes without complication (HCC 19); *Ibid.* at Table 1-4.

⁴¹ *Ibid.* at Table 1-4.

⁴² *Ibid.* at Table 1-4. The relative factor for HCC 19 for a non-institutionalized beneficiary is 0.181 and the relative factor for HCC 15 for that same beneficiary would be 0.608.

34. Consider Beneficiary 3 in **Exhibit 3** below. As with Beneficiary 1 and Beneficiary 2, this beneficiary has a demographic factor of 0.298 and had her first encounter in 2010 with Provider A on 1/1/2010. Again, Provider A reported diagnosis codes 25000 and 82100, which map to HCC 19 and HCC 158, respectively. If this were Beneficiary 3's only encounter during this service year, then she would have the same risk score as Beneficiary 1 and Beneficiary 2. However, Beneficiary 3 had one subsequent encounter with Provider A, for which Provider A reported diagnosis code 25040. Diagnosis code 25040 maps to HCC 15, which is a more severe condition in the same disease hierarchy as HCC 19.⁴³ For the purpose of risk adjustment, HCC 15 is included in Beneficiary 3's risk score and HCC 19 is not (HCC 19 is effectively subsumed by HCC 15). HCC 15 is assigned a factor of 0.608 and HCC 158 is assigned a factor of 0.450, resulting in a total risk score of 1.356 for Beneficiary 3.⁴⁴ If the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$135.60 for this beneficiary.

Exhibit 3
Risk Score Calculation for Hypothetical Beneficiary 3 (Hierarchy)

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
3	1/1/2010	A	Claims	25000	19	0.181
3	1/1/2010	A	Claims	82100	158	0.450
3	4/1/2010	A	Claims	25040	15	0.608

Distinct HCCs	HCC Factor
15	0.608
158	0.450
Demographic Factor	0.298
Total Risk Score	1.356
x Base Rate	\$100
Per Member Per Month Payment	\$135.60

35. The CMS HCC Model also accounts for anticipated costs associated with disease interactions, such that a risk score may be impacted if a beneficiary has a combination of

⁴³ *Ibid.* at Table 1-4.

⁴⁴ $1.356 = 0.298 \text{ demographic factor} + 0.608 \text{ HCC 15 factor} + 0.450 \text{ HCC 158 factor}$.

certain HCCs. In these cases, the beneficiary may receive an additional increase in their risk score.⁴⁵

36. To illustrate, consider Beneficiary 4 in **Exhibit 4** below. As with Beneficiaries 1, 2, and 3, this beneficiary has a demographic factor of 0.298 and had her first encounter in 2010 with Provider A on 1/1/2010. In this hypothetical, Provider A reported diagnosis codes 25000 and 436, which map to HCC 19, *Diabetes without complication*, and HCC 96, *Ischemic or unspecified stroke*, respectively. CMS applies a disease interaction factor for the combination of HCC 19 and HCC 96, which will increase this beneficiary's risk score by 0.149.⁴⁶ To calculate the risk score for Beneficiary 4, CMS totals the value of HCC 19 (which is assigned a factor of 0.181), HCC 96 (which is assigned a factor of 0.303), and the disease interaction factor (which is assigned a factor of 0.149), thereby resulting in a total risk score of 0.931 for this beneficiary.⁴⁷ If the base rate for this beneficiary's plan is \$100, then CMS would pay the MAO a risk adjusted per member per month payment of \$93.10 for this beneficiary.

⁴⁵ "Announcement of Calendar Year (CY) 2008 Medicare Advantage Capitation Rates and Payment Policies," Centers for Medicare & Medicaid Services, April 2, 2007, <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2008.pdf>, accessed September 5, 2023 at Table 1-4. CMS also applies a disabled/disease interaction factor if a beneficiary qualifies for disability status and has a combination of certain co-existing conditions, as reflected in the HCCs assigned to the beneficiary that result in a lift to the beneficiary's risk score. For the purposes of the examples included here, assume that the beneficiary does not qualify for disability status. "Medicare Managed Care Manual Chapter 7 - Risk Adjustment," Centers for Medicare & Medicaid Services, September 19, 2014, <https://www.cms.gov/Regulations-and-Guidance/Guidance/Manuals/Downloads/mc86c07.pdf>, accessed October 15, 2022 at § 70.2.7; "Announcement of Calendar Year (CY) 2008 Medicare Advantage Capitation Rates and Payment Policies," Centers for Medicare & Medicaid Services, April 2, 2007, <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2008.pdf>, accessed September 5, 2023, p. 29.

⁴⁶ "Announcement of Calendar Year (CY) 2008 Medicare Advantage Capitation Rates and Payment Policies," Centers for Medicare & Medicaid Services, April 2, 2007, <https://www.cms.gov/Medicare/Health-Plans/MedicareAdvtgSpecRateStats/downloads/announcement2008.pdf>, accessed September 5, 2023 at Table 1-4.

⁴⁷ $0.931 = 0.298 \text{ demographic factor} + 0.181 \text{ HCC 19 factor} + 0.303 \text{ HCC 96 factor} + 0.149 \text{ interaction factor for HCC 19 and HCC 96.}$

Exhibit 4
Risk Score Calculation for Hypothetical Beneficiary 4 (Disease Interactions)

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
4	1/1/2010	A	Claims	25000	19	0.181
4	1/1/2010	A	Claims	436	96	0.303
Demographic Factor						0.298
Disease Interaction Factor						0.149
Total Risk Score						0.931
x Base Rate						\$100
Per Member Per Month Payment						\$93.10

ii. Payments to MA-PD Plans

37. Risk adjustment is also a component of how CMS makes payments under Part D to MA-PD plans. The per member per month payment that CMS pays MA-PD plans for each beneficiary is based on a base rate, multiplied by a risk score.
38. The Part D risk score is calculated in a similar manner to the risk score for Part C and, as is true in Part C, is affected by the submission of diagnosis codes that map to Rx Hierarchical Condition Categories (“RxHCCs”) included within the CMS RxHCC Risk Adjustment Model (“CMS RxHCC Model”). The construction and use of RxHCCs is similar to the construction and use of HCCs. As with Part C, CMS makes publicly available on their website computer programs for calculating Part D risk scores based on the beneficiary diagnosis codes and demographics that are inputs to the program.⁴⁸
39. Many diagnosis codes map to both an HCC and an RxHCC, meaning that submission of such codes may impact payments under both models. Some diagnosis codes only map to an HCC or only map to an RxHCC and will only impact payments under the corresponding model. The same CMS rules discussed in the context of Part C above also apply to Part D: risk scores are calculated anew each year and are based only on diagnosis codes supported

⁴⁸ “Medicare risk adjustment information,” Centers for Medicare & Medicaid Services, <https://www.cms.gov/medicare/payment/medicare-advantage-rates-statistics/risk-adjustment>, downloaded on June 16, 2023.

by the beneficiary's medical records and, generally, resulting from face-to-face medical encounters with providers of certain specialties.⁴⁹

40. Part D payments from CMS to MA-PDs cover approximately 75% of the average total cost of prescription drug benefits, and beneficiary premiums cover the remainder.⁵⁰ CMS' portion of the payment is referred to as the "direct subsidy," and the beneficiary's portion is referred to as the "beneficiary premium."⁵¹ Like CMS' payment, the beneficiary's portion of the payment also depends on the risk score that CMS calculates based on diagnosis codes submitted to CMS for the beneficiary.
41. Additionally, unlike Part C, CMS applies "risk corridors" to Part D payments. Risk corridors are designed to reduce the risk that MAOs take on in providing prescription drug benefits to beneficiaries enrolled in MA-PD Plans.⁵² Risk corridors function at the plan level rather than at a beneficiary level. If an MAO's actual costs across all beneficiaries enrolled in a plan are higher than the expected costs, CMS will make additional payments to the MAO to help cover those costs. Conversely, if actual costs are lower than expected, the MAO must share those profits with CMS.
42. The expected costs for a given plan, referred to as the "target" amount, are set just below the amount the MAO receives to cover the beneficiaries in the plan, which includes CMS' portion of the payment (the direct subsidy) plus the beneficiaries' portion (the beneficiary premium), as MAOs are expected to incur some administrative costs in covering the

beneficiary.⁵³ If an MAO's actual costs for a given plan are less than 5% below the target amount, the MAO keeps all of those excess profits. Profits that the MAO earns based on costs that are between 5% and 10% below the target amount must be shared equally with CMS. For any profits the MAO earns based on costs that are more than 10% below the target, the majority (80%) must be returned to CMS. Conversely, the same tiers of risk sharing apply if the MAO incurs losses. The MAO must absorb all losses until their costs exceed the target amount by 5%. Losses associated with costs between 5% and 10% above the target amount are shared equally with CMS, and losses based on costs exceeding 10% above the target amount are largely borne by CMS (80%).

43. The diagnosis codes that MAOs submit to CMS for use in risk adjustment determine CMS' payment to MAOs, and these payments in turn are used to calculate the target amount for each MA-PD. The size of the gap between this target amount and the plan's actual costs may then result in an additional transfer of payment between MAOs and CMS under the risk corridors. In this way, under Part D, the diagnosis codes that MAOs submit for beneficiaries have an additional impact on payments which does not apply under Part C.

IV. DEFENDANTS' RISK ADJUSTMENT-RELATED PROGRAMS

44. In this section, I provide a description of certain programs Defendants implemented related to Medicare Advantage risk adjustment, which is based on my professional understanding and my review of the testimony and documents cited. My intent is to provide background and context relevant to understanding the analyses I have performed.
45. MAOs submit diagnosis code data for beneficiaries enrolled in their plans to CMS for use in risk adjustment.⁵⁴ Some of this data originates from provider-reported encounters, which providers report to MAOs as claims for reimbursement.⁵⁵ MAOs may also supplement this data with additional diagnosis codes that are supported by the beneficiary's medical records

⁵³ 42 CFR § 423.336(a)(2).

⁵⁴ 42 CFR § 422.310(a)-(b).

⁵⁵ *2008 Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide*, Centers for Medicare & Medicaid Services, January 1, 2008, <https://www.hhs.gov/guidance/document/2008-risk-adjustment-data-technical-assistance-medicare-advantage-organizations>, accessed September 5, 2023, Section 3.2.1 – 3.2.3.

from the relevant service year, but that may not have already been reported on the provider's claim.⁵⁶

46. For the years at issue in this matter, Defendants conducted retrospective reviews of their Medicare Advantage beneficiaries' medical records, also known as "Charts," to identify diagnosis codes that were supported by those Charts.⁵⁷ Defendants' primary program for conducting these reviews, the Chart Review Program, was implemented for every payment year at issue in this matter. For some of these years, Defendants also implemented an additional program called Claims Verification.

A. Defendants' Chart Review Program

47. In the Chart Review Program, Defendants, either themselves or through a third-party vendor,⁵⁸ identified and collected Charts from certain providers who had reported encounters with beneficiaries to Defendants, and for which Defendants had submitted diagnosis codes to CMS.⁵⁹ The collected Charts could include information about only one encounter for a beneficiary from the relevant service year or multiple encounters from that year.⁶⁰ Some of the collected Charts included information about encounters with multiple

⁵⁶ *Ibid.* Section 3.2.4.

⁵⁷ Deposition of Kathleen O. Baker 30(b)(6), *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, Case No. 2:16-cv-08697-FMO-SS, May 30, 2023 ("Baker Deposition Volume 1"), 33:10–20 ("Q. Okay. So broadly speaking, what is Optum's retrospective chart review program? A. Optum's retrospective chart review program is a program where we submit a more complete health status from medical records collected on a member for appropriate payment from CMS. Q. Okay. So what is the purpose of Optum's chart review program? A. To submit more complete health statuses to CMS on risk adjustment members.").

⁵⁸ *Ibid.*, 137:1–9 ("Q. Okay. So let's go back to our hypothetical patient, Mary, who's seeing doctors at Vanderbilt Health. So -- and we're -- I'm focused now on the 2008 and 2009 dates of service. Can you just -- what was the name of one of the coding vendors that you used at the time? A. TCS, The Coding Source.").

⁵⁹ *Ibid.*, 65:5–68:9 ("In the retrieval process itself, if it went to a -- a vendor for retrieval, for instance, it could be something along the lines of when you send the chart over -- you know, a chart is a member-provider combination where the provider is based upon -- is selected from a location, for instance. ... And then as you're retrieving the chart, what the vendor will do is they'll call up the provider. They'll do some sort of provider verification, like asking are there X number of providers and their ID there to make sure they've got the right area. Then they'll go through a member verification to say hey, do you have these members with this information. ... And then once we get validation from there, typically we either fax or we would secure E-mail the complete list of the members. And then, based upon the number, we'd work with them to schedule either on site or they could themselves decide to send us the charts").

⁶⁰ *Ibid.*, 35:1–15 ("So in my personal opinion, when I say more complete health status, it's the recognition that there's -- we may not ever be able to submit 100 percent of a person's medical status, but it's -- in context of the retrospective chart review program, it's being able to say based upon a chart that we have on a member, knowing that a member may have multiple charts from different providers that contain different providers

providers.⁶¹ Certified medical record coders (“Coders”) reviewed the collected Charts to identify and code medical conditions that were documented by physicians in the Charts.⁶²

48. Defendants’ Chart Review Program, which began prior to the first year I was asked to analyze for this matter, grew during the time period at issue. **Exhibit 5** shows the number of beneficiaries enrolled in Defendants’ Medicare Advantage plans,⁶³ according to their annual public filings, along with the number of beneficiaries and service dates that were reviewed in Defendants’ Chart Review Program for the years at issue in this matter, according to Defendants’ data.

within those charts on different dates of services that we're, you know, attempting for one of those charts to provide information.”); *Ibid.*, 222:1–2. (“A chart could contain multiple dates of services.”).

⁶¹ *Ibid.*, 119:13–120:2 (“Q. Okay. So as a result of Optum's consolidation process for that retrieval -- retrieval provider ID, was it possible to collect charts for members that included encounters with multiple providers? ... THE WITNESS: So after we -- after we released the charts to the retrieval vendor and they did their consolidation and they did their validation and we retrieved the chart under that method, it could include multiple providers.”).

⁶² *Ibid.*, 187:17–188:4 (“Q. And did you believe that the coders hired by Optum for the 2008-2016 date of service chart reviews were among the best in -- available in the business? ... THE WITNESS: We required that our coders be certified coders. And then from there, we provided them training on risk adjustment coding.”); Deposition of Kathleen O. Baker 30(b)(6) *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, Case No. 2:16-cv-08697-FMO-SS, May 31, 2023 (“Baker Deposition Volume 2”), 420:7–422:22 (“Q. Okay. And then going forward for subsequent date of service years, so date of -- dates of service 2013, 2014, 2015 and 2016, were coders consistently instructed to record all RxHCCs? ... THE WITNESS: They were asked to code all HCCs and RxHCCs that they could identify in the chart according to their ability, according to the chart difficulty levels.”); Deposition of Melissa Sedor 30(b)(6), *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. CV 16-08697 FMO, June 29, 2023 (“Sedor Deposition”), 184:17–20 (“The chart review is looking at the medical record to determine which diagnosis the doctor or provider had documented in that medical record.”).

⁶³ *2008 Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide*, Centers for Medicare & Medicaid Services, January 1, 2008, <https://www.hhs.gov/guidance/document/2008-risk-adjustment-data-technical-assistance-medicare-advantage-organizations>, accessed September 5, 2023, p. 168 (“During medical record review, the certified coder checks for the following: [t]he service was provided by an acceptable risk adjustment provider type and physician specialty ... [d]iagnoses supported by medical record submission.”).

Exhibit 5
Defendants' Medicare Advantage Beneficiaries⁶⁴ and
Beneficiaries and Service Dates Reviewed in Defendants' Chart Review Program
Service Years 2008–2016

Service Year	Defendants' Medicare Advantage Beneficiaries <i>based on 10-K filings</i>	Beneficiaries Reviewed	Beneficiary Service Dates Reviewed
	[A]	[B]	[C]
2008	1,495,000	540,037	1,962,873
2009	1,790,000	811,013	3,437,735
2010	2,005,000	1,040,460	5,150,626
2011	2,165,000	1,172,337	6,641,373
2012	2,565,000	1,291,814	7,255,206
2013	2,990,000	1,568,691	8,780,321
2014	3,005,000	1,901,809	11,949,263
2015	3,235,000	2,059,941	14,476,590
2016	3,630,000	2,212,997	16,412,551

49. While the number of beneficiaries enrolled in Defendants' Medicare Advantage plans grew by 143% from service year 2008 to 2016, the number of beneficiaries reviewed in Defendants' Chart Review Program grew by 310% and the number of service dates

reviewed grew by more than 736%.⁶⁵ In 2008, approximately 36% of the beneficiaries enrolled in Defendants' Medicare Advantage plans had a Chart reviewed in Defendants' Chart Review Program. By 2016, Defendants Chart Review Program included over 60% of Defendants' beneficiaries.⁶⁶

50. The Chart Review Program generally conducted reviews in a "blind" fashion,⁶⁷ meaning that the Coder did not know which diagnosis codes the provider had initially reported (and Defendants had submitted to CMS) for the encounter or encounters documented in the Chart under review.⁶⁸ In blind reviews, Defendants instructed their Coders to record all diagnosis codes eligible for risk adjustment that they determined were supported by the beneficiary's Chart.⁶⁹
51. For service years 2014-2016, Defendants also conducted a step in the Chart Review Program called "Second Level Review," where a *second* blind review was conducted for some Charts.⁷⁰ Based on Defendants' data, approximately 73% of the Charts reviewed in these years underwent a Second Level Review.⁷¹

⁶⁵ These calculations are based on the change in the number of beneficiaries (or beneficiary service dates) reviewed from 2008 to 2016, divided by the number of beneficiaries (or beneficiary service dates) reviewed in 2008, as shown in **Exhibit 5**.

⁶⁶ These calculations are based on the number of beneficiaries Defendants reviewed in the Chart Review Program [B], divided by the number of Defendants' Medicare Advantage beneficiaries [A] as shown in **Exhibit 5**.

⁶⁷ Baker Deposition Volume 1, 298:17–22 ("Q. Okay. Okay. So aside from the charts marked with the recode flag discussed here, Optum coded charts for UnitedHealthcare's chart review program using blind coding for the 2008 to 2016 dates of service, correct? A. Yes.").

⁶⁸ *Ibid.*, 260:1–260:16 ("[I]n blind coding a coder's given no additional information, other than the image of the chart to -- to code to the best of their ability.").

⁶⁹ *Ibid.*, 197:1–203:9 ("Q. And Optum also instructed its coders that the medical record had to support the diagnosis code selected, correct? ... THE WITNESS: We, as part of our QA process, would check to make sure that the code that the coder coded from the chart was supported appropriately within the medical record. But, again, that doesn't mean that they were 100 percent complete in what was coding from that chart.").

⁷⁰ *Ibid.*, 351:4–354:3 ("A. We would send charts to second-level review based upon the information that we saw where again, depending upon the coder's experience -- the complexity of the chart, the type of chart, if it was EMR or if it was handwritten -- that we would send it to second-level review."); 359:16–360:8 ("Q. Okay. So then if we're trying to figure out which one of Mary's chart reviews is first-time coding versus second-level review, would you determine that by looking at the dates that the chart was coded on? ... THE WITNESS: When we assigned a chart, we assigned it, like, in a work list. ... Q. Okay. A. And the work list would be this is work list 1LR. Then we would assign it, this is work list 2LR.").

⁷¹ See **Appendix D, Section III.A.ii.c** for an explanation of how I identified Charts that underwent a Second Level Review.

52. While most Chart Review Program reviews were blind, there were limited exceptions. In particular, in a project known as the “Recode Project,” Defendants gave Coders information about diagnosis codes previously submitted to CMS for the beneficiary, a type of review known as “informed coding.”⁷² In these instances, Defendants instructed Coders that it was not necessary to record diagnosis codes that had already been submitted for that year, since each distinct HCC only counts once per year toward a beneficiary’s risk score.⁷³ Based on Defendants’ data,⁷⁴ approximately 33% of the Charts reviewed in service years 2011 and 2012 were subject to informed coding.⁷⁵
53. Defendants analyzed diagnosis codes reported by providers and Chart Review Program results and identified the new diagnosis codes (*i.e.*, diagnosis codes not previously reported by the provider and not previously submitted by Defendants to CMS) that their Coders found as being documented in the Chart, and submitted those diagnosis codes to CMS for additional risk adjustment payments.⁷⁶ Defendants’ submission of these diagnosis codes, called “adds,” generally resulted in increases in beneficiaries’ risk scores and thus increases in CMS’ payments to Defendants to cover these beneficiaries. Defendants estimated that for payment years 2010-2015, the adds generated by their Chart Review Program resulted in over \$3.5 billion in additional risk adjustment payments made by CMS to Defendants.⁷⁷

⁷² Baker Deposition Volume 1, 263:14–264:11 (“A. I mean, I would maybe also just continue that further informed coding, as UnitedHealth uses the term to respond to this interrogatory was not specific to the rendering provider or date of service as the charts reviewed during chart review could contain information from multiple providers and multiple dates of services across different data collection years and different provider encounters.”).

⁷³ *Ibid.*, 285:6–14 (“Q. Okay. And those directions included a direction to only code each HCC once per year? A. Um-hmm. And I believe we also said do not – you do not need to code every RxHCC.”).

⁷⁴ Recode reviews were only conducted for services years 2011 and 2012. *Ibid.*, 268:9–269:11 and 298:6–15; UnitedHealth’s First Supplemental Responses and Objections to Plaintiff United States’ Sixth Set of Interrogatories, *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, CASE NO. CV 16-08697 (SSx), July 19, 2022 (“UnitedHealth’s First Supplemental Responses and Objections to Plaintiff United States’ Sixth Set of Interrogatories”).

⁷⁵ See **Appendix D, Section III.A.iii** for an explanation of how I identified informed coded Charts. Defendants also identified a small number of informed coded Charts outside of these years. These represent less than 0.5% of Charts in service years 2013-2016.

⁷⁶ Sedor Deposition, 181:8–22 (“So I would say that the chart review process identified all HCCs, and then a separate process that was not part of the chart review program itself but was part of the submission process would identify which of those codes from a chart review were new and unique for submission.”).

⁷⁷ Production of Responses and Documents Responsive to CR / CV Interrogatories 1(F),1(J), 1(K) and Document Requests 4(C)(iii)(t), 4(C)(vii)(i), 5, and 6(D), December 21, 2015, p. 5.

54. While Defendants submitted the new diagnosis codes that were found to be supported in the Chart Review Program but were not previously reported by providers, they did not, as part of the Chart Review Program, generally⁷⁸ delete, investigate, or even flag diagnosis codes that were previously reported by a provider and submitted by Defendants to CMS but were *not* found to be supported in the Chart Review Program.⁷⁹

B. Defendants' Claims Verification Program

55. From 2010 through April 2014, Defendants conducted a program called "Claims Verification" or "CV," which involved the re-review of some Charts from the Chart Review Program for service years 2009-2012.⁸⁰ According to Defendants, CV utilized Charts previously reviewed in the Chart Review Program to determine if there were any provider-reported diagnosis codes that had been submitted to CMS, but were not supported by the Chart.⁸¹
56. The CV program applied only to a subset of Charts that had been reviewed in the Chart Review Program. For example, a Chart was only eligible for inclusion in the CV program if it was associated with what Defendants called an "exclusive HCC."⁸² An exclusive HCC is an HCC that is exclusive to one provider in the service year, and was not found to be

⁷⁸ For two years, Defendants investigated some of these diagnosis codes and, in some instances, deleted them, as further discussed in **Section IV.B**.

⁷⁹ Sedor Deposition, 249:16–251:16 ("Q. But you didn't do anything in particular with respect to the charts that had gone through chart review, right, to make sure that anything that the coders did not find as supported to try to validate any of those codes; correct? ... THE WITNESS: Correct. ... Q. And I would say by definition, if you didn't have that type of process, then you were not submitting deletes that would have -- that would have resulted; correct? ... THE WITNESS: Correct. Without a program to identify the deletes, we would not have been submitting deletes.").

⁸⁰ Production of Responses and Documents Responsive to CR / CV Interrogatories 1(F),1(J), 1(K) and Document Requests 4(C)(iii)(t), 4(C)(vii)(i), 5, and 6(D), December 21, 2015, p. 7 ("... the Claims Verification program continually evolved between 2010 and 2014 ..."); Deposition of Jon H. Bird 30(b)(6), *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. CV 16-08697 FMO, June 22, 2023 ("Bird Deposition Volume 1"), 102:21–103:21.

⁸¹ Sedor Deposition, 115:9–18 ("What [the CV] program did was to, when a medical record was looked at for chart review purposes to identify diagnosis codes that were not on the claim, it would also utilize those medical records to compare against the claim submitted by the provider to see if there were any codes submitted on the claim that were not supported by the medical records.").

⁸² Bird Deposition Volume 1, 109:1–18 ("[An exclusive HCC] would be an HCC or diagnoses that mapped to an HCC and that HCC is submitted by one and only one provider.").

supported by the review of that provider's Chart in the Chart Review Program.⁸³ Put differently, an exclusive HCC is one that was included in a beneficiary's record solely on the basis of a diagnosis code (or diagnosis codes) reported by one provider in the service year, but Defendants' Coders in the Chart Review Program identified no diagnosis codes mapping to that HCC in the review of that provider's Chart.⁸⁴ According to Defendants' data, 53% of the Charts that went through the Chart Review Program in service years 2011 and 2012⁸⁵ were excluded from the CV program because they did not include an exclusive HCC.⁸⁶ Defendants had various other reasons for excluding Charts from CV.⁸⁷ According to Defendants' data, for service years 2011 and 2012 only 16% of the Charts reviewed in the Chart Review Program were re-reviewed in the CV program.

57. In the CV program, Defendants often had multiple Coders re-review Charts to look for support for a diagnosis code mapping to the same HCC as the diagnosis code that was reported by the provider but was not found to be supported by Coders in the Chart Review

⁸³ "Exhibit 712-5 of Bird Deposition," MARA2076620 ("Charts will only be eligible for CV if the provider linked to the chart reported at least one exclusive HCC or exclusive RXHCC in a claim. An Exclusive HCC is defined as an HCC reported only in a claim by the linked provider during the data collection period."); Bird Deposition Volume 1, 102:15–20 ("Q. Can you explain what the claims verification program is? A. It was a program that we operated during a certain time frame that identified and reviewed exclusive HCCs that were submitted by providers that were part of the chart review program.").

⁸⁴ For example, suppose two providers submitted diagnosis codes mapping to HCC 15 for a beneficiary from two distinct encounters in a given service year. Further suppose that both of these encounters were reviewed in Defendants' Chart Review Program and that the Coders found no supporting diagnosis codes in the Charts corresponding to either encounter. HCC 15 would not be considered an exclusive HCC for the beneficiary and not eligible for the CV program because it was associated with diagnosis codes submitted by two providers in the service year. In contrast, if only one provider had submitted a diagnosis code mapping to HCC 15 for this beneficiary, HCC 15 would have been eligible for the CV program.

⁸⁵ Defendants have not produced data related to the CV program for service years 2009-2010. The CV program was in pilot phases and thus limited in scope in these years. Production of Responses and Documents Responsive to CR / CV Document Request 4(C) for 2010 DOS, May 2, 2016, pp. 5–6.

⁸⁶ Defendants have indicated a reason for each Chart's exclusion from the CV program in two datasets, MARA2157340 and MARA2152921. This count of Charts excluded from the CV program because they did not meet the exclusive HCC criteria includes two reasons: 1) "[Chart IDs] with no exclusive HCC's present in claims" and 2) "Exclusive HCC not related to chart provider." Production of Responses and Documents Responsive to CR / CV Interrogatories 1(A), 1(E), 3(A)-(B), 3(E), 3(H), 3(M), and 6 and Document Requests 4(C)(iv)(n) and 5, January 29, 2016, p. 8.

⁸⁷ Defendants also excluded Charts associated with new enrollees, and Charts whose image was no longer available in their systems. Production of Responses and Documents Responsive to CR / CV Interrogatories 1(A), 1(E), 3(A)-(B), 3(E), 3(H), 3(M), and 6 and Document Requests 4(C)(iv)(n) and 5, January 29, 2016, p. 8.

Program.⁸⁸ These re-reviews were conducted by Coders employed by Defendants and third-party vendors engaged by Defendants.⁸⁹

58. Diagnosis codes that were still not found to be supported by the Chart in accordance with CMS guidelines after completing the re-reviews in the CV process were submitted as “deletes” to CMS.⁹⁰ If any CV Coder reported finding support for a diagnosis code mapping to the relevant HCC in any of the re-reviews, Defendants did not submit a delete to CMS for that diagnosis code.⁹¹
59. Defendants terminated the CV program in mid-2014.⁹² At the time that CV was terminated, Defendants had already identified a set of diagnosis codes associated with 2011 and 2012 services years that they had submitted to CMS based on a provider-reported claim but for which they found no support in the Chart Review Program. This set of diagnosis codes included 74,722 diagnosis codes associated with service year 2011 and 78,875 diagnosis codes associated with service year 2012.⁹³ Of these 153,597 diagnosis codes, Defendants

⁸⁸ Bird Deposition Volume 1, 311:2–22 (“And in this document -- or in this section it refers to RADV expert level review. Do you see that? A. I do see that. Q. And does that refer to external coders from your vendor, iCodify? A. iCodify was one of the vendors used. I don't know if it was exclusively used, but iCodify was one of the entities that did expert level review. Q. And when you say expert level review this is the review step that happens after the CVA analysis; is that right? A. CV analyst. Q. CV analyst? A. Correct. Q. And sometimes it's expert level review. Here it says RADV expert level review. But those refer to the same thing? A. Correct.”).

⁸⁹ *Ibid.*

⁹⁰ Sedor Deposition, 116:17–117:4 (“And then if you identified diagnosis codes through claims verification that had not been identified in the chart review, then you would delete -- you deleted those codes through the process that's depicted here. You'd submit the deletes to CMS; is that right? ... THE WITNESS: If through the claims verification process we obtained knowledge that that code was not supported in the medical record it would be submitted as a delete through the process depicted on the screen.”); Bird Deposition Volume 1, 119:12–120:10 (“[I]n terms of the main components that are listed here, outside of it being part of the chart review program, diagnoses were reviewed and they were -- to determine if supported, and deletes were processed.”).

⁹¹ Bird Deposition Volume 1, 232:6–13.

⁹² *Ibid.*, 104:7–105:11 (“Q. And so is that your testimony as the designee for UnitedHealthcare and Optum, that the suspension of CV went into place on April 18, 2014, and the termination of CV went into place on May 27, 2014? A. Yeah, my testimony is on or around April 18th is when I saw notification of delete processing, and I believe the program was also suspended on or around that date. And yeah, based upon the -- we have the exhibit in here which is Steve Nelson's email or memorandum to Scott Theisen. He indicates in there that the decision was made to terminate on May 27th, and then that memorandum was dated with notification to Scott and others that was on June 11th.”).

⁹³ MARA2164481 and MARA2160501.

identified only 800 codes that had not already been re-reviewed by one Coder in the CV program.⁹⁴

60. In general, the deletion of diagnosis codes results in a reduction in risk adjustment payments MAOs receive from CMS, because a deletion may result in the removal of an HCC, the removal of that HCC's factor from the risk score, and thus a lower payment for the beneficiary. During the CV program, Defendants accrued reductions in revenue to cover the reduction in risk adjustment payments from CMS that they expected the deletes might have.⁹⁵ At the time CV was terminated, Defendants were able to release the accrued reductions.⁹⁶ Defendants' estimate that these released funds total \$26 million for service year 2011 and \$166.7 million for service year 2012.⁹⁷

C. Example Calculations of Changes to Risk Scores Resulting from Submissions of Adds and Deletes

61. In this section, I provide example calculations of how risk scores might change due to the submission of adds and deletes resulting from Defendants' risk adjustment programs.
62. As an example, consider again hypothetical Beneficiary 4 presented in **Exhibit 4** above, whose provider-reported diagnosis codes 25000 and 436. Now suppose that in Defendants' Chart Review Program, a Coder reviewed the Chart from the 1/1/2010 encounter with Provider A, and that Coder identified support for diagnosis codes 25000 and 82100 in the Chart. However, the Coder did not find support for diagnosis code 436.

⁹⁴ Of the 78,875 diagnosis codes associated with service year 2012, Defendants have indicated in the spreadsheet that 800 had been reviewed in the Chart Review Program but not yet re-reviewed by any Coder in the Claims Verification program. For service year 2011, no such indicator exists in Defendants' spreadsheet.

⁹⁵ Sedor Deposition, 193:23–194:17 (“Q. I see. Now, you're here to talk about the claims verification roll forward schedules for certain quarters in 2013 and 2014. How did you use the roll forward schedules? A. The roll forward schedule was created on our entire risk adjustment receivable account which is at times, depending on the time of year, could be a very large account. Within that risk adjustment receivable account we're accruing for the midyear reconciliation, the final reconciliation. We have reserves against it for possible deletes that we're paying out. So across our entire Medicare Advantage business, that balance can be pretty large. So the roll forward is actually detailing that entire RAF receivable account and then breaking it down into subcategories of what is in that account based on the supporting schedules that add up to those balances.”).

⁹⁶ *Ibid.*, 217:22–218:2 (“Q. Okay. Why did you release the reserves for claims verification in 2014? ... THE WITNESS: The reserves were released because the program was discontinued.”).

⁹⁷ *Ibid.*, 210:1–211:21 and 212:5–214:8 ([For service year 2012] “Q. Okay. Because the total would have been 166.7? A. Across -- the total negative revenue would have been 166.7 across all of 2013 and Q1 of 2014.”) ([For service year 2011] (“So therefore our entire P&L activity was a favorable 26 million.”)).

63. For the purposes of this example calculation, assume that this beneficiary's Chart Review Program results were used to identify adds but not deletes. In this case, diagnosis code 82100 would have been added to this beneficiary's records, and diagnosis 436 would not have been deleted.

Exhibit 6
Beneficiary Diagnosis Codes if Chart Review Data Only Used for Adds

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
4	1/1/2010	A	Claims+Chart Review	25000	19	0.181
4	1/1/2010	A	Claims	436	96	0.303
4	1/1/2010	A	Chart Review	82100	158	0.450

Distinct HCCs	HCC Factor
19	0.181
96	0.303
158	0.450
Demographic Factor	0.298
Disease Interaction Factor	0.149
Total Risk Score	1.381
x Base Rate	\$100
Per Member Per Month Payment	\$138.10

64. In **Exhibit 6**, diagnosis codes 25000, 436, and 82100 are in HCC 19, HCC 96, and HCC 158, respectively. In the CMS HCC Model, HCC 19 is assigned a factor of 0.181, HCC 96 is assigned a factor of 0.303, and HCC 158 is assigned a factor of 0.450. After accounting for demographic factors and the disease interaction between HCC 19 and HCC 96, the use of Chart Review Program data results in a total risk score of 1.381 for this beneficiary.⁹⁸ If the base rate payment for this beneficiary's plan is \$100, then CMS would pay Defendants a risk adjustment per member per month payment of \$138.10 for this beneficiary, or \$45 more than if Defendants had not added diagnosis code 82100.⁹⁹

⁹⁸ $1.381 = 0.298 \text{ demographic factor} + 0.181 \text{ HCC 19 factor} + 0.303 \text{ HCC 96 factor} + 0.450 \text{ HCC 158 factor} + 0.149 \text{ interaction factor for HCC 19 and HCC 96}$.

⁹⁹ My assignment is not to calculate the value of adds from the Chart Review Program. I include this example to demonstrate how risk scores and per member per month payments are impacted by the submission of additional diagnosis codes.

65. Now reconsider the example from **Exhibit 6** if this beneficiary's Chart Review Program results were used to identify deletes as well as adds. Diagnosis code 82100 would have been added to the list of diagnosis codes submitted to CMS, *and* diagnosis 436 would have been reported to CMS as a delete. CMS increases the risk score by the value of HCC 158 and removes the risk score lift caused by the prior submission of HCC 96. Because HCC 19 and HCC 96 are no longer co-existing conditions assigned to this beneficiary, CMS also removes the risk score lift caused by the disease interaction factor.

Exhibit 7
Beneficiary Diagnosis Codes if Chart Review Data Used for Adds and Deletes

Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
4	1/1/2010	A	Claims+Chart Review	25000	19	0.181
4	1/1/2010	A	Claims	436	96	0.303
4	1/1/2010	A	Chart Review	82100	158	0.450

Distinct HCCs	HCC Factor
19	0.181
158	0.450
Demographic Factor	0.298
Disease Interaction Factor	0.149
Total Risk Score	0.929
x Base Rate	\$100
Per Member Per Month Payment	\$92.90

66. As shown in **Exhibit 7**, diagnosis codes 25000, 436, and 82100 map to HCC 19, HCC 96, and HCC 158, respectively, which are assigned factors of 0.181, 0.303, and 0.450, respectively. However, deleting diagnosis code 436 now excludes HCC 96 from the beneficiary's risk score calculation, reducing the total risk score from 1.381 to 0.929. If the base rate payment for this beneficiary's plan is \$100, then CMS would pay Defendants a risk adjustment per member per month payment of \$92.90 for this beneficiary, or \$45.20 less in per member per month payments than if Defendants had only added diagnosis code 82100 and not deleted diagnosis code 436.
67. The presence of other diagnosis information submitted to CMS for a beneficiary can mean that some deletes may not have had financial impact. Continuing with the example from **Exhibit 7**, suppose that the beneficiary had a second encounter in that service year, this time with Provider B on 2/1/2010. Further suppose that Provider B reported that the

beneficiary had diagnosis code 43491, which maps to HCC 96. In this example, even though the Coder did not find support for diagnosis code 436 in the Chart associated with Provider A's encounter with the beneficiary on 1/1/2010, HCC 96 nevertheless would be preserved in the beneficiary's risk score calculation because on 2/1/2010, Provider B reported diagnosis 43491, which also maps to HCC 96.

Exhibit 8						
Beneficiary Diagnosis Codes if Chart Review Data Used for Adds and Deletes						
Beneficiary	Date	Provider	Source	Diagnosis	HCC	HCC Factor
4	1/1/2010	A	Claims+Chart Review	25000	19	0.181
4	1/1/2010	A	Claims	436	96	0.303
4	1/1/2010	A	Chart Review	82100	158	0.450
4	2/1/2010	B	Claims	43491	96	0.303

Distinct HCCs	HCC Factor
19	0.181
158	0.450
96	0.303
Demographic Factor	0.298
Disease Interaction Factor	0.149
Total Risk Score	1.381
x Base Rate	\$100
Per Member Per Month Payment	\$138.10

68. The HCC factors for **Exhibit 8** are the same as those for Exhibit 6, resulting in the same total risk score of 1.381 for this beneficiary, implying the same per member per month payment of \$138.10 at a base rate of \$100. In this hypothetical, the use of Chart Review Program results to delete a diagnosis code does not affect the ultimate payment, because it does not impact the list of HCCs that CMS uses to calculate the payment for the beneficiary.

D. Defendants' Risk Adjustment Systems and Submission of Diagnosis Codes

i. Defendants' Risk Adjustment Systems

69. Defendants maintained databases to store diagnosis codes associated with their Medicare Advantage beneficiaries in order to submit them to CMS each year. Defendants pooled, validated, and filtered diagnosis codes from various sources into two final databases, hereinafter referred to collectively as "Defendants' Risk Adjustment Databases."

70. One of these databases, the Ingenix Risk Adjustment Data System (“IRADS”), was in use for all years at issue in this matter.¹⁰⁰ The other database, the Encounter Data Processing System (“EDPS”), was used from service year 2014 onwards.¹⁰¹
71. Defendants’ Risk Adjustment Databases generally tracked the source(s) of each diagnosis code.¹⁰² Many of the diagnosis codes in Defendants’ Risk Adjustment Databases came from one of two sources:
- i. **Provider-reported claims data.** When providers submit claim and encounter data to Defendants, they include diagnosis codes in the submission. Defendants passed diagnosis codes from these provider-reported claims into their Risk Adjustment Databases.¹⁰³
 - ii. **Defendants’ Chart Review Program data.** Defendants maintained data sets that contained the results of the Chart Review Program (“Chart Review Databases”).¹⁰⁴ Defendants passed diagnosis codes from their Chart Review Databases into their Risk Adjustment Databases.
72. Some of the diagnosis codes in Defendants’ Risk Adjustment Databases came from other sources and programs. For example, if a Chart was included in the CV program and the

¹⁰⁰ Deposition of Biggs T. Cannon, III 30(b)(6), *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. CV 16-08697 FMO, June 6, 2023 (“Cannon Deposition Volume 1”), 59:22–60:5 (“Q. Okay. IRADS. What is IRADS used for? A. IRADS is a database within Optum that is used to house information related to Medicare Advantage beneficiaries. Q. And how long has -- or actually, was IRADS used for data that was being housed for dates of service 2008 through 2016? A. Yes, it would have stored data at that time frame.”); Deposition of Biggs T. Cannon, III 30(b)(6), *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. CV 16-08697 FMO, June 7, 2023 (“Cannon Deposition Volume 2”), 353:5–353:23 (“Q. And my question for you is: Is there another system by which you use to submit that same type of data to CMS through the systems that we’ve mentioned that is outside of IRADS? ... THE WITNESS: The EDPS system also submits data to CMS for Medicare Advantage beneficiaries. BY MS. GLOVER: Q. Okay. Outside of EDPS and IRADS, are there any systems that you use to submit data to CMS for the beneficiaries enrolled in UnitedHealthcare’s plans? ... THE WITNESS: I believe IRADS and EDPS are the two systems that submit data for Medicare Advantage beneficiaries to CMS.”).

¹⁰¹ See **Section IV.D.i** for an explanation of why Defendants maintained two separate systems. While both databases served the same function for Defendants, they each have unique data elements and structures.

¹⁰² Cannon Deposition Volume 2, 353:5–353:23 Defendants produced EDPS data in two separate tables, one containing provider-report claims data and one containing data from other sources, including records from the Chart Review Program. In the data containing encounters from other sources, it is not clear how to distinguish records from the Chart Review Program from records from other sources.

¹⁰³ See **Appendix D, Section III.B** for a description of provider-reported claims data.

¹⁰⁴ See **Appendix D, Section III.A** for a description of Defendants’ chart review data.

CV Coder found support for an additional diagnosis code that was not previously reported by a provider or any Coders in the Chart Review Program, that diagnosis code might be added to Defendants' Risk Adjustment Databases.¹⁰⁵ A variety of other programs, such as provider attestations and hospital abstracts, also contributed diagnosis codes through what Defendants referred to as Alternative Submission Mechanism ("ASM").¹⁰⁶

73. The relationship between these databases is summarized in **Exhibit 9**.

ii. Defendants' Submission of Diagnosis Codes for Risk Adjustment

74. Defendants determined which diagnosis codes in their Risk Adjustment Databases could be submitted to CMS based on CMS requirements.¹⁰⁷ For example, was Defendants' policy not to submit diagnosis codes associated with Charts reviewed in the Chart Review

¹⁰⁵ Bird Deposition Volume 1, 167:13–168:9.

¹⁰⁶ *Ingenix Risk Adjustment Data System ("IRADS")*, UnitedHealth Group, December 16, 2014, p. 5. Production of Responses to Questions re: Document Request 4(C) – July 26th Letter, Attachment A, Sections B3, H, I, and J, September 23, 2016 September 23, 2016

¹⁰⁷ Defendants identified a specific set of conditions under which they would not submit diagnosis codes identified in the Chart Review Program. In particular, Defendants indicated that it was their policy not to submit diagnosis codes identified in the Chart Review Program if the Chart was not signed by a provider. Production of Responses and Documents Responsive to CR / CV Interrogatories 1(F), 1(J), 1(K) and Document Requests 4(C)(iii)(t), 4(C)(vii)(i), 5, and 6(D), December 21, 2015; Production of Responses to Questions re: Chart Reviewed File 4(C)(iv) – Chart Error & Omission Codes and Chart Reviewed File 4(C)(v) – Diagnosis Error & Omission Codes, December 1, 2016.

Program where the Coder noted that the Chart had not been signed by the provider.¹⁰⁸ As discussed in **Section III.B**, this is consistent with CMS policy regarding what constitutes a risk adjustment-eligible diagnosis code.

75. Defendants' Risk Adjustment Databases track whether each diagnosis code was submitted to CMS, and if so, CMS' response to the submission (*e.g.*, whether CMS accepted the diagnosis code for use in risk adjustment).
76. Just as Defendants maintained two risk adjustment systems during the at-issue time period, so did CMS, which I collectively refer to as "CMS' Risk Adjustment Databases."¹⁰⁹ For the entire time period at issue, Defendants' submitted diagnosis codes from their IRADS database to CMS' Risk Adjustment Processing System ("RAPS").^{110, 111} For service years 2014–2016, Defendants also submitted diagnosis codes from their EDPS database to the "CMS EDPS" database.¹¹² Two Risk Adjustment Databases were maintained by both Defendants and CMS starting in service year 2014 because this is when CMS began requiring MAOs to submit a broader set of information associated with beneficiaries

¹⁰⁸ Sedor Deposition, 125:3–20 ("Q. Okay. Did you ever delete diagnosis codes because they were missing a signature or a credential? . . . THE WITNESS: Yes. If we submitted something from a medical record that did not have a signature and we were not able to achieve or obtain some kind of attestation from that provider to tell us that was in fact their medical record, then we would have submitted a delete for it. Q. Okay. And do you now if you actually made deletes on that basis? A. Yes, we did.") and 168:13-20 ("Additionally, as we've discussed, charts or medical records need to have a provider signature and credentials. There could have been times where we submitted a code through our chart review process and then realized that they did not have the proper signature and credentials and then had to submit a closed period delete for that original submission.").

¹⁰⁹ These CMS Risk Adjustment Databases were used for Part C and Part D, such that MAOs could submit a diagnosis code just once for use in both risk score calculations.

¹¹⁰ *Ingenix Risk Adjustment Data System ("IRADS")*, UnitedHealth Group, December 16, 2014, p. 8; Cannon Deposition Volume 2 353:21–23 ("I believe IRADS and EDPS are the two systems that submit data for Medicare Advantage beneficiaries to CMS.")

¹¹¹ Each RAPS submission must include the following information, also referred to as a "cluster": the Medicare beneficiary's identification number; the date(s) of the medical encounter (the physician office visit, hospital outpatient visit, or hospital inpatient stay); the type of provider (inpatient, outpatient, or physician); and the diagnosis code(s) reported by the provider for the encounter. *2008 Risk Adjustment Data Technical Assistance For Medicare Advantage Organizations Participant Guide*, Centers for Medicare & Medicaid Services, January 1, 2008, <https://www.hhs.gov/guidance/document/2008-risk-adjustment-data-technical-assistance-medicare-advantage-organizations>, accessed September 5, 2023, at Section 4.6.

¹¹² Each CMS EDPS submission includes, at least, the information included in RAPS submissions as well as other information relating to the encounter.

enrolled in Medicare Advantage and MA-PD Plans.¹¹³ During service years 2014–2016, the new CMS EDPS database was phased in, while the RAPS database was phased out.

77. In service year 2014, all diagnosis codes submitted to both RAPS and CMS EDPS counted for a given beneficiary's total risk score. It did not matter to which system a diagnosis code was submitted or whether it was submitted to only one system or both. CMS credited all diagnosis codes submitted to either system and calculated a single, total risk score.
78. In service years 2015 and 2016, CMS calculated two separate risk scores for each beneficiary using diagnosis codes submitted to RAPS and CMS EDPS. CMS then blended the RAPS risk score and the CMS EDPS risk score to calculate the final risk score used for payment.¹¹⁴ In 2015, the blend was 90% RAPS and 10% CMS EDPS. In 2016, the blend was 75% RAPS and 25% CMS EDPS.¹¹⁵ For example, for service year 2016, if the diagnosis codes submitted to the RAPS system resulted in a risk score of 1.1, and the diagnosis codes submitted to CMS EDPS system resulted in a risk score of 0.9, the final risk score used for payment would be 1.05 (*i.e.*, 1.1 multiplied by 0.75 plus 0.9 multiplied by 0.25).¹¹⁶
79. Both of CMS' Risk Adjustment Databases allow MAOs to delete previously submitted diagnosis codes. While CMS imposes a deadline for MAOs to submit adds, it allows submission of deletes after that deadline.¹¹⁷ In the event that MAOs submit deletes after

¹¹³ "Advance Notice of Methodological Changes for Calendar Year (CY) 2015 for Medicare Advantage (MA) Capitation Rates, Part C and Part D Payment Policies and 2015 Call Letter," Centers for Medicare & Medicaid Services, February 21, 2014, <https://www.cms.gov/medicare/health-plans/medicareadvgtgspcratestats/downloads/advance2015.pdf>, accessed September 28, 2023, p. 28.

¹¹⁵ *Ibid.*, p. 56.

¹¹⁶ $(75\% \text{ RAPS} * 1.1 \text{ RAPS Risk Score}) + (25\% \text{ CMS EDPS} * 0.9 \text{ CMS EDPS Risk Score}) = 1.05 \text{ Weighted Risk Score}$.

¹¹⁷ 42 CFR § 422.310(g)(2)(ii).

the deadline, CMS effectively retroactively adjusts the per member per month payments that it previously paid the plan.^{118, 119}

E. Matching Provider-Reported Encounters to Chart Review Records

80. Defendants' Risk Adjustment Databases contain diagnosis codes from multiple sources, as discussed in **Section IV.D.i**. The same encounter may be associated with multiple sets of diagnosis codes, with variations in the diagnosis codes contained in each set. For example, an encounter in Defendants' Risk Adjustment Databases may be associated with (1) diagnosis codes reported by the provider; and (2) diagnosis codes identified as supported in the Chart Review Program. In order to compare the diagnosis codes reported by the provider and the diagnosis codes identified as supported in the Chart Review Program for a given encounter, I needed to address two issues arising from the structure of Defendants' databases.
81. First, provider-reported encounters in Defendants' Risk Adjustment Databases do not contain encounter identifiers that allow direct linkage to Chart Review Program results in Defendants' Risk Adjustment Databases or to Chart Review Program results in Defendants' Chart Review Databases. Because of this way in which Defendants structured these databases, connecting a provider-reported encounter to the Chart Review Program Coder's results for that same encounter necessitates taking additional analytic steps.
82. Second, Defendants' databases do not consistently track provider information associated with records from the Chart Review Program. In particular, for records from the Chart Review Program in IRADS, the provider identified on the record was typically a "dummy" identifier such as 1099999, which bore no relationship to the actual provider who had the

¹¹⁸ Sedor Deposition, 79:9–14 (“Q. Okay. And when you say their processing closed period deletes, that is because you can’t submit additional codes after the final submission deadline, but I think as you testified earlier you can submit deletes; right? A. Correct. Q. Okay. And functionally, what the rerun does is it’s a rerun of that final reconciliation; is that right? A. Yes. Q. Okay. So functionally, it’s retroactively adjusting the per member per month payments that the plan received for a given beneficiary in a given payment year; right? A. Yes, that’s correct.”).

¹¹⁹ During the CV program, it was Defendants’ practice to submit “closed period” deletes. “Exhibit 712-5 of Bird Deposition,” MARA2076620 (“Because of the nature of the CV process, closed period deletes are to be expected each year. This is because chart review is conducted up until the final sweep and the CV process occurs after the chart review is completed.”).

face-to-face encounter with the beneficiary.¹²⁰ Additionally, testimony and documents explain that the provider identifiers in Defendants' Chart Review Databases also do not always reflect the actual provider who had the face-to-face encounter with the beneficiary.¹²¹ This is a result of Defendants' process for collecting Charts in the Chart Review Program, which sometimes grouped providers together under a single provider identifier.¹²²

83. Because of these issues, comparing the diagnosis codes on a provider-reported encounter to diagnosis codes identified in the Chart Review Program for that same encounter required that I develop methods of carefully matching these encounters, which are described in **Section VI.A.ii** and in **Appendix D, Section III.B.i**.

V. METHOD OVERVIEW

84. As noted above, I have been asked to identify diagnosis codes that Defendants submitted to CMS and for which Defendants did not find support in their Chart Review Program. To be clear, my assignment was not to identify all diagnosis codes that Defendants submitted to CMS for which there may not be support. My assignment was limited to only diagnosis codes associated with Charts that Defendants reviewed in the Chart Review Program. As illustrated by **Exhibit 5** in **Section IV.A** above, which shows the number of Medicare Advantage beneficiaries listed in Defendants' annual public filings, not all of Defendants'

¹²⁰ In Defendants' EDPS data, it is not clear how to distinguish records from the Chart Review Program from records from other sources.

¹²¹ "Exhibit 712-5 of Bird Deposition," MARA2076620 ("... providers are rolled up at the location level (based on address) and, we currently only capture the main (header) provider in ChartSync."); Bird Deposition Volume 1, 259:21–260:25 ("... there was a lack of -- because a lot of these claim systems came together through acquisition, there could be duplicative IDs across systems and the addition of things like, you know, a suffix, prefix to try and make it unique ... So do you see a complete match in terms of what appears in the chart review system with what you see in IRADS? Probably not. But through these processes of crosswalk and enrichment, that's how the match was achieved. Q. Okay. And so it was considered a match even if the data element wasn't identical if you could, through the process of enrichment, remove a suffix or add a leading zero or do something of that nature that satisfied you that it was the same provider on both sides; is that right? ... THE WITNESS: It would be sufficient to move to the next stage of the process.").

¹²² Production of Responses to Questions re: Document Request 4(C) – July 26th Letter, Attachment A, Sections A1, B2, B5, B6, C1, E, F, & K, August 26, 2016 B2, B5, B6, C1, E, F, & K, August 26, 2016, p. 5 ("... information from other providers (outside of the retrieval provider) may have been present and subsequently coded from the chart"); Baker Deposition Volume 1, 65:5–68:22, 110:3–128:21 ("[T]he chart that included the encounters with potentially multiple providers would all be -- would be assigned one retrieval provider ID, correct? A. It would be assigned one retrieval provider ID for that specific member-provider group location, but that member could have seen, you know, five different doctors.").

beneficiaries were included in the Chart Review Program. My analysis pertains only to beneficiaries with Charts reviewed in the Chart Review Program.

85. To identify the list of diagnosis codes that Defendants submitted to CMS for which Defendants did not find support in their Chart Review Program, my analysis proceeds, for each beneficiary in each year, in six steps.¹²³

- i. First, I match provider-reported encounters in Defendants' Risk Adjustment Databases to data from the Chart Review Program in order to identify a list of encounters that Defendants reviewed in their Chart Review Program ("Reviewed Encounters").
- ii. Second, I identify the diagnosis codes that Defendants' Coders determined were supported by the beneficiary's Charts upon their review of those Charts ("Supported Diagnosis Codes").
- iii. Third, I identify the diagnosis codes that were submitted to CMS from these encounters and used to calculate risk scores ("Submitted Diagnosis Codes").
- iv. Fourth, I compare these Submitted Diagnosis Codes to the Supported Diagnosis Codes to identify a list of "Potential Deletes." A diagnosis code is considered a Potential Delete if it is a Submitted Diagnosis Code from a Reviewed Encounter but *not* a Supported Diagnosis Code for a chart review corresponding to the same Reviewed Encounter.
- v. Fifth, I classify diagnosis codes on the list of Potential Deletes according to the presence of other relevant diagnosis codes in Defendants' data that map to the same HCC.
- vi. Sixth, I use this classification and additional criteria to create a final list of "Deletes" that is composed of some, but not all, of the diagnosis codes on the Potential Deletes list.

¹²³ The method summarized herein provides an overview of the analytical steps I have undertaken. Further technical detail is provided in **Appendix D**, which along with the programs I have provided can be used to replicate my results.

86. I then calculate the financial impact of these Deletes on the Part C and Part D payments that Defendants received from CMS. My financial analysis proceeds in three steps.
- i. First, I calculate a revised risk score for each beneficiary, using the diagnosis codes that would have remained had Defendants submitted the Deletes to CMS.
 - ii. Second, I compare the revised risk score to the risk score used to calculate CMS' actual payment to Defendants, in order to calculate a change in risk score. As part of this step, I ensure I can replicate the calculation of the actual risk score for the beneficiaries on the Deletes list and filter out a small number of beneficiaries for whom I am unable to exactly replicate the risk score calculated by CMS.
 - iii. Third, I use the change in risk score to calculate the change in payment, which reflects the amount by which Defendants' risk adjustment payments would have been reduced had they submitted the Deletes to CMS.
87. I then count the number of beneficiaries per year whose risk adjustment payments would have been reduced had Defendants submitted the Deletes to CMS.
88. Finally, I was instructed to separately quantify the financial impact associated with the diagnosis codes on Defendants' CV Pipeline Lists.
89. The remainder of this report explains this analysis in greater detail.

VI. METHOD FOR IDENTIFYING DELETES

A. Identification of Reviewed Encounters

90. To identify Reviewed Encounters, I use data from two sources: Defendants' Risk Adjustment Databases and Defendants' Chart Review Databases.

i. Identification of Encounters in Chart Review Data

91. When Defendants' Coders reviewed a Chart in the Chart Review Program, the diagnosis codes that Coders found to be supported in the Chart were recorded in Defendants' Chart Review Databases. In general, the diagnosis codes found to be supported in the Chart were also passed into Defendants' Risk Adjustment Databases with an indicator that the record originated from the Chart Review Program. To identify the encounters reviewed in the Chart Review Program, I rely on both of these sources. I cannot exclusively rely on

Defendants' Risk Adjustment Databases for two reasons. First, in some cases, the Coder identified no risk adjustment-eligible diagnosis codes on the Chart, and so no information about that review is recorded in Defendants' Risk Adjustment Databases, but the existence of that review is recorded in Defendants' Chart Review Databases. Second, in EDPS, Defendants' Risk Adjustment Database that was used for service years 2014-2016, there is no clear indicator for whether each record originated from the Chart Review Program, and thus I cannot rely on such records to identify encounters reviewed in the Chart Review Program. For these reasons, to identify the full set of encounters that were reviewed in the Chart Review Program, I supplement the data from the Chart Review Program in Defendants' Risk Adjustment Databases with the data in Defendants' Chart Review Databases.

92. As discussed in **Section IV.A**, in Defendants' Chart Review Program, 65% of Charts for 2014-2016 service years were reviewed by a second blind Coder in Second Level Review. Defendants' Chart Review Databases for service years 2014-2016 contain an indicator to identify these Charts. When creating the list of Reviewed Encounters, I include an indicator for whether each encounter was identified in Defendants' Chart Review Databases as originating from a Chart that went through Second Level Review.¹²⁴
93. See **Appendix D, Section III.A.ii** for details on my use of Defendants' Chart Review Databases to identify encounters reviewed in the Chart Review Program, and identification of encounters subject to Second Level Review.

ii. Matching Encounters from Chart Review Data to Provider-Reported Encounters

94. Having generated a list of encounters that were reviewed in the Chart Review Program, I then match these encounters to their corresponding provider-reported encounters in Defendants' Risk Adjustment Databases. I must match these encounters in order to later compare the diagnosis codes found to be supported in the Chart Review Program to the diagnosis codes reported by the provider for the same encounter. I apply the same method

¹²⁴ Of the \$997,051,302 total financial impact for Part C and Part D in service years 2014-2016 shown in **Exhibit 10**, \$799,407,848 is associated with diagnosis codes submitted by Defendants to CMS associated with Charts that were reviewed in Defendants' Second Level Review program.

to match records from the Chart Review Program to each of Defendants' Risk Adjustment Databases, IRADS and EDPS.

95. As discussed in **Section IV.E**, Defendants' Risk Adjustment Databases do not assign a unique encounter identifier to each encounter and do not consistently track provider information associated with each record. For these reasons, I employ two methodologies for matching encounters reviewed in the Chart Review Program to their associated encounters reported by providers.
96. The first method matches the beneficiary identifier, date of service, and provider identifier associated with the provider-reported encounter in Defendants' Risk Adjustment Databases with the beneficiary identifier, date of service, and provider identifier associated with the Chart in Defendants' Chart Review Databases.¹²⁵ If these data elements match, I conclude that the provider-reported encounter in Defendants' Risk Adjustment Databases must be a Reviewed Encounter. See **Appendix D, Section III.C.i** for a detailed description and example of this method for identifying Reviewed Encounters.
97. The second method of matching applies when all provider-reported diagnosis codes for a given beneficiary on a particular service date were reported by a single provider. I am able to ascertain whether a single provider reported all diagnosis codes on a given service date by counting the unique provider identifiers across all entries where Defendants' Risk Adjustment Databases indicate the encounter originated from a provider submission (and not another one of Defendants' Risk Adjustment programs, *i.e.*, Chart Review or CV). If Defendants' Risk Adjustment Databases indicate a single provider for all provider-reported diagnosis codes on a given service date, and Defendants' data also shows that a Chart with that service date was reviewed in the Chart Review Program, I conclude that the provider-reported encounter in Defendants' Risk Adjustment Databases must be a Reviewed

¹²⁵ I rely on the records from the Chart Review Program in Defendants' Chart Review Databases for this matching method, as opposed to the chart review data in Defendants' Risk Adjustment Database, as provider identifier information was not always passed from Defendants' Chart Review Databases to Defendants' Risk Adjustment Databases.

Encounter.¹²⁶ See **Appendix D, Section III.C.ii** for a detailed description and example of this method for identifying Reviewed Encounters.

98. With these matching methods, I am able determine which provider-reported encounters in Defendants' Risk Adjustment Databases are Reviewed Encounters.¹²⁷
99. In some cases, I am able to match a provider-reported encounter to a corresponding record from the Chart Review Program using one or both of these methods, but I nevertheless do not include that encounter in the final list of Reviewed Encounters. For example, if it is not clear that the provider-reported encounter is risk adjustment-eligible (*e.g.*, it is not a face-to-face encounter with an acceptable provider specialty), I exclude it even if it clearly matches to an encounter reviewed in the Chart Review Program. See **Appendix D, Section III.B.i** for details on how I identify provider-reported, risk adjustment-eligible encounters.
100. I also exclude from the final list of Reviewed Encounters all encounters for which the data from the Chart Review Program is potentially incomplete because the Coder was "informed." As discussed in **Section IV.A**, informed Coders were made aware of which diagnosis codes were already submitted to CMS for that beneficiary, and so, to avoid duplication, may not have recorded those diagnosis codes, resulting in an incomplete record of their findings. Therefore, I exclude the encounters on these Charts from the list of Reviewed Encounters.¹²⁸ See **Appendix D, Section III.A.iii** for details on my identification encounters subject to informed coding.
101. Some encounters from the Chart Review Program were not matched to a provider-reported encounter in Defendants' Risk Adjustment Databases using these methods. Of the 76

¹²⁶ The provider identifiers in the Reviewed Encounters identified under this second method do not always match the provider identifiers in their corresponding record from the Chart Review Program. This is an expected result, as Defendants have explained that that is because the chart review data does not always reflect the actual provider in the face-to-face encounter with the beneficiary. See **Section IV.E**.

¹²⁷ Of the \$2,135,252,375 total financial impact for Part C and Part D shown in **Exhibit 10**, \$1,382,953,493 is associated with only method one.

¹²⁸ Defendants produced data to identify the specific Charts that underwent informed coding, and I have excluded from the list of Reviewed Encounters every encounter associated with a Chart that Defendants' data identified as informed coded. Defendants have indicated that a small number of additional Charts were subject to informed coding during a pilot project that was operational for only one month in 2013. Should Defendants produce data identifying these, I may update my analyses to exclude them. Production of Responses and Documents Responsive to CR / CV Interrogatories 1(A), 1(E), 3(A)-(B), 3(E), 3(H), 3(M), and 6 and Document Requests 4(C)(iv)(n) and 5, January 29, 2016.

million beneficiary service dates in Defendants' Chart Review Databases for the at-issue service years, I was not able to identify a corresponding provider-reported encounter with the same service date in either of Defendants' Risk Adjustment Databases for approximately 16%. While these records from the Chart Review Program may correspond to a provider-reported encounter in Defendants' Risk Adjustment Database, they were not matched under either of my two methods. It is therefore possible that the final list of Reviewed Encounters undercounts the actual number of provider-reported encounters that Defendants reviewed in the Chart Review Program.

B. Identification of Supported Diagnosis Codes

102. After identifying Reviewed Encounters, I compare the diagnosis codes reported by the provider to the diagnosis codes found to be supported in the Chart Review Program. If a diagnosis code was reported by the provider and was found to be supported in the Chart Review Program (either in the initial review or the Second Level Review), I consider the diagnosis code to be a Supported Diagnosis Code. See **Appendix D, Section IV** for a detailed description of how I identify Supported Diagnosis Codes.

C. Identification of Submitted Diagnosis Codes

103. Next, I analyze Defendants' Risk Adjustment Databases to identify the diagnosis codes from Reviewed Encounters that Defendants submitted to CMS. Each of Defendants' Risk Adjustment Databases, IRADS and EDPS, contains fields that indicate whether each instance of a diagnosis code was submitted to, and accepted by, CMS. See **Appendix D, Section V** for details on how I identify these diagnosis codes.

D. Identification of Potential Deletes

104. To identify Potential Deletes, I identify all diagnosis codes that are Submitted Diagnosis Codes but not Supported Diagnosis Codes (*i.e.*, all diagnosis codes from Reviewed Encounters that were submitted to CMS but were not found to be supported in the Chart Review Program).
105. For example, if diagnosis code 436, *Acute, but ill-defined, cerebrovascular disease*, was reported by a provider and submitted to CMS, it would be on the Submitted Diagnosis Codes list. If the provider encounter that was the source of this code was matched to a

Chart Review encounter, but the Chart Reviewer did not find support for diagnosis code 436, then diagnosis code 436 would not be on the Supported Diagnosis Codes list. Comparison of the Submitted Diagnosis Codes to the Supported Diagnosis Codes would therefore identify diagnosis code 436 as a Potential Delete. It remains to be determined, however, whether 436 should be on the final Deletes list.

E. Classification of Potential Deletes

106. Next, I use three criteria related to HCC-mapping to classify the diagnosis codes on my list of Potential Deletes.¹²⁹ These criteria, which are not mutually exclusive, assess whether diagnosis codes on my list of Potential Deletes map to the same HCC as other diagnosis codes (or, in the instance of Claims Verification, other recorded HCCs) in Defendants' databases. Only Potential Deletes that do not meet any of these criteria are included in the final Deletes list.

i. Potential Deletes Sharing HCCs with Other Submitted Diagnosis Codes

107. For the first criterion, I assess whether the diagnosis code, if deleted, would have an effect on the beneficiary's risk score and in turn, a financial impact on the risk adjustment payments Defendants received from CMS. A diagnosis code would not affect the beneficiary's risk score when deleted if it maps to the same HCC as another diagnosis code that is *not* on the Potential Deletes list and that was submitted to CMS for the beneficiary in the relevant year.¹³⁰ In this case, deleting the diagnosis code would not result in a deletion of the HCC for the beneficiary, and thus it would not impact financial payments from CMS, as it is the HCC that is relevant to the beneficiary's risk score, as explained in **Section III.B** above. For example, suppose diagnosis code 436, which maps to HCC 96, appears on the Potential Deletes list for a beneficiary. If diagnosis code 43491, which also maps to HCC 96, was also submitted for the beneficiary that year and does *not* appear on the Potential Deletes list, the deletion of diagnosis code 436 would have no effect on the beneficiary's risk score. I consider diagnosis codes on the Potential Deletes list that share an HCC with another submitted diagnosis code *not* on the Potential Deletes list to meet this first criterion.

¹²⁹ While I refer to HCCs in this section, the same concepts and methods apply to RxHCCs for my Part D analysis.

¹³⁰ For ease of exposition, I use the phrase "submitted to CMS" in this section to refer to diagnosis codes that were both submitted to CMS by Defendants' and accepted by CMS.

108. To assess whether diagnosis codes on the Potential Deletes list meet this criterion, I examine the full set of diagnosis codes submitted to CMS for the beneficiary in the year. I identify these diagnosis codes in IRADS and EDPS following the method described in **Section VI.D** above, but do not limit to those associated with Reviewed Encounters or even provider-reported encounters. Diagnosis codes relevant to this assessment, like diagnosis code 43491 above, include diagnosis codes submitted from provider-reported, risk adjustment-eligible encounters, that I do not identify as Reviewed Encounters.¹³¹ I also examine submitted diagnosis codes associated with other encounter types, including Chart Review encounters, in Defendants' Risk Adjustment Databases.

ii. Potential Deletes Sharing HCCs with Other Unsubmitted Diagnosis Codes

109. The second criterion is similar to the first criterion in that I again assess whether the diagnosis code on the Potential Deletes list map to the same HCC as another diagnosis code in Defendants' databases. However, in contrast to the first criterion, the other diagnosis codes I examine for this second criterion are risk adjustment-eligible but were *not* submitted to CMS for the beneficiary in the relevant year. Since Potential Deletes only include codes submitted to CMS, these unsubmitted diagnosis codes would, by definition, not be on the Potential Deletes list. Continuing with the above example, I would consider diagnosis code 436 to meet this criterion – but not the first criterion – if diagnosis code 43491 was also observed in Defendants' databases as a risk adjustment-eligible diagnosis code, but had not been submitted to CMS.¹³² In this case, the deletion of diagnosis code 436 could affect the beneficiary's risk score, depending on whether any other diagnosis codes, also mapping to HCC 96, were submitted to CMS that year. I consider diagnosis codes on the Potential Deletes list that share an HCC with another unsubmitted diagnosis code that is *not* on the Potential Deletes list to meet this second criterion.

¹³¹ In addition to encounters that were not reviewed by Defendants, this set of encounters may include certain encounters that *were* reviewed as part of Defendants' Chart Review Program, but which I do not identify as Reviewed Encounters using either of my two methodologies.

¹³² An instance of a diagnosis code may not have been submitted to CMS if it was a duplicate of a diagnosis code that Defendants already submitted for a beneficiary in the service year. Instances of diagnosis codes outside of Defendants' Risk Adjustment Databases are by definition unsubmitted.

110. To assess whether diagnosis codes on the Potential Deletes list meet this criterion, I examine four types of unsubmitted diagnosis codes within and outside of Defendants' Risk Adjustment Databases:
- i. Diagnosis codes associated with chart review encounters in Defendants' Risk Adjustment Databases;
 - ii. Diagnosis codes associated with provider-reported, risk adjustment-eligible encounters in Defendants' Risk Adjustment Databases;
 - iii. Diagnosis codes from Defendants' Chart Review Databases that do not appear in Defendants' Risk Adjustment Databases; and
 - iv. Diagnosis codes from Defendants' Provider-reported Claims databases that do not appear in Defendants' Risk Adjustment Databases.¹³³
111. First, I examine unsubmitted diagnosis codes associated with chart review encounters in Defendants' Risk Adjustment Databases. Diagnosis codes associated with these encounters may be unsubmitted as a result of Defendants' policy to not submit duplicate diagnosis codes for a beneficiary.¹³⁴
112. Second, I examine unsubmitted diagnosis codes associated with provider-reported, risk adjustment-eligible encounters in Defendants' Risk Adjustment Databases, including but not limited to those I identify as Reviewed Encounters. Diagnosis codes associated with provider-reported, risk adjustment-eligible encounters may be unsubmitted for the same reason that chart review encounters in Defendants' Risk Adjustment Databases were not submitted.
113. Third, I examine diagnosis codes from Defendants' Chart Review Databases that do not appear in Defendants' Risk Adjustment Databases. The absence of these codes in Defendants' Risk Adjustment Databases necessarily makes them unsubmitted. I rely on Defendants' Chart Review Databases to identify these diagnosis codes. In general, Defendants passed all diagnosis codes that were identified in the Chart Review Program

¹³³ Out of caution, I do not apply a risk adjustment-eligible requirement to these diagnosis codes.

¹³⁴ Bird Deposition Volume 1, 194:25–196:10.

into their Risk Adjustment Databases. However, Defendants held some diagnosis codes back and did not transmit them from their Chart Review Databases to their Risk Adjustment Databases. Regardless, I consider *all* diagnosis codes found by *any* of the Coders in my assessment, regardless of whether they were transmitted from Defendants' Chart Review Databases to its Risk Adjustment Databases.¹³⁵ The only diagnosis codes in this category which I do not consider are diagnosis codes which are not risk adjustment-eligible. As discussed in **Section IV.D**, Defendants had internal policies that governed which diagnosis code from Chart Review were submitted for risk adjustment through their Risk Adjustment Databases. In particular, Defendants had a policy not to submit diagnosis codes associated with unsigned Charts, as these diagnosis codes were not considered risk adjustment-eligible.^{136, 137} Consistent with Defendants' policy, I do not examine these codes in my assessment of this criterion.¹³⁸

114. Fourth, I examine diagnosis codes from Defendants' Provider-reported Claims databases that do not appear in Defendants' Risk Adjustment Databases. Like the third category, the absence of these diagnosis codes in Defendants' Risk Adjustment Databases necessarily means that these diagnosis codes were unsubmitted. I examine these diagnosis codes because deposition testimony in this matter has indicated that, for a period of time, some diagnosis codes reported by providers may not have been added to IRADS due to a technical issue.¹³⁹

¹³⁵ I include diagnosis codes associated with informed coded Charts as well.

¹³⁶ Bird Deposition Volume 1, 217:9–221:19 (“Q. And if a chart was assigned one of those EO codes, the HCCs associated with that chart review were not included in the comparison list; right? A. At this point, correct.”).

¹³⁷ Defendants identified a specific set of “error and omission” codes which, when associated with a Chart or diagnosis code in chart review, would prevent transmission of those results to Defendants' Risk Adjustment Databases. Production of Responses to Questions re: Chart Reviewed File 4(C)(iv) – Chart Error & Omission Codes and Chart Reviewed File 4(C)(v) – Diagnosis Error & Omission Codes, December 1, 2016, p. 2.

¹³⁸ If these diagnosis codes were examined in this step, the total financial impact for Part C and Part D would be reduced to \$2,070,024,611.

¹³⁹ Deposition of Marybeth Meyer, *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. 16-08697 FMO, June 7, 2022 (“Meyer Deposition”), 232:19–234:5 (“Well, the focus on the data issues really came with the implementation of the Encounter Data System. That was also one of the ways where we identified that the data being submitted to Optum and then being submitted to CMS via the new encounter data submitted system was -- had gaps in it.”).

115. See **Appendix D, Section VII.A** for more details regarding these categories of unsubmitted diagnosis codes.

iii. Potential Deletes Mapping to HCCs Recorded in Claims Verification

The third criterion relates to Defendants' Claims Verification program and therefore applies only to diagnosis codes on the Potential Deletes list with dates of service in 2011 and 2012. In particular, I assess whether any of these diagnosis codes map to an HCC that was found to be supported as part of the Claims Verification program. As discussed above in **Section IV.B**, the Claims Verification program identified support for diagnosis codes at the HCC level. To identify these HCCs, I use data in Defendants' Risk Adjustment Databases, as well as other data produced by Defendants that houses CV results. I consider diagnosis codes on the Potential Deletes list which share an HCC with one of these CV-recorded HCCs to meet this third criterion.

F. Identification of Deletes

116. I identify as Deletes those diagnosis codes from the Potential Deletes list which did not meet *any* of the three criteria above. In other words, I identify Deletes as those diagnosis codes on the Potential Deletes list that do not share an HCC with any other submitted diagnosis code, do not share an HCC with any other risk adjustment-eligible but unsubmitted diagnosis code, *and* do not map to an HCC recorded in the Claims Verification program.¹⁴⁰ I also require that Deletes satisfy several additional checks, discussed below.
117. The first check pertains to service years 2014-2016, when both of Defendants' Risk Adjustment Databases – IRADS and EDPS – were in use. In these years, I identify Potential Deletes separately for each database, based on information in that database, as well as data

¹⁴⁰ Testimony indicates that this method also follows Defendants' practice during the operation of the CV program. Specifically, it is my understanding that Defendants would delete an HCC if a diagnosis code in that HCC was not supported by the medical record, and there were no other diagnosis codes in that HCC that were supported by the medical record. See Deposition of Rebecca Martin, *United States of America, ex rel. Benjamin Poehling v. UnitedHealth Group, Inc., et al.*, No. 16-08697 FMO, August 5, 2022 ("Martin Deposition"), 79:12–80:11 ("Q. And if it is the only diagnosis code that maps to the risk adjustment -- risk adjusting HCC, there's no other ones that can be submitted or take its place, is it your understanding that a diagnosis that's not supported by medical record documentation needs to be deleted? ... THE WITNESS: In the context of what you just described where it is the only diagnosis code that supports the HCC, there's no other X19 or other risk adjusting transaction that would otherwise support the HCC and we learn that the HCC is no longer supported or that there's something about the medical record that cannot support the condition, then yes, there would be an expectation that upon learning of that information, we would delete the code.").

external to both of Defendants' Risk Adjustment Databases. I use the same method to identify Potential Deletes for each database, which was specifically designed to limit false positives. However, the structural differences between the two databases introduce the possibility that a given diagnosis code, which is submitted to and accepted by CMS in both systems, meets one or more of the criteria from **Section VI.E** in one system but none of the criteria from **Section VI.E** in the other system. Out of an abundance of caution, I do not consider such diagnosis code to be a Delete in either system.

118. I also do not consider as Deletes any of the following:¹⁴¹

- i. Diagnosis codes that did not impact risk adjustment payments for the beneficiary, including diagnosis codes for newly enrolled beneficiaries;¹⁴²
- ii. Diagnosis codes associated with beneficiaries who were not enrolled in a Medicare Advantage plan (or in the case of Part D, a MA-PD plan) for the whole year;
- iii. Diagnosis codes associated with beneficiaries who were not enrolled in Defendants' plans during the year; and
- iv. Diagnosis codes associated with beneficiaries with end stage renal disease, whose risk adjustment payments are not determined by the CMS HCC Model or the CMS RxHCC Model.

119. My final list of Deletes can be found in **Attachment 1**.^{143, 144}

¹⁴¹ See **Appendix D, Section VIII** for a description of how I identify the referenced groups of beneficiaries.

¹⁴² Sedor Deposition, 90:13–17 (“Not all risk scores are calculated using HCCs if the person is newly aged into Medicare and is only 65. I believe for the first year of their enrollment they are not getting a risk score based on any HCCs.”).

¹⁴³ There is a separate list for each year at issue in this matter. There are also separate lists for each of Defendants' Risk Adjustment Databases. Each list contains columns indicating whether the diagnosis code is a Delete under each CMS model.

¹⁴⁴ As explained in **Section VII** below, the final Deletes list is limited to beneficiaries for whom I can perfectly replicate actual risk scores. The final Deletes list for Part D additionally excludes diagnosis codes which only impact Part D risk scores and which are associated with beneficiaries enrolled in MA-PD plans for which changes in risk corridor payments fully offset changes in direct subsidy payments.

VII. CALCULATING FINANCIAL IMPACT OF DEFENDANTS' FAILURE TO SUBMIT DELETES

120. I rely on data and publicly available computer programs from CMS to calculate the amount of risk adjustment payments that Defendants retained for the Deletes.¹⁴⁵ I proceed as follows.
121. First, I calculate a revised risk score for each beneficiary, based on a list of diagnosis codes that does *not* include diagnosis codes on the Deletes list.
122. Second, I compare the revised risk score to the actual risk score that was used by CMS in order to calculate the actual per member per month payment for that beneficiary (*i.e.*, the risk score that was calculated based on diagnosis codes that Defendants submitted to CMS, which includes the diagnosis codes on the Deletes list). I calculate the change in risk score as the actual risk score used by CMS to calculate the payment, minus the revised risk score. As part of this step, I ensure I can replicate actual risk scores calculated by CMS for beneficiaries on the Deletes list and filter out a small number of beneficiaries for whom I am unable to do so.
123. Third, I use the change in risk score to calculate a change in the per member per month payment for each beneficiary. I then aggregate across all beneficiaries to calculate the amount of risk adjustment payments that Defendants retained for the Deletes across all years.
124. I perform these steps for Part C and for Part D separately, and then aggregate the results to calculate the amount of risk adjustment payments that Defendants retained for the Deletes for Part C and Part D combined.

A. Revised Risk Scores

125. To calculate a revised risk score for each beneficiary, I begin with a list of unique diagnosis codes that Defendants submitted to CMS based on the data in their Risk Adjustment Databases, and I remove the diagnosis codes that appear on the Deletes list. Then, using CMS' Risk Adjustment Database I identify and add to this list all diagnosis codes that other

¹⁴⁵ "Medicare risk adjustment information," Centers for Medicare & Medicaid Services, <https://www.cms.gov/medicare/payment/medicare-advantage-rates-statistics/risk-adjustment>, downloaded on June 16, 2023.

MAOs submitted to CMS for the beneficiary in the relevant service year (these may exist if the beneficiary switched plans mid-year).¹⁴⁶ I input this list of diagnosis codes into the publicly available CMS HCC Model and CMS RxHCC Model computer programs discussed in **Section III.B**, which calculate the beneficiary's risk score.¹⁴⁷

126. As discussed in **Section III.B**, these computer programs require information on the beneficiary's demographics.¹⁴⁸ I rely on a CMS-produced database called MARx ("Medicare Advantage Prescription Drug System"), as well as other data produced by CMS to obtain information on the beneficiary's demographics and input that into CMS' computer program along with the list of diagnosis codes.
127. See **Appendix D, Section IX.A** for detailed information about how I identify diagnosis codes that Defendants submitted to CMS, how I identify diagnosis codes that other MAOs submitted to CMS, how I identify beneficiary demographic information in MARx, and how I use the CMS HCC Model and CMS RxHCC Model computer programs to calculate a risk score for each beneficiary and how I replicate the additional adjustments CMS applies to calculate a final risk score.
128. I calculate a Part C revised risk score and as relevant, a Part D revised risk score for each beneficiary in each year.

B. Changes in Risk Scores

129. Having calculated a revised risk score for each beneficiary based on the list of diagnosis codes that does not include the diagnosis codes on the Deletes list, I subtract each revised risk score from the actual risk score that was used by CMS in order to calculate the actual

¹⁴⁶ Some beneficiaries may also have switched mid-year from or to a Traditional Medicare plan. I do not have data on those diagnosis codes and therefore drop these beneficiaries from my analyses and do not calculate any financial impact associated with them.

¹⁴⁷ As discussed in **Section IV.D**, for service year 2014, submitted diagnosis codes were pooled from CMS' two Risk Adjustment Databases to calculate a single risk score. Therefore, for service year 2014, I pool diagnosis codes from both databases to input into CMS' models. For service years 2015 and 2016, when two separate risk scores were calculated and then weighted, I perform this step twice, once using diagnosis codes submitted by Defendants from IRADS and diagnosis codes submitted by other MAOs from RAPS, and once using diagnosis codes submitted by Defendants from EDPS and diagnosis codes submitted by other MAOs from CMS EDPS.

¹⁴⁸ "Medicare risk adjustment information," Centers for Medicare & Medicaid Services, <https://www.cms.gov/medicare/payment/medicare-advantage-rates-statistics/risk-adjustment>, downloaded on June 16, 2023.

per member per month payment for that beneficiary (*i.e.*, the risk score that was calculated based on diagnosis codes that Defendants submitted to CMS, which includes the diagnosis codes on the Deletes list). The actual risk score that was used by CMS to calculate each beneficiary's actual payment can be derived from CMS' MARx database.¹⁴⁹ See **Appendix D, Section IX.B** for detailed information on how I derived the actual risk score that was used by CMS for payment.

130. By subtracting the revised risk score from the actual risk score that was used by CMS for payment, I obtain a change in risk score for each beneficiary. This represents the change in risk score that would have occurred had Defendants submitted the diagnosis codes identified on the Deletes list as deletes to CMS. I calculate a Part C change in risk score and a Part D change in risk score for each beneficiary in each year.
131. As a confirmatory step, for each beneficiary, I also rerun CMS' computer programs using the full set of diagnosis codes that Defendants and other MAOs submitted to CMS, and the demographic information from MARx, to ensure that I can replicate exactly the MARx-derived risk score that was actually used by CMS to calculate payments. This ensures that the change in risk score that I calculate for each beneficiary is entirely attributable to the change in the list of diagnosis codes input into CMS' computer programs (*i.e.*, entirely due to Defendants' failure to submit the Deletes), and not some other inaccuracies in demographic data in MARx or missing diagnosis codes from other MAOs. I am able to exactly replicate approximately 98% of the actual risk scores used by CMS for payment.¹⁵⁰ I conservatively remove from my analysis any beneficiary whose risk score I was not able to perfectly replicate, such that these beneficiaries are not included in the final list of Deletes or my quantification of financial impact of the Deletes. See **Appendix D, Section IX** for detailed information on how I replicated risk scores.

¹⁴⁹ Sedor Deposition, 97:4–12 (“The MARX system is a CMS system that they utilize to generate the payments on a monthly basis.”).

¹⁵⁰ This reflects the number of beneficiary months in which I am able to replicate Part C risk scores across all years, using the diagnosis codes in IRADS/RAPS or diagnosis codes in EDPS/CMS EDPS. I exclude from this calculation beneficiaries who were not enrolled in one of Defendants' plans for the entirety of the year, as well as beneficiaries who were enrolled in Traditional Medicare at any point during the year. It also excludes beneficiaries who are not on either the CMS HCC Model or the CMS RxHCC model, such as beneficiaries with end stage renal disease or on hospice or newly enrolled in Medicare.

C. Changes in Payment for Part C

132. Having calculated a change in each beneficiary's Part C risk score that is attributable to Deletes, I multiply it by the plan's base rate to calculate a change in payment. The base rate for plans is generally available in the MARx database, but in some cases, it is not. In cases where the plan base rate is not available in the MARx database, I derive it using other variables that are available. See **Appendix D, Section IX.C** for details on how I derive the base rate when it is not available.
133. Across all beneficiaries and years, I calculate an aggregated Part C change in payments of \$2,109,423,348. This represents the total amount by which Defendants' Part C risk adjustment payments from CMS would have been reduced had Defendants submitted the diagnosis codes identified on the Deletes list as deletes to CMS.

D. Changes in Payment for Part D

134. Similar to Part C, having calculated a change in each beneficiary's Part D risk score that is attributable to Deletes, I multiply it by the plan's base rate to calculate a change in payment. As discussed above in **Section III.B**, under Part D, the base rate includes two elements, both of which are determined by the beneficiary's risk score: the direct subsidy, paid by CMS, and the beneficiary premium, paid by the beneficiary. I separately calculate the change in CMS' payment and the change in beneficiary payments based on the change in risk score. Across all of Defendants plans in all years of my analysis, I calculate the change in beneficiary payments to be \$28,927,661. In other words, had Defendants submitted the diagnosis codes on the Deletes list, beneficiaries on Defendants' plans would have, in aggregate, paid \$28,927,661 less in premiums. Because this cost was not covered by CMS, it is not subject to the risk corridors payments discussed in **Section III.B.ii**. It is also not included in my final calculations of the financial impact of Defendants' failure to submit Deletes, as my assignment was to assess the financial impact to CMS, not beneficiaries on Defendants plans.
135. For the CMS portion of Part D payments, as a final step, I calculate the change in payment that results from the application of risk corridors. I calculate this change at the plan level, rather than the beneficiary level consistent with how CMS calculates risk corridors. As described in **Section III.B.ii**, the size of the gap between a plan's target spending and actual

spending affects the profit sharing between MAOs and CMS. As a plan's target spending amount depends on risk adjustment payments, a change to risk adjustment payments may impact this profit sharing. I therefore calculate a change in risk corridor payments for each of Defendants' Part D plans based on their calculated change in risk adjustment payments, including both the change in direct subsidies and the change in beneficiary premiums. I then calculate each plan's change in Part D payments from CMS as the change in their direct subsidy payments less the change in their risk corridor payments. For some plans, the change in risk corridor payments offsets the entire change in direct subsidy payments, and I remove beneficiaries associated with those plans from the Deletes list as explained below in **Section VII.E**. See **Appendix D, Section IX.D** for a detailed description of how I calculate changes in Part D payments, including these risk corridor payments.

136. Across all beneficiaries and years, after accounting for risk corridors, I calculate an aggregated Part D change in CMS payments of \$25,829,027.¹⁵¹ This represents the total amount by which Defendants' Part D risk adjustment payments from CMS would have been reduced had Defendants submitted the diagnosis codes identified on the Deletes list as deletes to CMS.

E. Total Financial Impact of Defendants' Failure to Submit Deletes

137. I calculate the amount that was retained by Defendants by not deleting the diagnosis codes identified as Deletes in my analysis by summing the Part C and Part D payment amounts calculated above. **Exhibit 10** shows these amounts by year. See **Attachment 2** for a list of these amounts by year and contract. See **Attachment 3** for a list of these amounts by beneficiary, year, and contract.¹⁵²

¹⁵¹ Prior to the application of risk corridors, this amounts to \$67,445,692.

¹⁵² There is a separate list for each year at issue in this matter. Because risk corridors are applied at the plan level rather than the beneficiary level, the Part D amounts in these lists do not account for risk corridor payments.

Exhibit 10
Total Financial Impact of Defendants' Failure to Submit Deletes

Service Year	Part C	Part D	Total
2008	\$82,582,771	\$1,997,923	\$84,580,694
2009	\$147,171,500	\$3,001,475	\$150,172,975
2010	\$331,821,261	\$6,781,677	\$338,602,938
2011	\$100,694,304	\$1,595,961	\$102,290,264
2012	\$214,581,077	\$2,512,619	\$217,093,696
2013	\$242,617,635	\$2,842,871	\$245,460,506
2014	\$272,202,891	\$1,214,241	\$273,417,133
2015	\$322,034,749	\$2,507,514	\$324,542,263
2016	\$395,717,161	\$3,374,745	\$399,091,906
TOTAL	\$2,109,423,348	\$25,829,027	\$2,135,252,375

VIII. CALCULATING THE NUMBER OF BENEFICIARIES YEAR-BY-YEAR FOR WHOM DEFENDANTS WOULD HAVE RECEIVED REDUCED RISK ADJUSTMENT PAYMENTS FROM CMS

138. As stated above, I was also asked to calculate the number of beneficiaries in each payment year for whom Defendants would have received reduced risk adjustment payments from CMS had they submitted the Deletes.
139. Because I have already calculated the total amount that was retained by Defendants by not deleting the diagnosis codes identified as Deletes across all beneficiaries, determining the total number of impacted beneficiaries is straightforward. For each year, I sum the total number of unique beneficiaries who have at least one Delete, as reflected in **Attachment 1**.
140. Individual beneficiaries are counted once per year if they have a change in their risk score for Part C and/or Part D. Thus, a beneficiary enrolled in an MA-PD plan who has a change in both their Part C risk score and Part D risk score would be counted once not twice. I make one exception to this counting rule, which pertains to beneficiaries enrolled in MA-PD plans for which changes in risk corridor payments fully offset changes in direct subsidy payments for Part D. These beneficiaries are only counted if they have a change in their Part C risk score, as the changes in their Part D risk scores do not impact Part D payments due to the risk corridors.

141. For payment years 2009-2017, the total number of beneficiaries counted year-by-year where the beneficiary's risk score would have changed *and* for whom Defendants would have received reduced risk adjustment payments, either under Part C or Part D or both, had Defendants submitted the Deletes is 1,132,418. **Exhibit 11** shows the number of beneficiaries by year.

Exhibit 11
Total Beneficiaries Resulting in a Payment Change Due to
Defendants' Failure to Submit Deletes

Service Year	Part C	Part D	Total
2008	24,579	58,012	66,013
2009	44,549	102,395	116,115
2010	98,171	154,091	187,372
2011	32,418	59,046	70,832
2012	70,663	78,282	107,894
2013	90,731	95,960	134,036
2014	104,298	96,640	144,945
2015	107,152	64,628	135,361
2016	134,592	82,555	169,850
TOTAL	707,153	791,609	1,132,418

Note: total counts do not equal the sum of counts for Part C and Part D for the reasons described in Paragraph 140.

IX. CALCULATING FINANCIAL IMPACT OF DELETING DIAGNOSIS CODES ON DEFENDANTS' CV PIPELINE LISTS

142. As stated above, I was also asked to separately calculate the financial impact on Defendants' Medicare Advantage and Medicare Part D risk adjustment payments resulting from their failure to delete the diagnosis codes on Defendants' CV Pipeline Lists.¹⁵³
143. One of these lists includes "2011 [service date] encounters in RAPS for which the multi-stage CV process was begun but not completed" at the time Defendants terminated their CV program.¹⁵⁴ The other list "includes a complete list of all identified 2012 [service date]

¹⁵³ MARA2164481; MARA2160501.

¹⁵⁴ Production of Replacement File for MARA2117116, September 30, 2016, p. 1.

In Process CV Encounters or CV Cancelled Deletes with Part C financial impact.”¹⁵⁵ The second list includes approximately 800 encounters that “were not reviewed by any coder as part of the CV process.”¹⁵⁶

144. Had Defendants deleted the diagnosis codes on these lists, the risk adjustment payments Defendants received from CMS would have been reduced by \$36,032,222 in 2011 and \$152,370,126 in 2012 for Part C and Part D, or \$188,402,348 in aggregate across the two years.¹⁵⁷

Signed on September 29, 2023.

A handwritten signature in black ink, appearing to read 'CG', is written above a horizontal line.

Craig Garthwaite

¹⁵⁵ Response to Follow Up Questions on March 18, 2016 Letter re: 2012 DOS Encounters Identified for CV Review, May 27, 2016, p. 1.

¹⁵⁶ *Ibid.*, p. 2.

¹⁵⁷ The value associated with the 800 diagnosis codes on the 2012 service date list that Defendants identified as not reviewed by any coded as part of the CV process are associated with \$955,195 of this total.
